The class vtkGeoSphereTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoSphereTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoSphereTransform = obj.NewInstance ()`
- `vtkGeoSphereTransform = obj.SafeDownCast (vtkObject o)`
- `obj.Inverse ()` - Invert the transformation.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.
- `obj.SetToRectangular (bool )` - If on, this transform converts (long,lat,alt) triples to (x,y,z) as an offset from the center of the earth. Alt, x, y, and z are all be in meters. If off, the tranform works in the reverse direction. Initial value is on.
- `bool = obj.GetToRectangular ()` - If on, this transform converts (long,lat,alt) triples to (x,y,z) as an offset from the center of the earth. Alt, x, y, and z are all be in meters. If off, the tranform works in the reverse direction. Initial value is on.
- `obj.ToRectangularOn ()` - If on, this transform converts (long,lat,alt) triples to (x,y,z) as an offset from the center of the earth. Alt, x, y, and z are all be in meters. If off, the tranform works in the reverse direction. Initial value is on.
- `obj.ToRectangularOff ()` - If on, this transform converts (long,lat,alt) triples to (x,y,z) as an offset from the center of the earth. Alt, x, y, and z are all be in meters. If off, the tranform works in the reverse direction. Initial value is on.
- `obj.SetBaseAltitude (double )` - The base altitude to transform coordinates to. This can be useful for transforming lines just above the earth's surface. Default is 0.
- `double = obj.GetBaseAltitude ()` - The base altitude to transform coordinates to. This can be useful for transforming lines just above the earth's surface. Default is 0.

32.21 vtkGeoTerrain

32.21.1 Usage

vtkGeoTerrain contains a multi-resolution tree of geometry representing the globe. It uses a vtkGeoSource subclass to generate the terrain, such as vtkGeoGlobeSource. This source must be set before using the terrain in a vtkGeoView. The terrain also contains an AddActors() method which will update the set of actors representing the globe given the current camera position.

To create an instance of class vtkGeoTerrain, simply invoke its constructor as follows

```
obj = vtkGeoTerrain
```

32.21.2 Methods

The class vtkGeoTerrain has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoTerrain class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoTerrain = obj.NewInstance ()`
- `vtkGeoTerrain = obj.SafeDownCast (vtkObject o)`
- `vtkGeoSource = obj.GetSource ()` - The source used to obtain geometry patches.
- `obj.SetSource (vtkGeoSource source)` - The source used to obtain geometry patches.
- `obj.SaveDatabase (string path, int depth)` - Save the set of patches up to a given maximum depth.
- `obj.AddActors (vtkRenderer ren, vtkAssembly assembly, vtkCollection imageReps)` - Update the actors in an assembly used to render the globe. ren is the current renderer, and imageReps holds the collection of vtkGeoAlignedImageRepresentations that will be blended together to form the image on the globe.
- `obj.SetOrigin (double , double , double )` - The world-coordinate origin offset used to eliminate precision errors when zoomed in to a particular region of the globe.
- `obj.SetOrigin (double a[3])` - The world-coordinate origin offset used to eliminate precision errors when zoomed in to a particular region of the globe.
- `double = obj. GetOrigin ()` - The world-coordinate origin offset used to eliminate precision errors when zoomed in to a particular region of the globe.
- `obj.SetMaxLevel (int )` - The maximum level of the terrain tree.
- `int = obj.GetMaxLevelMinValue ()` - The maximum level of the terrain tree.
- `int = obj.GetMaxLevelMaxValue ()` - The maximum level of the terrain tree.
- `int = obj.GetMaxLevel ()` - The maximum level of the terrain tree.

32.22 vtkGeoTerrain2D

32.22.1 Usage

vtkGeoTerrain2D contains a multi-resolution tree of geometry representing the globe. It uses a vtkGeoSource subclass to generate the terrain, such as vtkGeoProjectionSource. This source must be set before using the terrain in a vtkGeoView2D. The terrain also contains an AddActors() method which updates the set of actors representing the globe given the current camera position.

To create an instance of class vtkGeoTerrain2D, simply invoke its constructor as follows

```
obj = vtkGeoTerrain2D
```

32.22.2 Methods

The class vtkGeoTerrain2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoTerrain2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoTerrain2D = obj.NewInstance ()`
- `vtkGeoTerrain2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetTextureTolerance (double )` - The maximum size of a single texel in pixels. Images will be refined if a texel becomes larger than the tolerance.
- `double = obj.GetTextureTolerance ()` - The maximum size of a single texel in pixels. Images will be refined if a texel becomes larger than the tolerance.
- `obj.SetLocationTolerance (double )` - The maximum allowed deviation of geometry in pixels. Geometry will be refined if the deviation is larger than the tolerance.
- `double = obj.GetLocationTolerance ()` - The maximum allowed deviation of geometry in pixels. Geometry will be refined if the deviation is larger than the tolerance.
- `vtkAbstractTransform = obj.GetTransform ()` - Return the projection transformation used by this 2D terrain.

32.23 vtkGeoTerrainNode

32.23.1 Usage

To create an instance of class vtkGeoTerrainNode, simply invoke its constructor as follows

```
obj = vtkGeoTerrainNode
```

32.23.2 Methods

The class vtkGeoTerrainNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoTerrainNode class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkGeoTerrainNode = obj.NewInstance ()`
- `vtkGeoTerrainNode = obj.SafeDownCast (vtkObject o)`
- `vtkGeoTerrainNode = obj.GetChild (int idx)`
- `vtkGeoTerrainNode = obj.GetParent ()`
- `double = obj.GetAltitude (double longitude, double latitude)`
- `vtkPolyData = obj.GetModel ()` - Get the terrrain model. The user has to copy the terrain into this object.
- `obj.SetModel (vtkPolyData model)` - Get the terrrain model. The user has to copy the terrain into this object.
- `obj.UpdateBoundingSphere ()` - Bounding sphere is precomputed for faster updates of terrain.
- `double = obj.GetBoundingSphereRadius ()` - Bounding sphere is precomputed for faster updates of terrain.
- `double = obj. GetBoundingSphereCenter ()` - Bounding sphere is precomputed for faster updates of terrain.
- `double = obj. GetCornerNormal00 ()`
- `double = obj. GetCornerNormal01 ()`
- `double = obj. GetCornerNormal10 ()`
- `double = obj. GetCornerNormal11 ()`
- `double = obj. GetProjectionBounds ()` - For 2D projections, store the bounds of the node in projected space to quickly determine if a node is offscreen.
- `obj.SetProjectionBounds (double , double , double , double )` - For 2D projections, store the bounds of the node in projected space to quickly determine if a node is offscreen.
- `obj.SetProjectionBounds (double a[4])` - For 2D projections, store the bounds of the node in projected space to quickly determine if a node is offscreen.
- `int = obj.GetGraticuleLevel ()` - For 2D projections, store the granularity of the graticule in this node.
- `obj.SetGraticuleLevel (int )` - For 2D projections, store the granularity of the graticule in this node.
- `double = obj.GetError ()` - For 2D projections, store the maximum deviation of line segment centers from the actual projection value.
- `obj.SetError (double )` - For 2D projections, store the maximum deviation of line segment centers from the actual projection value.
- `float = obj.GetCoverage ()` - For 2D projections, store the maximum deviation of line segment centers from the actual projection value.
- `obj.SetCoverage (float )` - For 2D projections, store the maximum deviation of line segment centers from the actual projection value.
- `obj.ShallowCopy (vtkGeoTreeNode src)` - Shallow and Deep copy.

- `obj.DeepCopy (vtkGeoTreeNode src)` - Shallow and Deep copy.
- `bool = obj.HasData ()` - Returns whether this node has valid data associated with it, or if it is an "empty" node.
- `obj.DeleteData ()` - Deletes the data associated with the node to make this an "empty" node. This is performed when the node has been unused for a certain amount of time.

32.24 vtkGeoTransform

32.24.1 Usage

This class takes two geographic projections and transforms point coordinates between them.

To create an instance of class vtkGeoTransform, simply invoke its constructor as follows

```
obj = vtkGeoTransform
```

32.24.2 Methods

The class vtkGeoTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoTransform = obj.NewInstance ()`
- `vtkGeoTransform = obj.SafeDownCast (vtkObject o)`
- `obj.SetSourceProjection (vtkGeoProjection source)` - The source geographic projection.
- `vtkGeoProjection = obj.GetSourceProjection ()` - The source geographic projection.
- `obj.SetDestinationProjection (vtkGeoProjection dest)` - The target geographic projection.
- `vtkGeoProjection = obj.GetDestinationProjection ()` - The target geographic projection.
- `obj.TransformPoints (vtkPoints src, vtkPoints dst)` - Transform many points at once.
- `obj.Inverse ()` - Invert the transformation.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

32.25 vtkGeoTreeNode

32.25.1 Usage

A self-referential data structure for storing geometry or imagery for the geospatial views. The data is organized in a quadtree. Each node contains a pointer to its parent and owns references to its four child nodes. The ID of each node is unique in its level, and encodes the path from the root node in its bits.

To create an instance of class vtkGeoTreeNode, simply invoke its constructor as follows

```
obj = vtkGeoTreeNode
```

32.25.2 Methods

The class vtkGeoTreeNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoTreeNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoTreeNode = obj.NewInstance ()`
- `vtkGeoTreeNode = obj.SafeDownCast (vtkObject o)`
- `obj.SetId (long )` - The id uniquely specified this node. For this implementation I am going to store the branch path in the bits.
- `long = obj.GetId ()` - The id uniquely specified this node. For this implementation I am going to store the branch path in the bits.
- `obj.SetLevel (int )`
- `int = obj.GetLevel ()`
- `obj.SetLongitudeRange (double , double )` - Longitude and latitude range of the terrain model.
- `obj.SetLongitudeRange (double  a[2])` - Longitude and latitude range of the terrain model.
- `double = obj. GetLongitudeRange ()` - Longitude and latitude range of the terrain model.
- `obj.SetLatitudeRange (double , double )` - Longitude and latitude range of the terrain model.
- `obj.SetLatitudeRange (double  a[2])` - Longitude and latitude range of the terrain model.
- `double = obj. GetLatitudeRange ()` - Longitude and latitude range of the terrain model.
- `obj.SetChild (vtkGeoTreeNode node, int idx)` - Get a child of this node. If one is set, then they all should set. No not mix subclasses.
- `obj.SetParent (vtkGeoTreeNode node)` - Manage links to older and newer tree nodes. These are used to periodically delete unused patches.
- `obj.SetOlder (vtkGeoTreeNode node)` - Manage links to older and newer tree nodes. These are used to periodically delete unused patches.
- `vtkGeoTreeNode = obj.GetOlder ()` - Manage links to older and newer tree nodes. These are used to periodically delete unused patches.
- `obj.SetNewer (vtkGeoTreeNode node)` - Manage links to older and newer tree nodes. These are used to periodically delete unused patches.
- `vtkGeoTreeNode = obj.GetNewer ()` - Returns whether this node has valid data associated with it, or if it is an "empty" node.
- `bool = obj.HasData ()` - Deletes the data associated with the node to make this an "empty" node. This is performed when the node has been unused for a certain amount of time.
- `obj.DeleteData ()`
- `int = obj.GetWhichChildAreYou ()`

- `bool = obj.IsDescendantOf (vtkGeoTreeNode elder)` - This method returns true if this node descends from the elder node. The descision is made from the node ids, so the nodes do not have to be in the same tree!
- `int = obj.CreateChildren ()`
- `vtkGeoTreeNode = obj.GetChildTreeNode (int idx)` - Get the parent as a vtkGeoTreeNode. Subclasses also implement GetParent() which returns the parent as the appropriate subclass type.
- `vtkGeoTreeNode = obj.GetParentTreeNode ()` - Shallow and Deep copy. Deep copy performs a shallow copy of the Child nodes.
- `obj.ShallowCopy (vtkGeoTreeNode src)` - Shallow and Deep copy. Deep copy performs a shallow copy of the Child nodes.
- `obj.DeepCopy (vtkGeoTreeNode src)` - Shallow and Deep copy. Deep copy performs a shallow copy of the Child nodes.

32.26 vtkGeoTreeNodeCache

32.26.1 Usage

vtkGeoTreeNodeCache keeps track of a linked list of vtkGeoTreeNodes, and has operations to move nodes to the front of the list and to delete data from the least used nodes. This is used to recover memory from nodes that store data that hasn't been used in a while.

To create an instance of class vtkGeoTreeNodeCache, simply invoke its constructor as follows

```
obj = vtkGeoTreeNodeCache
```

32.26.2 Methods

The class vtkGeoTreeNodeCache has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoTreeNodeCache class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoTreeNodeCache = obj.NewInstance ()`
- `vtkGeoTreeNodeCache = obj.SafeDownCast (vtkObject o)`
- `obj.SetCacheMaximumLimit (int )` - The size of the cache of geospatial nodes. When the size reaches this limit, the list of non-empty nodes will be shortened to CacheMinimumLimit.
- `int = obj.GetCacheMaximumLimit ()` - The size of the cache of geospatial nodes. When the size reaches this limit, the list of non-empty nodes will be shortened to CacheMinimumLimit.
- `obj.SetCacheMinimumLimit (int )` - The cache is reduced to this size when the maximum limit is reached.
- `int = obj.GetCacheMinimumLimit ()` - The cache is reduced to this size when the maximum limit is reached.
- `obj.SendToFront (vtkGeoTreeNode node)` - Send a node to the front of the list. Perform this whenever a node is accessed, so that the most recently accessed nodes' data are not deleted.
- `obj.RemoveNode (vtkGeoTreeNode node)` - Remove the node from the list.
- `int = obj.GetSize ()` - The current size of the list.

32.27 vtkGeoView

32.27.1 Usage

vtkGeoView is a 3D globe view. The globe may contain a multi-resolution geometry source (vtkGeoTerrain), multiple multi-resolution image sources (vtkGeoAlignedImageRepresentation), as well as other representations such as vtkRenderedGraphRepresentation. At a minimum, the view must have a terrain and one image representation. The view uses vtkGeoInteractorStyle to orbit, zoom, and tilt the view, and contains a vtkCompassWidget for manipulating the camera.

Each terrain or image representation contains a vtkGeoSource subclass which generates geometry or imagery at multiple resolutions. As the camera position changes, the terrain and/or image representations may ask its vtkGeoSource to refine the geometry. This refinement is performed on a separate thread, and the data is added to the view when it becomes available.

To create an instance of class vtkGeoView, simply invoke its constructor as follows

```
obj = vtkGeoView
```

32.27.2 Methods

The class vtkGeoView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoView = obj.NewInstance ()`
- `vtkGeoView = obj.SafeDownCast (vtkObject o)`
- `vtkGeoAlignedImageRepresentation = obj.AddDefaultImageRepresentation (vtkImageData image)` - Adds an image representation with a simple terrain model using the image in the specified file as the globe terrain.
- `obj.PrepareForRendering ()`
- `obj.BuildLowResEarth (double origin[3])` - Rebuild low-res earth source; call after (re)setting origin.
- `obj.SetLockHeading (bool lock)` - Whether the view locks the heading when panning. Default is off.
- `bool = obj.GetLockHeading ()` - Whether the view locks the heading when panning. Default is off.
- `obj.LockHeadingOn ()` - Whether the view locks the heading when panning. Default is off.
- `obj.LockHeadingOff ()` - Whether the view locks the heading when panning. Default is off.
- `vtkGeoInteractorStyle = obj.GetGeoInteractorStyle ()` - Convenience method for obtaining the internal interactor style.
- `obj.SetGeoInteractorStyle (vtkGeoInteractorStyle style)` - Method to change the interactor style.
- `obj.SetTerrain (vtkGeoTerrain terrain)` - The terrain (geometry) model for this earth view.
- `vtkGeoTerrain = obj.GetTerrain ()` - The terrain (geometry) model for this earth view.
- `obj.Render ()` - Update and render the view.

32.28 vtkGeoView2D

32.28.1 Usage

vtkGeoView is a 2D globe view. The globe may contain a multi-resolution geometry source (vtkGeoTerrain2D), multiple multi-resolution image sources (vtkGeoAlignedImageRepresentation), as well as other representations such as vtkGeoGraphRepresentation2D. At a minimum, the view must have a terrain and one image representation. By default, you may select in the view with the left mouse button, pan with the middle button, and zoom with the right mouse button or scroll wheel.

Each terrain or image representation contains a vtkGeoSource subclass which generates geometry or imagery at multiple resolutions. As the camera position changes, the terrain and/or image representations may ask its vtkGeoSource to refine the geometry. This refinement is performed on a separate thread, and the data is added to the view when it becomes available.

To create an instance of class vtkGeoView2D, simply invoke its constructor as follows

```
obj = vtkGeoView2D
```

32.28.2 Methods

The class vtkGeoView2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoView2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoView2D = obj.NewInstance ()`
- `vtkGeoView2D = obj.SafeDownCast (vtkObject o)`
- `vtkGeoView2D = obj.()`
- `~vtkGeoView2D = obj.()`
- `vtkGeoTerrain2D = obj.GetSurface ()`
- `obj.SetSurface (vtkGeoTerrain2D surf)`
- `vtkAbstractTransform = obj.GetTransform ()` - Returns the transform associated with the surface.
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply the view theme to this view.
- `obj.Render ()` - Update and render the view.

32.29 vtkGlobeSource

32.29.1 Usage

vtkGlobeSource will generate any "rectangular" patch of the globe given its Longitude-Latitude extent. It adds two point scalar arrays Longitude and Latitude to the output. These arrays can be transformed to generate texture coordinates for any texture map. This source is imperfect near the poles as implmented. It should really reduce the longitude resolution as the triangles become slivers.

To create an instance of class vtkGlobeSource, simply invoke its constructor as follows

```
obj = vtkGlobeSource
```

32.29.2 Methods

The class vtkGlobeSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGlobeSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGlobeSource = obj.NewInstance ()`
- `vtkGlobeSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetOrigin (double , double , double )`
- `obj.SetOrigin (double  a[3])`
- `obj.SetStartLongitude (double )` - Longitude Latitude clamps.
- `double = obj.GetStartLongitudeMinValue ()` - Longitude Latitude clamps.
- `double = obj.GetStartLongitudeMaxValue ()` - Longitude Latitude clamps.
- `obj.SetEndLongitude (double )` - Longitude Latitude clamps.
- `double = obj.GetEndLongitudeMinValue ()` - Longitude Latitude clamps.
- `double = obj.GetEndLongitudeMaxValue ()` - Longitude Latitude clamps.
- `obj.SetStartLatitude (double )` - Longitude Latitude clamps.
- `double = obj.GetStartLatitudeMinValue ()` - Longitude Latitude clamps.
- `double = obj.GetStartLatitudeMaxValue ()` - Longitude Latitude clamps.
- `obj.SetEndLatitude (double )` - Longitude Latitude clamps.
- `double = obj.GetEndLatitudeMinValue ()` - Longitude Latitude clamps.
- `double = obj.GetEndLatitudeMaxValue ()` - Longitude Latitude clamps.
- `obj.SetLongitudeResolution (int )` - Set the number of points in the longitude direction (ranging from StartLongitude to EndLongitude).
- `int = obj.GetLongitudeResolutionMinValue ()` - Set the number of points in the longitude direction (ranging from StartLongitude to EndLongitude).
- `int = obj.GetLongitudeResolutionMaxValue ()` - Set the number of points in the longitude direction (ranging from StartLongitude to EndLongitude).
- `int = obj.GetLongitudeResolution ()` - Set the number of points in the longitude direction (ranging from StartLongitude to EndLongitude).
- `obj.SetLatitudeResolution (int )` - Set the number of points in the latitude direction (ranging from StartLatitude to EndLatitude).
- `int = obj.GetLatitudeResolutionMinValue ()` - Set the number of points in the latitude direction (ranging from StartLatitude to EndLatitude).
- `int = obj.GetLatitudeResolutionMaxValue ()` - Set the number of points in the latitude direction (ranging from StartLatitude to EndLatitude).

- `int = obj.GetLatitudeResolution ()` - Set the number of points in the latitude direction (ranging from StartLatitude to EndLatitude).
- `obj.SetRadius (double )` - Set radius of sphere. Default is 6356750.0
- `double = obj.GetRadiusMinValue ()` - Set radius of sphere. Default is 6356750.0
- `double = obj.GetRadiusMaxValue ()` - Set radius of sphere. Default is 6356750.0
- `double = obj.GetRadius ()` - Set radius of sphere. Default is 6356750.0
- `obj.SetCurtainHeight (double )`
- `double = obj.GetCurtainHeightMinValue ()`
- `double = obj.GetCurtainHeightMaxValue ()`
- `double = obj.GetCurtainHeight ()`
- `obj.SetQuadrilateralTessellation (int )` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.
- `int = obj.GetQuadrilateralTessellation ()` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.
- `obj.QuadrilateralTessellationOn ()` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.
- `obj.QuadrilateralTessellationOff ()` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.

Chapter 33

Visualization Toolkit Graphics Classes

33.1 vtkAnnotationLink

33.1.1 Usage

vtkAnnotationLink is a simple source filter which outputs the vtkAnnotationLayers object stored internally. Multiple objects may share the same annotation link filter and connect it to an internal pipeline so that if one object changes the annotation set, it will be pulled into all the other objects when their pipelines update.

The shared vtkAnnotationLayers object (a collection of annotations) is shallow copied to output port 0.

vtkAnnotationLink can also store a set of domain maps. A domain map is simply a table associating values between domains. The domain of each column is defined by the array name of the column. The domain maps are sent to a multi-block dataset in output port 1.

Output ports 0 and 1 can be set as input ports 0 and 1 to vtkConvertSelectionDomain, which can use the domain maps to convert the domains of selections in the vtkAnnotationLayers to match a particular data object (set as port 2 on vtkConvertSelectionDomain).

The shared vtkAnnotationLayers object also stores a "current selection" normally interpreted as the interactive selection of an application. As a convenience, this selection is sent to output port 2 so that it can be connected to pipelines requiring a vtkSelection.

To create an instance of class vtkAnnotationLink, simply invoke its constructor as follows

```
obj = vtkAnnotationLink
```

33.1.2 Methods

The class vtkAnnotationLink has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnnotationLink class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnnotationLink = obj.NewInstance ()`
- `vtkAnnotationLink = obj.SafeDownCast (vtkObject o)`
- `vtkAnnotationLayers = obj.GetAnnotationLayers ()` - The annotations to be shared.
- `obj.SetAnnotationLayers (vtkAnnotationLayers layers)` - The annotations to be shared.
- `obj.SetCurrentSelection (vtkSelection sel)` - Set or get the current selection in the annotation layers.

- `vtkSelection = obj.GetCurrentSelection ()` - Set or get the current selection in the annotation layers.
- `obj.AddDomainMap (vtkTable map)` - The domain mappings.
- `obj.RemoveDomainMap (vtkTable map)` - The domain mappings.
- `obj.RemoveAllDomainMaps ()` - The domain mappings.
- `int = obj.GetNumberOfDomainMaps ()` - The domain mappings.
- `vtkTable = obj.GetDomainMap (int i)` - The domain mappings.
- `long = obj.GetMTime ()` - Get the mtime of this object.

33.2 vtkAppendCompositeDataLeaves

33.2.1 Usage

vtkAppendCompositeDataLeaves is a filter that takes input composite datasets with the same structure: (1) the same number of entries and – if any children are composites – the same constraint holds from them; and (2) the same type of dataset at each position. It then creates an output dataset with the same structure whose leaves contain all the cells from the datasets at the corresponding leaves of the input datasets.

Currently, only input polydata and unstructured grids are handled; other types of leaf datasets will be ignored and their positions in the output dataset will be NULL pointers. Point attributes (i.e., scalars, vectors, normals, field data, etc.) are extracted and appended only if all datasets have the point attributes available. (For example, if one dataset has scalars but another does not, scalars will not be appended.)

To create an instance of class vtkAppendCompositeDataLeaves, simply invoke its constructor as follows

```
obj = vtkAppendCompositeDataLeaves
```

33.2.2 Methods

The class vtkAppendCompositeDataLeaves has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAppendCompositeDataLeaves class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAppendCompositeDataLeaves = obj.NewInstance ()`
- `vtkAppendCompositeDataLeaves = obj.SafeDownCast (vtkObject o)`
- `obj.RemoveInput (vtkDataSet in)` - Remove a dataset from the list of data to append.
- `obj.SetAppendFieldData (int )` - Set/get whether the field data of each dataset in the composite dataset is copied to the output. If AppendFieldData is non-zero, then field data arrays from all the inputs are added to the output. If there are duplicates, the array on the first input encountered is taken.
- `int = obj.GetAppendFieldData ()` - Set/get whether the field data of each dataset in the composite dataset is copied to the output. If AppendFieldData is non-zero, then field data arrays from all the inputs are added to the output. If there are duplicates, the array on the first input encountered is taken.

- `obj.AppendFieldDataOn ()` - Set/get whether the field data of each dataset in the composite dataset is copied to the output. If AppendFieldData is non-zero, then field data arrays from all the inputs are added to the output. If there are duplicates, the array on the first input encountered is taken.

- `obj.AppendFieldDataOff ()` - Set/get whether the field data of each dataset in the composite dataset is copied to the output. If AppendFieldData is non-zero, then field data arrays from all the inputs are added to the output. If there are duplicates, the array on the first input encountered is taken.

33.3 vtkAppendFilter

33.3.1 Usage

vtkAppendFilter is a filter that appends one of more datasets into a single unstructured grid. All geometry is extracted and appended, but point attributes (i.e., scalars, vectors, normals, field data, etc.) are extracted and appended only if all datasets have the point attributes available. (For example, if one dataset has scalars but another does not, scalars will not be appended.)

To create an instance of class vtkAppendFilter, simply invoke its constructor as follows

```
obj = vtkAppendFilter
```

33.3.2 Methods

The class vtkAppendFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAppendFilter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkAppendFilter = obj.NewInstance ()`

- `vtkAppendFilter = obj.SafeDownCast (vtkObject o)`

- `obj.RemoveInput (vtkDataSet in)` - Remove a dataset from the list of data to append.

- `vtkDataSetCollection = obj.GetInputList ()` - Returns a copy of the input array. Modifications to this list will not be reflected in the actual inputs.

33.4 vtkAppendPolyData

33.4.1 Usage

vtkAppendPolyData is a filter that appends one of more polygonal datasets into a single polygonal dataset. All geometry is extracted and appended, but point and cell attributes (i.e., scalars, vectors, normals) are extracted and appended only if all datasets have the point and/or cell attributes available. (For example, if one dataset has point scalars but another does not, point scalars will not be appended.)

To create an instance of class vtkAppendPolyData, simply invoke its constructor as follows

```
obj = vtkAppendPolyData
```

33.4.2 Methods

The class vtkAppendPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAppendPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAppendPolyData = obj.NewInstance ()`
- `vtkAppendPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetUserManagedInputs (int )` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `int = obj.GetUserManagedInputs ()` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `obj.UserManagedInputsOn ()` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `obj.UserManagedInputsOff ()` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `obj.AddInput (vtkPolyData )` - Add a dataset to the list of data to append. Should not be used when UserManagedInputs is true, use SetInputByNumber instead.
- `obj.RemoveInput (vtkPolyData )` - Remove a dataset from the list of data to append. Should not be used when UserManagedInputs is true, use SetInputByNumber (NULL) instead.
- `obj.SetNumberOfInputs (int num)` - Directly set(allocate) number of inputs, should only be used when UserManagedInputs is true.
- `obj.SetInputByNumber (int num, vtkPolyData input)`
- `obj.SetParallelStreaming (int )` - ParallelStreaming is for a particular application. It causes this filter to ask for a different piece from each of its inputs. If all the inputs are the same, then the output of this append filter is the whole dataset pieced back together. Duplicate points are create along the seams. The purpose of this feature is to get data parallelism at a course scale. Each of the inputs can be generated in a different process at the same time.
- `int = obj.GetParallelStreaming ()` - ParallelStreaming is for a particular application. It causes this filter to ask for a different piece from each of its inputs. If all the inputs are the same, then the output of this append filter is the whole dataset pieced back together. Duplicate points are create along the seams. The purpose of this feature is to get data parallelism at a course scale. Each of the inputs can be generated in a different process at the same time.
- `obj.ParallelStreamingOn ()` - ParallelStreaming is for a particular application. It causes this filter to ask for a different piece from each of its inputs. If all the inputs are the same, then the output of this append filter is the whole dataset pieced back together. Duplicate points are create along the seams. The purpose of this feature is to get data parallelism at a course scale. Each of the inputs can be generated in a different process at the same time.

- `obj.ParallelStreamingOff ()` - ParallelStreaming is for a particular application. It causes this filter to ask for a different piece from each of its inputs. If all the inputs are the same, then the output of this append filter is the whole dataset pieced back together. Duplicate points are create along the seams. The purpose of this feature is to get data parallelism at a course scale. Each of the inputs can be generated in a different process at the same time.

33.5 vtkAppendSelection

33.5.1 Usage

vtkAppendSelection is a filter that appends one of more selections into a single selection. All selections must have the same content type unless AppendByUnion is false.

To create an instance of class vtkAppendSelection, simply invoke its constructor as follows

```
obj = vtkAppendSelection
```

33.5.2 Methods

The class vtkAppendSelection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAppendSelection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAppendSelection = obj.NewInstance ()`
- `vtkAppendSelection = obj.SafeDownCast (vtkObject o)`
- `obj.SetUserManagedInputs (int )` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `int = obj.GetUserManagedInputs ()` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `obj.UserManagedInputsOn ()` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `obj.UserManagedInputsOff ()` - UserManagedInputs allows the user to set inputs by number instead of using the AddInput/RemoveInput functions. Calls to SetNumberOfInputs/SetInputByNumber should not be mixed with calls to AddInput/RemoveInput. By default, UserManagedInputs is false.
- `obj.AddInput (vtkSelection )` - Add a dataset to the list of data to append. Should not be used when UserManagedInputs is true, use SetInputByNumber instead.
- `obj.RemoveInput (vtkSelection )` - Remove a dataset from the list of data to append. Should not be used when UserManagedInputs is true, use SetInputByNumber (NULL) instead.
- `obj.SetNumberOfInputs (int num)` - Directly set(allocate) number of inputs, should only be used when UserManagedInputs is true.
- `obj.SetInputByNumber (int num, vtkSelection input)`

- `obj.SetAppendByUnion (int )` - When set to true, all the selections are combined together to form a single vtkSelection output. When set to false, the output is a composite selection with input selections as the children of the composite selection. This allows for selections with different content types and properties. Default is true.
- `int = obj.GetAppendByUnion ()` - When set to true, all the selections are combined together to form a single vtkSelection output. When set to false, the output is a composite selection with input selections as the children of the composite selection. This allows for selections with different content types and properties. Default is true.
- `obj.AppendByUnionOn ()` - When set to true, all the selections are combined together to form a single vtkSelection output. When set to false, the output is a composite selection with input selections as the children of the composite selection. This allows for selections with different content types and properties. Default is true.
- `obj.AppendByUnionOff ()` - When set to true, all the selections are combined together to form a single vtkSelection output. When set to false, the output is a composite selection with input selections as the children of the composite selection. This allows for selections with different content types and properties. Default is true.

33.6 vtkApproximatingSubdivisionFilter

33.6.1 Usage

vtkApproximatingSubdivisionFilter is an abstract class that defines the protocol for Approximating subdivision surface filters.

To create an instance of class vtkApproximatingSubdivisionFilter, simply invoke its constructor as follows

```
obj = vtkApproximatingSubdivisionFilter
```

33.6.2 Methods

The class vtkApproximatingSubdivisionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkApproximatingSubdivisionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkApproximatingSubdivisionFilter = obj.NewInstance ()`
- `vtkApproximatingSubdivisionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfSubdivisions (int )` - Set/get the number of subdivisions.
- `int = obj.GetNumberOfSubdivisions ()` - Set/get the number of subdivisions.

33.7 vtkArcSource

33.7.1 Usage

vtkArcSource is a source object that creates an arc defined by two endpoints and a center. The number of segments composing the polyline is controlled by setting the object resolution.

To create an instance of class vtkArcSource, simply invoke its constructor as follows

```
obj = vtkArcSource
```

33.7.2 Methods

The class vtkArcSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArcSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArcSource = obj.NewInstance ()`
- `vtkArcSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetPoint1 (double , double , double )` - Set position of first end point.
- `obj.SetPoint1 (double  a[3])` - Set position of first end point.
- `double = obj. GetPoint1 ()` - Set position of first end point.
- `obj.SetPoint2 (double , double , double )` - Set position of other end point.
- `obj.SetPoint2 (double  a[3])` - Set position of other end point.
- `double = obj. GetPoint2 ()` - Set position of other end point.
- `obj.SetCenter (double , double , double )` - Set position of the center of the circle that define the arc. Note: you can use the function vtkMath::Solve3PointCircle to find the center from 3 points located on a circle.
- `obj.SetCenter (double  a[3])` - Set position of the center of the circle that define the arc. Note: you can use the function vtkMath::Solve3PointCircle to find the center from 3 points located on a circle.
- `double = obj. GetCenter ()` - Set position of the center of the circle that define the arc. Note: you can use the function vtkMath::Solve3PointCircle to find the center from 3 points located on a circle.
- `obj.SetResolution (int )` - Divide line into resolution number of pieces. Note: if Resolution is set to 1 (default), the arc is a straight line.
- `int = obj.GetResolutionMinValue ()` - Divide line into resolution number of pieces. Note: if Resolution is set to 1 (default), the arc is a straight line.
- `int = obj.GetResolutionMaxValue ()` - Divide line into resolution number of pieces. Note: if Resolution is set to 1 (default), the arc is a straight line.
- `int = obj.GetResolution ()` - Divide line into resolution number of pieces. Note: if Resolution is set to 1 (default), the arc is a straight line.
- `obj.SetNegative (bool )` - Use the angle that is a negative coterminal of the vectors angle: the longest angle. Note: false by default.
- `bool = obj.GetNegative ()` - Use the angle that is a negative coterminal of the vectors angle: the longest angle. Note: false by default.
- `obj.NegativeOn ()` - Use the angle that is a negative coterminal of the vectors angle: the longest angle. Note: false by default.
- `obj.NegativeOff ()` - Use the angle that is a negative coterminal of the vectors angle: the longest angle. Note: false by default.

33.8 vtkArrayCalculator

33.8.1 Usage

vtkArrayCalculator performs operations on vectors or scalars in field data arrays. It uses vtkFunctionParser to do the parsing and to evaluate the function for each entry in the input arrays. The arrays used in a given function must be all in point data or all in cell data. The resulting array will be stored as a field data array. The result array can either be stored in a new array or it can overwrite an existing array.

The functions that this array calculator understands is:

```
standard operations: + - * / \^ .
build unit vectors: iHat, jHat, kHat (ie (1,0,0), (0,1,0), (0,0,1))
abs
acos
asin
atan
ceil
cos
cosh
exp
floor
log
mag
min
max
norm
sign
sin
sinh
sqrt
tan
tanh
```

Note that some of these operations work on scalars, some on vectors, and some on both (e.g., you can multiply a scalar times a vector). The operations are performed tuple-wise (i.e., tuple-by-tuple). The user must specify which arrays to use as vectors and/or scalars, and the name of the output data array.

To create an instance of class vtkArrayCalculator, simply invoke its constructor as follows

```
obj = vtkArrayCalculator
```

33.8.2 Methods

The class vtkArrayCalculator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayCalculator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayCalculator = obj.NewInstance ()`
- `vtkArrayCalculator = obj.SafeDownCast (vtkObject o)`
- `obj.SetFunction (string function)` - Set/Get the function to be evaluated.

- `string = obj.GetFunction ()` - Set/Get the function to be evaluated.
- `obj.AddScalarArrayName (string arrayName, int component)` - Add an array name to the list of arrays used in the function and specify which components of the array to use in evaluating the function. The array name must match the name in the function. Use AddScalarVariable or AddVectorVariable to use a variable name different from the array name.
- `obj.AddVectorArrayName (string arrayName, int component0, int component1, int component2)` - Add an array name to the list of arrays used in the function and specify which components of the array to use in evaluating the function. The array name must match the name in the function. Use AddScalarVariable or AddVectorVariable to use a variable name different from the array name.
- `obj.AddScalarVariable (string variableName, string arrayName, int component)` - Add a variable name, a corresponding array name, and which components of the array to use.
- `obj.AddVectorVariable (string variableName, string arrayName, int component0, int component1, int c` - Add a variable name, a corresponding array name, and which components of the array to use.
- `obj.AddCoordinateScalarVariable (string variableName, int component)` - Add a variable name, a corresponding array name, and which components of the array to use.
- `obj.AddCoordinateVectorVariable (string variableName, int component0, int component1, int component` - Add a variable name, a corresponding array name, and which components of the array to use.
- `obj.SetResultArrayName (string name)` - Set the name of the array in which to store the result of evaluating this function. If this is the name of an existing array, that array will be overwritten. Otherwise a new array will be created with the specified name.
- `string = obj.GetResultArrayName ()` - Set the name of the array in which to store the result of evaluating this function. If this is the name of an existing array, that array will be overwritten. Otherwise a new array will be created with the specified name.
- `int = obj.GetResultArrayType ()` - Type of the result array. It is ignored if CoordinateResults is true. Initial value is VTK_DOUBLE.
- `obj.SetResultArrayType (int )` - Type of the result array. It is ignored if CoordinateResults is true. Initial value is VTK_DOUBLE.
- `int = obj.GetCoordinateResults ()` - Set whether to output results as coordinates. ResultArrayName will be ignored. Outputing as coordinates is only valid with vector results and if the AttributeMode is AttributeModeToUsePointData. If a valid output can't be made, an error will occur.
- `obj.SetCoordinateResults (int )` - Set whether to output results as coordinates. ResultArrayName will be ignored. Outputing as coordinates is only valid with vector results and if the AttributeMode is AttributeModeToUsePointData. If a valid output can't be made, an error will occur.
- `obj.CoordinateResultsOn ()` - Set whether to output results as coordinates. ResultArrayName will be ignored. Outputing as coordinates is only valid with vector results and if the AttributeMode is AttributeModeToUsePointData. If a valid output can't be made, an error will occur.
- `obj.CoordinateResultsOff ()` - Set whether to output results as coordinates. ResultArrayName will be ignored. Outputing as coordinates is only valid with vector results and if the AttributeMode is AttributeModeToUsePointData. If a valid output can't be made, an error will occur.
- `obj.SetAttributeMode (int )` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).

- `int = obj.GetAttributeMode ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `obj.SetAttributeModeToDefault ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `obj.SetAttributeModeToUsePointData ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `obj.SetAttributeModeToUseCellData ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `obj.SetAttributeModeToUseVertexData ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `obj.SetAttributeModeToUseEdgeData ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `string = obj.GetAttributeModeAsString ()` - Control whether the filter operates on point data or cell data. By default (AttributeModeToDefault), the filter uses point data. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData). For graphs you can set the filter to use vertex data (AttributeModeToUseVertexData) or edge data (AttributeModeToUseEdgeData).
- `obj.RemoveAllVariables ()` - Remove all the variable names and their associated array names.
- `obj.RemoveScalarVariables ()` - Remove all the scalar variable names and their associated array names.
- `obj.RemoveVectorVariables ()` - Remove all the scalar variable names and their associated array names.
- `obj.RemoveCoordinateScalarVariables ()` - Remove all the coordinate variables.
- `obj.RemoveCoordinateVectorVariables ()` - Remove all the coordinate variables.
- `string = obj.GetScalarArrayName (int i)` - Methods to get information about the current variables.
- `string = obj.GetVectorArrayName (int i)` - Methods to get information about the current variables.

- `string = obj.GetScalarVariableName (int i)` - Methods to get information about the current variables.
- `string = obj.GetVectorVariableName (int i)` - Methods to get information about the current variables.
- `int = obj.GetSelectedScalarComponent (int i)` - Methods to get information about the current variables.
- `int = obj.GetNumberOfScalarArrays ()` - Methods to get information about the current variables.
- `int = obj.GetNumberOfVectorArrays ()` - Methods to get information about the current variables.
- `obj.SetReplaceInvalidValues (int )` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `int = obj.GetReplaceInvalidValues ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `obj.ReplaceInvalidValuesOn ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `obj.ReplaceInvalidValuesOff ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `obj.SetReplacementValue (double )` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `double = obj.GetReplacementValue ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported

33.9 vtkArrowSource

33.9.1 Usage

vtkArrowSource was intended to be used as the source for a glyph. The shaft base is always at (0,0,0). The arrow tip is always at (1,0,0). If "Invert" is true, then the ends are flipped i.e. tip is at (0,0,0) while base is at (1, 0, 0). The resolution of the cone and shaft can be set and default to 6. The radius of the cone and shaft can be set and default to 0.03 and 0.1. The length of the tip can also be set, and defaults to 0.35.

To create an instance of class vtkArrowSource, simply invoke its constructor as follows

```
obj = vtkArrowSource
```

33.9.2 Methods

The class vtkArrowSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrowSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkArrowSource = obj.NewInstance ()`
- `vtkArrowSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetTipLength (double )` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `double = obj.GetTipLengthMinValue ()` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `double = obj.GetTipLengthMaxValue ()` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `double = obj.GetTipLength ()` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `obj.SetTipRadius (double )` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `double = obj.GetTipRadiusMinValue ()` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `double = obj.GetTipRadiusMaxValue ()` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `double = obj.GetTipRadius ()` - Set the length, and radius of the tip. They default to 0.35 and 0.1
- `obj.SetTipResolution (int )` - Set the resolution of the tip. The tip behaves the same as a cone. Resoultion 1 gives a single triangle, 2 gives two crossed triangles.
- `int = obj.GetTipResolutionMinValue ()` - Set the resolution of the tip. The tip behaves the same as a cone. Resoultion 1 gives a single triangle, 2 gives two crossed triangles.
- `int = obj.GetTipResolutionMaxValue ()` - Set the resolution of the tip. The tip behaves the same as a cone. Resoultion 1 gives a single triangle, 2 gives two crossed triangles.
- `int = obj.GetTipResolution ()` - Set the resolution of the tip. The tip behaves the same as a cone. Resoultion 1 gives a single triangle, 2 gives two crossed triangles.
- `obj.SetShaftRadius (double )` - Set the radius of the shaft. Defaults to 0.03.
- `double = obj.GetShaftRadiusMinValue ()` - Set the radius of the shaft. Defaults to 0.03.
- `double = obj.GetShaftRadiusMaxValue ()` - Set the radius of the shaft. Defaults to 0.03.
- `double = obj.GetShaftRadius ()` - Set the radius of the shaft. Defaults to 0.03.
- `obj.SetShaftResolution (int )` - Set the resolution of the shaft. 2 gives a rectangle. I would like to extend the cone to produce a line, but this is not an option now.
- `int = obj.GetShaftResolutionMinValue ()` - Set the resolution of the shaft. 2 gives a rectangle. I would like to extend the cone to produce a line, but this is not an option now.
- `int = obj.GetShaftResolutionMaxValue ()` - Set the resolution of the shaft. 2 gives a rectangle. I would like to extend the cone to produce a line, but this is not an option now.
- `int = obj.GetShaftResolution ()` - Set the resolution of the shaft. 2 gives a rectangle. I would like to extend the cone to produce a line, but this is not an option now.
- `obj.InvertOn ()` - Inverts the arrow direction. When set to true, base is at (1, 0, 0) while the tip is at (0, 0, 0). The default is false, i.e. base at (0, 0, 0) and the tip at (1, 0, 0).
- `obj.InvertOff ()` - Inverts the arrow direction. When set to true, base is at (1, 0, 0) while the tip is at (0, 0, 0). The default is false, i.e. base at (0, 0, 0) and the tip at (1, 0, 0).

- `obj.SetInvert (bool )` - Inverts the arrow direction. When set to true, base is at (1, 0, 0) while the tip is at (0, 0, 0). The default is false, i.e. base at (0, 0, 0) and the tip at (1, 0, 0).
- `bool = obj.GetInvert ()` - Inverts the arrow direction. When set to true, base is at (1, 0, 0) while the tip is at (0, 0, 0). The default is false, i.e. base at (0, 0, 0) and the tip at (1, 0, 0).

33.10 vtkAssignAttribute

33.10.1 Usage

vtkAssignAttribute is use to label a field (vtkDataArray) as an attribute. A field name or an attribute to labeled can be specified. For example: @verbatim aa-¿Assign("foo", vtkDataSetAttributes::SCALARS, vtkAssignAttribute::POINT_DATA); @endverbatim tells vtkAssignAttribute to make the array in the point data called "foo" the active scalars. On the other hand, @verbatim aa-¿Assign(vtkDataSetAttributes::VECTORS, vtkDataSetAttributes::SCALARS, vtkAssignAttribute::POINT_DATA); @endverbatim tells vtkAssignAttribute to make the active vectors also the active scalars. The same can be done more easily from Tcl by using the Assign() method which takes strings: @verbatim aa Assign "foo" SCALARS POINT_DATA or aa Assign SCALARS VECTORS POINT_DATA

AttributeTypes: SCALARS, VECTORS, NORMALS, TCOORDS, TENSORS Attribute locations: POINT_DATA, CELL_DATA @endverbatim

To create an instance of class vtkAssignAttribute, simply invoke its constructor as follows

```
obj = vtkAssignAttribute
```

33.10.2 Methods

The class vtkAssignAttribute has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssignAttribute class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssignAttribute = obj.NewInstance ()`
- `vtkAssignAttribute = obj.SafeDownCast (vtkObject o)`
- `obj.Assign (int inputAttributeType, int attributeType, int attributeLoc)` - Label an attribute as another attribute.
- `obj.Assign (string fieldName, int attributeType, int attributeLoc)` - Label an array as an attribute.
- `obj.Assign (string name, string attributeType, string attributeLoc)` - Helper method used by other language bindings. Allows the caller to specify arguments as strings instead of enums.

33.11 vtkAttributeDataToFieldDataFilter

33.11.1 Usage

vtkAttributeDataToFieldDataFilter is a class that maps attribute data into field data. Since this filter is a subclass of vtkDataSetAlgorithm, the output dataset (whose structure is the same as the input dataset), will contain the field data that is generated. The filter will convert point and cell attribute data to field data and assign it as point and cell field data, replacing any point or field data that was there previously. By default,

the original non-field point and cell attribute data will be passed to the output of the filter, although you can shut this behavior down.

To create an instance of class vtkAttributeDataToFieldDataFilter, simply invoke its constructor as follows

```
obj = vtkAttributeDataToFieldDataFilter
```

33.11.2 Methods

The class vtkAttributeDataToFieldDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAttributeDataToFieldDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAttributeDataToFieldDataFilter = obj.NewInstance ()`
- `vtkAttributeDataToFieldDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPassAttributeData (int )` - Turn on/off the passing of point and cell non-field attribute data to the output of the filter.
- `int = obj.GetPassAttributeData ()` - Turn on/off the passing of point and cell non-field attribute data to the output of the filter.
- `obj.PassAttributeDataOn ()` - Turn on/off the passing of point and cell non-field attribute data to the output of the filter.
- `obj.PassAttributeDataOff ()` - Turn on/off the passing of point and cell non-field attribute data to the output of the filter.

33.12 vtkAxes

33.12.1 Usage

vtkAxes creates three lines that form an x-y-z axes. The origin of the axes is user specified (0,0,0 is default), and the size is specified with a scale factor. Three scalar values are generated for the three lines and can be used (via color map) to indicate a particular coordinate axis.

To create an instance of class vtkAxes, simply invoke its constructor as follows

```
obj = vtkAxes
```

33.12.2 Methods

The class vtkAxes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAxes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAxes = obj.NewInstance ()`
- `vtkAxes = obj.SafeDownCast (vtkObject o)`
- `obj.SetOrigin (double , double , double )` - Set the origin of the axes.

- `obj.SetOrigin (double  a[3])` - Set the origin of the axes.
- `double = obj. GetOrigin ()` - Set the origin of the axes.
- `obj.SetScaleFactor (double )` - Set the scale factor of the axes. Used to control size.
- `double = obj.GetScaleFactor ()` - Set the scale factor of the axes. Used to control size.
- `obj.SetSymmetric (int )` - If Symetric is on, the the axis continue to negative values.
- `int = obj.GetSymmetric ()` - If Symetric is on, the the axis continue to negative values.
- `obj.SymmetricOn ()` - If Symetric is on, the the axis continue to negative values.
- `obj.SymmetricOff ()` - If Symetric is on, the the axis continue to negative values.
- `obj.SetComputeNormals (int )` - Option for computing normals. By default they are computed.
- `int = obj.GetComputeNormals ()` - Option for computing normals. By default they are computed.
- `obj.ComputeNormalsOn ()` - Option for computing normals. By default they are computed.
- `obj.ComputeNormalsOff ()` - Option for computing normals. By default they are computed.

33.13 vtkBandedPolyDataContourFilter

33.13.1 Usage

vtkBandedPolyDataContourFilter is a filter that takes as input vtkPolyData and produces as output filled contours (also represented as vtkPolyData). Filled contours are bands of cells that all have the same cell scalar value, and can therefore be colored the same. The method is also referred to as filled contour generation.

To use this filter you must specify one or more contour values. You can either use the method SetValue() to specify each contour value, or use GenerateValues() to generate a series of evenly spaced contours. Each contour value divides (or clips) the data into two pieces, values below the contour value, and values above it. The scalar values of each band correspond to the specified contour value. Note that if the first and last contour values are not the minimum/maximum contour range, then two extra contour values are added corresponding to the minimum and maximum range values. These extra contour bands can be prevented from being output by turning clipping on.

To create an instance of class vtkBandedPolyDataContourFilter, simply invoke its constructor as follows

```
obj = vtkBandedPolyDataContourFilter
```

33.13.2 Methods

The class vtkBandedPolyDataContourFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBandedPolyDataContourFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBandedPolyDataContourFilter = obj.NewInstance ()`
- `vtkBandedPolyDataContourFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `double = obj.GetValue (int i)` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `obj.GetValues (double contourValues)` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `obj.SetNumberOfContours (int number)` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `int = obj.GetNumberOfContours ()` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `obj.GenerateValues (int numContours, double range[2])` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Methods to set / get contour values. A single value at a time can be set with SetValue(). Multiple contour values can be set with GenerateValues(). Note that GenerateValues() generates n values inclusive of the start and end range values.

- `obj.SetClipping (int )` - Indicate whether to clip outside the range specified by the user. (The range is contour value[0] to contour value[numContours-1].) Clipping means all cells outside of the range specified are not sent to the output.

- `int = obj.GetClipping ()` - Indicate whether to clip outside the range specified by the user. (The range is contour value[0] to contour value[numContours-1].) Clipping means all cells outside of the range specified are not sent to the output.

- `obj.ClippingOn ()` - Indicate whether to clip outside the range specified by the user. (The range is contour value[0] to contour value[numContours-1].) Clipping means all cells outside of the range specified are not sent to the output.

- `obj.ClippingOff ()` - Indicate whether to clip outside the range specified by the user. (The range is contour value[0] to contour value[numContours-1].) Clipping means all cells outside of the range specified are not sent to the output.

- `obj.SetScalarMode (int )` - Control whether the cell scalars are output as an integer index or a scalar value. If an index, the index refers to the bands produced by the clipping range. If a value, then a scalar value which is a value between clip values is used.

- `int = obj.GetScalarModeMinValue ()` - Control whether the cell scalars are output as an integer index or a scalar value. If an index, the index refers to the bands produced by the clipping range. If a value, then a scalar value which is a value between clip values is used.

- `int = obj.GetScalarModeMaxValue ()` - Control whether the cell scalars are output as an integer index or a scalar value. If an index, the index refers to the bands produced by the clipping range. If a value, then a scalar value which is a value between clip values is used.

- `int = obj.GetScalarMode ()` - Control whether the cell scalars are output as an integer index or a scalar value. If an index, the index refers to the bands produced by the clipping range. If a value, then a scalar value which is a value between clip values is used.

- `obj.SetScalarModeToIndex ()` - Control whether the cell scalars are output as an integer index or a scalar value. If an index, the index refers to the bands produced by the clipping range. If a value, then a scalar value which is a value between clip values is used.
- `obj.SetScalarModeToValue ()` - Turn on/off a flag to control whether contour edges are generated. Contour edges are the edges between bands. If enabled, they are generated from polygons/triangle strips and placed into the second output (the ContourEdgesOutput).
- `obj.SetGenerateContourEdges (int )` - Turn on/off a flag to control whether contour edges are generated. Contour edges are the edges between bands. If enabled, they are generated from polygons/triangle strips and placed into the second output (the ContourEdgesOutput).
- `int = obj.GetGenerateContourEdges ()` - Turn on/off a flag to control whether contour edges are generated. Contour edges are the edges between bands. If enabled, they are generated from polygons/triangle strips and placed into the second output (the ContourEdgesOutput).
- `obj.GenerateContourEdgesOn ()` - Turn on/off a flag to control whether contour edges are generated. Contour edges are the edges between bands. If enabled, they are generated from polygons/triangle strips and placed into the second output (the ContourEdgesOutput).
- `obj.GenerateContourEdgesOff ()` - Turn on/off a flag to control whether contour edges are generated. Contour edges are the edges between bands. If enabled, they are generated from polygons/triangle strips and placed into the second output (the ContourEdgesOutput).
- `vtkPolyData = obj.GetContourEdgesOutput ()` - Get the second output which contains the edges dividing the contour bands. This output is empty unless GenerateContourEdges is enabled.
- `long = obj.GetMTime ()` - Overload GetMTime because we delegate to vtkContourValues so its modified time must be taken into account.

33.14 vtkBlankStructuredGrid

33.14.1 Usage

vtkBlankStructuredGrid is a filter that sets the blanking field in a vtkStructuredGrid dataset. The blanking field is set by examining a specified point attribute data array (e.g., scalars) and converting values in the data array to either a "1" (visible) or "0" (blanked) value in the blanking array. The values to be blanked are specified by giving a min/max range. All data values in the data array indicated and laying within the range specified (inclusive on both ends) are translated to a "off" blanking value.

To create an instance of class vtkBlankStructuredGrid, simply invoke its constructor as follows

```
obj = vtkBlankStructuredGrid
```

33.14.2 Methods

The class vtkBlankStructuredGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBlankStructuredGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBlankStructuredGrid = obj.NewInstance ()`
- `vtkBlankStructuredGrid = obj.SafeDownCast (vtkObject o)`

- `obj.SetMinBlankingValue (double )` - Specify the lower data value in the data array specified which will be converted into a "blank" (or off) value in the blanking array.
- `double = obj.GetMinBlankingValue ()` - Specify the lower data value in the data array specified which will be converted into a "blank" (or off) value in the blanking array.
- `obj.SetMaxBlankingValue (double )` - Specify the upper data value in the data array specified which will be converted into a "blank" (or off) value in the blanking array.
- `double = obj.GetMaxBlankingValue ()` - Specify the upper data value in the data array specified which will be converted into a "blank" (or off) value in the blanking array.
- `obj.SetArrayName (string )` - Specify the data array name to use to generate the blanking field. Alternatively, you can specify the array id. (If both are set, the array name takes precedence.)
- `string = obj.GetArrayName ()` - Specify the data array name to use to generate the blanking field. Alternatively, you can specify the array id. (If both are set, the array name takes precedence.)
- `obj.SetArrayId (int )` - Specify the data array id to use to generate the blanking field. Alternatively, you can specify the array name. (If both are set, the array name takes precedence.)
- `int = obj.GetArrayId ()` - Specify the data array id to use to generate the blanking field. Alternatively, you can specify the array name. (If both are set, the array name takes precedence.)
- `obj.SetComponent (int )` - Specify the component in the data array to use to generate the blanking field.
- `int = obj.GetComponentMinValue ()` - Specify the component in the data array to use to generate the blanking field.
- `int = obj.GetComponentMaxValue ()` - Specify the component in the data array to use to generate the blanking field.
- `int = obj.GetComponent ()` - Specify the component in the data array to use to generate the blanking field.

33.15 vtkBlankStructuredGridWithImage

33.15.1 Usage

This filter can be used to set the blanking in a structured grid with an image. The filter takes two inputs: the structured grid to blank, and the image used to set the blanking. Make sure that the dimensions of both the image and the structured grid are identical.

Note that the image is interpreted as follows: zero values indicate that the structured grid point is blanked; non-zero values indicate that the structured grid point is visible. The blanking data must be unsigned char.

To create an instance of class vtkBlankStructuredGridWithImage, simply invoke its constructor as follows

```
obj = vtkBlankStructuredGridWithImage
```

33.15.2 Methods

The class vtkBlankStructuredGridWithImage has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBlankStructuredGridWithImage class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkBlankStructuredGridWithImage = obj.NewInstance ()`
- `vtkBlankStructuredGridWithImage = obj.SafeDownCast (vtkObject o)`
- `obj.SetBlankingInput (vtkImageData input)` - Set / get the input image used to perform the blanking.
- `vtkImageData = obj.GetBlankingInput ()` - Set / get the input image used to perform the blanking.

33.16 vtkBlockIdScalars

33.16.1 Usage

vtkBlockIdScalars is a filter that generates scalars using the block index for each block. Note that all sub-blocks within a block get the same scalar. The new scalars array is named ßlockIdScalars.

To create an instance of class vtkBlockIdScalars, simply invoke its constructor as follows

```
obj = vtkBlockIdScalars
```

33.16.2 Methods

The class vtkBlockIdScalars has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBlockIdScalars class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBlockIdScalars = obj.NewInstance ()`
- `vtkBlockIdScalars = obj.SafeDownCast (vtkObject o)`

33.17 vtkBoxClipDataSet

33.17.1 Usage

Clipping means that is actually 'cuts' through the cells of the dataset, returning tetrahedral cells inside of the box. The output of this filter is an unstructured grid.

This filter can be configured to compute a second output. The second output is the part of the cell that is clipped away. Set the GenerateClippedData boolean on if you wish to access this output data.

The vtkBoxClipDataSet will triangulate all types of 3D cells (i.e, create tetrahedra). This is necessary to preserve compatibility across face neighbors.

To use this filter,you can decide if you will be clipping with a box or a hexahedral box. 1) Set orientation if(SetOrientation(0)): box (parallel with coordinate axis) SetBoxClip(xmin,xmax,ymin,ymax,zmin,zmax) if(SetOrientation(1)): hexahedral box (Default) SetBoxClip(n[0],o[0],n[1],o[1],n[2],o[2],n[3],o[3],n[4],o[4],n[5],o[5]) PlaneNormal[] normal of each plane PlanePoint[] point on the plane 2) Apply the GenerateClipScalarsOn() 3) Execute clipping Update();

To create an instance of class vtkBoxClipDataSet, simply invoke its constructor as follows

```
obj = vtkBoxClipDataSet
```

33.17.2 Methods

The class vtkBoxClipDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoxClipDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBoxClipDataSet = obj.NewInstance ()`
- `vtkBoxClipDataSet = obj.SafeDownCast (vtkObject o)`
- `obj.SetBoxClip (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)`
- `obj.SetBoxClip (double n0, double o0, double n1, double o1, double n2, double o2, double n3, double`
- `obj.SetGenerateClipScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated, and not the input scalar data.
- `int = obj.GetGenerateClipScalars ()` - If this flag is enabled, then the output scalar values will be interpolated, and not the input scalar data.
- `obj.GenerateClipScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated, and not the input scalar data.
- `obj.GenerateClipScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated, and not the input scalar data.
- `obj.SetGenerateClippedOutput (int )` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `int = obj.GetGenerateClippedOutput ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOn ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOff ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `vtkUnstructuredGrid = obj.GetClippedOutput ()` - Return the Clipped output.
- `int = obj.GetNumberOfOutputs ()` - Return the Clipped output.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `long = obj.GetMTime ()` - Return the mtime also considering the locator.
- `int = obj.GetOrientation ()` - Tells if clipping happens with a box parallel with coordinate axis (0) or with an hexahedral box (1). Initial value is 1.
- `obj.SetOrientation (int )` - Tells if clipping happens with a box parallel with coordinate axis (0) or with an hexahedral box (1). Initial value is 1.

- obj.ClipBox (vtkPoints newPoints, vtkGenericCell cell, vtkIncrementalPointLocator locator, vtkCellA
- obj.ClipHexahedron (vtkPoints newPoints, vtkGenericCell cell, vtkIncrementalPointLocator locator, v
- obj.ClipBox2D (vtkPoints newPoints, vtkGenericCell cell, vtkIncrementalPointLocator locator, vtkCel
- obj.ClipHexahedron2D (vtkPoints newPoints, vtkGenericCell cell, vtkIncrementalPointLocator locator,
- obj.ClipBox1D (vtkPoints newPoints, vtkGenericCell cell, vtkIncrementalPointLocator locator, vtkCel
- obj.ClipHexahedron1D (vtkPoints newPoints, vtkGenericCell cell, vtkIncrementalPointLocator locator,
- obj.ClipBox0D (vtkGenericCell cell, vtkIncrementalPointLocator locator, vtkCellArray verts, vtkPoi
- obj.ClipHexahedron0D (vtkGenericCell cell, vtkIncrementalPointLocator locator, vtkCellArray verts,

33.18 vtkBrownianPoints

33.18.1 Usage

vtkBrownianPoints is a filter object that assigns a random vector (i.e., magnitude and direction) to each point. The minimum and maximum speed values can be controlled by the user.

To create an instance of class vtkBrownianPoints, simply invoke its constructor as follows

```
obj = vtkBrownianPoints
```

33.18.2 Methods

The class vtkBrownianPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBrownianPoints class.

- string = obj.GetClassName ()
- int = obj.IsA (string name)
- vtkBrownianPoints = obj.NewInstance ()
- vtkBrownianPoints = obj.SafeDownCast (vtkObject o)
- obj.SetMinimumSpeed (double) - Set the minimum speed value.
- double = obj.GetMinimumSpeedMinValue () - Set the minimum speed value.
- double = obj.GetMinimumSpeedMaxValue () - Set the minimum speed value.
- double = obj.GetMinimumSpeed () - Set the minimum speed value.
- obj.SetMaximumSpeed (double) - Set the maximum speed value.
- double = obj.GetMaximumSpeedMinValue () - Set the maximum speed value.
- double = obj.GetMaximumSpeedMaxValue () - Set the maximum speed value.
- double = obj.GetMaximumSpeed () - Set the maximum speed value.

33.19 vtkButterflySubdivisionFilter

33.19.1 Usage

vtkButterflySubdivisionFilter is an interpolating subdivision scheme that creates four new triangles for each triangle in the mesh. The user can specify the NumberOfSubdivisions. This filter implements the 8-point butterfly scheme described in: Zorin, D., Schroder, P., and Sweldens, W., "Interpolating Subdivisions for Meshes with Arbitrary Topology," Computer Graphics Proceedings, Annual Conference Series, 1996, ACM SIGGRAPH, pp.189-192. This scheme improves previous butterfly subdivisions with special treatment of vertices with valence other than 6.

Currently, the filter only operates on triangles. Users should use the vtkTriangleFilter to triangulate meshes that contain polygons or triangle strips.

The filter interpolates point data using the same scheme. New triangles created at a subdivision step will have the cell data of their parent cell.

To create an instance of class vtkButterflySubdivisionFilter, simply invoke its constructor as follows

```
obj = vtkButterflySubdivisionFilter
```

33.19.2 Methods

The class vtkButterflySubdivisionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkButterflySubdivisionFilter class.

- `string = obj.GetClassName ()` - Construct object with NumberOfSubdivisions set to 1.
- `int = obj.IsA (string name)` - Construct object with NumberOfSubdivisions set to 1.
- `vtkButterflySubdivisionFilter = obj.NewInstance ()` - Construct object with NumberOfSubdivisions set to 1.
- `vtkButterflySubdivisionFilter = obj.SafeDownCast (vtkObject o)` - Construct object with NumberOfSubdivisions set to 1.

33.20 vtkButtonSource

33.20.1 Usage

vtkButtonSource is an abstract class that defines an API for creating "button-like" objects in VTK. A button is a geometry with a rectangular region that can be textured. The button is divided into two regions: the texture region and the shoulder region. The points in both regions are assigned texture coordinates. The texture region has texture coordinates consistent with the image to be placed on it. All points in the shoulder regions are assigned a texture coordinate specified by the user. In this way the shoulder region can be colored by the texture.

Creating a vtkButtonSource requires specifying its center point. (Subclasses have other attributes that must be set to control the shape of the button.) You must also specify how to control the shape of the texture region; i.e., wheter to size the texture region proportional to the texture dimensions or whether to size the texture region proportional to the button. Also, buttons can be created single sided are mirrored to create two-sided buttons.

To create an instance of class vtkButtonSource, simply invoke its constructor as follows

```
obj = vtkButtonSource
```

33.20.2 Methods

The class vtkButtonSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkButtonSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkButtonSource = obj.NewInstance ()`
- `vtkButtonSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetCenter (double , double , double )` - Specify a point defining the origin (center) of the button.
- `obj.SetCenter (double a[3])` - Specify a point defining the origin (center) of the button.
- `double = obj. GetCenter ()` - Specify a point defining the origin (center) of the button.
- `obj.SetTextureStyle (int )` - Set/Get the style of the texture region: whether to size it according to the x-y dimensions of the texture, or whether to make the texture region proportional to the width/height of the button.
- `int = obj.GetTextureStyleMinValue ()` - Set/Get the style of the texture region: whether to size it according to the x-y dimensions of the texture, or whether to make the texture region proportional to the width/height of the button.
- `int = obj.GetTextureStyleMaxValue ()` - Set/Get the style of the texture region: whether to size it according to the x-y dimensions of the texture, or whether to make the texture region proportional to the width/height of the button.
- `int = obj.GetTextureStyle ()` - Set/Get the style of the texture region: whether to size it according to the x-y dimensions of the texture, or whether to make the texture region proportional to the width/height of the button.
- `obj.SetTextureStyleToFitImage ()` - Set/Get the style of the texture region: whether to size it according to the x-y dimensions of the texture, or whether to make the texture region proportional to the width/height of the button.
- `obj.SetTextureStyleToProportional ()` - Set/get the texture dimension. This needs to be set if the texture style is set to fit the image.
- `obj.SetTextureDimensions (int , int )` - Set/get the texture dimension. This needs to be set if the texture style is set to fit the image.
- `obj.SetTextureDimensions (int a[2])` - Set/get the texture dimension. This needs to be set if the texture style is set to fit the image.
- `int = obj. GetTextureDimensions ()` - Set/get the texture dimension. This needs to be set if the texture style is set to fit the image.
- `obj.SetShoulderTextureCoordinate (double , double )` - Set/Get the default texture coordinate to set the shoulder region to.
- `obj.SetShoulderTextureCoordinate (double a[2])` - Set/Get the default texture coordinate to set the shoulder region to.
- `double = obj. GetShoulderTextureCoordinate ()` - Set/Get the default texture coordinate to set the shoulder region to.

- `obj.SetTwoSided (int )` - Indicate whether the button is single or double sided. A double sided button can be viewed from two sides...it looks sort of like a "pill." A single-sided button is meant to viewed from a single side; it looks like a "clam-shell."
- `int = obj.GetTwoSided ()` - Indicate whether the button is single or double sided. A double sided button can be viewed from two sides...it looks sort of like a "pill." A single-sided button is meant to viewed from a single side; it looks like a "clam-shell."
- `obj.TwoSidedOn ()` - Indicate whether the button is single or double sided. A double sided button can be viewed from two sides...it looks sort of like a "pill." A single-sided button is meant to viewed from a single side; it looks like a "clam-shell."
- `obj.TwoSidedOff ()` - Indicate whether the button is single or double sided. A double sided button can be viewed from two sides...it looks sort of like a "pill." A single-sided button is meant to viewed from a single side; it looks like a "clam-shell."

33.21 vtkCellCenters

33.21.1 Usage

vtkCellCenters is a filter that takes as input any dataset and generates on output points at the center of the cells in the dataset. These points can be used for placing glyphs (vtkGlyph3D) or labeling (vtkLabeledDataMapper). (The center is the parametric center of the cell, not necessarily the geometric or bounding box center.) The cell attributes will be associated with the points on output.

To create an instance of class vtkCellCenters, simply invoke its constructor as follows

```
obj = vtkCellCenters
```

33.21.2 Methods

The class vtkCellCenters has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellCenters class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellCenters = obj.NewInstance ()`
- `vtkCellCenters = obj.SafeDownCast (vtkObject o)`
- `obj.SetVertexCells (int )` - Enable/disable the generation of vertex cells. The default is Off.
- `int = obj.GetVertexCells ()` - Enable/disable the generation of vertex cells. The default is Off.
- `obj.VertexCellsOn ()` - Enable/disable the generation of vertex cells. The default is Off.
- `obj.VertexCellsOff ()` - Enable/disable the generation of vertex cells. The default is Off.

33.22 vtkCellDataToPointData

33.22.1 Usage

vtkCellDataToPointData is a filter that transforms cell data (i.e., data specified per cell) into point data (i.e., data specified at cell points). The method of transformation is based on averaging the data values of all cells using a particular point. Optionally, the input cell data can be passed through to the output as well.

To create an instance of class vtkCellDataToPointData, simply invoke its constructor as follows

```
obj = vtkCellDataToPointData
```

33.22.2 Methods

The class vtkCellDataToPointData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellDataToPointData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellDataToPointData = obj.NewInstance ()`
- `vtkCellDataToPointData = obj.SafeDownCast (vtkObject o)`
- `obj.SetPassCellData (int )` - Control whether the input cell data is to be passed to the output. If on, then the input cell data is passed through to the output; otherwise, only generated point data is placed into the output.
- `int = obj.GetPassCellData ()` - Control whether the input cell data is to be passed to the output. If on, then the input cell data is passed through to the output; otherwise, only generated point data is placed into the output.
- `obj.PassCellDataOn ()` - Control whether the input cell data is to be passed to the output. If on, then the input cell data is passed through to the output; otherwise, only generated point data is placed into the output.
- `obj.PassCellDataOff ()` - Control whether the input cell data is to be passed to the output. If on, then the input cell data is passed through to the output; otherwise, only generated point data is placed into the output.

33.23 vtkCellDerivatives

33.23.1 Usage

vtkCellDerivatives is a filter that computes derivatives of scalars and vectors at the center of cells. You can choose to generate different output including the scalar gradient (a vector), computed tensor vorticity (a vector), gradient of input vectors (a tensor), and strain matrix of the input vectors (a tensor); or you may choose to pass data through to the output.

Note that it is assumed that on input scalars and vector point data is available, which are then used to generate cell vectors and tensors. (The interpolation functions of the cells are used to compute the derivatives which is why point data is required.)

To create an instance of class vtkCellDerivatives, simply invoke its constructor as follows

```
obj = vtkCellDerivatives
```

33.23.2 Methods

The class vtkCellDerivatives has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellDerivatives class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkCellDerivatives = obj.NewInstance ()`
- `vtkCellDerivatives = obj.SafeDownCast (vtkObject o)`
- `obj.SetVectorMode (int )` - Control how the filter works to generate vector cell data. You can choose to pass the input cell vectors, compute the gradient of the input scalars, or extract the vorticity of the computed vector gradient tensor. By default (VectorModeToComputeGradient), the filter will take the gradient of the input scalar data.
- `int = obj.GetVectorMode ()` - Control how the filter works to generate vector cell data. You can choose to pass the input cell vectors, compute the gradient of the input scalars, or extract the vorticity of the computed vector gradient tensor. By default (VectorModeToComputeGradient), the filter will take the gradient of the input scalar data.
- `obj.SetVectorModeToPassVectors ()` - Control how the filter works to generate vector cell data. You can choose to pass the input cell vectors, compute the gradient of the input scalars, or extract the vorticity of the computed vector gradient tensor. By default (VectorModeToComputeGradient), the filter will take the gradient of the input scalar data.
- `obj.SetVectorModeToComputeGradient ()` - Control how the filter works to generate vector cell data. You can choose to pass the input cell vectors, compute the gradient of the input scalars, or extract the vorticity of the computed vector gradient tensor. By default (VectorModeToComputeGradient), the filter will take the gradient of the input scalar data.
- `obj.SetVectorModeToComputeVorticity ()` - Control how the filter works to generate vector cell data. You can choose to pass the input cell vectors, compute the gradient of the input scalars, or extract the vorticity of the computed vector gradient tensor. By default (VectorModeToComputeGradient), the filter will take the gradient of the input scalar data.
- `string = obj.GetVectorModeAsString ()` - Control how the filter works to generate vector cell data. You can choose to pass the input cell vectors, compute the gradient of the input scalars, or extract the vorticity of the computed vector gradient tensor. By default (VectorModeToComputeGradient), the filter will take the gradient of the input scalar data.
- `obj.SetTensorMode (int )` - Control how the filter works to generate tensor cell data. You can choose to pass the input cell tensors, compute the gradient of the input vectors, or compute the strain tensor of the vector gradient tensor. By default (TensorModeToComputeGradient), the filter will take the gradient of the vector data to construct a tensor.
- `int = obj.GetTensorMode ()` - Control how the filter works to generate tensor cell data. You can choose to pass the input cell tensors, compute the gradient of the input vectors, or compute the strain tensor of the vector gradient tensor. By default (TensorModeToComputeGradient), the filter will take the gradient of the vector data to construct a tensor.
- `obj.SetTensorModeToPassTensors ()` - Control how the filter works to generate tensor cell data. You can choose to pass the input cell tensors, compute the gradient of the input vectors, or compute the strain tensor of the vector gradient tensor. By default (TensorModeToComputeGradient), the filter will take the gradient of the vector data to construct a tensor.
- `obj.SetTensorModeToComputeGradient ()` - Control how the filter works to generate tensor cell data. You can choose to pass the input cell tensors, compute the gradient of the input vectors, or compute the strain tensor of the vector gradient tensor. By default (TensorModeToComputeGradient), the filter will take the gradient of the vector data to construct a tensor.
- `obj.SetTensorModeToComputeStrain ()` - Control how the filter works to generate tensor cell data. You can choose to pass the input cell tensors, compute the gradient of the input vectors, or compute the strain tensor of the vector gradient tensor. By default (TensorModeToComputeGradient), the filter will take the gradient of the vector data to construct a tensor.

- `string = obj.GetTensorModeAsString ()` - Control how the filter works to generate tensor cell data. You can choose to pass the input cell tensors, compute the gradient of the input vectors, or compute the strain tensor of the vector gradient tensor. By default (TensorModeToComputeGradient), the filter will take the gradient of the vector data to construct a tensor.

33.24 vtkCleanPolyData

33.24.1 Usage

vtkCleanPolyData is a filter that takes polygonal data as input and generates polygonal data as output. vtkCleanPolyData can merge duplicate points (within specified tolerance and if enabled), eliminate points that are not used, and if enabled, transform degenerate cells into appropriate forms (for example, a triangle is converted into a line if two points of triangle are merged).

Conversion of degenerate cells is controlled by the flags ConvertLinesToPoints, ConvertPolysToLines, ConvertStripsToPolys which act cumulatively such that a degenerate strip may become a poly. The full set is Line with 1 points -¿ Vert (if ConvertLinesToPoints) Poly with 2 points -¿ Line (if ConvertPolysToLines) Poly with 1 points -¿ Vert (if ConvertPolysToLines && ConvertLinesToPoints) Strp with 3 points -¿ Poly (if ConvertStripsToPolys) Strp with 2 points -¿ Line (if ConvertStripsToPolys && ConvertPolysToLines) Strp with 1 points -¿ Vert (if ConvertStripsToPolys && ConvertPolysToLines && ConvertLinesToPoints)

If tolerance is specified precisely=0.0, then vtkCleanPolyData will use the vtkMergePoints object to merge points (which is faster). Otherwise the slower vtkIncrementalPointLocator is used. Before inserting points into the point locator, this class calls a function OperateOnPoint which can be used (in subclasses) to further refine the cleaning process. See vtkQuantizePolyDataPoints.

Note that merging of points can be disabled. In this case, a point locator will not be used, and points that are not used by any cells will be eliminated, but never merged.

To create an instance of class vtkCleanPolyData, simply invoke its constructor as follows

```
obj = vtkCleanPolyData
```

33.24.2 Methods

The class vtkCleanPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCleanPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCleanPolyData = obj.NewInstance ()`
- `vtkCleanPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetToleranceIsAbsolute (int )` - By default ToleranceIsAbsolute is false and Tolerance is a fraction of Bounding box diagonal, if true, AbsoluteTolerance is used when adding points to locator (merging)
- `obj.ToleranceIsAbsoluteOn ()` - By default ToleranceIsAbsolute is false and Tolerance is a fraction of Bounding box diagonal, if true, AbsoluteTolerance is used when adding points to locator (merging)
- `obj.ToleranceIsAbsoluteOff ()` - By default ToleranceIsAbsolute is false and Tolerance is a fraction of Bounding box diagonal, if true, AbsoluteTolerance is used when adding points to locator (merging)
- `int = obj.GetToleranceIsAbsolute ()` - By default ToleranceIsAbsolute is false and Tolerance is a fraction of Bounding box diagonal, if true, AbsoluteTolerance is used when adding points to locator (merging)

- `obj.SetTolerance (double )` - Specify tolerance in terms of fraction of bounding box length.
- `double = obj.GetToleranceMinValue ()` - Specify tolerance in terms of fraction of bounding box length.
- `double = obj.GetToleranceMaxValue ()` - Specify tolerance in terms of fraction of bounding box length.
- `double = obj.GetTolerance ()` - Specify tolerance in terms of fraction of bounding box length.
- `obj.SetAbsoluteTolerance (double )` - Specify tolerance in absolute terms
- `double = obj.GetAbsoluteToleranceMinValue ()` - Specify tolerance in absolute terms
- `double = obj.GetAbsoluteToleranceMaxValue ()` - Specify tolerance in absolute terms
- `double = obj.GetAbsoluteTolerance ()` - Specify tolerance in absolute terms
- `obj.SetConvertLinesToPoints (int )` - Turn on/off conversion of degenerate lines to points
- `obj.ConvertLinesToPointsOn ()` - Turn on/off conversion of degenerate lines to points
- `obj.ConvertLinesToPointsOff ()` - Turn on/off conversion of degenerate lines to points
- `int = obj.GetConvertLinesToPoints ()` - Turn on/off conversion of degenerate lines to points
- `obj.SetConvertPolysToLines (int )` - Turn on/off conversion of degenerate polys to lines
- `obj.ConvertPolysToLinesOn ()` - Turn on/off conversion of degenerate polys to lines
- `obj.ConvertPolysToLinesOff ()` - Turn on/off conversion of degenerate polys to lines
- `int = obj.GetConvertPolysToLines ()` - Turn on/off conversion of degenerate polys to lines
- `obj.SetConvertStripsToPolys (int )` - Turn on/off conversion of degenerate strips to polys
- `obj.ConvertStripsToPolysOn ()` - Turn on/off conversion of degenerate strips to polys
- `obj.ConvertStripsToPolysOff ()` - Turn on/off conversion of degenerate strips to polys
- `int = obj.GetConvertStripsToPolys ()` - Turn on/off conversion of degenerate strips to polys
- `obj.SetPointMerging (int )` - Set/Get a boolean value that controls whether point merging is performed. If on, a locator will be used, and points laying within the appropriate tolerance may be merged. If off, points are never merged. By default, merging is on.
- `int = obj.GetPointMerging ()` - Set/Get a boolean value that controls whether point merging is performed. If on, a locator will be used, and points laying within the appropriate tolerance may be merged. If off, points are never merged. By default, merging is on.
- `obj.PointMergingOn ()` - Set/Get a boolean value that controls whether point merging is performed. If on, a locator will be used, and points laying within the appropriate tolerance may be merged. If off, points are never merged. By default, merging is on.
- `obj.PointMergingOff ()` - Set/Get a boolean value that controls whether point merging is performed. If on, a locator will be used, and points laying within the appropriate tolerance may be merged. If off, points are never merged. By default, merging is on.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set/Get a spatial locator for speeding the search process. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set/Get a spatial locator for speeding the search process. By default an instance of vtkMergePoints is used.

- `obj.CreateDefaultLocator (vtkPolyData input)` - Create default locator. Used to create one when none is specified.
- `obj.ReleaseLocator ()` - Get the MTime of this object also considering the locator.
- `long = obj.GetMTime ()` - Get the MTime of this object also considering the locator.
- `obj.OperateOnPoint (double in[3], double out[3])` - Perform operation on a point
- `obj.OperateOnBounds (double in[6], double out[6])` - Perform operation on bounds
- `obj.SetPieceInvariant (int )`
- `int = obj.GetPieceInvariant ()`
- `obj.PieceInvariantOn ()`
- `obj.PieceInvariantOff ()`

33.25 vtkClipConvexPolyData

33.25.1 Usage

vtkClipConvexPolyData is a filter that clips a convex polydata with a set of planes. Its main usage is for clipping a bounding volume with frustum planes (used later one in volume rendering).

To create an instance of class vtkClipConvexPolyData, simply invoke its constructor as follows

```
obj = vtkClipConvexPolyData
```

33.25.2 Methods

The class vtkClipConvexPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClipConvexPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkClipConvexPolyData = obj.NewInstance ()`
- `vtkClipConvexPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetPlanes (vtkPlaneCollection planes)` - Set all the planes at once using a vtkPlanes implicit function. This also sets the D value.
- `vtkPlaneCollection = obj.GetPlanes ()` - Set all the planes at once using a vtkPlanes implicit function. This also sets the D value.
- `long = obj.GetMTime ()` - Redefines this method, as this filter depends on time of its components (planes)

33.26 vtkClipDataSet

33.26.1 Usage

vtkClipDataSet is a filter that clips any type of dataset using either any subclass of vtkImplicitFunction, or the input scalar data. Clipping means that it actually "cuts" through the cells of the dataset, returning everything inside of the specified implicit function (or greater than the scalar value) including "pieces" of a cell. (Compare this with vtkExtractGeometry, which pulls out entire, uncut cells.) The output of this filter is an unstructured grid.

To use this filter, you must decide if you will be clipping with an implicit function, or whether you will be using the input scalar data. If you want to clip with an implicit function, you must: 1) define an implicit function 2) set it with the SetClipFunction method 3) apply the GenerateClipScalarsOn method If a ClipFunction is not specified, or GenerateClipScalars is off (the default), then the input's scalar data will be used to clip the polydata.

You can also specify a scalar value, which is used to decide what is inside and outside of the implicit function. You can also reverse the sense of what inside/outside is by setting the InsideOut instance variable. (The clipping algorithm proceeds by computing an implicit function value or using the input scalar data for each point in the dataset. This is compared to the scalar value to determine inside/outside.)

This filter can be configured to compute a second output. The second output is the part of the cell that is clipped away. Set the GenerateClippedData boolean on if you wish to access this output data.

To create an instance of class vtkClipDataSet, simply invoke its constructor as follows

```
obj = vtkClipDataSet
```

33.26.2 Methods

The class vtkClipDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClipDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkClipDataSet = obj.NewInstance ()`
- `vtkClipDataSet = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (double )` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0. This value is ignored if UseValueAsOffset is true and a clip function is defined.
- `double = obj.GetValue ()` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0. This value is ignored if UseValueAsOffset is true and a clip function is defined.
- `obj.SetUseValueAsOffset (bool )` - If UseValueAsOffset is true, Value is used as an offset parameter to the implicit function. Otherwise, Value is used only when clipping using a scalar array. Default is true.
- `bool = obj.GetUseValueAsOffset ()` - If UseValueAsOffset is true, Value is used as an offset parameter to the implicit function. Otherwise, Value is used only when clipping using a scalar array. Default is true.
- `obj.UseValueAsOffsetOn ()` - If UseValueAsOffset is true, Value is used as an offset parameter to the implicit function. Otherwise, Value is used only when clipping using a scalar array. Default is true.

- `obj.UseValueAsOffsetOff ()` - If UseValueAsOffset is true, Value is used as an offset parameter to the implicit function. Otherwise, Value is used only when clipping using a scalar array. Default is true.
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.SetClipFunction (vtkImplicitFunction )`
- `vtkImplicitFunction = obj.GetClipFunction ()`
- `obj.SetGenerateClipScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `int = obj.GetGenerateClipScalars ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.GenerateClipScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.GenerateClipScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.SetGenerateClippedOutput (int )` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `int = obj.GetGenerateClippedOutput ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOn ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOff ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.SetMergeTolerance (double )` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate primitives. Note that only 3D cells actually use this instance variable.

- `double = obj.GetMergeToleranceMinValue ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate primitives. Note that only 3D cells actually use this instance variable.
- `double = obj.GetMergeToleranceMaxValue ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate primitives. Note that only 3D cells actually use this instance variable.
- `double = obj.GetMergeTolerance ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate primitives. Note that only 3D cells actually use this instance variable.
- `vtkUnstructuredGrid = obj.GetClippedOutput ()` - Return the Clipped output.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `long = obj.GetMTime ()` - Return the mtime also considering the locator and clip function.

33.27 vtkClipHyperOctree

33.27.1 Usage

vtkClipHyperOctree is a filter that clips an hyperoctree using either any subclass of vtkImplicitFunction, or the input scalar data. Clipping means that it actually "cuts" through the leaves (cells) of the hyperoctree, returning everything inside of the specified implicit function (or greater than the scalar value) including "pieces" of a cell. (Compare this with vtkExtractGeometry, which pulls out entire, uncut cells.) The output of this filter is an unstructured grid.

To use this filter, you must decide if you will be clipping with an implicit function, or whether you will be using the input scalar data. If you want to clip with an implicit function, you must: 1) define an implicit function 2) set it with the SetClipFunction method 3) apply the GenerateClipScalarsOn method If a ClipFunction is not specified, or GenerateClipScalars is off (the default), then the input's scalar data will be used to clip the polydata.

You can also specify a scalar value, which is used to decide what is inside and outside of the implicit function. You can also reverse the sense of what inside/outside is by setting the InsideOut instance variable. (The clipping algorithm proceeds by computing an implicit function value or using the input scalar data for each point in the dataset. This is compared to the scalar value to determine inside/outside.)

This filter can be configured to compute a second output. The second output is the part of the cell that is clipped away. Set the GenerateClippedData boolean on if you wish to access this output data.

To create an instance of class vtkClipHyperOctree, simply invoke its constructor as follows

```
obj = vtkClipHyperOctree
```

33.27.2 Methods

The class vtkClipHyperOctree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClipHyperOctree class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkClipHyperOctree = obj.NewInstance ()`
- `vtkClipHyperOctree = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (double )` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0.
- `double = obj.GetValue ()` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0.
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.SetClipFunction (vtkImplicitFunction )`
- `vtkImplicitFunction = obj.GetClipFunction ()`
- `obj.SetGenerateClipScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `int = obj.GetGenerateClipScalars ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.GenerateClipScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.GenerateClipScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.SetGenerateClippedOutput (int )` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `int = obj.GetGenerateClippedOutput ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOn ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.

- `obj.GenerateClippedOutputOff ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `vtkUnstructuredGrid = obj.GetClippedOutput ()` - Return the Clipped output.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `long = obj.GetMTime ()` - Return the mtime also considering the locator and clip function.

33.28 vtkClipPolyData

33.28.1 Usage

vtkClipPolyData is a filter that clips polygonal data using either any subclass of vtkImplicitFunction, or the input scalar data. Clipping means that it actually "cuts" through the cells of the dataset, returning everything inside of the specified implicit function (or greater than the scalar value) including "pieces" of a cell. (Compare this with vtkExtractGeometry, which pulls out entire, uncut cells.) The output of this filter is polygonal data.

To use this filter, you must decide if you will be clipping with an implicit function, or whether you will be using the input scalar data. If you want to clip with an implicit function, you must: 1) define an implicit function 2) set it with the SetClipFunction method 3) apply the GenerateClipScalarsOn method If a ClipFunction is not specified, or GenerateClipScalars is off (the default), then the input's scalar data will be used to clip the polydata.

You can also specify a scalar value, which is used to decide what is inside and outside of the implicit function. You can also reverse the sense of what inside/outside is by setting the InsideOut instance variable. (The cutting algorithm proceeds by computing an implicit function value or using the input scalar data for each point in the dataset. This is compared to the scalar value to determine inside/outside.)

This filter can be configured to compute a second output. The second output is the polygonal data that is clipped away. Set the GenerateClippedData boolean on if you wish to access this output data.

To create an instance of class vtkClipPolyData, simply invoke its constructor as follows

```
obj = vtkClipPolyData
```

33.28.2 Methods

The class vtkClipPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClipPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkClipPolyData = obj.NewInstance ()`
- `vtkClipPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (double )` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0.

- `double = obj.GetValue ()` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0.
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.
- `obj.SetClipFunction (vtkImplicitFunction )`
- `vtkImplicitFunction = obj.GetClipFunction ()`
- `obj.SetGenerateClipScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `int = obj.GetGenerateClipScalars ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.GenerateClipScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.GenerateClipScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.
- `obj.SetGenerateClippedOutput (int )` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `int = obj.GetGenerateClippedOutput ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOn ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `obj.GenerateClippedOutputOff ()` - Control whether a second output is generated. The second output contains the polygonal data that's been clipped away.
- `vtkPolyData = obj.GetClippedOutput ()` - Return the Clipped output.
- `vtkAlgorithmOutput = obj.GetClippedOutputPort ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.

- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `long = obj.GetMTime ()` - Return the mtime also considering the locator and clip function.

33.29 vtkClipVolume

33.29.1 Usage

vtkClipVolume is a filter that clips volume data (i.e., vtkImageData) using either: any subclass of vtkImplicitFunction or the input scalar data. The clipping operation cuts through the cells of the dataset–converting 3D image data into a 3D unstructured grid–returning everything inside of the specified implicit function (or greater than the scalar value). During the clipping the filter will produce pieces of a cell. (Compare this with vtkExtractGeometry or vtkGeometryFilter, which produces entire, uncut cells.) The output of this filter is a 3D unstructured grid (e.g., tetrahedra or other 3D cell types).

To use this filter, you must decide if you will be clipping with an implicit function, or whether you will be using the input scalar data. If you want to clip with an implicit function, you must first define and then set the implicit function with the SetClipFunction() method. Otherwise, you must make sure input scalar data is available. You can also specify a scalar value, which is used to decide what is inside and outside of the implicit function. You can also reverse the sense of what inside/outside is by setting the InsideOut instance variable. (The cutting algorithm proceeds by computing an implicit function value or using the input scalar data for each point in the dataset. This is compared to the scalar value to determine inside/outside.)

This filter can be configured to compute a second output. The second output is the portion of the volume that is clipped away. Set the GenerateClippedData boolean on if you wish to access this output data.

The filter will produce an unstructured grid of entirely tetrahedra or a mixed grid of tetrahedra and other 3D cell types (e.g., wedges). Control this behavior by setting the Mixed3DCellGeneration. By default the Mixed3DCellGeneration is on and a combination of cell types will be produced. Note that producing mixed cell types is a faster than producing only tetrahedra.

To create an instance of class vtkClipVolume, simply invoke its constructor as follows

```
obj = vtkClipVolume
```

33.29.2 Methods

The class vtkClipVolume has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClipVolume class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkClipVolume = obj.NewInstance ()`
- `vtkClipVolume = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (double )` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0.
- `double = obj.GetValue ()` - Set the clipping value of the implicit function (if clipping with implicit function) or scalar value (if clipping with scalars). The default value is 0.0.

- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.

- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.

- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.

- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. When off, a vertex is considered inside the implicit function if its value is greater than the Value ivar. When InsideOutside is turned on, a vertex is considered inside the implicit function if its implicit function value is less than or equal to the Value ivar. InsideOut is off by default.

- `obj.SetClipFunction (vtkImplicitFunction )`

- `vtkImplicitFunction = obj.GetClipFunction ()`

- `obj.SetGenerateClipScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.

- `int = obj.GetGenerateClipScalars ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.

- `obj.GenerateClipScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.

- `obj.GenerateClipScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data. If you enable this flag but do not provide an implicit function an error will be reported.

- `obj.SetGenerateClippedOutput (int )` - Control whether a second output is generated. The second output contains the unstructured grid that's been clipped away.

- `int = obj.GetGenerateClippedOutput ()` - Control whether a second output is generated. The second output contains the unstructured grid that's been clipped away.

- `obj.GenerateClippedOutputOn ()` - Control whether a second output is generated. The second output contains the unstructured grid that's been clipped away.

- `obj.GenerateClippedOutputOff ()` - Control whether a second output is generated. The second output contains the unstructured grid that's been clipped away.

- `vtkUnstructuredGrid = obj.GetClippedOutput ()` - Return the clipped output.

- `obj.SetMixed3DCellGeneration (int )` - Control whether the filter produces a mix of 3D cell types on output, or whether the output cells are all tetrahedra. By default, a mixed set of cells (e.g., tetrahedra and wedges) is produced. (Note: mixed type generation is faster and less overall data is generated.)

- `int = obj.GetMixed3DCellGeneration ()` - Control whether the filter produces a mix of 3D cell types on output, or whether the output cells are all tetrahedra. By default, a mixed set of cells (e.g., tetrahedra and wedges) is produced. (Note: mixed type generation is faster and less overall data is generated.)
- `obj.Mixed3DCellGenerationOn ()` - Control whether the filter produces a mix of 3D cell types on output, or whether the output cells are all tetrahedra. By default, a mixed set of cells (e.g., tetrahedra and wedges) is produced. (Note: mixed type generation is faster and less overall data is generated.)
- `obj.Mixed3DCellGenerationOff ()` - Control whether the filter produces a mix of 3D cell types on output, or whether the output cells are all tetrahedra. By default, a mixed set of cells (e.g., tetrahedra and wedges) is produced. (Note: mixed type generation is faster and less overall data is generated.)
- `obj.SetMergeTolerance (double )` - Set the tolerance for merging clip intersection points that are near the corners of voxels. This tolerance is used to prevent the generation of degenerate tetrahedra.
- `double = obj.GetMergeToleranceMinValue ()` - Set the tolerance for merging clip intersection points that are near the corners of voxels. This tolerance is used to prevent the generation of degenerate tetrahedra.
- `double = obj.GetMergeToleranceMaxValue ()` - Set the tolerance for merging clip intersection points that are near the corners of voxels. This tolerance is used to prevent the generation of degenerate tetrahedra.
- `double = obj.GetMergeTolerance ()` - Set the tolerance for merging clip intersection points that are near the corners of voxels. This tolerance is used to prevent the generation of degenerate tetrahedra.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / Get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / Get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `long = obj.GetMTime ()` - Return the mtime also considering the locator and clip function.

33.30 vtkCoincidentPoints

33.30.1 Usage

This class provides a collection of points that is organized such that each coordinate is stored with a set of point id's of points that are all coincident.

To create an instance of class vtkCoincidentPoints, simply invoke its constructor as follows

```
obj = vtkCoincidentPoints
```

33.30.2 Methods

The class vtkCoincidentPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCoincidentPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkCoincidentPoints = obj.NewInstance ()`
- `vtkCoincidentPoints = obj.SafeDownCast (vtkObject o)`
- `obj.AddPoint (vtkIdType Id, double point[3])` - Accumulates a set of Ids in a map where the point coordinate is the key. All Ids in a given map entry are thus coincident. @param Id - a unique Id for the given point that will be stored in an vtkIdList. @param[in] point - the point coordinate that we will store in the map to test if any other points are coincident with it.
- `vtkIdList = obj.GetCoincidentPointIds (double point[3])` - Retrieve the list of point Ids that are coincident with the given point. @param[in] point - the coordinate of coincident points we want to retrieve.
- `vtkIdList = obj.GetNextCoincidentPointIds ()` - Used to iterate the sets of coincident points within the map. InitTraversal must be called first or NULL will always be returned.
- `obj.InitTraversal ()`
- `obj.RemoveNonCoincidentPoints ()`
- `obj.Clear ()`

33.31 vtkCompositeDataGeometryFilter

33.31.1 Usage

vtkCompositeDataGeometryFilter applies vtkGeometryFilter to all leaves in vtkCompositeDataSet. Place this filter at the end of a pipeline before a polydata consumer such as a polydata mapper to extract geometry from all blocks and append them to one polydata object.

To create an instance of class vtkCompositeDataGeometryFilter, simply invoke its constructor as follows

```
obj = vtkCompositeDataGeometryFilter
```

33.31.2 Methods

The class vtkCompositeDataGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeDataGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeDataGeometryFilter = obj.NewInstance ()`
- `vtkCompositeDataGeometryFilter = obj.SafeDownCast (vtkObject o)`

33.32 vtkCompositeDataProbeFilter

33.32.1 Usage

vtkCompositeDataProbeFilter supports probing into multi-group datasets. It sequentially probes through each concrete dataset within the composite probing at only those locations at which there were no hits when probing earlier datasets. For Hierarchical datasets, this traversal through leaf datasets is done in reverse order of levels i.e. highest level first.

When dealing with composite datasets, partial arrays are common i.e. data-arrays that are not available in all of the blocks. By default, this filter only passes those point and cell data-arrays that are available

in all the blocks i.e. partial array are removed. When PassPartialArrays is turned on, this behavior is changed to take a union of all arrays present thus partial arrays are passed as well. However, for composite dataset input, this filter still produces a non-composite output. For all those locations in a block of where a particular data array is missing, this filter uses vtkMath::Nan() for double and float arrays, while 0 for all other types of arrays i.e int, char etc.

To create an instance of class vtkCompositeDataProbeFilter, simply invoke its constructor as follows

```
obj = vtkCompositeDataProbeFilter
```

33.32.2 Methods

The class vtkCompositeDataProbeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeDataProbeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeDataProbeFilter = obj.NewInstance ()`
- `vtkCompositeDataProbeFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPassPartialArrays (bool )` - When dealing with composite datasets, partial arrays are common i.e. data-arrays that are not available in all of the blocks. By default, this filter only passes those point and cell data-arrays that are available in all the blocks i.e. partial array are removed. When PassPartialArrays is turned on, this behavior is changed to take a union of all arrays present thus partial arrays are passed as well. However, for composite dataset input, this filter still produces a non-composite output. For all those locations in a block of where a particular data array is missing, this filter uses vtkMath::Nan() for double and float arrays, while 0 for all other types of arrays i.e int, char etc.
- `bool = obj.GetPassPartialArrays ()` - When dealing with composite datasets, partial arrays are common i.e. data-arrays that are not available in all of the blocks. By default, this filter only passes those point and cell data-arrays that are available in all the blocks i.e. partial array are removed. When PassPartialArrays is turned on, this behavior is changed to take a union of all arrays present thus partial arrays are passed as well. However, for composite dataset input, this filter still produces a non-composite output. For all those locations in a block of where a particular data array is missing, this filter uses vtkMath::Nan() for double and float arrays, while 0 for all other types of arrays i.e int, char etc.
- `obj.PassPartialArraysOn ()` - When dealing with composite datasets, partial arrays are common i.e. data-arrays that are not available in all of the blocks. By default, this filter only passes those point and cell data-arrays that are available in all the blocks i.e. partial array are removed. When PassPartialArrays is turned on, this behavior is changed to take a union of all arrays present thus partial arrays are passed as well. However, for composite dataset input, this filter still produces a non-composite output. For all those locations in a block of where a particular data array is missing, this filter uses vtkMath::Nan() for double and float arrays, while 0 for all other types of arrays i.e int, char etc.
- `obj.PassPartialArraysOff ()` - When dealing with composite datasets, partial arrays are common i.e. data-arrays that are not available in all of the blocks. By default, this filter only passes those point and cell data-arrays that are available in all the blocks i.e. partial array are removed. When PassPartialArrays is turned on, this behavior is changed to take a union of all arrays present thus partial arrays are passed as well. However, for composite dataset input, this filter still produces a non-composite output. For all those locations in a block of where a particular data array is missing, this filter uses vtkMath::Nan() for double and float arrays, while 0 for all other types of arrays i.e int, char etc.

33.33 vtkConeSource

33.33.1 Usage

vtkConeSource creates a cone centered at a specified point and pointing in a specified direction. (By default, the center is the origin and the direction is the x-axis.) Depending upon the resolution of this object, different representations are created. If resolution=0 a line is created; if resolution=1, a single triangle is created; if resolution=2, two crossed triangles are created. For resolution ¿ 2, a 3D cone (with resolution number of sides) is created. It also is possible to control whether the bottom of the cone is capped with a (resolution-sided) polygon, and to specify the height and radius of the cone.

To create an instance of class vtkConeSource, simply invoke its constructor as follows

```
obj = vtkConeSource
```

33.33.2 Methods

The class vtkConeSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConeSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConeSource = obj.NewInstance ()`
- `vtkConeSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetHeight (double )` - Set the height of the cone. This is the height along the cone in its specified direction.
- `double = obj.GetHeightMinValue ()` - Set the height of the cone. This is the height along the cone in its specified direction.
- `double = obj.GetHeightMaxValue ()` - Set the height of the cone. This is the height along the cone in its specified direction.
- `double = obj.GetHeight ()` - Set the height of the cone. This is the height along the cone in its specified direction.
- `obj.SetRadius (double )` - Set the base radius of the cone.
- `double = obj.GetRadiusMinValue ()` - Set the base radius of the cone.
- `double = obj.GetRadiusMaxValue ()` - Set the base radius of the cone.
- `double = obj.GetRadius ()` - Set the base radius of the cone.
- `obj.SetResolution (int )` - Set the number of facets used to represent the cone.
- `int = obj.GetResolutionMinValue ()` - Set the number of facets used to represent the cone.
- `int = obj.GetResolutionMaxValue ()` - Set the number of facets used to represent the cone.
- `int = obj.GetResolution ()` - Set the number of facets used to represent the cone.
- `obj.SetCenter (double , double , double )` - Set the center of the cone. It is located at the middle of the axis of the cone. Warning: this is not the center of the base of the cone! The default is 0,0,0.

- `obj.SetCenter (double a[3])` - Set the center of the cone. It is located at the middle of the axis of the cone. Warning: this is not the center of the base of the cone! The default is 0,0,0.
- `double = obj. GetCenter ()` - Set the center of the cone. It is located at the middle of the axis of the cone. Warning: this is not the center of the base of the cone! The default is 0,0,0.
- `obj.SetDirection (double , double , double )` - Set the orientation vector of the cone. The vector does not have to be normalized. The direction goes from the center of the base toward the apex. The default is (1,0,0).
- `obj.SetDirection (double a[3])` - Set the orientation vector of the cone. The vector does not have to be normalized. The direction goes from the center of the base toward the apex. The default is (1,0,0).
- `double = obj. GetDirection ()` - Set the orientation vector of the cone. The vector does not have to be normalized. The direction goes from the center of the base toward the apex. The default is (1,0,0).
- `obj.SetAngle (double angle)` - Set the angle of the cone. This is the angle between the axis of the cone and a generatrix. Warning: this is not the aperture! The aperture is twice this angle. As a side effect, the angle plus height sets the base radius of the cone. Angle is expressed in degrees.
- `double = obj.GetAngle ()` - Set the angle of the cone. This is the angle between the axis of the cone and a generatrix. Warning: this is not the aperture! The aperture is twice this angle. As a side effect, the angle plus height sets the base radius of the cone. Angle is expressed in degrees.
- `obj.SetCapping (int )` - Turn on/off whether to cap the base of the cone with a polygon.
- `int = obj.GetCapping ()` - Turn on/off whether to cap the base of the cone with a polygon.
- `obj.CappingOn ()` - Turn on/off whether to cap the base of the cone with a polygon.
- `obj.CappingOff ()` - Turn on/off whether to cap the base of the cone with a polygon.

33.34 vtkConnectivityFilter

33.34.1 Usage

vtkConnectivityFilter is a filter that extracts cells that share common points and/or meet other connectivity criterion. (Cells that share vertices and meet other connectivity criterion such as scalar range are known as a region.) The filter works in one of six ways: 1) extract the largest connected region in the dataset; 2) extract specified region numbers; 3) extract all regions sharing specified point ids; 4) extract all regions sharing specified cell ids; 5) extract the region closest to the specified point; or 6) extract all regions (used to color the data by region).

vtkConnectivityFilter is generalized to handle any type of input dataset. It generates output data of type vtkUnstructuredGrid. If you know that your input type is vtkPolyData, you may wish to use vtkPolyDataConnectivityFilter.

The behavior of vtkConnectivityFilter can be modified by turning on the boolean ivar ScalarConnectivity. If this flag is on, the connectivity algorithm is modified so that cells are considered connected only if 1) they are geometrically connected (share a point) and 2) the scalar values of one of the cell's points falls in the scalar range specified. This use of ScalarConnectivity is particularly useful for volume datasets: it can be used as a simple "connected segmentation" algorithm. For example, by using a seed voxel (i.e., cell) on a known anatomical structure, connectivity will pull out all voxels "containing" the anatomical structure. These voxels can then be contoured or processed by other visualization filters.

To create an instance of class vtkConnectivityFilter, simply invoke its constructor as follows

```
obj = vtkConnectivityFilter
```

33.34.2 Methods

The class vtkConnectivityFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConnectivityFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConnectivityFilter = obj.NewInstance ()`
- `vtkConnectivityFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetScalarConnectivity (int )` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `int = obj.GetScalarConnectivity ()` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `obj.ScalarConnectivityOn ()` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `obj.ScalarConnectivityOff ()` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `obj.SetScalarRange (double , double )` - Set the scalar range to use to extract cells based on scalar connectivity.
- `obj.SetScalarRange (double  a[2])` - Set the scalar range to use to extract cells based on scalar connectivity.
- `double = obj. GetScalarRange ()` - Set the scalar range to use to extract cells based on scalar connectivity.
- `obj.SetExtractionMode (int )` - Control the extraction of connected surfaces.
- `int = obj.GetExtractionModeMinValue ()` - Control the extraction of connected surfaces.
- `int = obj.GetExtractionModeMaxValue ()` - Control the extraction of connected surfaces.
- `int = obj.GetExtractionMode ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToPointSeededRegions ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToCellSeededRegions ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToLargestRegion ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToSpecifiedRegions ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToClosestPointRegion ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToAllRegions ()` - Control the extraction of connected surfaces.
- `string = obj.GetExtractionModeAsString ()` - Control the extraction of connected surfaces.
- `obj.InitializeSeedList ()` - Initialize list of point ids/cell ids used to seed regions.
- `obj.AddSeed (vtkIdType id)` - Add a seed id (point or cell id). Note: ids are 0-offset.

- `obj.DeleteSeed (vtkIdType id)` - Delete a seed id (point or cell id). Note: ids are 0-offset.
- `obj.InitializeSpecifiedRegionList ()` - Initialize list of region ids to extract.
- `obj.AddSpecifiedRegion (int id)` - Add a region id to extract. Note: ids are 0-offset.
- `obj.DeleteSpecifiedRegion (int id)` - Delete a region id to extract. Note: ids are 0-offset.
- `obj.SetClosestPoint (double , double , double )` - Use to specify x-y-z point coordinates when extracting the region closest to a specified point.
- `obj.SetClosestPoint (double a[3])` - Use to specify x-y-z point coordinates when extracting the region closest to a specified point.
- `double = obj. GetClosestPoint ()` - Use to specify x-y-z point coordinates when extracting the region closest to a specified point.
- `int = obj.GetNumberOfExtractedRegions ()` - Obtain the number of connected regions.
- `obj.SetColorRegions (int )` - Turn on/off the coloring of connected regions.
- `int = obj.GetColorRegions ()` - Turn on/off the coloring of connected regions.
- `obj.ColorRegionsOn ()` - Turn on/off the coloring of connected regions.
- `obj.ColorRegionsOff ()` - Turn on/off the coloring of connected regions.

33.35 vtkContourFilter

33.35.1 Usage

vtkContourFilter is a filter that takes as input any dataset and generates on output isosurfaces and/or isolines. The exact form of the output depends upon the dimensionality of the input data. Data consisting of 3D cells will generate isosurfaces, data consisting of 2D cells will generate isolines, and data with 1D or 0D cells will generate isopoints. Combinations of output type are possible if the input dimension is mixed.

To use this filter you must specify one or more contour values. You can either use the method SetValue() to specify each contour value, or use GenerateValues() to generate a series of evenly spaced contours. It is also possible to accelerate the operation of this filter (at the cost of extra memory) by using a vtkScalarTree. A scalar tree is used to quickly locate cells that contain a contour surface. This is especially effective if multiple contours are being extracted. If you want to use a scalar tree, invoke the method UseScalarTreeOn().

To create an instance of class vtkContourFilter, simply invoke its constructor as follows

```
obj = vtkContourFilter
```

33.35.2 Methods

The class vtkContourFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContourFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkContourFilter = obj.NewInstance ()`
- `vtkContourFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Methods to set / get contour values.

- `double = obj.GetValue (int i)` - Methods to set / get contour values.
- `obj.GetValues (double contourValues)` - Methods to set / get contour values.
- `obj.SetNumberOfContours (int number)` - Methods to set / get contour values.
- `int = obj.GetNumberOfContours ()` - Methods to set / get contour values.
- `obj.GenerateValues (int numContours, double range[2])` - Methods to set / get contour values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Methods to set / get contour values.
- `long = obj.GetMTime ()` - Modified GetMTime Because we delegate to vtkContourValues
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.
- `obj.SetUseScalarTree (int )` - Enable the use of a scalar tree to accelerate contour extraction.

- `int = obj.GetUseScalarTree ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.UseScalarTreeOn ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.UseScalarTreeOff ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.SetScalarTree (vtkScalarTree )` - Enable the use of a scalar tree to accelerate contour extraction.
- `vtkScalarTree = obj.GetScalarTree ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `obj.SetArrayComponent (int )` - Set/get which component of the scalar array to contour on; defaults to 0. Currently this feature only works if the input is a vtkImageData.
- `int = obj.GetArrayComponent ()` - Set/get which component of the scalar array to contour on; defaults to 0. Currently this feature only works if the input is a vtkImageData.

33.36 vtkContourGrid

33.36.1 Usage

vtkContourGrid is a filter that takes as input datasets of type vtkUnstructuredGrid and generates on output isosurfaces and/or isolines. The exact form of the output depends upon the dimensionality of the input data. Data consisting of 3D cells will generate isosurfaces, data consisting of 2D cells will generate isolines, and data with 1D or 0D cells will generate isopoints. Combinations of output type are possible if the input dimension is mixed.

To use this filter you must specify one or more contour values. You can either use the method SetValue() to specify each contour value, or use GenerateValues() to generate a series of evenly spaced contours. It is also possible to accelerate the operation of this filter (at the cost of extra memory) by using a vtkScalarTree. A scalar tree is used to quickly locate cells that contain a contour surface. This is especially effective if multiple contours are being extracted. If you want to use a scalar tree, invoke the method UseScalarTreeOn().

To create an instance of class vtkContourGrid, simply invoke its constructor as follows

```
obj = vtkContourGrid
```

33.36.2 Methods

The class vtkContourGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContourGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkContourGrid = obj.NewInstance ()`
- `vtkContourGrid = obj.SafeDownCast (vtkObject o)`

- `obj.SetValue (int i, double value)` - Methods to set / get contour values.
- `double = obj.GetValue (int i)` - Methods to set / get contour values.
- `obj.GetValues (double contourValues)` - Methods to set / get contour values.
- `obj.SetNumberOfContours (int number)` - Methods to set / get contour values.
- `int = obj.GetNumberOfContours ()` - Methods to set / get contour values.
- `obj.GenerateValues (int numContours, double range[2])` - Methods to set / get contour values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Methods to set / get contour values.
- `long = obj.GetMTime ()` - Modified GetMTime Because we delegate to vtkContourValues
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.

- `obj.SetUseScalarTree (int )` - Enable the use of a scalar tree to accelerate contour extraction.
- `int = obj.GetUseScalarTree ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.UseScalarTreeOn ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.UseScalarTreeOff ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.37 vtkConvertSelection

33.37.1 Usage

vtkConvertSelection converts an input selection from one type to another in the context of a data object being selected. The first input is the selection, while the second input is the data object that the selection relates to.

To create an instance of class vtkConvertSelection, simply invoke its constructor as follows

```
obj = vtkConvertSelection
```

33.37.2 Methods

The class vtkConvertSelection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConvertSelection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConvertSelection = obj.NewInstance ()`
- `vtkConvertSelection = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataObjectConnection (vtkAlgorithmOutput in)` - A convenience method for setting the second input (i.e. the data object).
- `obj.SetInputFieldType (int )` - The input field type. If this is set to a number other than -1, ignores the input selection field type and instead assumes that all selection nodes have the field type specified. This should be one of the constants defined in vtkSelectionNode.h. Default is -1.
- `int = obj.GetInputFieldType ()` - The input field type. If this is set to a number other than -1, ignores the input selection field type and instead assumes that all selection nodes have the field type specified. This should be one of the constants defined in vtkSelectionNode.h. Default is -1.
- `obj.SetOutputType (int )` - The output selection content type. This should be one of the constants defined in vtkSelectionNode.h.
- `int = obj.GetOutputType ()` - The output selection content type. This should be one of the constants defined in vtkSelectionNode.h.

- `obj.SetArrayName (string )` - The output array name for value or threshold selections.
- `string = obj.GetArrayName ()` - The output array name for value or threshold selections.
- `obj.SetArrayNames (vtkStringArray )` - The output array names for value selection.
- `vtkStringArray = obj.GetArrayNames ()` - The output array names for value selection.
- `obj.AddArrayName (string )` - Convenience methods used by UI
- `obj.ClearArrayNames ()` - Convenience methods used by UI
- `obj.SetMatchAnyValues (bool )` - When on, creates a separate selection node for each array. Defaults to OFF.
- `bool = obj.GetMatchAnyValues ()` - When on, creates a separate selection node for each array. Defaults to OFF.
- `obj.MatchAnyValuesOn ()` - When on, creates a separate selection node for each array. Defaults to OFF.
- `obj.MatchAnyValuesOff ()` - When on, creates a separate selection node for each array. Defaults to OFF.

33.38 vtkCubeSource

33.38.1 Usage

vtkCubeSource creates a cube centered at origin. The cube is represented with four-sided polygons. It is possible to specify the length, width, and height of the cube independently.

To create an instance of class vtkCubeSource, simply invoke its constructor as follows

```
obj = vtkCubeSource
```

33.38.2 Methods

The class vtkCubeSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCubeSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCubeSource = obj.NewInstance ()`
- `vtkCubeSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetXLength (double )` - Set the length of the cube in the x-direction.
- `double = obj.GetXLengthMinValue ()` - Set the length of the cube in the x-direction.
- `double = obj.GetXLengthMaxValue ()` - Set the length of the cube in the x-direction.
- `double = obj.GetXLength ()` - Set the length of the cube in the x-direction.
- `obj.SetYLength (double )` - Set the length of the cube in the y-direction.
- `double = obj.GetYLengthMinValue ()` - Set the length of the cube in the y-direction.

- `double = obj.GetYLengthMaxValue ()` - Set the length of the cube in the y-direction.
- `double = obj.GetYLength ()` - Set the length of the cube in the y-direction.
- `obj.SetZLength (double )` - Set the length of the cube in the z-direction.
- `double = obj.GetZLengthMinValue ()` - Set the length of the cube in the z-direction.
- `double = obj.GetZLengthMaxValue ()` - Set the length of the cube in the z-direction.
- `double = obj.GetZLength ()` - Set the length of the cube in the z-direction.
- `obj.SetCenter (double , double , double )` - Set the center of the cube.
- `obj.SetCenter (double  a[3])` - Set the center of the cube.
- `double = obj. GetCenter ()` - Set the center of the cube.
- `obj.SetBounds (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)` - Convenience method allows creation of cube by specifying bounding box.
- `obj.SetBounds (double bounds[6])` - Convenience method allows creation of cube by specifying bounding box.

33.39 vtkCursor2D

33.39.1 Usage

vtkCursor2D is a class that generates a 2D cursor representation. The cursor consists of two intersection axes lines that meet at the cursor focus. Several optional features are available as well. An optional 2D bounding box may be enabled. An inner radius, centered at the focal point, can be set that erases the intersecting lines (e.g., it leaves a clear area under the focal point so you can see what you are selecting). And finally, an optional point can be enabled located at the focal point. All of these features can be turned on and off independently.

To create an instance of class vtkCursor2D, simply invoke its constructor as follows

```
obj = vtkCursor2D
```

33.39.2 Methods

The class vtkCursor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCursor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCursor2D = obj.NewInstance ()`
- `vtkCursor2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetModelBounds (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set / get the bounding box of the 2D cursor. This defines the outline of the cursor, and where the focal point should lie.
- `obj.SetModelBounds (double bounds[6])` - Set / get the bounding box of the 2D cursor. This defines the outline of the cursor, and where the focal point should lie.

- `double = obj. GetModelBounds ()` - Set / get the bounding box of the 2D cursor. This defines the outline of the cursor, and where the focal point should lie.
- `obj.SetFocalPoint (double x[3])` - Set/Get the position of cursor focus. If translation mode is on, then the entire cursor (including bounding box, cursor, and shadows) is translated. Otherwise, the focal point will either be clamped to the bounding box, or wrapped, if Wrap is on. (Note: this behavior requires that the bounding box is set prior to the focal point.) Note that the method takes a 3D point but ignores the z-coordinate value.
- `obj.SetFocalPoint (double x, double y, double z)` - Set/Get the position of cursor focus. If translation mode is on, then the entire cursor (including bounding box, cursor, and shadows) is translated. Otherwise, the focal point will either be clamped to the bounding box, or wrapped, if Wrap is on. (Note: this behavior requires that the bounding box is set prior to the focal point.) Note that the method takes a 3D point but ignores the z-coordinate value.
- `double = obj. GetFocalPoint ()` - Set/Get the position of cursor focus. If translation mode is on, then the entire cursor (including bounding box, cursor, and shadows) is translated. Otherwise, the focal point will either be clamped to the bounding box, or wrapped, if Wrap is on. (Note: this behavior requires that the bounding box is set prior to the focal point.) Note that the method takes a 3D point but ignores the z-coordinate value.
- `obj.SetOutline (int )` - Turn on/off the wireframe bounding box.
- `int = obj.GetOutline ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOn ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOff ()` - Turn on/off the wireframe bounding box.
- `obj.SetAxes (int )` - Turn on/off the wireframe axes.
- `int = obj.GetAxes ()` - Turn on/off the wireframe axes.
- `obj.AxesOn ()` - Turn on/off the wireframe axes.
- `obj.AxesOff ()` - Turn on/off the wireframe axes.
- `obj.SetRadius (double )` - Specify a radius for a circle. This erases the cursor lines around the focal point.
- `double = obj.GetRadiusMinValue ()` - Specify a radius for a circle. This erases the cursor lines around the focal point.
- `double = obj.GetRadiusMaxValue ()` - Specify a radius for a circle. This erases the cursor lines around the focal point.
- `double = obj.GetRadius ()` - Specify a radius for a circle. This erases the cursor lines around the focal point.
- `obj.SetPoint (int )` - Turn on/off the point located at the cursor focus.
- `int = obj.GetPoint ()` - Turn on/off the point located at the cursor focus.
- `obj.PointOn ()` - Turn on/off the point located at the cursor focus.
- `obj.PointOff ()` - Turn on/off the point located at the cursor focus.
- `obj.SetTranslationMode (int )` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.
- `int = obj.GetTranslationMode ()` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.

- `obj.TranslationModeOn ()` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.
- `obj.TranslationModeOff ()` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.
- `obj.SetWrap (int )` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `int = obj.GetWrap ()` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `obj.WrapOn ()` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `obj.WrapOff ()` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `obj.AllOn ()` - Turn every part of the cursor on or off.
- `obj.AllOff ()` - Turn every part of the cursor on or off.

33.40 vtkCursor3D

33.40.1 Usage

vtkCursor3D is an object that generates a 3D representation of a cursor. The cursor consists of a wireframe bounding box, three intersecting axes lines that meet at the cursor focus, and "shadows" or projections of the axes against the sides of the bounding box. Each of these components can be turned on/off.

This filter generates two output datasets. The first (Output) is just the geometric representation of the cursor. The second (Focus) is a single point at the focal point.

To create an instance of class vtkCursor3D, simply invoke its constructor as follows

```
obj = vtkCursor3D
```

33.40.2 Methods

The class vtkCursor3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCursor3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCursor3D = obj.NewInstance ()`
- `vtkCursor3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetModelBounds (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set / get the boundary of the 3D cursor.
- `obj.SetModelBounds (double bounds[6])` - Set / get the boundary of the 3D cursor.

- `double = obj. GetModelBounds ()` - Set / get the boundary of the 3D cursor.
- `obj.SetFocalPoint (double x[3])` - Set/Get the position of cursor focus. If translation mode is on, then the entire cursor (including bounding box, cursor, and shadows) is translated. Otherwise, the focal point will either be clamped to the bounding box, or wrapped, if Wrap is on. (Note: this behavior requires that the bounding box is set prior to the focal point.)
- `obj.SetFocalPoint (double x, double y, double z)` - Set/Get the position of cursor focus. If translation mode is on, then the entire cursor (including bounding box, cursor, and shadows) is translated. Otherwise, the focal point will either be clamped to the bounding box, or wrapped, if Wrap is on. (Note: this behavior requires that the bounding box is set prior to the focal point.)
- `double = obj. GetFocalPoint ()` - Set/Get the position of cursor focus. If translation mode is on, then the entire cursor (including bounding box, cursor, and shadows) is translated. Otherwise, the focal point will either be clamped to the bounding box, or wrapped, if Wrap is on. (Note: this behavior requires that the bounding box is set prior to the focal point.)
- `obj.SetOutline (int )` - Turn on/off the wireframe bounding box.
- `int = obj.GetOutline ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOn ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOff ()` - Turn on/off the wireframe bounding box.
- `obj.SetAxes (int )` - Turn on/off the wireframe axes.
- `int = obj.GetAxes ()` - Turn on/off the wireframe axes.
- `obj.AxesOn ()` - Turn on/off the wireframe axes.
- `obj.AxesOff ()` - Turn on/off the wireframe axes.
- `obj.SetXShadows (int )` - Turn on/off the wireframe x-shadows.
- `int = obj.GetXShadows ()` - Turn on/off the wireframe x-shadows.
- `obj.XShadowsOn ()` - Turn on/off the wireframe x-shadows.
- `obj.XShadowsOff ()` - Turn on/off the wireframe x-shadows.
- `obj.SetYShadows (int )` - Turn on/off the wireframe y-shadows.
- `int = obj.GetYShadows ()` - Turn on/off the wireframe y-shadows.
- `obj.YShadowsOn ()` - Turn on/off the wireframe y-shadows.
- `obj.YShadowsOff ()` - Turn on/off the wireframe y-shadows.
- `obj.SetZShadows (int )` - Turn on/off the wireframe z-shadows.
- `int = obj.GetZShadows ()` - Turn on/off the wireframe z-shadows.
- `obj.ZShadowsOn ()` - Turn on/off the wireframe z-shadows.
- `obj.ZShadowsOff ()` - Turn on/off the wireframe z-shadows.
- `obj.SetTranslationMode (int )` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.
- `int = obj.GetTranslationMode ()` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.

- `obj.TranslationModeOn ()` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.
- `obj.TranslationModeOff ()` - Enable/disable the translation mode. If on, changes in cursor position cause the entire widget to translate along with the cursor. By default, translation mode is off.
- `obj.SetWrap (int )` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `int = obj.GetWrap ()` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `obj.WrapOn ()` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `obj.WrapOff ()` - Turn on/off cursor wrapping. If the cursor focus moves outside the specified bounds, the cursor will either be restrained against the nearest "wall" (Wrap=off), or it will wrap around (Wrap=on).
- `vtkPolyData = obj.GetFocus ()` - Get the focus for this filter.
- `obj.AllOn ()` - Turn every part of the 3D cursor on or off.
- `obj.AllOff ()` - Turn every part of the 3D cursor on or off.

33.41 vtkCurvatures

33.41.1 Usage

vtkCurvatures takes a polydata input and computes the curvature of the mesh at each point. Four possible methods of computation are available :

Gauss Curvature discrete Gauss curvature (K) computation, $K(vertexv) = 2*PI - \sum_{facetneighbsfofv}(angle_fatv)$ The contribution of every facet is for the moment weighted by $Area(facet)/3$ The units of Gaussian Curvature are $[1/m^2]$

Mean Curvature $H(vertexv) = averageoveredgesneighbseofH(e)\ H(edgee) = length(e)*dihedral_angle(e)$ NB: dihedral_angle is the ORIENTED angle between -PI and PI, this means that the surface is assumed to be orientable the computation creates the orientation The units of Mean Curvature are [1/m]

Maximum (k_max) and Minimum (k_min) Principal Curvatures $k_max = H + sqrt(H^2 - K)$ $k_min = H - sqrt(H^2 - K)$ Excepting spherical and planar surfaces which have equal principal curvatures, the curvature at a point on a surface varies with the direction one "sets off" from the point. For all directions, the curvature will pass through two extrema: a minimum (k_min) and a maximum (k_max) which occur at mutually orthogonal directions to each other.

NB. The sign of the Gauss curvature is a geometric ivariant, it should be +ve when the surface looks like a sphere, -ve when it looks like a saddle, however, the sign of the Mean curvature is not, it depends on the convention for normals - This code assumes that normals point outwards (ie from the surface of a sphere outwards). If a given mesh produces curvatures of opposite senses then the flag InvertMeanCurvature can be set and the Curvature reported by the Mean calculation will be inverted.

.SECTION Thanks Philip Batchelor philipp.batchelor@kcl.ac.uk for creating and contributing the class and Andrew Maclean a.maclean@acfr.usyd.edu.au for cleanups and fixes. Thanks also to Goodwin Lawlor for contributing patch to calculate principal curvatures

To create an instance of class vtkCurvatures, simply invoke its constructor as follows

```
obj = vtkCurvatures
```

33.41.2 Methods

The class vtkCurvatures has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCurvatures class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCurvatures = obj.NewInstance ()`
- `vtkCurvatures = obj.SafeDownCast (vtkObject o)`
- `obj.SetCurvatureType (int )` - Set/Get Curvature type VTK_CURVATURE_GAUSS: Gaussian curvature, stored as DataArray "Gauss_Curvature" VTK_CURVATURE_MEAN : Mean curvature, stored as DataArray "Mean_Curvature"
- `int = obj.GetCurvatureType ()` - Set/Get Curvature type VTK_CURVATURE_GAUSS: Gaussian curvature, stored as DataArray "Gauss_Curvature" VTK_CURVATURE_MEAN : Mean curvature, stored as DataArray "Mean_Curvature"
- `obj.SetCurvatureTypeToGaussian ()` - Set/Get Curvature type VTK_CURVATURE_GAUSS: Gaussian curvature, stored as DataArray "Gauss_Curvature" VTK_CURVATURE_MEAN : Mean curvature, stored as DataArray "Mean_Curvature"
- `obj.SetCurvatureTypeToMean ()` - Set/Get Curvature type VTK_CURVATURE_GAUSS: Gaussian curvature, stored as DataArray "Gauss_Curvature" VTK_CURVATURE_MEAN : Mean curvature, stored as DataArray "Mean_Curvature"
- `obj.SetCurvatureTypeToMaximum ()` - Set/Get Curvature type VTK_CURVATURE_GAUSS: Gaussian curvature, stored as DataArray "Gauss_Curvature" VTK_CURVATURE_MEAN : Mean curvature, stored as DataArray "Mean_Curvature"
- `obj.SetCurvatureTypeToMinimum ()` - Set/Get the flag which inverts the mean curvature calculation for meshes with inward pointing normals (default false)
- `obj.SetInvertMeanCurvature (int )` - Set/Get the flag which inverts the mean curvature calculation for meshes with inward pointing normals (default false)
- `int = obj.GetInvertMeanCurvature ()` - Set/Get the flag which inverts the mean curvature calculation for meshes with inward pointing normals (default false)
- `obj.InvertMeanCurvatureOn ()` - Set/Get the flag which inverts the mean curvature calculation for meshes with inward pointing normals (default false)
- `obj.InvertMeanCurvatureOff ()` - Set/Get the flag which inverts the mean curvature calculation for meshes with inward pointing normals (default false)

33.42 vtkCutter

33.42.1 Usage

vtkCutter is a filter to cut through data using any subclass of vtkImplicitFunction. That is, a polygonal surface is created corresponding to the implicit function F(x,y,z) = value(s), where you can specify one or more values used to cut with.

In VTK, cutting means reducing a cell of dimension N to a cut surface of dimension N-1. For example, a tetrahedron when cut by a plane (i.e., vtkPlane implicit function) will generate triangles. (In comparison, clipping takes a N dimensional cell and creates N dimension primitives.)

vtkCutter is generally used to "slice-through" a dataset, generating a surface that can be visualized. It is also possible to use vtkCutter to do a form of volume rendering. vtkCutter does this by generating multiple cut surfaces (usually planes) which are ordered (and rendered) from back-to-front. The surfaces are set translucent to give a volumetric rendering effect.

Note that data can be cut using either 1) the scalar values associated with the dataset or 2) an implicit function associated with this class. By default, if an implicit function is set it is used to clip the data set, otherwise the dataset scalars are used to perform the clipping.

To create an instance of class vtkCutter, simply invoke its constructor as follows

```
obj = vtkCutter
```

33.42.2 Methods

The class vtkCutter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCutter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCutter = obj.NewInstance ()`
- `vtkCutter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Override GetMTime because we delegate to vtkContourValues and refer to vtkImplicitFunction.
- `long = obj.GetMTime ()` - Override GetMTime because we delegate to vtkContourValues and refer to vtkImplicitFunction.
- `obj.SetCutFunction (vtkImplicitFunction )`
- `vtkImplicitFunction = obj.GetCutFunction ()`
- `obj.SetGenerateCutScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `int = obj.GetGenerateCutScalars ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `obj.GenerateCutScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.

- `obj.GenerateCutScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.SetSortBy (int )` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `int = obj.GetSortByMinValue ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `int = obj.GetSortByMaxValue ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `int = obj.GetSortBy ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `obj.SetSortByToSortByValue ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `obj.SetSortByToSortByCell ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.

- `string = obj.GetSortByAsString ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.

- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.43 vtkCylinderSource

33.43.1 Usage

vtkCylinderSource creates a polygonal cylinder centered at Center; The axis of the cylinder is aligned along the global y-axis. The height and radius of the cylinder can be specified, as well as the number of sides. It is also possible to control whether the cylinder is open-ended or capped.

To create an instance of class vtkCylinderSource, simply invoke its constructor as follows

```
obj = vtkCylinderSource
```

33.43.2 Methods

The class vtkCylinderSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCylinderSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCylinderSource = obj.NewInstance ()`
- `vtkCylinderSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetHeight (double )` - Set the height of the cylinder. Initial value is 1.
- `double = obj.GetHeightMinValue ()` - Set the height of the cylinder. Initial value is 1.
- `double = obj.GetHeightMaxValue ()` - Set the height of the cylinder. Initial value is 1.
- `double = obj.GetHeight ()` - Set the height of the cylinder. Initial value is 1.
- `obj.SetRadius (double )` - Set the radius of the cylinder. Initial value is 0.5
- `double = obj.GetRadiusMinValue ()` - Set the radius of the cylinder. Initial value is 0.5
- `double = obj.GetRadiusMaxValue ()` - Set the radius of the cylinder. Initial value is 0.5
- `double = obj.GetRadius ()` - Set the radius of the cylinder. Initial value is 0.5
- `obj.SetCenter (double , double , double )` - Set/Get cylinder center. Initial value is (0.0,0.0,0.0)
- `obj.SetCenter (double  a[3])` - Set/Get cylinder center. Initial value is (0.0,0.0,0.0)
- `double = obj. GetCenter ()` - Set/Get cylinder center. Initial value is (0.0,0.0,0.0)
- `obj.SetResolution (int )` - Set the number of facets used to define cylinder. Initial value is 6.

- `int = obj.GetResolutionMinValue ()` - Set the number of facets used to define cylinder. Initial value is 6.
- `int = obj.GetResolutionMaxValue ()` - Set the number of facets used to define cylinder. Initial value is 6.
- `int = obj.GetResolution ()` - Set the number of facets used to define cylinder. Initial value is 6.
- `obj.SetCapping (int )` - Turn on/off whether to cap cylinder with polygons. Initial value is true.
- `int = obj.GetCapping ()` - Turn on/off whether to cap cylinder with polygons. Initial value is true.
- `obj.CappingOn ()` - Turn on/off whether to cap cylinder with polygons. Initial value is true.
- `obj.CappingOff ()` - Turn on/off whether to cap cylinder with polygons. Initial value is true.

33.44 vtkDashedStreamLine

33.44.1 Usage

vtkDashedStreamLine is a filter that generates a "dashed" streamline for an arbitrary dataset. The streamline consists of a series of dashes, each of which represents (approximately) a constant time increment. Thus, in the resulting visual representation, relatively long dashes represent areas of high velocity, and small dashes represent areas of low velocity.

vtkDashedStreamLine introduces the instance variable DashFactor. DashFactor interacts with its superclass' instance variable StepLength to create the dashes. DashFactor is the percentage of the StepLength line segment that is visible. Thus, if the DashFactor=0.75, the dashes will be "three-quarters on" and "one-quarter off".

To create an instance of class vtkDashedStreamLine, simply invoke its constructor as follows

```
obj = vtkDashedStreamLine
```

33.44.2 Methods

The class vtkDashedStreamLine has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDashedStreamLine class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDashedStreamLine = obj.NewInstance ()`
- `vtkDashedStreamLine = obj.SafeDownCast (vtkObject o)`
- `obj.SetDashFactor (double )` - For each dash, specify the fraction of the dash that is "on". A factor of 1.0 will result in a continuous line, a factor of 0.5 will result in dashed that are half on and half off.
- `double = obj.GetDashFactorMinValue ()` - For each dash, specify the fraction of the dash that is "on". A factor of 1.0 will result in a continuous line, a factor of 0.5 will result in dashed that are half on and half off.
- `double = obj.GetDashFactorMaxValue ()` - For each dash, specify the fraction of the dash that is "on". A factor of 1.0 will result in a continuous line, a factor of 0.5 will result in dashed that are half on and half off.
- `double = obj.GetDashFactor ()` - For each dash, specify the fraction of the dash that is "on". A factor of 1.0 will result in a continuous line, a factor of 0.5 will result in dashed that are half on and half off.

33.45 vtkDataObjectGenerator

33.45.1 Usage

vtkDataObjectGenerator parses a string and produces dataobjects from the dataobject template names it sees in the string. For example, if the string contains "ID1" the generator will create a vtkImageData. "UF1", "RG1", "SG1", "PD1", and "UG1" will produce vtkUniformGrid, vtkRectilinearGrid, vtkStructuredGrid, vtkPolyData and vtkUnstructuredGrid respectively. "PD2" will produce an alternate vtkPolyData. You can compose composite datasets from the atomic ones listed above by placing them within one of the two composite dataset identifiers - "MB" or "HB[]". "MB ID1 PD1 MB " for example will create a vtkMultiBlockDataSet consisting of three blocks: image data, poly data, multi-block (empty). Hierarchical Box data sets additionally require the notion of groups, declared within "()" braces, to specify AMR depth. "HB[(UF1)(UF1)(UF1)]" will create a vtkHierarchicalBoxDataSet representing an octree that is three levels deep, in which the firstmost cell in each level is refined.

To create an instance of class vtkDataObjectGenerator, simply invoke its constructor as follows

```
obj = vtkDataObjectGenerator
```

33.45.2 Methods

The class vtkDataObjectGenerator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectGenerator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectGenerator = obj.NewInstance ()`
- `vtkDataObjectGenerator = obj.SafeDownCast (vtkObject o)`
- `obj.SetProgram (string )` - The string that will be parsed to specify a dataobject structure.
- `string = obj.GetProgram ()` - The string that will be parsed to specify a dataobject structure.

33.46 vtkDataObjectToDataSetFilter

33.46.1 Usage

vtkDataObjectToDataSetFilter is an class that maps a data object (i.e., a field) into a concrete dataset, i.e., gives structure to the field by defining a geometry and topology.

To use this filter you associate components in the input field data with portions of the output dataset. (A component is an array of values from the field.) For example, you would specify x-y-z points by assigning components from the field for the x, then y, then z values of the points. You may also have to specify component ranges (for each z-y-z) to make sure that the number of x, y, and z values is the same. Also, you may want to normalize the components which helps distribute the data uniformly. Once you've setup the filter to combine all the pieces of data into a specified dataset (the geometry, topology, point and cell data attributes), the various output methods (e.g., GetPolyData()) are used to retrieve the final product.

This filter is often used in conjunction with vtkFieldDataToAttributeDataFilter. vtkFieldDataToAttributeDataFilter takes field data and transforms it into attribute data (e.g., point and cell data attributes such as scalars and vectors). To do this, use this filter which constructs a concrete dataset and passes the input data object field data to its output. and then use vtkFieldDataToAttributeDataFilter to generate the attribute data associated with the dataset.

To create an instance of class vtkDataObjectToDataSetFilter, simply invoke its constructor as follows

```
obj = vtkDataObjectToDataSetFilter
```

33.46.2 Methods

The class vtkDataObjectToDataSetFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectToDataSetFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectToDataSetFilter = obj.NewInstance ()`
- `vtkDataObjectToDataSetFilter = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetInput ()` - Get the input to the filter.
- `obj.SetDataSetType (int )` - Control what type of data is generated for output.
- `int = obj.GetDataSetType ()` - Control what type of data is generated for output.
- `obj.SetDataSetTypeToPolyData ()` - Control what type of data is generated for output.
- `obj.SetDataSetTypeToStructuredPoints ()` - Control what type of data is generated for output.
- `obj.SetDataSetTypeToStructuredGrid ()` - Control what type of data is generated for output.
- `obj.SetDataSetTypeToRectilinearGrid ()` - Control what type of data is generated for output.
- `obj.SetDataSetTypeToUnstructuredGrid ()` - Control what type of data is generated for output.
- `vtkDataSet = obj.GetOutput ()` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)
- `vtkDataSet = obj.GetOutput (int idx)` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)

- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output in different forms. The particular method invoked should be consistent with the SetDataSetType() method. (Note: GetOutput() will always return a type consistent with SetDataSetType(). Also, GetOutput() will return NULL if the filter aborted due to inconsistent data.)

- `obj.SetPointComponent (int comp, string arrayName, int arrayComp, int min, int max, int normalize)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `obj.SetPointComponent (int comp, string arrayName, int arrayComp)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `string = obj.GetPointComponentArrayName (int comp)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `int = obj.GetPointComponentArrayComponent (int comp)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `int = obj.GetPointComponentMinRange (int comp)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `int = obj.GetPointComponentMaxRange (int comp)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is

also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `int = obj.GetPointComponentNormailzeFlag (int comp)` - Define the component of the field to be used for the x, y, and z values of the points. Note that the parameter comp must lie between (0,2) and refers to the x-y-z (i.e., 0,1,2) components of the points. To define the field component to use you can specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract. (This method should be used for vtkPolyData, vtkUnstructuredGrid, vtkStructuredGrid, and vtkRectilinearGrid.) A convenience method, SetPointComponent(),is also provided which does not require setting the (min,max) component range or the normalize flag (normalize is set to DefaulatNormalize value).

- `obj.SetVertsComponent (string arrayName, int arrayComp, int min, int max)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetVertsComponent (string arrayName, int arrayComp)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `string = obj.GetVertsComponentArrayName ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetVertsComponentArrayComponent ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetVertsComponentMinRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetVertsComponentMaxRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetLinesComponent (string arrayName, int arrayComp, int min, int max)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetLinesComponent (string arrayName, int arrayComp)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `string = obj.GetLinesComponentArrayName ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetLinesComponentArrayComponent ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetLinesComponentMinRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetLinesComponentMaxRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetPolysComponent (string arrayName, int arrayComp, int min, int max)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetPolysComponent (string arrayName, int arrayComp)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `string = obj.GetPolysComponentArrayName ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetPolysComponentArrayComponent ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetPolysComponentMinRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetPolysComponentMaxRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetStripsComponent (string arrayName, int arrayComp, int min, int max)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetStripsComponent (string arrayName, int arrayComp)` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `string = obj.GetStripsComponentArrayName ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetStripsComponentArrayComponent ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetStripsComponentMinRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetStripsComponentMaxRange ()` - Define cell connectivity when creating vtkPolyData. You can define vertices, lines, polygons, and/or triangle strips via these methods. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of values that (for each cell) includes the number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetCellTypeComponent (string arrayName, int arrayComp, int min, int max)` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetCellTypeComponent (string arrayName, int arrayComp)` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `string = obj.GetCellTypeComponentArrayName ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `int = obj.GetCellTypeComponentArrayComponent ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `int = obj.GetCellTypeComponentMinRange ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `int = obj.GetCellTypeComponentMaxRange ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `obj.SetCellConnectivityComponent (string arrayName, int arrayComp, int min, int max)` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `obj.SetCellConnectivityComponent (string arrayName, int arrayComp)` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `string = obj.GetCellConnectivityComponentArrayName ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)
- `int = obj.GetCellConnectivityComponentArrayComponent ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetCellConnectivityComponentMinRange ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `int = obj.GetCellConnectivityComponentMaxRange ()` - Define cell types and cell connectivity when creating unstructured grid data. These methods are similar to those for defining points, except that no normalization of the data is possible. Basically, you need to define an array of cell types (an integer value per cell), and another array consisting (for each cell) of a number of points per cell, and then the cell connectivity. (This is the vtk file format described in in the textbook or User's Guide.)

- `obj.SetDefaultNormalize (int )` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetPointComponent).

- `int = obj.GetDefaultNormalize ()` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetPointComponent).

- `obj.DefaultNormalizeOn ()` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetPointComponent).

- `obj.DefaultNormalizeOff ()` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetPointComponent).

- `obj.SetDimensions (int , int , int )`

- `obj.SetDimensions (int  a[3])`

- `int = obj. GetDimensions ()`

- `obj.SetOrigin (double , double , double )`

- `obj.SetOrigin (double  a[3])`

- `double = obj. GetOrigin ()`

- `obj.SetSpacing (double , double , double )`

- `obj.SetSpacing (double  a[3])`

- `double = obj. GetSpacing ()`

- `obj.SetDimensionsComponent (string arrayName, int arrayComp, int min, int max)`

- `obj.SetDimensionsComponent (string arrayName, int arrayComp)`

- `obj.SetSpacingComponent (string arrayName, int arrayComp, int min, int max)`

- `obj.SetSpacingComponent (string arrayName, int arrayComp)`

- `obj.SetOriginComponent (string arrayName, int arrayComp, int min, int max)`

- `obj.SetOriginComponent (string arrayName, int arrayComp)`

33.47 vtkDataSetEdgeSubdivisionCriterion

33.47.1 Usage

This is a subclass of vtkEdgeSubdivisionCriterion that is used for tessellating cells of a vtkDataSet, particularly nonlinear cells.

It provides functions for setting the current cell being tessellated and a convenience routine, EvaluateFields() to evaluate field values at a point. You should call EvaluateFields() from inside EvaluateEdge() whenever the result of EvaluateEdge() will be true. Otherwise, do not call EvaluateFields() as the midpoint is about to be discarded. (¡i¿Implementor's note¡/i¿: This isn't true if UGLY_ASPECT_RATIO_HACK has been defined. But in that case, we don't want the exact field values; we need the linearly interpolated ones at the midpoint for continuity.)

To create an instance of class vtkDataSetEdgeSubdivisionCriterion, simply invoke its constructor as follows

```
obj = vtkDataSetEdgeSubdivisionCriterion
```

33.47.2 Methods

The class vtkDataSetEdgeSubdivisionCriterion has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetEdgeSubdivisionCriterion class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetEdgeSubdivisionCriterion = obj.NewInstance ()`
- `vtkDataSetEdgeSubdivisionCriterion = obj.SafeDownCast (vtkObject o)`
- `obj.SetMesh (vtkDataSet )`
- `vtkDataSet = obj.GetMesh ()`
- `obj.SetCellId (vtkIdType cell)`
- `vtkIdType = obj.GetCellId () const`
- `vtkCell = obj.GetCell ()`
- `bool = obj.EvaluateEdge (double p0, double midpt, double p1, int field\_start)`
- `obj.EvaluatePointDataField (double result, double weights, int field)` - Evaluate either a cell or nodal field. This exists because of the funky way that Exodus data will be handled. Sure, it's a hack, but what are ya gonna do?
- `obj.EvaluateCellDataField (double result, double weights, int field)` - Evaluate either a cell or nodal field. This exists because of the funky way that Exodus data will be handled. Sure, it's a hack, but what are ya gonna do?
- `obj.SetChordError2 (double )` - Get/Set the square of the allowable chord error at any edge's midpoint. This value is used by EvaluateEdge.
- `double = obj.GetChordError2 ()` - Get/Set the square of the allowable chord error at any edge's midpoint. This value is used by EvaluateEdge.
- `obj.SetFieldError2 (int s, double err)` - Get/Set the square of the allowable error magnitude for the scalar field s at any edge's midpoint. A value less than or equal to 0 indicates that the field should not be used as a criterion for subdivision.

- `double = obj.GetFieldError2 (int s) const` - Get/Set the square of the allowable error magnitude for the scalar field s at any edge's midpoint. A value less than or equal to 0 indicates that the field should not be used as a criterion for subdivision.
- `obj.ResetFieldError2 ()` - Tell the subdivider not to use any field values as subdivision criteria. Effectively calls SetFieldError2(a, -1.) for all fields.
- `int = obj.GetActiveFieldCriteria ()` - Return a bitfield specifying which FieldError2 criteria are positive (i.e., actively used to decide edge subdivisions). This is stored as separate state to make subdivisions go faster.
- `int = obj.GetActiveFieldCriteria () const`

33.48 vtkDataSetGradient

33.48.1 Usage

vtkDataSetGradient Computes per cell gradient of point scalar field or per point gradient of cell scalar field.

.SECTION Thanks This file is part of the generalized Youngs material interface reconstruction algorithm contributed by CEA/DIF - Commissariat a l'Energie Atomique, Centre DAM Ile-De-France ¡br¿ BP12, F-91297 Arpajon, France. ¡br¿ Implementation by Thierry Carrard (CEA)

To create an instance of class vtkDataSetGradient, simply invoke its constructor as follows

```
obj = vtkDataSetGradient
```

33.48.2 Methods

The class vtkDataSetGradient has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetGradient class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetGradient = obj.NewInstance ()`
- `vtkDataSetGradient = obj.SafeDownCast (vtkObject o)`
- `obj.SetResultArrayName (string )` - Set/Get the name of computed vector array.
- `string = obj.GetResultArrayName ()` - Set/Get the name of computed vector array.

33.49 vtkDataSetGradientPrecompute

33.49.1 Usage

Computes a geometry based vector field that the DataSetGradient filter uses to accelerate gradient computation. This vector field is added to FieldData since it has a different value for each vertex of each cell (a vertex shared by two cell has two differents values).

.SECTION Thanks This file is part of the generalized Youngs material interface reconstruction algorithm contributed by CEA/DIF - Commissariat a l'Energie Atomique, Centre DAM Ile-De-France ¡br¿ BP12, F-91297 Arpajon, France. ¡br¿ Implementation by Thierry Carrard (CEA)

To create an instance of class vtkDataSetGradientPrecompute, simply invoke its constructor as follows

```
obj = vtkDataSetGradientPrecompute
```

33.49.2 Methods

The class vtkDataSetGradientPrecompute has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetGradientPrecompute class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetGradientPrecompute = obj.NewInstance ()`
- `vtkDataSetGradientPrecompute = obj.SafeDownCast (vtkObject o)`

33.50 vtkDataSetSurfaceFilter

33.50.1 Usage

vtkDataSetSurfaceFilter is a faster version of vtkGeometry filter, but it does not have an option to select bounds. It may use more memory than vtkGeometryFilter. It only has one option: whether to use triangle strips when the input type is structured.

To create an instance of class vtkDataSetSurfaceFilter, simply invoke its constructor as follows

```
obj = vtkDataSetSurfaceFilter
```

33.50.2 Methods

The class vtkDataSetSurfaceFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetSurfaceFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetSurfaceFilter = obj.NewInstance ()`
- `vtkDataSetSurfaceFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetUseStrips (int )` - When input is structured data, this flag will generate faces with triangle strips. This should render faster and use less memory, but no cell data is copied. By default, UseStrips is Off.
- `int = obj.GetUseStrips ()` - When input is structured data, this flag will generate faces with triangle strips. This should render faster and use less memory, but no cell data is copied. By default, UseStrips is Off.
- `obj.UseStripsOn ()` - When input is structured data, this flag will generate faces with triangle strips. This should render faster and use less memory, but no cell data is copied. By default, UseStrips is Off.
- `obj.UseStripsOff ()` - When input is structured data, this flag will generate faces with triangle strips. This should render faster and use less memory, but no cell data is copied. By default, UseStrips is Off.
- `obj.SetPieceInvariant (int )` - If PieceInvariant is true, vtkDataSetSurfaceFilter requests 1 ghost level from input in order to remove internal surface that are between processes. False by default.

- `int = obj.GetPieceInvariant ()` - If PieceInvariant is true, vtkDataSetSurfaceFilter requests 1 ghost level from input in order to remove internal surface that are between processes. False by default.

- `obj.SetPassThroughCellIds (int )` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `int = obj.GetPassThroughCellIds ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `obj.PassThroughCellIdsOn ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `obj.PassThroughCellIdsOff ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `obj.SetPassThroughPointIds (int )` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `int = obj.GetPassThroughPointIds ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `obj.PassThroughPointIdsOn ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `obj.PassThroughPointIdsOff ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory. Note that PassThroughCellIds will be ignored if UseStrips is on, since in that case each tringle strip can represent more than on of the input cells.

- `int = obj.StructuredExecute (vtkDataSet input, vtkPolyData output, int ext32, int wholeExt32)` - Direct access methods that can be used to use the this class as an algorithm without using it as a filter.

- `int = obj.UnstructuredGridExecute (vtkDataSet input, vtkPolyData output)` - Direct access methods that can be used to use the this class as an algorithm without using it as a filter.

- `int = obj.DataSetExecute (vtkDataSet input, vtkPolyData output)` - Direct access methods that can be used to use the this class as an algorithm without using it as a filter.

33.51 vtkDataSetToDataObjectFilter

33.51.1 Usage

vtkDataSetToDataObjectFilter is an class that transforms a dataset into data object (i.e., a field). The field will have labeled data arrays corresponding to the topology, geometry, field data, and point and cell attribute data.

You can control what portions of the dataset are converted into the output data object's field data. The instance variables Geometry, Topology, FieldData, PointData, and CellData are flags that control whether the dataset's geometry (e.g., points, spacing, origin); topology (e.g., cell connectivity, dimensions); the field data associated with the dataset's superclass data object; the dataset's point data attributes; and the dataset's cell data attributes. (Note: the data attributes include scalars, vectors, tensors, normals, texture coordinates, and field data.)

The names used to create the field data are as follows. For vtkPolyData, "Points", "Verts", "Lines", "Polys", and "Strips". For vtkUnstructuredGrid, "Cells" and "CellTypes". For vtkStructuredPoints, "Dimensions", "Spacing", and "Origin". For vtkStructuredGrid, "Points" and "Dimensions". For vtkRectilinearGrid, "XCoordinates", "YCoordinates", and "ZCoordinates". for point attribute data, "PointScalars", "PointVectors", etc. For cell attribute data, "CellScalars", "CellVectors", etc. Field data arrays retain their original name.

To create an instance of class vtkDataSetToDataObjectFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToDataObjectFilter
```

33.51.2 Methods

The class vtkDataSetToDataObjectFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToDataObjectFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToDataObjectFilter = obj.NewInstance ()`
- `vtkDataSetToDataObjectFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetGeometry (int )` - Turn on/off the conversion of dataset geometry to a data object.
- `int = obj.GetGeometry ()` - Turn on/off the conversion of dataset geometry to a data object.
- `obj.GeometryOn ()` - Turn on/off the conversion of dataset geometry to a data object.
- `obj.GeometryOff ()` - Turn on/off the conversion of dataset geometry to a data object.
- `obj.SetTopology (int )` - Turn on/off the conversion of dataset topology to a data object.
- `int = obj.GetTopology ()` - Turn on/off the conversion of dataset topology to a data object.
- `obj.TopologyOn ()` - Turn on/off the conversion of dataset topology to a data object.
- `obj.TopologyOff ()` - Turn on/off the conversion of dataset topology to a data object.
- `obj.SetFieldData (int )` - Turn on/off the conversion of dataset field data to a data object.
- `int = obj.GetFieldData ()` - Turn on/off the conversion of dataset field data to a data object.
- `obj.FieldDataOn ()` - Turn on/off the conversion of dataset field data to a data object.
- `obj.FieldDataOff ()` - Turn on/off the conversion of dataset field data to a data object.

- `obj.SetPointData (int )` - Turn on/off the conversion of dataset point data to a data object.
- `int = obj.GetPointData ()` - Turn on/off the conversion of dataset point data to a data object.
- `obj.PointDataOn ()` - Turn on/off the conversion of dataset point data to a data object.
- `obj.PointDataOff ()` - Turn on/off the conversion of dataset point data to a data object.
- `obj.SetCellData (int )` - Turn on/off the conversion of dataset cell data to a data object.
- `int = obj.GetCellData ()` - Turn on/off the conversion of dataset cell data to a data object.
- `obj.CellDataOn ()` - Turn on/off the conversion of dataset cell data to a data object.
- `obj.CellDataOff ()` - Turn on/off the conversion of dataset cell data to a data object.

33.52 vtkDataSetTriangleFilter

33.52.1 Usage

vtkDataSetTriangleFilter generates n-dimensional simplices from any input dataset. That is, 3D cells are converted to tetrahedral meshes, 2D cells to triangles, and so on. The triangulation is guaranteed to be compatible.

This filter uses simple 1D and 2D triangulation techniques for cells that are of topological dimension 2 or less. For 3D cells–due to the issue of face compatibility across quadrilateral faces (which way to orient the diagonal?)–a fancier ordered Delaunay triangulation is used. This approach produces templates on the fly for triangulating the cells. The templates are then used to do the actual triangulation.

To create an instance of class vtkDataSetTriangleFilter, simply invoke its constructor as follows

```
obj = vtkDataSetTriangleFilter
```

33.52.2 Methods

The class vtkDataSetTriangleFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetTriangleFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetTriangleFilter = obj.NewInstance ()`
- `vtkDataSetTriangleFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetTetrahedraOnly (int )` - When On this filter will cull all 1D and 2D cells from the output. The default is Off.
- `int = obj.GetTetrahedraOnly ()` - When On this filter will cull all 1D and 2D cells from the output. The default is Off.
- `obj.TetrahedraOnlyOn ()` - When On this filter will cull all 1D and 2D cells from the output. The default is Off.
- `obj.TetrahedraOnlyOff ()` - When On this filter will cull all 1D and 2D cells from the output. The default is Off.

33.53 vtkDecimatePolylineFilter

33.53.1 Usage

vtkDecimatePolylineFilter is a filter to reduce the number of lines in a polyline. The algorithm functions by evaluating an error metric for each vertex (i.e., the distance of the vertex to a line defined from the two vertices on either side of the vertex). Then, these vertices are placed into a priority queue, and those with larger errors are deleted first. The decimation continues until the target reduction is reached.

To create an instance of class vtkDecimatePolylineFilter, simply invoke its constructor as follows

```
obj = vtkDecimatePolylineFilter
```

33.53.2 Methods

The class vtkDecimatePolylineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDecimatePolylineFilter class.

- `string = obj.GetClassName ()` - Standard methods for type information and printing.
- `int = obj.IsA (string name)` - Standard methods for type information and printing.
- `vtkDecimatePolylineFilter = obj.NewInstance ()` - Standard methods for type information and printing.
- `vtkDecimatePolylineFilter = obj.SafeDownCast (vtkObject o)` - Standard methods for type information and printing.
- `obj.SetTargetReduction (double )` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10
- `double = obj.GetTargetReductionMinValue ()` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10
- `double = obj.GetTargetReductionMaxValue ()` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10
- `double = obj.GetTargetReduction ()` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10

33.54 vtkDecimatePro

33.54.1 Usage

vtkDecimatePro is a filter to reduce the number of triangles in a triangle mesh, forming a good approximation to the original geometry. The input to vtkDecimatePro is a vtkPolyData object, and only triangles are treated. If you desire to decimate polygonal meshes, first triangulate the polygons with vtkTriangleFilter object.

The implementation of vtkDecimatePro is similar to the algorithm originally described in "Decimation of Triangle Meshes", Proc Siggraph '92, with three major differences. First, this algorithm does not necessarily preserve the topology of the mesh. Second, it is guaranteed to give the a mesh reduction factor specified by the user (as long as certain constraints are not set - see Caveats). Third, it is set up generate progressive meshes, that is a stream of operations that can be easily transmitted and incrementally updated (see Hugues Hoppe's Siggraph '96 paper on progressive meshes).

The algorithm proceeds as follows. Each vertex in the mesh is classified and inserted into a priority queue. The priority is based on the error to delete the vertex and retriangulate the hole. Vertices that cannot be deleted or triangulated (at this point in the algorithm) are skipped. Then, each vertex in the priority queue

is processed (i.e., deleted followed by hole triangulation using edge collapse). This continues until the priority queue is empty. Next, all remaining vertices are processed, and the mesh is split into separate pieces along sharp edges or at non-manifold attachment points and reinserted into the priority queue. Again, the priority queue is processed until empty. If the desired reduction is still not achieved, the remaining vertices are split as necessary (in a recursive fashion) so that it is possible to eliminate every triangle as necessary.

To use this object, at a minimum you need to specify the ivar TargetReduction. The algorithm is guaranteed to generate a reduced mesh at this level as long as the following four conditions are met: 1) topology modification is allowed (i.e., the ivar PreserveTopology is off); 2) mesh splitting is enabled (i.e., the ivar Splitting is on); 3) the algorithm is allowed to modify the boundary of the mesh (i.e., the ivar BoundaryVertexDeletion is on); and 4) the maximum allowable error (i.e., the ivar MaximumError) is set to VTK_DOUBLE_MAX. Other important parameters to adjust include the FeatureAngle and SplitAngle ivars, since these can impact the quality of the final mesh. Also, you can set the ivar AccumulateError to force incremental error update and distribution to surrounding vertices as each vertex is deleted. The accumulated error is a conservative global error bounds and decimation error, but requires additional memory and time to compute.

To create an instance of class vtkDecimatePro, simply invoke its constructor as follows

```
obj = vtkDecimatePro
```

33.54.2 Methods

The class vtkDecimatePro has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDecimatePro class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDecimatePro = obj.NewInstance ()`
- `vtkDecimatePro = obj.SafeDownCast (vtkObject o)`
- `obj.SetTargetReduction (double )` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10reduction may not be realized. If you want to guarantee a particular reduction, you must turn off PreserveTopology, turn on SplitEdges and BoundaryVertexDeletion, and set the MaximumError to VTK_DOUBLE_MAX (these ivars are initialized this way when the object is instantiated).
- `double = obj.GetTargetReductionMinValue ()` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10reduction may not be realized. If you want to guarantee a particular reduction, you must turn off PreserveTopology, turn on SplitEdges and BoundaryVertexDeletion, and set the MaximumError to VTK_DOUBLE_MAX (these ivars are initialized this way when the object is instantiated).
- `double = obj.GetTargetReductionMaxValue ()` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10reduction may not be realized. If you want to guarantee a particular reduction, you must turn off PreserveTopology, turn on SplitEdges and BoundaryVertexDeletion, and set the MaximumError to VTK_DOUBLE_MAX (these ivars are initialized this way when the object is instantiated).
- `double = obj.GetTargetReduction ()` - Specify the desired reduction in the total number of polygons (e.g., if TargetReduction is set to 0.9, this filter will try to reduce the data set to 10reduction may not be realized. If you want to guarantee a particular reduction, you must turn off PreserveTopology, turn on SplitEdges and BoundaryVertexDeletion, and set the MaximumError to VTK_DOUBLE_MAX (these ivars are initialized this way when the object is instantiated).

- `obj.SetPreserveTopology (int )` - Turn on/off whether to preserve the topology of the original mesh. If on, mesh splitting and hole elimination will not occur. This may limit the maximum reduction that may be achieved.
- `int = obj.GetPreserveTopology ()` - Turn on/off whether to preserve the topology of the original mesh. If on, mesh splitting and hole elimination will not occur. This may limit the maximum reduction that may be achieved.
- `obj.PreserveTopologyOn ()` - Turn on/off whether to preserve the topology of the original mesh. If on, mesh splitting and hole elimination will not occur. This may limit the maximum reduction that may be achieved.
- `obj.PreserveTopologyOff ()` - Turn on/off whether to preserve the topology of the original mesh. If on, mesh splitting and hole elimination will not occur. This may limit the maximum reduction that may be achieved.
- `obj.SetFeatureAngle (double )` - Specify the mesh feature angle. This angle is used to define what an edge is (i.e., if the surface normal between two adjacent triangles is ¿= FeatureAngle, an edge exists).
- `double = obj.GetFeatureAngleMinValue ()` - Specify the mesh feature angle. This angle is used to define what an edge is (i.e., if the surface normal between two adjacent triangles is ¿= FeatureAngle, an edge exists).
- `double = obj.GetFeatureAngleMaxValue ()` - Specify the mesh feature angle. This angle is used to define what an edge is (i.e., if the surface normal between two adjacent triangles is ¿= FeatureAngle, an edge exists).
- `double = obj.GetFeatureAngle ()` - Specify the mesh feature angle. This angle is used to define what an edge is (i.e., if the surface normal between two adjacent triangles is ¿= FeatureAngle, an edge exists).
- `obj.SetSplitting (int )` - Turn on/off the splitting of the mesh at corners, along edges, at non-manifold points, or anywhere else a split is required. Turning splitting off will better preserve the original topology of the mesh, but you may not obtain the requested reduction.
- `int = obj.GetSplitting ()` - Turn on/off the splitting of the mesh at corners, along edges, at non-manifold points, or anywhere else a split is required. Turning splitting off will better preserve the original topology of the mesh, but you may not obtain the requested reduction.
- `obj.SplittingOn ()` - Turn on/off the splitting of the mesh at corners, along edges, at non-manifold points, or anywhere else a split is required. Turning splitting off will better preserve the original topology of the mesh, but you may not obtain the requested reduction.
- `obj.SplittingOff ()` - Turn on/off the splitting of the mesh at corners, along edges, at non-manifold points, or anywhere else a split is required. Turning splitting off will better preserve the original topology of the mesh, but you may not obtain the requested reduction.
- `obj.SetSplitAngle (double )` - Specify the mesh split angle. This angle is used to control the splitting of the mesh. A split line exists when the surface normals between two edge connected triangles are ¿= SplitAngle.
- `double = obj.GetSplitAngleMinValue ()` - Specify the mesh split angle. This angle is used to control the splitting of the mesh. A split line exists when the surface normals between two edge connected triangles are ¿= SplitAngle.
- `double = obj.GetSplitAngleMaxValue ()` - Specify the mesh split angle. This angle is used to control the splitting of the mesh. A split line exists when the surface normals between two edge connected triangles are ¿= SplitAngle.

- `double = obj.GetSplitAngle ()` - Specify the mesh split angle. This angle is used to control the splitting of the mesh. A split line exists when the surface normals between two edge connected triangles are ¿= SplitAngle.

- `obj.SetPreSplitMesh (int )` - In some cases you may wish to split the mesh prior to algorithm execution. This separates the mesh into semi-planar patches, which are disconnected from each other. This can give superior results in some cases. If the ivar PreSplitMesh ivar is enabled, the mesh is split with the specified SplitAngle. Otherwise mesh splitting is deferred as long as possible.

- `int = obj.GetPreSplitMesh ()` - In some cases you may wish to split the mesh prior to algorithm execution. This separates the mesh into semi-planar patches, which are disconnected from each other. This can give superior results in some cases. If the ivar PreSplitMesh ivar is enabled, the mesh is split with the specified SplitAngle. Otherwise mesh splitting is deferred as long as possible.

- `obj.PreSplitMeshOn ()` - In some cases you may wish to split the mesh prior to algorithm execution. This separates the mesh into semi-planar patches, which are disconnected from each other. This can give superior results in some cases. If the ivar PreSplitMesh ivar is enabled, the mesh is split with the specified SplitAngle. Otherwise mesh splitting is deferred as long as possible.

- `obj.PreSplitMeshOff ()` - In some cases you may wish to split the mesh prior to algorithm execution. This separates the mesh into semi-planar patches, which are disconnected from each other. This can give superior results in some cases. If the ivar PreSplitMesh ivar is enabled, the mesh is split with the specified SplitAngle. Otherwise mesh splitting is deferred as long as possible.

- `obj.SetMaximumError (double )` - Set the largest decimation error that is allowed during the decimation process. This may limit the maximum reduction that may be achieved. The maximum error is specified as a fraction of the maximum length of the input data bounding box.

- `double = obj.GetMaximumErrorMinValue ()` - Set the largest decimation error that is allowed during the decimation process. This may limit the maximum reduction that may be achieved. The maximum error is specified as a fraction of the maximum length of the input data bounding box.

- `double = obj.GetMaximumErrorMaxValue ()` - Set the largest decimation error that is allowed during the decimation process. This may limit the maximum reduction that may be achieved. The maximum error is specified as a fraction of the maximum length of the input data bounding box.

- `double = obj.GetMaximumError ()` - Set the largest decimation error that is allowed during the decimation process. This may limit the maximum reduction that may be achieved. The maximum error is specified as a fraction of the maximum length of the input data bounding box.

- `obj.SetAccumulateError (int )` - The computed error can either be computed directly from the mesh or the error may be accumulated as the mesh is modified. If the error is accumulated, then it represents a global error bounds, and the ivar MaximumError becomes a global bounds on mesh error. Accumulating the error requires extra memory proportional to the number of vertices in the mesh. If AccumulateError is off, then the error is not accumulated.

- `int = obj.GetAccumulateError ()` - The computed error can either be computed directly from the mesh or the error may be accumulated as the mesh is modified. If the error is accumulated, then it represents a global error bounds, and the ivar MaximumError becomes a global bounds on mesh error. Accumulating the error requires extra memory proportional to the number of vertices in the mesh. If AccumulateError is off, then the error is not accumulated.

- `obj.AccumulateErrorOn ()` - The computed error can either be computed directly from the mesh or the error may be accumulated as the mesh is modified. If the error is accumulated, then it represents a global error bounds, and the ivar MaximumError becomes a global bounds on mesh error. Accumulating the error requires extra memory proportional to the number of vertices in the mesh. If AccumulateError is off, then the error is not accumulated.

- `obj.AccumulateErrorOff ()` - The computed error can either be computed directly from the mesh or the error may be accumulated as the mesh is modified. If the error is accumulated, then it represents a global error bounds, and the ivar MaximumError becomes a global bounds on mesh error. Accumulating the error requires extra memory proportional to the number of vertices in the mesh. If AccumulateError is off, then the error is not accumulated.

- `obj.SetErrorIsAbsolute (int )` - The MaximumError is normally defined as a fraction of the dataset bounding diagonal. By setting ErrorIsAbsolute to 1, the error is instead defined as that specified by AbsoluteError. By default ErrorIsAbsolute=0.

- `int = obj.GetErrorIsAbsolute ()` - The MaximumError is normally defined as a fraction of the dataset bounding diagonal. By setting ErrorIsAbsolute to 1, the error is instead defined as that specified by AbsoluteError. By default ErrorIsAbsolute=0.

- `obj.SetAbsoluteError (double )` - Same as MaximumError, but to be used when ErrorIsAbsolute is 1

- `double = obj.GetAbsoluteErrorMinValue ()` - Same as MaximumError, but to be used when ErrorIsAbsolute is 1

- `double = obj.GetAbsoluteErrorMaxValue ()` - Same as MaximumError, but to be used when ErrorIsAbsolute is 1

- `double = obj.GetAbsoluteError ()` - Same as MaximumError, but to be used when ErrorIsAbsolute is 1

- `obj.SetBoundaryVertexDeletion (int )` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.

- `int = obj.GetBoundaryVertexDeletion ()` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.

- `obj.BoundaryVertexDeletionOn ()` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.

- `obj.BoundaryVertexDeletionOff ()` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.

- `obj.SetDegree (int )` - If the number of triangles connected to a vertex exceeds "Degree", then the vertex will be split. (NOTE: the complexity of the triangulation algorithm is proportional to Degree$\hat{}$2. Setting degree small can improve the performance of the algorithm.)

- `int = obj.GetDegreeMinValue ()` - If the number of triangles connected to a vertex exceeds "Degree", then the vertex will be split. (NOTE: the complexity of the triangulation algorithm is proportional to Degree$\hat{}$2. Setting degree small can improve the performance of the algorithm.)

- `int = obj.GetDegreeMaxValue ()` - If the number of triangles connected to a vertex exceeds "Degree", then the vertex will be split. (NOTE: the complexity of the triangulation algorithm is proportional to Degree$\hat{}$2. Setting degree small can improve the performance of the algorithm.)

- `int = obj.GetDegree ()` - If the number of triangles connected to a vertex exceeds "Degree", then the vertex will be split. (NOTE: the complexity of the triangulation algorithm is proportional to Degree$\hat{}$2. Setting degree small can improve the performance of the algorithm.)

- `obj.SetInflectionPointRatio (double )` - Specify the inflection point ratio. An inflection point occurs when the ratio of reduction error between two iterations is greater than or equal to the InflectionPointRatio.

- `double = obj.GetInflectionPointRatioMinValue ()` - Specify the inflection point ratio. An inflection point occurs when the ratio of reduction error between two iterations is greater than or equal to the InflectionPointRatio.
- `double = obj.GetInflectionPointRatioMaxValue ()` - Specify the inflection point ratio. An inflection point occurs when the ratio of reduction error between two iterations is greater than or equal to the InflectionPointRatio.
- `double = obj.GetInflectionPointRatio ()` - Specify the inflection point ratio. An inflection point occurs when the ratio of reduction error between two iterations is greater than or equal to the InflectionPointRatio.
- `vtkIdType = obj.GetNumberOfInflectionPoints ()` - Get the number of inflection points. Only returns a valid value after the filter has executed. The values in the list are mesh reduction values at each inflection point. Note: the first inflection point always occurs right before non-planar triangles are decimated (i.e., as the error becomes non-zero).
- `obj.GetInflectionPoints (double inflectionPoints)` - Get a list of inflection points. These are double values 0 ¡ r ¡= 1.0 corresponding to reduction level, and there are a total of NumberOfInflectionPoints() values. You must provide an array (of the correct size) into which the inflection points are written.

33.55 vtkDelaunay2D

33.55.1 Usage

vtkDelaunay2D is a filter that constructs a 2D Delaunay triangulation from a list of input points. These points may be represented by any dataset of type vtkPointSet and subclasses. The output of the filter is a polygonal dataset. Usually the output is a triangle mesh, but if a non-zero alpha distance value is specified (called the "alpha" value), then only triangles, edges, and vertices lying within the alpha radius are output. In other words, non-zero alpha values may result in arbitrary combinations of triangles, lines, and vertices. (The notion of alpha value is derived from Edelsbrunner's work on "alpha shapes".) Also, it is possible to generate "constrained triangulations" using this filter. A constrained triangulation is one where edges and loops (i.e., polygons) can be defined and the triangulation will preserve them (read on for more information).

The 2D Delaunay triangulation is defined as the triangulation that satisfies the Delaunay criterion for n-dimensional simplexes (in this case n=2 and the simplexes are triangles). This criterion states that a circumsphere of each simplex in a triangulation contains only the n+1 defining points of the simplex. (See "The Visualization Toolkit" text for more information.) In two dimensions, this translates into an optimal triangulation. That is, the maximum interior angle of any triangle is less than or equal to that of any possible triangulation.

Delaunay triangulations are used to build topological structures from unorganized (or unstructured) points. The input to this filter is a list of points specified in 3D, even though the triangulation is 2D. Thus the triangulation is constructed in the x-y plane, and the z coordinate is ignored (although carried through to the output). If you desire to triangulate in a different plane, you can use the vtkTransformFilter to transform the points into and out of the x-y plane or you can specify a transform to the Delaunay2D directly. In the latter case, the input points are transformed, the transformed points are triangulated, and the output will use the triangulated topology for the original (non-transformed) points. This avoids transforming the data back as would be required when using the vtkTransformFilter method. Specifying a transform directly also allows any transform to be used: rigid, non-rigid, non-invertible, etc.

If an input transform is used, then alpha values are applied (for the most part) in the original data space. The exception is when BoundingTriangulation is on. In this case, alpha values are applied in the original data space unless a cell uses a bounding vertex.

The Delaunay triangulation can be numerically sensitive in some cases. To prevent problems, try to avoid injecting points that will result in triangles with bad aspect ratios (1000:1 or greater). In practice this means inserting points that are "widely dispersed", and enables smooth transition of triangle sizes throughout the

mesh. (You may even want to add extra points to create a better point distribution.) If numerical problems are present, you will see a warning message to this effect at the end of the triangulation process.

To create constrained meshes, you must define an additional input. This input is an instance of vtkPolyData which contains lines, polylines, and/or polygons that define constrained edges and loops. Only the topology of (lines and polygons) from this second input are used. The topology is assumed to reference points in the input point set (the one to be triangulated). In other words, the lines and polygons use point ids from the first input point set. Lines and polylines found in the input will be mesh edges in the output. Polygons define a loop with inside and outside regions. The inside of the polygon is determined by using the right-hand-rule, i.e., looking down the z-axis a polygon should be ordered counter-clockwise. Holes in a polygon should be ordered clockwise. If you choose to create a constrained triangulation, the final mesh may not satisfy the Delaunay criterion. (Noted: the lines/polygon edges must not intersect when projected onto the 2D plane. It may not be possible to recover all edges due to not enough points in the triangulation, or poorly defined edges (coincident or excessively long). The form of the lines or polygons is a list of point ids that correspond to the input point ids used to generate the triangulation.)

If an input transform is used, constraints are defined in the "transformed" space. So when the right hand rule is used for a polygon constraint, that operation is applied using the transformed points. Since the input transform can be any transformation (rigid or non-rigid), care must be taken in constructing constraints when an input transform is used.

To create an instance of class vtkDelaunay2D, simply invoke its constructor as follows

```
obj = vtkDelaunay2D
```

33.55.2 Methods

The class vtkDelaunay2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDelaunay2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDelaunay2D = obj.NewInstance ()`
- `vtkDelaunay2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetSource (vtkPolyData )` - Specify the source object used to specify constrained edges and loops. (This is optional.) If set, and lines/polygons are defined, a constrained triangulation is created. The lines/polygons are assumed to reference points in the input point set (i.e. point ids are identical in the input and source). Old style. See SetSourceConnection.
- `obj.SetSourceConnection (vtkAlgorithmOutput algOutput)` - Specify the source object used to specify constrained edges and loops. (This is optional.) If set, and lines/polygons are defined, a constrained triangulation is created. The lines/polygons are assumed to reference points in the input point set (i.e. point ids are identical in the input and source). New style. This method is equivalent to SetInputConnection(1, algOutput).
- `vtkPolyData = obj.GetSource ()` - Get a pointer to the source object.
- `obj.SetAlpha (double )` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges or triangles contained within a sphere centered at mesh vertices will be output. Otherwise, only triangles will be output.
- `double = obj.GetAlphaMinValue ()` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges or triangles contained within a sphere centered at mesh vertices will be output. Otherwise, only triangles will be output.

- `double = obj.GetAlphaMaxValue ()` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges or triangles contained within a sphere centered at mesh vertices will be output. Otherwise, only triangles will be output.
- `double = obj.GetAlpha ()` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges or triangles contained within a sphere centered at mesh vertices will be output. Otherwise, only triangles will be output.
- `obj.SetTolerance (double )` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.
- `double = obj.GetToleranceMinValue ()` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.
- `double = obj.GetToleranceMaxValue ()` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.
- `double = obj.GetTolerance ()` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.
- `obj.SetOffset (double )` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.
- `double = obj.GetOffsetMinValue ()` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.
- `double = obj.GetOffsetMaxValue ()` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.
- `double = obj.GetOffset ()` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.
- `obj.SetBoundingTriangulation (int )` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)
- `int = obj.GetBoundingTriangulation ()` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)
- `obj.BoundingTriangulationOn ()` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)
- `obj.BoundingTriangulationOff ()` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)
- `obj.SetTransform (vtkAbstractTransform )` - Set / get the transform which is applied to points to generate a 2D problem. This maps a 3D dataset into a 2D dataset where triangulation can be done on the XY plane. The points are transformed and triangulated. The topology of triangulated points is used as the output topology. The output points are the original (untransformed) points. The transform can be any subclass of vtkAbstractTransform (thus it does not need to be a linear or invertible transform).
- `vtkAbstractTransform = obj.GetTransform ()` - Set / get the transform which is applied to points to generate a 2D problem. This maps a 3D dataset into a 2D dataset where triangulation can be done on the XY plane. The points are transformed and triangulated. The topology of triangulated points is used as the output topology. The output points are the original (untransformed) points. The transform can be any subclass of vtkAbstractTransform (thus it does not need to be a linear or invertible transform).

- `obj.SetProjectionPlaneMode (int )` - Define
- `int = obj.GetProjectionPlaneModeMinValue ()` - Define
- `int = obj.GetProjectionPlaneModeMaxValue ()` - Define
- `int = obj.GetProjectionPlaneMode ()` - Define

33.56 vtkDelaunay3D

33.56.1 Usage

vtkDelaunay3D is a filter that constructs a 3D Delaunay triangulation from a list of input points. These points may be represented by any dataset of type vtkPointSet and subclasses. The output of the filter is an unstructured grid dataset. Usually the output is a tetrahedral mesh, but if a non-zero alpha distance value is specified (called the "alpha" value), then only tetrahedra, triangles, edges, and vertices lying within the alpha radius are output. In other words, non-zero alpha values may result in arbitrary combinations of tetrahedra, triangles, lines, and vertices. (The notion of alpha value is derived from Edelsbrunner's work on "alpha shapes".)

The 3D Delaunay triangulation is defined as the triangulation that satisfies the Delaunay criterion for n-dimensional simplexes (in this case n=3 and the simplexes are tetrahedra). This criterion states that a circumsphere of each simplex in a triangulation contains only the n+1 defining points of the simplex. (See text for more information.) While in two dimensions this translates into an "optimal" triangulation, this is not true in 3D, since a measurement for optimality in 3D is not agreed on.

Delaunay triangulations are used to build topological structures from unorganized (or unstructured) points. The input to this filter is a list of points specified in 3D. (If you wish to create 2D triangulations see vtkDelaunay2D.) The output is an unstructured grid.

The Delaunay triangulation can be numerically sensitive. To prevent problems, try to avoid injecting points that will result in triangles with bad aspect ratios (1000:1 or greater). In practice this means inserting points that are "widely dispersed", and enables smooth transition of triangle sizes throughout the mesh. (You may even want to add extra points to create a better point distribution.) If numerical problems are present, you will see a warning message to this effect at the end of the triangulation process.

To create an instance of class vtkDelaunay3D, simply invoke its constructor as follows

```
obj = vtkDelaunay3D
```

33.56.2 Methods

The class vtkDelaunay3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDelaunay3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDelaunay3D = obj.NewInstance ()`
- `vtkDelaunay3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetAlpha (double )` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges, faces, or tetra contained within the circumsphere (of radius alpha) will be output. Otherwise, only tetrahedra will be output.
- `double = obj.GetAlphaMinValue ()` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges, faces, or tetra contained within the circumsphere (of radius alpha) will be output. Otherwise, only tetrahedra will be output.

- `double = obj.GetAlphaMaxValue ()` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges, faces, or tetra contained within the circumsphere (of radius alpha) will be output. Otherwise, only tetrahedra will be output.

- `double = obj.GetAlpha ()` - Specify alpha (or distance) value to control output of this filter. For a non-zero alpha value, only edges, faces, or tetra contained within the circumsphere (of radius alpha) will be output. Otherwise, only tetrahedra will be output.

- `obj.SetTolerance (double )` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.

- `double = obj.GetToleranceMinValue ()` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.

- `double = obj.GetToleranceMaxValue ()` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.

- `double = obj.GetTolerance ()` - Specify a tolerance to control discarding of closely spaced points. This tolerance is specified as a fraction of the diagonal length of the bounding box of the points.

- `obj.SetOffset (double )` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.

- `double = obj.GetOffsetMinValue ()` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.

- `double = obj.GetOffsetMaxValue ()` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.

- `double = obj.GetOffset ()` - Specify a multiplier to control the size of the initial, bounding Delaunay triangulation.

- `obj.SetBoundingTriangulation (int )` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)

- `int = obj.GetBoundingTriangulation ()` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)

- `obj.BoundingTriangulationOn ()` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)

- `obj.BoundingTriangulationOff ()` - Boolean controls whether bounding triangulation points (and associated triangles) are included in the output. (These are introduced as an initial triangulation to begin the triangulation process. This feature is nice for debugging output.)

- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkPointLocator is used.

- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkPointLocator is used.

- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to eliminate "coincident" points.

- `obj.InsertPoint (vtkUnstructuredGrid Mesh, vtkPoints points, vtkIdType id, double x[3], vtkIdList h` - This is a helper method used with InitPointInsertion() to create tetrahedronalizations of points. Its purpose is to inject point at coordinates specified into tetrahedronalization. The point id is an index into the list of points in the mesh structure. (See vtkDelaunay3D::InitPointInsertion() for more information.) When you have completed inserting points, traverse the mesh structure to extract desired tetrahedra (or tetra faces and edges).The holeTetras id list lists all the tetrahedra that are deleted (invalid) in the mesh structure.
- `obj.EndPointInsertion ()` - Invoke this method after all points have been inserted. The purpose of the method is to clean up internal data structures. Note that the (vtkUnstructuredGrid *)Mesh returned from InitPointInsertion() is NOT deleted, you still are responsible for cleaning that up.
- `long = obj.GetMTime ()` - Return the MTime also considering the locator.

33.57 vtkDensifyPolyData

33.57.1 Usage

The filter takes any polygonal data as input and will tessellate cells that are planar polygons present by fanning out triangles from its centroid. Other cells are simply passed through to the output. PointData, if present, is interpolated via linear interpolation. CellData for any tessellated cell is simply copied over from its parent cell. Planar polygons are assumed to be convex. Funny things will happen if they are not.

The number of subdivisions can be controlled by the parameter NumberOfSubdivisions.

To create an instance of class vtkDensifyPolyData, simply invoke its constructor as follows

```
obj = vtkDensifyPolyData
```

33.57.2 Methods

The class vtkDensifyPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDensifyPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDensifyPolyData = obj.NewInstance ()`
- `vtkDensifyPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfSubdivisions (int )` - Number of recursive subdivisions. Initial value is 1.
- `int = obj.GetNumberOfSubdivisions ()` - Number of recursive subdivisions. Initial value is 1.

33.58 vtkDicer

33.58.1 Usage

Subclasses of vtkDicer divides the input dataset into separate pieces. These pieces can then be operated on by other filters (e.g., vtkThreshold). One application is to break very large polygonal models into pieces and performing viewing and occlusion culling on the pieces. Multiple pieces can also be streamed through the visualization pipeline.

To use this filter, you must specify the execution mode of the filter; i.e., set the way that the piece size is controlled (do this by setting the DiceMode ivar). The filter does not change the geometry or topology of the input dataset, rather it generates integer numbers that indicate which piece a particular point belongs

to (i.e., it modifies the point and cell attribute data). The integer number can be placed into the output scalar data, or the output field data.

To create an instance of class vtkDicer, simply invoke its constructor as follows

```
obj = vtkDicer
```

33.58.2 Methods

The class vtkDicer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDicer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDicer = obj.NewInstance ()`
- `vtkDicer = obj.SafeDownCast (vtkObject o)`
- `obj.SetFieldData (int )` - Set/Get the flag which controls whether to generate point scalar data or point field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Note that the generated the data are integer numbers indicating which piece a particular point belongs to.
- `int = obj.GetFieldData ()` - Set/Get the flag which controls whether to generate point scalar data or point field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Note that the generated the data are integer numbers indicating which piece a particular point belongs to.
- `obj.FieldDataOn ()` - Set/Get the flag which controls whether to generate point scalar data or point field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Note that the generated the data are integer numbers indicating which piece a particular point belongs to.
- `obj.FieldDataOff ()` - Set/Get the flag which controls whether to generate point scalar data or point field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Note that the generated the data are integer numbers indicating which piece a particular point belongs to.
- `obj.SetDiceMode (int )` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `int = obj.GetDiceModeMinValue ()` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `int = obj.GetDiceModeMaxValue ()` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `int = obj.GetDiceMode ()` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `obj.SetDiceModeToNumberOfPointsPerPiece ()` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `obj.SetDiceModeToSpecifiedNumberOfPieces ()` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `obj.SetDiceModeToMemoryLimitPerPiece ()` - Specify the method to determine how many pieces the data should be broken into. By default, the number of points per piece is used.
- `int = obj.GetNumberOfActualPieces ()` - Use the following method after the filter has updated to determine the actual number of pieces the data was separated into.

- `obj.SetNumberOfPointsPerPiece (int )` - Control piece size based on the maximum number of points per piece. (This ivar has effect only when the DiceMode is set to SetDiceModeToNumberOfPoints().)
- `int = obj.GetNumberOfPointsPerPieceMinValue ()` - Control piece size based on the maximum number of points per piece. (This ivar has effect only when the DiceMode is set to SetDiceModeToNumberOfPoints().)
- `int = obj.GetNumberOfPointsPerPieceMaxValue ()` - Control piece size based on the maximum number of points per piece. (This ivar has effect only when the DiceMode is set to SetDiceModeToNumberOfPoints().)
- `int = obj.GetNumberOfPointsPerPiece ()` - Control piece size based on the maximum number of points per piece. (This ivar has effect only when the DiceMode is set to SetDiceModeToNumberOfPoints().)
- `obj.SetNumberOfPieces (int )` - Set/Get the number of pieces the object is to be separated into. (This ivar has effect only when the DiceMode is set to SetDiceModeToSpecifiedNumber()). Note that the ivar NumberOfPieces is a target - depending on the particulars of the data, more or less number of pieces than the target value may be created.
- `int = obj.GetNumberOfPiecesMinValue ()` - Set/Get the number of pieces the object is to be separated into. (This ivar has effect only when the DiceMode is set to SetDiceModeToSpecifiedNumber()). Note that the ivar NumberOfPieces is a target - depending on the particulars of the data, more or less number of pieces than the target value may be created.
- `int = obj.GetNumberOfPiecesMaxValue ()` - Set/Get the number of pieces the object is to be separated into. (This ivar has effect only when the DiceMode is set to SetDiceModeToSpecifiedNumber()). Note that the ivar NumberOfPieces is a target - depending on the particulars of the data, more or less number of pieces than the target value may be created.
- `int = obj.GetNumberOfPieces ()` - Set/Get the number of pieces the object is to be separated into. (This ivar has effect only when the DiceMode is set to SetDiceModeToSpecifiedNumber()). Note that the ivar NumberOfPieces is a target - depending on the particulars of the data, more or less number of pieces than the target value may be created.
- `obj.SetMemoryLimit (long )` - Control piece size based on a memory limit. (This ivar has effect only when the DiceMode is set to SetDiceModeToMemoryLimit()). The memory limit should be set in kilobytes.
- `GetMemoryLimitMinValue = obj.()` - Control piece size based on a memory limit. (This ivar has effect only when the DiceMode is set to SetDiceModeToMemoryLimit()). The memory limit should be set in kilobytes.
- `GetMemoryLimitMaxValue = obj.()` - Control piece size based on a memory limit. (This ivar has effect only when the DiceMode is set to SetDiceModeToMemoryLimit()). The memory limit should be set in kilobytes.
- `long = obj.GetMemoryLimit ()` - Control piece size based on a memory limit. (This ivar has effect only when the DiceMode is set to SetDiceModeToMemoryLimit()). The memory limit should be set in kilobytes.

33.59 vtkDijkstraGraphGeodesicPath

33.59.1 Usage

Takes as input a polygonal mesh and performs a single source shortest path calculation. Dijkstra's algorithm is used. The implementation is similar to the one described in Introduction to Algorithms (Second Edition)

by Thomas H. Cormen, Charles E. Leiserson, Ronald L. Rivest, and Cliff Stein, published by MIT Press and McGraw-Hill. Some minor enhancement are added though. All vertices are not pushed on the heap at start, instead a front set is maintained. The heap is implemented as a binary heap. The output of the filter is a set of lines describing the shortest path from StartVertex to EndVertex.

To create an instance of class vtkDijkstraGraphGeodesicPath, simply invoke its constructor as follows

```
obj = vtkDijkstraGraphGeodesicPath
```

33.59.2 Methods

The class vtkDijkstraGraphGeodesicPath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDijkstraGraphGeodesicPath class.

- `string = obj.GetClassName ()` - Standard methids for printing and determining type information.
- `int = obj.IsA (string name)` - Standard methids for printing and determining type information.
- `vtkDijkstraGraphGeodesicPath = obj.NewInstance ()` - Standard methids for printing and determining type information.
- `vtkDijkstraGraphGeodesicPath = obj.SafeDownCast (vtkObject o)` - Standard methids for printing and determining type information.
- `vtkIdList = obj.GetIdList ()` - The vertex ids (of the input polydata) on the shortest path
- `obj.SetStopWhenEndReached (int )` - Stop when the end vertex is reached or calculate shortest path to all vertices
- `int = obj.GetStopWhenEndReached ()` - Stop when the end vertex is reached or calculate shortest path to all vertices
- `obj.StopWhenEndReachedOn ()` - Stop when the end vertex is reached or calculate shortest path to all vertices
- `obj.StopWhenEndReachedOff ()` - Stop when the end vertex is reached or calculate shortest path to all vertices
- `obj.SetUseScalarWeights (int )` - Use scalar values in the edge weight (experimental)
- `int = obj.GetUseScalarWeights ()` - Use scalar values in the edge weight (experimental)
- `obj.UseScalarWeightsOn ()` - Use scalar values in the edge weight (experimental)
- `obj.UseScalarWeightsOff ()` - Use scalar values in the edge weight (experimental)
- `obj.SetRepelPathFromVertices (int )` - Use the input point to repel the path by assigning high costs.
- `int = obj.GetRepelPathFromVertices ()` - Use the input point to repel the path by assigning high costs.
- `obj.RepelPathFromVerticesOn ()` - Use the input point to repel the path by assigning high costs.
- `obj.RepelPathFromVerticesOff ()` - Use the input point to repel the path by assigning high costs.
- `obj.SetRepelVertices (vtkPoints )` - Specify vtkPoints to use to repel the path from.
- `vtkPoints = obj.GetRepelVertices ()` - Specify vtkPoints to use to repel the path from.
- `double = obj.GetGeodesicLength ()`
- `obj.GetCumulativeWeights (vtkDoubleArray weights)`

33.60 vtkDijkstraImageGeodesicPath

33.60.1 Usage

Takes as input a polyline and an image representing a 2D cost function and performs a single source shortest path calculation. Dijkstra's algorithm is used. The implementation is similar to the one described in Introduction to Algorithms (Second Edition) by Thomas H. Cormen, Charles E. Leiserson, Ronald L. Rivest, and Cliff Stein, published by MIT Press and McGraw-Hill. Some minor enhancement are added though. All vertices are not pushed on the heap at start, instead a front set is maintained. The heap is implemented as a binary heap. The output of the filter is a set of lines describing the shortest path from StartVertex to EndVertex. See parent class vtkDijkstraGraphGeodesicPath for the implementation.

To create an instance of class vtkDijkstraImageGeodesicPath, simply invoke its constructor as follows

```
obj = vtkDijkstraImageGeodesicPath
```

33.60.2 Methods

The class vtkDijkstraImageGeodesicPath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDijkstraImageGeodesicPath class.

- `string = obj.GetClassName ()` - Standard methids for printing and determining type information.
- `int = obj.IsA (string name)` - Standard methids for printing and determining type information.
- `vtkDijkstraImageGeodesicPath = obj.NewInstance ()` - Standard methids for printing and determining type information.
- `vtkDijkstraImageGeodesicPath = obj.SafeDownCast (vtkObject o)` - Standard methids for printing and determining type information.
- `obj.SetInput (vtkDataObject )` - Specify the image object which is used as a cost function.
- `vtkImageData = obj.GetInputAsImageData ()` - Specify the image object which is used as a cost function.
- `obj.SetImageWeight (double )` - Image cost weight.
- `double = obj.GetImageWeight ()` - Image cost weight.
- `obj.SetEdgeLengthWeight (double )` - Edge length cost weight.
- `double = obj.GetEdgeLengthWeight ()` - Edge length cost weight.
- `obj.SetCurvatureWeight (double )` - Curvature cost weight.
- `double = obj.GetCurvatureWeightMinValue ()` - Curvature cost weight.
- `double = obj.GetCurvatureWeightMaxValue ()` - Curvature cost weight.
- `double = obj.GetCurvatureWeight ()` - Curvature cost weight.

33.61 vtkDiscreteMarchingCubes

33.61.1 Usage

takes as input a volume (e.g., 3D structured point set) of segmentation labels and generates on output one or more models representing the boundaries between the specified label and the adjacent structures. One or more label values must be specified to generate the models. The boundary positions are always defined to be half-way between adjacent voxels. This filter works best with integral scalar values. If ComputeScalars is on (the default), each output cell will have cell data that corresponds to the scalar value (segmentation label) of the corresponding cube. Note that this differs from vtkMarchingCubes, which stores the scalar value as point data. The rationale for this difference is that cell vertices may be shared between multiple cells. This also means that the resultant polydata may be non-manifold (cell faces may be coincident). To further process the polydata, users should either: 1) extract cells that have a common scalar value using vtkThreshold, or 2) process the data with filters that can handle non-manifold polydata (e.g. vtkWindowedSincPolyDataFilter). Also note, Normals and Gradients are not computed.

To create an instance of class vtkDiscreteMarchingCubes, simply invoke its constructor as follows

```
obj = vtkDiscreteMarchingCubes
```

33.61.2 Methods

The class vtkDiscreteMarchingCubes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDiscreteMarchingCubes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDiscreteMarchingCubes = obj.NewInstance ()`
- `vtkDiscreteMarchingCubes = obj.SafeDownCast (vtkObject o)`

33.62 vtkDiskSource

33.62.1 Usage

vtkDiskSource creates a polygonal disk with a hole in the center. The disk has zero height. The user can specify the inner and outer radius of the disk, and the radial and circumferential resolution of the polygonal representation.

To create an instance of class vtkDiskSource, simply invoke its constructor as follows

```
obj = vtkDiskSource
```

33.62.2 Methods

The class vtkDiskSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDiskSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDiskSource = obj.NewInstance ()`

- `vtkDiskSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetInnerRadius (double )` - Specify inner radius of hole in disc.
- `double = obj.GetInnerRadiusMinValue ()` - Specify inner radius of hole in disc.
- `double = obj.GetInnerRadiusMaxValue ()` - Specify inner radius of hole in disc.
- `double = obj.GetInnerRadius ()` - Specify inner radius of hole in disc.
- `obj.SetOuterRadius (double )` - Specify outer radius of disc.
- `double = obj.GetOuterRadiusMinValue ()` - Specify outer radius of disc.
- `double = obj.GetOuterRadiusMaxValue ()` - Specify outer radius of disc.
- `double = obj.GetOuterRadius ()` - Specify outer radius of disc.
- `obj.SetRadialResolution (int )` - Set the number of points in radius direction.
- `int = obj.GetRadialResolutionMinValue ()` - Set the number of points in radius direction.
- `int = obj.GetRadialResolutionMaxValue ()` - Set the number of points in radius direction.
- `int = obj.GetRadialResolution ()` - Set the number of points in radius direction.
- `obj.SetCircumferentialResolution (int )` - Set the number of points in circumferential direction.
- `int = obj.GetCircumferentialResolutionMinValue ()` - Set the number of points in circumferential direction.
- `int = obj.GetCircumferentialResolutionMaxValue ()` - Set the number of points in circumferential direction.
- `int = obj.GetCircumferentialResolution ()` - Set the number of points in circumferential direction.

33.63 vtkEdgePoints

33.63.1 Usage

vtkEdgePoints is a filter that takes as input any dataset and generates for output a set of points that lie on an isosurface. The points are created by interpolation along cells edges whose end-points are below and above the contour value.

To create an instance of class vtkEdgePoints, simply invoke its constructor as follows

```
obj = vtkEdgePoints
```

33.63.2 Methods

The class vtkEdgePoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgePoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgePoints = obj.NewInstance ()`

- `vtkEdgePoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (double )` - Set/get the contour value.
- `double = obj.GetValue ()` - Set/get the contour value.

33.64 vtkEdgeSubdivisionCriterion

33.64.1 Usage

Descendants of this abstract class are used to decide whether a piecewise linear approximation (triangles, lines, ...) to some nonlinear geometry should be subdivided. This decision may be based on an absolute error metric (chord error) or on some view-dependent metric (chord error compared to device resolution) or on some abstract metric (color error). Or anything else, really. Just so long as you implement the EvaluateEdge member, all will be well.

To create an instance of class vtkEdgeSubdivisionCriterion, simply invoke its constructor as follows

```
obj = vtkEdgeSubdivisionCriterion
```

33.64.2 Methods

The class vtkEdgeSubdivisionCriterion has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgeSubdivisionCriterion class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgeSubdivisionCriterion = obj.NewInstance ()`
- `vtkEdgeSubdivisionCriterion = obj.SafeDownCast (vtkObject o)`
- `bool = obj.EvaluateEdge (double p0, double p1, double p2, int field\_start)` - You must implement this member function in a subclass. It will be called by vtkStreamingTessellator for each edge in each primitive that vtkStreamingTessellator generates.
- `int = obj.PassField (int sourceId, int sourceSize, vtkStreamingTessellator t)` - This is a helper routine called by PassFields() which you may also call directly; it adds sourceSize to the size of the output vertex field values. The offset of the sourceId field in the output vertex array is returned. -1 is returned if sourceSize would force the output to have more than vtkStreamingTessellator::MaxFieldSize field values per vertex.
- `obj.ResetFieldList ()` - Don't pass any field values in the vertex pointer. This is used to reset the list of fields to pass after a successful run of vtkStreamingTessellator.
- `bool = obj.DontPassField (int sourceId, vtkStreamingTessellator t)` - This does the opposite of PassField(); it removes a field from the output (assuming the field was set to be passed). Returns true if any action was taken, false otherwise.
- `int = obj.GetOutputField (int fieldId) const` - Return the output ID of an input field. Returns -1 if fieldId is not set to be passed to the output.
- `int = obj.GetNumberOfFields () const` - Return the number of fields being evaluated at each output vertex. This is the length of the arrays returned by GetFieldIds() and GetFieldOffsets().

33.65 vtkElevationFilter

33.65.1 Usage

vtkElevationFilter is a filter to generate scalar values from a dataset. The scalar values lie within a user specified range, and are generated by computing a projection of each dataset point onto a line. The line can be oriented arbitrarily. A typical example is to generate scalars based on elevation or height above a plane.

To create an instance of class vtkElevationFilter, simply invoke its constructor as follows

```
obj = vtkElevationFilter
```

33.65.2 Methods

The class vtkElevationFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkElevationFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkElevationFilter = obj.NewInstance ()`
- `vtkElevationFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetLowPoint (double , double , double )` - Define one end of the line (small scalar values). Default is (0,0,0).
- `obj.SetLowPoint (double  a[3])` - Define one end of the line (small scalar values). Default is (0,0,0).
- `double = obj. GetLowPoint ()` - Define one end of the line (small scalar values). Default is (0,0,0).
- `obj.SetHighPoint (double , double , double )` - Define other end of the line (large scalar values). Default is (0,0,1).
- `obj.SetHighPoint (double  a[3])` - Define other end of the line (large scalar values). Default is (0,0,1).
- `double = obj. GetHighPoint ()` - Define other end of the line (large scalar values). Default is (0,0,1).
- `obj.SetScalarRange (double , double )` - Specify range to map scalars into. Default is [0, 1].
- `obj.SetScalarRange (double  a[2])` - Specify range to map scalars into. Default is [0, 1].
- `double = obj. GetScalarRange ()` - Specify range to map scalars into. Default is [0, 1].

33.66 vtkEllipticalButtonSource

33.66.1 Usage

vtkEllipticalButtonSource creates a ellipsoidal shaped button with texture coordinates suitable for application of a texture map. This provides a way to make nice looking 3D buttons. The buttons are represented as vtkPolyData that includes texture coordinates and normals. The button lies in the x-y plane.

To use this class you must define the major and minor axes lengths of an ellipsoid (expressed as width (x), height (y) and depth (z)). The button has a rectangular mesh region in the center with texture coordinates that range smoothly from (0,1). (This flat region is called the texture region.) The outer, curved portion of the button (called the shoulder) has texture coordinates set to a user specified value (by default (0,0). (This results in coloring the button curve the same color as the (s,t) location of the texture map.) The resolution

in the radial direction, the texture region, and the shoulder region must also be set. The button can be moved by specifying an origin.

To create an instance of class vtkEllipticalButtonSource, simply invoke its constructor as follows

```
obj = vtkEllipticalButtonSource
```

33.66.2 Methods

The class vtkEllipticalButtonSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEllipticalButtonSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEllipticalButtonSource = obj.NewInstance ()`
- `vtkEllipticalButtonSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetWidth (double )` - Set/Get the width of the button (the x-ellipsoid axis length * 2).
- `double = obj.GetWidthMinValue ()` - Set/Get the width of the button (the x-ellipsoid axis length * 2).
- `double = obj.GetWidthMaxValue ()` - Set/Get the width of the button (the x-ellipsoid axis length * 2).
- `double = obj.GetWidth ()` - Set/Get the width of the button (the x-ellipsoid axis length * 2).
- `obj.SetHeight (double )` - Set/Get the height of the button (the y-ellipsoid axis length * 2).
- `double = obj.GetHeightMinValue ()` - Set/Get the height of the button (the y-ellipsoid axis length * 2).
- `double = obj.GetHeightMaxValue ()` - Set/Get the height of the button (the y-ellipsoid axis length * 2).
- `double = obj.GetHeight ()` - Set/Get the height of the button (the y-ellipsoid axis length * 2).
- `obj.SetDepth (double )` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `double = obj.GetDepthMinValue ()` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `double = obj.GetDepthMaxValue ()` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `double = obj.GetDepth ()` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `obj.SetCircumferentialResolution (int )` - Specify the resolution of the button in the circumferential direction.
- `int = obj.GetCircumferentialResolutionMinValue ()` - Specify the resolution of the button in the circumferential direction.
- `int = obj.GetCircumferentialResolutionMaxValue ()` - Specify the resolution of the button in the circumferential direction.
- `int = obj.GetCircumferentialResolution ()` - Specify the resolution of the button in the circumferential direction.

- `obj.SetTextureResolution (int )` - Specify the resolution of the texture in the radial direction in the texture region.
- `int = obj.GetTextureResolutionMinValue ()` - Specify the resolution of the texture in the radial direction in the texture region.
- `int = obj.GetTextureResolutionMaxValue ()` - Specify the resolution of the texture in the radial direction in the texture region.
- `int = obj.GetTextureResolution ()` - Specify the resolution of the texture in the radial direction in the texture region.
- `obj.SetShoulderResolution (int )` - Specify the resolution of the texture in the radial direction in the shoulder region.
- `int = obj.GetShoulderResolutionMinValue ()` - Specify the resolution of the texture in the radial direction in the shoulder region.
- `int = obj.GetShoulderResolutionMaxValue ()` - Specify the resolution of the texture in the radial direction in the shoulder region.
- `int = obj.GetShoulderResolution ()` - Specify the resolution of the texture in the radial direction in the shoulder region.
- `obj.SetRadialRatio (double )` - Set/Get the radial ratio. This is the measure of the radius of the outer ellipsoid to the inner ellipsoid of the button. The outer ellipsoid is the boundary of the button defined by the height and width. The inner ellipsoid circumscribes the texture region. Larger RadialRatio's cause the button to be more rounded (and the texture region to be smaller); smaller ratios produce sharply curved shoulders with a larger texture region.
- `double = obj.GetRadialRatioMinValue ()` - Set/Get the radial ratio. This is the measure of the radius of the outer ellipsoid to the inner ellipsoid of the button. The outer ellipsoid is the boundary of the button defined by the height and width. The inner ellipsoid circumscribes the texture region. Larger RadialRatio's cause the button to be more rounded (and the texture region to be smaller); smaller ratios produce sharply curved shoulders with a larger texture region.
- `double = obj.GetRadialRatioMaxValue ()` - Set/Get the radial ratio. This is the measure of the radius of the outer ellipsoid to the inner ellipsoid of the button. The outer ellipsoid is the boundary of the button defined by the height and width. The inner ellipsoid circumscribes the texture region. Larger RadialRatio's cause the button to be more rounded (and the texture region to be smaller); smaller ratios produce sharply curved shoulders with a larger texture region.
- `double = obj.GetRadialRatio ()` - Set/Get the radial ratio. This is the measure of the radius of the outer ellipsoid to the inner ellipsoid of the button. The outer ellipsoid is the boundary of the button defined by the height and width. The inner ellipsoid circumscribes the texture region. Larger RadialRatio's cause the button to be more rounded (and the texture region to be smaller); smaller ratios produce sharply curved shoulders with a larger texture region.

33.67 vtkExtractArraysOverTime

33.67.1 Usage

vtkExtractArraysOverTime extracts a selection over time. The output is a multiblock dataset. If selection content type is vtkSelection::Locations, then each output block corresponds to each probed location. Otherwise, each output block corresponds to an extracted cell/point depending on whether the selection field type is CELL or POINT. Each block is a vtkTable with a column named Time (or TimeData if Time exists in the input). When extracting point data, the input point coordinates are copied to a column named Point Coordinates or Points (if Point Coordinates exists in the input). This algorithm does not produce a

TIME_STEPS or TIME_RANGE information because it works across time. .Section Caveat This algorithm works only with source that produce TIME_STEPS(). Continuous time range is not yet supported.

To create an instance of class vtkExtractArraysOverTime, simply invoke its constructor as follows

```
obj = vtkExtractArraysOverTime
```

33.67.2 Methods

The class vtkExtractArraysOverTime has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractArraysOverTime class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractArraysOverTime = obj.NewInstance ()`
- `vtkExtractArraysOverTime = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfTimeSteps ()` - Get the number of time steps
- `obj.SetSelectionConnection (vtkAlgorithmOutput algOutput)`

33.68 vtkExtractBlock

33.68.1 Usage

vtkExtractBlock is a filter that extracts blocks from a multiblock dataset. Each node in the multi-block tree is identified by an įndex. The index can be obtained by performing a preorder traversal of the tree (including empty nodes). eg. A(B (D, E), C(F, G)). Inorder traversal yields: A, B, D, E, C, F, G Index of A is 0, while index of C is 4.

To create an instance of class vtkExtractBlock, simply invoke its constructor as follows

```
obj = vtkExtractBlock
```

33.68.2 Methods

The class vtkExtractBlock has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractBlock class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractBlock = obj.NewInstance ()`
- `vtkExtractBlock = obj.SafeDownCast (vtkObject o)`
- `obj.AddIndex (int index)` - Select the block indices to extract. Each node in the multi-block tree is identified by an įndex. The index can be obtained by performing a preorder traversal of the tree (including empty nodes). eg. A(B (D, E), C(F, G)). Inorder traversal yields: A, B, D, E, C, F, G Index of A is 0, while index of C is 4.

- `obj.RemoveIndex (int index)` - Select the block indices to extract. Each node in the multi-block tree is identified by an ţndex. The index can be obtained by performing a preorder traversal of the tree (including empty nodes). eg. A(B (D, E), C(F, G)). Inorder traversal yields: A, B, D, E, C, F, G Index of A is 0, while index of C is 4.

- `obj.RemoveAllIndices ()` - Select the block indices to extract. Each node in the multi-block tree is identified by an ţndex. The index can be obtained by performing a preorder traversal of the tree (including empty nodes). eg. A(B (D, E), C(F, G)). Inorder traversal yields: A, B, D, E, C, F, G Index of A is 0, while index of C is 4.

- `obj.SetPruneOutput (int )` - When set, the output mutliblock dataset will be pruned to remove empty nodes. On by default.

- `int = obj.GetPruneOutput ()` - When set, the output mutliblock dataset will be pruned to remove empty nodes. On by default.

- `obj.PruneOutputOn ()` - When set, the output mutliblock dataset will be pruned to remove empty nodes. On by default.

- `obj.PruneOutputOff ()` - When set, the output mutliblock dataset will be pruned to remove empty nodes. On by default.

- `obj.SetMaintainStructure (int )` - This is used only when PruneOutput is ON. By default, when pruning the output i.e. remove empty blocks, if node has only 1 non-null child block, then that node is removed. To preserve these parent nodes, set this flag to true. Off by default.

- `int = obj.GetMaintainStructure ()` - This is used only when PruneOutput is ON. By default, when pruning the output i.e. remove empty blocks, if node has only 1 non-null child block, then that node is removed. To preserve these parent nodes, set this flag to true. Off by default.

- `obj.MaintainStructureOn ()` - This is used only when PruneOutput is ON. By default, when pruning the output i.e. remove empty blocks, if node has only 1 non-null child block, then that node is removed. To preserve these parent nodes, set this flag to true. Off by default.

- `obj.MaintainStructureOff ()` - This is used only when PruneOutput is ON. By default, when pruning the output i.e. remove empty blocks, if node has only 1 non-null child block, then that node is removed. To preserve these parent nodes, set this flag to true. Off by default.

33.69 vtkExtractCells

33.69.1 Usage

Given a vtkDataSet and a list of cell Ids, create a vtkUnstructuredGrid composed of these cells. If the cell list is empty when vtkExtractCells executes, it will set up the ugrid, point and cell arrays, with no points, cells or data.

To create an instance of class vtkExtractCells, simply invoke its constructor as follows

```
obj = vtkExtractCells
```

33.69.2 Methods

The class vtkExtractCells has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractCells class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkExtractCells = obj.NewInstance ()`
- `vtkExtractCells = obj.SafeDownCast (vtkObject o)`
- `obj.SetCellList (vtkIdList l)`
- `obj.AddCellList (vtkIdList l)`
- `obj.AddCellRange (vtkIdType from, vtkIdType to)`

33.70 vtkExtractDataOverTime

33.70.1 Usage

This filter extracts the point data from a time sequence and specified index and creates an output of the same type as the input but with Points containing "number of time steps" points; the point and PointData corresponding to the PointIndex are extracted at each time step and added to the output. A PointData array is added called "Time" (or "TimeData" if there is already an array called "Time"), which is the time at each index.

To create an instance of class vtkExtractDataOverTime, simply invoke its constructor as follows

```
obj = vtkExtractDataOverTime
```

33.70.2 Methods

The class vtkExtractDataOverTime has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractDataOverTime class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractDataOverTime = obj.NewInstance ()`
- `vtkExtractDataOverTime = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointIndex (int )` - Index of point to extract at each time step
- `int = obj.GetPointIndex ()` - Index of point to extract at each time step
- `int = obj.GetNumberOfTimeSteps ()` - Get the number of time steps

33.71 vtkExtractDataSets

33.71.1 Usage

vtkExtractDataSets accepts a vtkHierarchicalBoxDataSet as input and extracts different datasets from different levels. The output is vtkHierarchicalBoxDataSet with same structure as the input with only the selected datasets passed through.

To create an instance of class vtkExtractDataSets, simply invoke its constructor as follows

```
obj = vtkExtractDataSets
```

33.71.2 Methods

The class vtkExtractDataSets has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractDataSets class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractDataSets = obj.NewInstance ()`
- `vtkExtractDataSets = obj.SafeDownCast (vtkObject o)`
- `obj.AddDataSet (int level, int idx)` - Add a dataset to be extracted.
- `obj.ClearDataSetList ()` - Remove all entries from the list of datasets to be extracted.

33.72 vtkExtractEdges

33.72.1 Usage

vtkExtractEdges is a filter to extract edges from a dataset. Edges are extracted as lines or polylines.

To create an instance of class vtkExtractEdges, simply invoke its constructor as follows

```
obj = vtkExtractEdges
```

33.72.2 Methods

The class vtkExtractEdges has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractEdges class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractEdges = obj.NewInstance ()`
- `vtkExtractEdges = obj.SafeDownCast (vtkObject o)`
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.
- `long = obj.GetMTime ()` - Return MTime also considering the locator.

33.73 vtkExtractGeometry

33.73.1 Usage

vtkExtractGeometry extracts from its input dataset all cells that are either completely inside or outside of a specified implicit function. Any type of dataset can be input to this filter. On output the filter generates an unstructured grid.

To use this filter you must specify an implicit function. You must also specify whethter to extract cells lying inside or outside of the implicit function. (The inside of an implicit function is the negative values region.) An option exists to extract cells that are neither inside or outside (i.e., boundary).

A more efficient version of this filter is available for vtkPolyData input. See vtkExtractPolyDataGeometry.

To create an instance of class vtkExtractGeometry, simply invoke its constructor as follows

```
obj = vtkExtractGeometry
```

33.73.2 Methods

The class vtkExtractGeometry has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractGeometry class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractGeometry = obj.NewInstance ()`
- `vtkExtractGeometry = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime taking into account changes to the implicit function
- `obj.SetImplicitFunction (vtkImplicitFunction )` - Specify the implicit function for inside/outside checks.
- `vtkImplicitFunction = obj.GetImplicitFunction ()` - Specify the implicit function for inside/outside checks.
- `obj.SetExtractInside (int )` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `int = obj.GetExtractInside ()` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `obj.ExtractInsideOn ()` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `obj.ExtractInsideOff ()` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `obj.SetExtractBoundaryCells (int )` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `int = obj.GetExtractBoundaryCells ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `obj.ExtractBoundaryCellsOn ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.

- `obj.ExtractBoundaryCellsOff ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `obj.SetExtractOnlyBoundaryCells (int )` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `int = obj.GetExtractOnlyBoundaryCells ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `obj.ExtractOnlyBoundaryCellsOn ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `obj.ExtractOnlyBoundaryCellsOff ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.

33.74 vtkExtractGrid

33.74.1 Usage

vtkExtractGrid is a filter that selects a portion of an input structured grid dataset, or subsamples an input dataset. (The selected portion of interested is referred to as the Volume Of Interest, or VOI.) The output of this filter is a structured grid dataset. The filter treats input data of any topological dimension (i.e., point, line, image, or volume) and can generate output data of any topological dimension.

To use this filter set the VOI ivar which are i-j-k min/max indices that specify a rectangular region in the data. (Note that these are 0-offset.) You can also specify a sampling rate to subsample the data.

Typical applications of this filter are to extract a plane from a grid for contouring, subsampling large grids to reduce data size, or extracting regions of a grid with interesting data.

To create an instance of class vtkExtractGrid, simply invoke its constructor as follows

```
obj = vtkExtractGrid
```

33.74.2 Methods

The class vtkExtractGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractGrid = obj.NewInstance ()`
- `vtkExtractGrid = obj.SafeDownCast (vtkObject o)`
- `obj.SetVOI (int , int , int , int , int , int )` - Specify i-j-k (min,max) pairs to extract. The resulting structured grid dataset can be of any topological dimension (i.e., point, line, plane, or 3D grid).
- `obj.SetVOI (int  a[6])` - Specify i-j-k (min,max) pairs to extract. The resulting structured grid dataset can be of any topological dimension (i.e., point, line, plane, or 3D grid).
- `int = obj. GetVOI ()` - Specify i-j-k (min,max) pairs to extract. The resulting structured grid dataset can be of any topological dimension (i.e., point, line, plane, or 3D grid).
- `obj.SetSampleRate (int , int , int )` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.

- `obj.SetSampleRate (int  a[3])` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.
- `int = obj. GetSampleRate ()` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.
- `obj.SetIncludeBoundary (int )` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)
- `int = obj.GetIncludeBoundary ()` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)
- `obj.IncludeBoundaryOn ()` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)
- `obj.IncludeBoundaryOff ()` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)

33.75 vtkExtractLevel

33.75.1 Usage

vtkExtractLevel filter extracts the levels between (and including) the user specified min and max levels.

To create an instance of class vtkExtractLevel, simply invoke its constructor as follows

```
obj = vtkExtractLevel
```

33.75.2 Methods

The class vtkExtractLevel has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractLevel class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractLevel = obj.NewInstance ()`
- `vtkExtractLevel = obj.SafeDownCast (vtkObject o)`
- `obj.AddLevel (int level)` - Select the levels that should be extracted. All other levels will have no datasets in them.

- `obj.RemoveLevel (int level)` - Select the levels that should be extracted. All other levels will have no datasets in them.
- `obj.RemoveAllLevels ()` - Select the levels that should be extracted. All other levels will have no datasets in them.

33.76 vtkExtractPolyDataGeometry

33.76.1 Usage

vtkExtractPolyDataGeometry extracts from its input vtkPolyData all cells that are either completely inside or outside of a specified implicit function. This filter is specialized to vtkPolyData. On output the filter generates vtkPolyData.

To use this filter you must specify an implicit function. You must also specify whether to extract cells lying inside or outside of the implicit function. (The inside of an implicit function is the negative values region.) An option exists to extract cells that are neither inside nor outside (i.e., boundary).

A more general version of this filter is available for arbitrary vtkDataSet input (see vtkExtractGeometry).

To create an instance of class vtkExtractPolyDataGeometry, simply invoke its constructor as follows

```
obj = vtkExtractPolyDataGeometry
```

33.76.2 Methods

The class vtkExtractPolyDataGeometry has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractPolyDataGeometry class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractPolyDataGeometry = obj.NewInstance ()`
- `vtkExtractPolyDataGeometry = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime taking into account changes to the implicit function
- `obj.SetImplicitFunction (vtkImplicitFunction )` - Specify the implicit function for inside/outside checks.
- `vtkImplicitFunction = obj.GetImplicitFunction ()` - Specify the implicit function for inside/outside checks.
- `obj.SetExtractInside (int )` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `int = obj.GetExtractInside ()` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `obj.ExtractInsideOn ()` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `obj.ExtractInsideOff ()` - Boolean controls whether to extract cells that are inside of implicit function (ExtractInside == 1) or outside of implicit function (ExtractInside == 0).
- `obj.SetExtractBoundaryCells (int )` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.

- `int = obj.GetExtractBoundaryCells ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `obj.ExtractBoundaryCellsOn ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.
- `obj.ExtractBoundaryCellsOff ()` - Boolean controls whether to extract cells that are partially inside. By default, ExtractBoundaryCells is off.

33.77 vtkExtractRectilinearGrid

33.77.1 Usage

vtkExtractRectilinearGrid rounds out the set of filters that extract a subgrid out of a larger structured data set. RIght now, this filter only supports extracting a VOI. In the future, it might support strides like the vtkExtract grid filter.

To create an instance of class vtkExtractRectilinearGrid, simply invoke its constructor as follows

```
obj = vtkExtractRectilinearGrid
```

33.77.2 Methods

The class vtkExtractRectilinearGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractRectilinearGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractRectilinearGrid = obj.NewInstance ()`
- `vtkExtractRectilinearGrid = obj.SafeDownCast (vtkObject o)`
- `obj.SetVOI (int , int , int , int , int , int )` - Specify i-j-k (min,max) pairs to extract. The resulting structured grid dataset can be of any topological dimension (i.e., point, line, plane, or 3D grid).
- `obj.SetVOI (int a[6])` - Specify i-j-k (min,max) pairs to extract. The resulting structured grid dataset can be of any topological dimension (i.e., point, line, plane, or 3D grid).
- `int = obj. GetVOI ()` - Specify i-j-k (min,max) pairs to extract. The resulting structured grid dataset can be of any topological dimension (i.e., point, line, plane, or 3D grid).
- `obj.SetSampleRate (int , int , int )` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.
- `obj.SetSampleRate (int a[3])` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.
- `int = obj. GetSampleRate ()` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.

- `obj.SetIncludeBoundary (int )` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)
- `int = obj.GetIncludeBoundary ()` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)
- `obj.IncludeBoundaryOn ()` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)
- `obj.IncludeBoundaryOff ()` - Control whether to enforce that the "boundary" of the grid is output in the subsampling process. (This ivar only has effect when the SampleRate in any direction is not equal to 1.) When this ivar IncludeBoundary is on, the subsampling will always include the boundary of the grid even though the sample rate is not an even multiple of the grid dimensions. (By default IncludeBoundary is off.)

33.78 vtkExtractSelectedBlock

33.78.1 Usage

To create an instance of class vtkExtractSelectedBlock, simply invoke its constructor as follows

```
obj = vtkExtractSelectedBlock
```

33.78.2 Methods

The class vtkExtractSelectedBlock has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedBlock class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedBlock = obj.NewInstance ()`
- `vtkExtractSelectedBlock = obj.SafeDownCast (vtkObject o)`

33.79 vtkExtractSelectedFrustum

33.79.1 Usage

This class intersects the input DataSet with a frustum and determines which cells and points lie within the frustum. The frustum is defined with a vtkPlanes containing six cutting planes. The output is a DataSet that is either a shallow copy of the input dataset with two new "vtkInsidedness" attribute arrays, or a completely new UnstructuredGrid that contains only the cells and points of the input that are inside the frustum. The PreserveTopology flag controls which occurs. When PreserveTopology is off this filter adds

a scalar array called vtkOriginalCellIds that says what input cell produced each output cell. This is an example of a Pedigree ID which helps to trace back results.

To create an instance of class vtkExtractSelectedFrustum, simply invoke its constructor as follows

```
obj = vtkExtractSelectedFrustum
```

33.79.2 Methods

The class vtkExtractSelectedFrustum has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedFrustum class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedFrustum = obj.NewInstance ()`
- `vtkExtractSelectedFrustum = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime taking into account changes to the Frustum
- `obj.SetFrustum (vtkPlanes )` - Set the selection frustum. The planes object must contain six planes.
- `vtkPlanes = obj.GetFrustum ()` - Set the selection frustum. The planes object must contain six planes.
- `obj.CreateFrustum (double vertices[32])` - Given eight vertices, creates a frustum. each pt is x,y,z,1 in the following order near lower left, far lower left near upper left, far upper left near lower right, far lower right near upper right, far upper right
- `vtkPoints = obj.GetClipPoints ()` - Return eight points that define the selection frustum. Valid if create Frustum was used, invalid if SetFrustum was.
- `obj.SetFieldType (int )` - Sets/gets the intersection test type.
- `int = obj.GetFieldType ()` - Sets/gets the intersection test type.
- `obj.SetContainingCells (int )` - Sets/gets the intersection test type. Only meaningful when fieldType is vtkSelection::POINT
- `int = obj.GetContainingCells ()` - Sets/gets the intersection test type. Only meaningful when fieldType is vtkSelection::POINT
- `int = obj.OverallBoundsTest (double bounds)` - Does a quick test on the AABBox defined by the bounds.
- `obj.SetShowBounds (int )` - When On, this returns an unstructured grid that outlines selection area. Off is the default.
- `int = obj.GetShowBounds ()` - When On, this returns an unstructured grid that outlines selection area. Off is the default.
- `obj.ShowBoundsOn ()` - When On, this returns an unstructured grid that outlines selection area. Off is the default.
- `obj.ShowBoundsOff ()` - When On, this returns an unstructured grid that outlines selection area. Off is the default.
- `obj.SetInsideOut (int )` - When on, extracts cells outside the frustum instead of inside.

- `int = obj.GetInsideOut ()` - When on, extracts cells outside the frustum instead of inside.
- `obj.InsideOutOn ()` - When on, extracts cells outside the frustum instead of inside.
- `obj.InsideOutOff ()` - When on, extracts cells outside the frustum instead of inside.

33.80 vtkExtractSelectedIds

33.80.1 Usage

vtkExtractSelectedIds extracts a set of cells and points from within a vtkDataSet. The set of ids to extract are listed within a vtkSelection. This filter adds a scalar array called vtkOriginalCellIds that says what input cell produced each output cell. This is an example of a Pedigree ID which helps to trace back results. Depending on whether the selection has GLOBALIDS, VALUES or INDICES, the selection will use the contents of the array named in the GLOBALIDS DataSetAttribute, and arbitrary array, or the position (tuple id or number) within the cell or point array.

To create an instance of class vtkExtractSelectedIds, simply invoke its constructor as follows

```
obj = vtkExtractSelectedIds
```

33.80.2 Methods

The class vtkExtractSelectedIds has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedIds class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedIds = obj.NewInstance ()`
- `vtkExtractSelectedIds = obj.SafeDownCast (vtkObject o)`

33.81 vtkExtractSelectedLocations

33.81.1 Usage

vtkExtractSelectedLocations extracts all cells whose volume contain at least one point listed in the LOCATIONS content of the vtkSelection. This filter adds a scalar array called vtkOriginalCellIds that says what input cell produced each output cell. This is an example of a Pedigree ID which helps to trace back results.

To create an instance of class vtkExtractSelectedLocations, simply invoke its constructor as follows

```
obj = vtkExtractSelectedLocations
```

33.81.2 Methods

The class vtkExtractSelectedLocations has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedLocations class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedLocations = obj.NewInstance ()`
- `vtkExtractSelectedLocations = obj.SafeDownCast (vtkObject o)`

33.82 vtkExtractSelectedPolyDataIds

33.82.1 Usage

vtkExtractSelectedPolyDataIds extracts all cells in vtkSelection from a vtkPolyData.

To create an instance of class vtkExtractSelectedPolyDataIds, simply invoke its constructor as follows

```
obj = vtkExtractSelectedPolyDataIds
```

33.82.2 Methods

The class vtkExtractSelectedPolyDataIds has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedPolyDataIds class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedPolyDataIds = obj.NewInstance ()`
- `vtkExtractSelectedPolyDataIds = obj.SafeDownCast (vtkObject o)`

33.83 vtkExtractSelectedRows

33.83.1 Usage

The first input is a vtkTable to extract rows from. The second input is a vtkSelection containing the selected indices. The third input is a vtkAnnotationLayers containing selected indices. The field type of the input selection is ignored when converted to row indices.

To create an instance of class vtkExtractSelectedRows, simply invoke its constructor as follows

```
obj = vtkExtractSelectedRows
```

33.83.2 Methods

The class vtkExtractSelectedRows has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedRows class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedRows = obj.NewInstance ()`
- `vtkExtractSelectedRows = obj.SafeDownCast (vtkObject o)`
- `obj.SetSelectionConnection (vtkAlgorithmOutput in)` - A convenience method for setting the second input (i.e. the selection).
- `obj.SetAnnotationLayersConnection (vtkAlgorithmOutput in)` - A convenience method for setting the third input (i.e. the annotation layers).
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Specify the first vtkGraph input and the second vtkSelection input.

- `obj.SetAddOriginalRowIdsArray (bool )` - When set, a column named vtkOriginalRowIds will be added to the output. False by default.
- `bool = obj.GetAddOriginalRowIdsArray ()` - When set, a column named vtkOriginalRowIds will be added to the output. False by default.
- `obj.AddOriginalRowIdsArrayOn ()` - When set, a column named vtkOriginalRowIds will be added to the output. False by default.
- `obj.AddOriginalRowIdsArrayOff ()` - When set, a column named vtkOriginalRowIds will be added to the output. False by default.

33.84 vtkExtractSelectedThresholds

33.84.1 Usage

vtkExtractSelectedThresholds extracts all cells and points with attribute values that lie within a vtkSelection's THRESHOLD contents. The selecion can specify to threshold a particular array within either the point or cell attribute data of the input. This is similar to vtkThreshold but allows mutliple thresholds ranges. This filter adds a scalar array called vtkOriginalCellIds that says what input cell produced each output cell. This is an example of a Pedigree ID which helps to trace back results.

To create an instance of class vtkExtractSelectedThresholds, simply invoke its constructor as follows

```
obj = vtkExtractSelectedThresholds
```

33.84.2 Methods

The class vtkExtractSelectedThresholds has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedThresholds class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedThresholds = obj.NewInstance ()`
- `vtkExtractSelectedThresholds = obj.SafeDownCast (vtkObject o)`

33.85 vtkExtractSelection

33.85.1 Usage

vtkExtractSelection extracts some subset of cells and points from its input dataset. The dataset is given on its first input port. The subset is described by the contents of the vtkSelection on its second input port. Depending on the content of the vtkSelection, this will use either a vtkExtractSelectedIds, vtkExtractSelectedFrustum vtkExtractSelectedLocations or a vtkExtractSelectedThreshold to perform the extraction.

To create an instance of class vtkExtractSelection, simply invoke its constructor as follows

```
obj = vtkExtractSelection
```

33.85.2 Methods

The class vtkExtractSelection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelection = obj.NewInstance ()`
- `vtkExtractSelection = obj.SafeDownCast (vtkObject o)`
- `obj.SetShowBounds (int )` - When On, this returns an unstructured grid that outlines selection area. Off is the default. Applicable only to Frustum selection extraction.
- `int = obj.GetShowBounds ()` - When On, this returns an unstructured grid that outlines selection area. Off is the default. Applicable only to Frustum selection extraction.
- `obj.ShowBoundsOn ()` - When On, this returns an unstructured grid that outlines selection area. Off is the default. Applicable only to Frustum selection extraction.
- `obj.ShowBoundsOff ()` - When On, this returns an unstructured grid that outlines selection area. Off is the default. Applicable only to Frustum selection extraction.
- `obj.SetUseProbeForLocations (int )` - When On, vtkProbeSelectedLocations is used for extracting selections of content type vtkSelection::LOCATIONS. Default is off and then vtkExtractSelectedLocations is used.
- `int = obj.GetUseProbeForLocations ()` - When On, vtkProbeSelectedLocations is used for extracting selections of content type vtkSelection::LOCATIONS. Default is off and then vtkExtractSelectedLocations is used.
- `obj.UseProbeForLocationsOn ()` - When On, vtkProbeSelectedLocations is used for extracting selections of content type vtkSelection::LOCATIONS. Default is off and then vtkExtractSelectedLocations is used.
- `obj.UseProbeForLocationsOff ()` - When On, vtkProbeSelectedLocations is used for extracting selections of content type vtkSelection::LOCATIONS. Default is off and then vtkExtractSelectedLocations is used.

33.86 vtkExtractSelectionBase

33.86.1 Usage

vtkExtractSelectionBase is an abstract base class for all extract selection filters. It defines some properties common to all extract selection filters.

To create an instance of class vtkExtractSelectionBase, simply invoke its constructor as follows

```
obj = vtkExtractSelectionBase
```

33.86.2 Methods

The class vtkExtractSelectionBase has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectionBase class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectionBase = obj.NewInstance ()`
- `vtkExtractSelectionBase = obj.SafeDownCast (vtkObject o)`
- `obj.SetSelectionConnection (vtkAlgorithmOutput algOutput)` - This flag tells the extraction filter not to convert the selected output into an unstructured grid, but instead to produce a vtkInsidedness array and add it to the input dataset. Default value is false(0).
- `obj.SetPreserveTopology (int )` - This flag tells the extraction filter not to convert the selected output into an unstructured grid, but instead to produce a vtkInsidedness array and add it to the input dataset. Default value is false(0).
- `int = obj.GetPreserveTopology ()` - This flag tells the extraction filter not to convert the selected output into an unstructured grid, but instead to produce a vtkInsidedness array and add it to the input dataset. Default value is false(0).
- `obj.PreserveTopologyOn ()` - This flag tells the extraction filter not to convert the selected output into an unstructured grid, but instead to produce a vtkInsidedness array and add it to the input dataset. Default value is false(0).
- `obj.PreserveTopologyOff ()` - This flag tells the extraction filter not to convert the selected output into an unstructured grid, but instead to produce a vtkInsidedness array and add it to the input dataset. Default value is false(0).

33.87 vtkExtractTemporalFieldData

33.87.1 Usage

vtkExtractTemporalFieldData extracts arrays from the input vtkFieldData. These arrays are assumed to contain temporal data, where the nth tuple contains the value for the nth timestep. The output is a 1D rectilinear grid where the XCoordinates correspond to time (the same array is also copied to a point array named Time or TimeData (if Time exists in the input). This algorithm does not produce a TIME_STEPS or TIME_RANGE information because it works across time. .Section Caveat vtkExtractTemporalFieldData puts a vtkOnePieceExtentTranslator in the output during RequestInformation(). As a result, the same whole extented is produced independent of the piece request. This algorithm works only with source that produce TIME_STEPS(). Continuous time range is not yet supported.

To create an instance of class vtkExtractTemporalFieldData, simply invoke its constructor as follows

```
obj = vtkExtractTemporalFieldData
```

33.87.2 Methods

The class vtkExtractTemporalFieldData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractTemporalFieldData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractTemporalFieldData = obj.NewInstance ()`
- `vtkExtractTemporalFieldData = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfTimeSteps ()` - Get the number of time steps

33.88 vtkExtractTensorComponents

33.88.1 Usage

vtkExtractTensorComponents is a filter that extracts components of a tensor to create a scalar, vector, normal, or texture coords. For example, if the tensor contains components of stress, then you could extract the normal stress in the x-direction as a scalar (i.e., tensor component (0,0).

To use this filter, you must set some boolean flags to control which data is extracted from the tensors, and whether you want to pass the tensor data through to the output. Also, you must specify the tensor component(s) for each type of data you want to extract. The tensor component(s) is(are) specified using matrix notation into a 3x3 matrix. That is, use the (row,column) address to specify a particular tensor component; and if the data you are extracting requires more than one component, use a list of addresses. (Note that the addresses are 0-offset -¿ (0,0) specifies upper left corner of the tensor.)

There are two optional methods to extract scalar data. You can extract the determinant of the tensor, or you can extract the effective stress of the tensor. These require that the ivar ExtractScalars is on, and the appropriate scalar extraction mode is set.

To create an instance of class vtkExtractTensorComponents, simply invoke its constructor as follows

```
obj = vtkExtractTensorComponents
```

33.88.2 Methods

The class vtkExtractTensorComponents has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractTensorComponents class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractTensorComponents = obj.NewInstance ()`
- `vtkExtractTensorComponents = obj.SafeDownCast (vtkObject o)`
- `obj.SetPassTensorsToOutput (int )` - Boolean controls whether tensor data is passed through to output.
- `int = obj.GetPassTensorsToOutput ()` - Boolean controls whether tensor data is passed through to output.
- `obj.PassTensorsToOutputOn ()` - Boolean controls whether tensor data is passed through to output.
- `obj.PassTensorsToOutputOff ()` - Boolean controls whether tensor data is passed through to output.
- `obj.SetExtractScalars (int )` - Boolean controls whether scalar data is extracted from tensor.
- `int = obj.GetExtractScalars ()` - Boolean controls whether scalar data is extracted from tensor.
- `obj.ExtractScalarsOn ()` - Boolean controls whether scalar data is extracted from tensor.

- `obj.ExtractScalarsOff ()` - Boolean controls whether scalar data is extracted from tensor.
- `obj.SetScalarComponents (int , int )` - Specify the (row,column) tensor component to extract as a scalar.
- `obj.SetScalarComponents (int a[2])` - Specify the (row,column) tensor component to extract as a scalar.
- `int = obj. GetScalarComponents ()` - Specify the (row,column) tensor component to extract as a scalar.
- `obj.SetScalarMode (int )` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `int = obj.GetScalarMode ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.SetScalarModeToComponent ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.SetScalarModeToEffectiveStress ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.SetScalarModeToDeterminant ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.ScalarIsComponent ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.ScalarIsEffectiveStress ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.ScalarIsDeterminant ()` - Specify how to extract the scalar. You can extract it as one of the components of the tensor, as effective stress, or as the determinant of the tensor. If you extract a component make sure that you set the ScalarComponents ivar.
- `obj.SetExtractVectors (int )` - Boolean controls whether vector data is extracted from tensor.
- `int = obj.GetExtractVectors ()` - Boolean controls whether vector data is extracted from tensor.
- `obj.ExtractVectorsOn ()` - Boolean controls whether vector data is extracted from tensor.
- `obj.ExtractVectorsOff ()` - Boolean controls whether vector data is extracted from tensor.
- `obj.SetVectorComponents (int , int , int , int , int , int )` - Specify the ((row,column)0,(row,column)1,(r tensor components to extract as a vector.
- `obj.SetVectorComponents (int a[6])` - Specify the ((row,column)0,(row,column)1,(row,column)2) tensor components to extract as a vector.
- `int = obj. GetVectorComponents ()` - Specify the ((row,column)0,(row,column)1,(row,column)2) tensor components to extract as a vector.
- `obj.SetExtractNormals (int )` - Boolean controls whether normal data is extracted from tensor.

- `int = obj.GetExtractNormals ()` - Boolean controls whether normal data is extracted from tensor.
- `obj.ExtractNormalsOn ()` - Boolean controls whether normal data is extracted from tensor.
- `obj.ExtractNormalsOff ()` - Boolean controls whether normal data is extracted from tensor.
- `obj.SetNormalizeNormals (int )` - Boolean controls whether normal vector is converted to unit normal after extraction.
- `int = obj.GetNormalizeNormals ()` - Boolean controls whether normal vector is converted to unit normal after extraction.
- `obj.NormalizeNormalsOn ()` - Boolean controls whether normal vector is converted to unit normal after extraction.
- `obj.NormalizeNormalsOff ()` - Boolean controls whether normal vector is converted to unit normal after extraction.
- `obj.SetNormalComponents (int , int , int , int , int , int )` - Specify the ((row,column)0,(row,column)1,(r tensor components to extract as a vector.
- `obj.SetNormalComponents (int a[6])` - Specify the ((row,column)0,(row,column)1,(row,column)2) tensor components to extract as a vector.
- `int = obj. GetNormalComponents ()` - Specify the ((row,column)0,(row,column)1,(row,column)2) tensor components to extract as a vector.
- `obj.SetExtractTCoords (int )` - Boolean controls whether texture coordinates are extracted from tensor.
- `int = obj.GetExtractTCoords ()` - Boolean controls whether texture coordinates are extracted from tensor.
- `obj.ExtractTCoordsOn ()` - Boolean controls whether texture coordinates are extracted from tensor.
- `obj.ExtractTCoordsOff ()` - Boolean controls whether texture coordinates are extracted from tensor.
- `obj.SetNumberOfTCoords (int )` - Set the dimension of the texture coordinates to extract.
- `int = obj.GetNumberOfTCoordsMinValue ()` - Set the dimension of the texture coordinates to extract.
- `int = obj.GetNumberOfTCoordsMaxValue ()` - Set the dimension of the texture coordinates to extract.
- `int = obj.GetNumberOfTCoords ()` - Set the dimension of the texture coordinates to extract.
- `obj.SetTCoordComponents (int , int , int , int , int , int )` - Specify the ((row,column)0,(row,column)1,(r tensor components to extract as a vector. Up to NumberOfTCoords components are extracted.
- `obj.SetTCoordComponents (int a[6])` - Specify the ((row,column)0,(row,column)1,(row,column)2) tensor components to extract as a vector. Up to NumberOfTCoords components are extracted.
- `int = obj. GetTCoordComponents ()` - Specify the ((row,column)0,(row,column)1,(row,column)2) tensor components to extract as a vector. Up to NumberOfTCoords components are extracted.

33.89 vtkExtractUnstructuredGrid

33.89.1 Usage

vtkExtractUnstructuredGrid is a general-purpose filter to extract geometry (and associated data) from an unstructured grid dataset. The extraction process is controlled by specifying a range of point ids, cell ids, or a bounding box (referred to as "Extent"). Those cells lying within these regions are sent to the output. The user has the choice of merging coincident points (Merging is on) or using the original point set (Merging is off).

To create an instance of class vtkExtractUnstructuredGrid, simply invoke its constructor as follows

```
obj = vtkExtractUnstructuredGrid
```

33.89.2 Methods

The class vtkExtractUnstructuredGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractUnstructuredGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractUnstructuredGrid = obj.NewInstance ()`
- `vtkExtractUnstructuredGrid = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointClipping (int )` - Turn on/off selection of geometry by point id.
- `int = obj.GetPointClipping ()` - Turn on/off selection of geometry by point id.
- `obj.PointClippingOn ()` - Turn on/off selection of geometry by point id.
- `obj.PointClippingOff ()` - Turn on/off selection of geometry by point id.
- `obj.SetCellClipping (int )` - Turn on/off selection of geometry by cell id.
- `int = obj.GetCellClipping ()` - Turn on/off selection of geometry by cell id.
- `obj.CellClippingOn ()` - Turn on/off selection of geometry by cell id.
- `obj.CellClippingOff ()` - Turn on/off selection of geometry by cell id.
- `obj.SetExtentClipping (int )` - Turn on/off selection of geometry via bounding box.
- `int = obj.GetExtentClipping ()` - Turn on/off selection of geometry via bounding box.
- `obj.ExtentClippingOn ()` - Turn on/off selection of geometry via bounding box.
- `obj.ExtentClippingOff ()` - Turn on/off selection of geometry via bounding box.
- `obj.SetPointMinimum (vtkIdType )` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimumMinValue ()` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimumMaxValue ()` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimum ()` - Specify the minimum point id for point id selection.
- `obj.SetPointMaximum (vtkIdType )` - Specify the maximum point id for point id selection.

- `vtkIdType = obj.GetPointMaximumMinValue ()` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximumMaxValue ()` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximum ()` - Specify the maximum point id for point id selection.
- `obj.SetCellMinimum (vtkIdType )` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimumMinValue ()` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimumMaxValue ()` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimum ()` - Specify the minimum cell id for point id selection.
- `obj.SetCellMaximum (vtkIdType )` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximumMinValue ()` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximumMaxValue ()` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximum ()` - Specify the maximum cell id for point id selection.
- `obj.SetExtent (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)` - Specify a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `obj.SetExtent (double extent[6])` - Set / get a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `double = obj.GetExtent ()` - Set / get a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `obj.SetMerging (int )` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `int = obj.GetMerging ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOn ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOff ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.
- `long = obj.GetMTime ()` - Return the MTime also considering the locator.

33.90 vtkExtractVectorComponents

33.90.1 Usage

vtkExtractVectorComponents is a filter that extracts vector components as separate scalars. This is accomplished by creating three different outputs. Each output is the same as the input, except that the scalar values will be one of the three components of the vector. These can be found in the VxComponent, VyComponent, and VzComponent. Alternatively, if the ExtractToFieldData flag is set, the filter will put all the components in the field data. The first component will be the scalar and the others will be non-attribute arrays.

To create an instance of class vtkExtractVectorComponents, simply invoke its constructor as follows

```
obj = vtkExtractVectorComponents
```

33.90.2 Methods

The class vtkExtractVectorComponents has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractVectorComponents class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractVectorComponents = obj.NewInstance ()`
- `vtkExtractVectorComponents = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Specify the input data or filter.
- `vtkDataSet = obj.GetVxComponent ()` - Get the output dataset representing velocity x-component. If output is NULL then input hasn't been set, which is necessary for abstract objects. (Note: this method returns the same information as the GetOutput() method with an index of 0.)
- `vtkDataSet = obj.GetVyComponent ()` - Get the output dataset representing velocity y-component. If output is NULL then input hasn't been set, which is necessary for abstract objects. (Note: this method returns the same information as the GetOutput() method with an index of 1.) Note that if ExtractToFieldData is true, this output will be empty.
- `vtkDataSet = obj.GetVzComponent ()` - Get the output dataset representing velocity z-component. If output is NULL then input hasn't been set, which is necessary for abstract objects. (Note: this method returns the same information as the GetOutput() method with an index of 2.) Note that if ExtractToFieldData is true, this output will be empty.
- `obj.SetExtractToFieldData (int )` - Determines whether the vector components will be put in separate outputs or in the first output's field data
- `int = obj.GetExtractToFieldData ()` - Determines whether the vector components will be put in separate outputs or in the first output's field data
- `obj.ExtractToFieldDataOn ()` - Determines whether the vector components will be put in separate outputs or in the first output's field data
- `obj.ExtractToFieldDataOff ()` - Determines whether the vector components will be put in separate outputs or in the first output's field data

33.91 vtkFeatureEdges

33.91.1 Usage

vtkFeatureEdges is a filter to extract special types of edges from input polygonal data. These edges are either 1) boundary (used by one polygon) or a line cell; 2) non-manifold (used by three or more polygons); 3) feature edges (edges used by two triangles and whose dihedral angle ¿ FeatureAngle); or 4) manifold edges (edges used by exactly two polygons). These edges may be extracted in any combination. Edges may also be "colored" (i.e., scalar values assigned) based on edge type. The cell coloring is assigned to the cell data of the extracted edges.

To create an instance of class vtkFeatureEdges, simply invoke its constructor as follows

```
obj = vtkFeatureEdges
```

33.91.2 Methods

The class vtkFeatureEdges has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFeatureEdges class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFeatureEdges = obj.NewInstance ()`
- `vtkFeatureEdges = obj.SafeDownCast (vtkObject o)`
- `obj.SetBoundaryEdges (int )` - Turn on/off the extraction of boundary edges.
- `int = obj.GetBoundaryEdges ()` - Turn on/off the extraction of boundary edges.
- `obj.BoundaryEdgesOn ()` - Turn on/off the extraction of boundary edges.
- `obj.BoundaryEdgesOff ()` - Turn on/off the extraction of boundary edges.
- `obj.SetFeatureEdges (int )` - Turn on/off the extraction of feature edges.
- `int = obj.GetFeatureEdges ()` - Turn on/off the extraction of feature edges.
- `obj.FeatureEdgesOn ()` - Turn on/off the extraction of feature edges.
- `obj.FeatureEdgesOff ()` - Turn on/off the extraction of feature edges.
- `obj.SetFeatureAngle (double )` - Specify the feature angle for extracting feature edges.
- `double = obj.GetFeatureAngleMinValue ()` - Specify the feature angle for extracting feature edges.
- `double = obj.GetFeatureAngleMaxValue ()` - Specify the feature angle for extracting feature edges.
- `double = obj.GetFeatureAngle ()` - Specify the feature angle for extracting feature edges.
- `obj.SetNonManifoldEdges (int )` - Turn on/off the extraction of non-manifold edges.
- `int = obj.GetNonManifoldEdges ()` - Turn on/off the extraction of non-manifold edges.
- `obj.NonManifoldEdgesOn ()` - Turn on/off the extraction of non-manifold edges.
- `obj.NonManifoldEdgesOff ()` - Turn on/off the extraction of non-manifold edges.
- `obj.SetManifoldEdges (int )` - Turn on/off the extraction of manifold edges.

- `int = obj.GetManifoldEdges ()` - Turn on/off the extraction of manifold edges.
- `obj.ManifoldEdgesOn ()` - Turn on/off the extraction of manifold edges.
- `obj.ManifoldEdgesOff ()` - Turn on/off the extraction of manifold edges.
- `obj.SetColoring (int )` - Turn on/off the coloring of edges by type.
- `int = obj.GetColoring ()` - Turn on/off the coloring of edges by type.
- `obj.ColoringOn ()` - Turn on/off the coloring of edges by type.
- `obj.ColoringOff ()` - Turn on/off the coloring of edges by type.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.
- `long = obj.GetMTime ()` - Return MTime also considering the locator.

33.92 vtkFieldDataToAttributeDataFilter

33.92.1 Usage

vtkFieldDataToAttributeDataFilter is a class that maps field data into dataset attributes. The input to this filter is any type of dataset and the output is the same dataset (geometry/topology) with new attribute data (attribute data is passed through if not replaced during filter execution).

To use this filter you must specify which field data from the input dataset to use. There are three possibilities: the cell field data, the point field data, or the field data associated with the data object superclass. Then you specify which attribute data to create: either cell attribute data or point attribute data. Finally, you must define how to construct the various attribute data types (e.g., scalars, vectors, normals, etc.) from the arrays and the components of the arrays from the field data. This is done by associating components in the input field with components making up the attribute data. For example, you would specify a scalar with three components (RGB) by assigning components from the field for the R, then G, then B values of the scalars. You may also have to specify component ranges (for each R-G-B) to make sure that the number of R, G, and B values is the same. Also, you may want to normalize the components which helps distribute the data uniformly.

This filter is often used in conjunction with vtkDataObjectToDataSetFilter. vtkDataObjectToDataSet-Filter filter generates dataset topology and geometry and passes its input field data along to its output. Then this filter is used to generate the attribute data to go along with the dataset.

To create an instance of class vtkFieldDataToAttributeDataFilter, simply invoke its constructor as follows

```
obj = vtkFieldDataToAttributeDataFilter
```

33.92.2 Methods

The class vtkFieldDataToAttributeDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFieldDataToAttributeDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkFieldDataToAttributeDataFilter = obj.NewInstance ()`
- `vtkFieldDataToAttributeDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInputField (int )` - Specify which field data to use to generate the output attribute data. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `int = obj.GetInputField ()` - Specify which field data to use to generate the output attribute data. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetInputFieldToDataObjectField ()` - Specify which field data to use to generate the output attribute data. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetInputFieldToPointDataField ()` - Specify which field data to use to generate the output attribute data. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetInputFieldToCellDataField ()` - Specify which field data to use to generate the output attribute data. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetOutputAttributeData (int )` - Specify which attribute data to output: point or cell data attributes.
- `int = obj.GetOutputAttributeData ()` - Specify which attribute data to output: point or cell data attributes.
- `obj.SetOutputAttributeDataToCellData ()` - Specify which attribute data to output: point or cell data attributes.
- `obj.SetOutputAttributeDataToPointData ()` - Specify which attribute data to output: point or cell data attributes.
- `obj.SetScalarComponent (int comp, string arrayName, int arrayComp, int min, int max, int normalize)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `obj.SetScalarComponent (int comp, string arrayName, int arrayComp)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `string = obj.GetScalarComponentArrayName (int comp)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetScalarComponentArrayComponent (int comp)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetScalarComponentMinRange (int comp)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `int = obj.GetScalarComponentMaxRange (int comp)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `int = obj.GetScalarComponentNormalizeFlag (int comp)` - Define the component(s) of the field to be used for the scalar components. Note that the parameter comp must lie between (0,4). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `obj.SetVectorComponent (int comp, string arrayName, int arrayComp, int min, int max, int normalize)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `obj.SetVectorComponent (int comp, string arrayName, int arrayComp)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `string = obj.GetVectorComponentArrayName (int comp)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `int = obj.GetVectorComponentArrayComponent (int comp)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `int = obj.GetVectorComponentMinRange (int comp)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `int = obj.GetVectorComponentMaxRange (int comp)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `int = obj.GetVectorComponentNormalizeFlag (int comp)` - Define the component(s) of the field to be used for the vector components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `obj.SetNormalComponent (int comp, string arrayName, int arrayComp, int min, int max, int normalize)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `obj.SetNormalComponent (int comp, string arrayName, int arrayComp)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `string = obj.GetNormalComponentArrayName (int comp)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetNormalComponentArrayComponent (int comp)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetNormalComponentMinRange (int comp)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetNormalComponentMaxRange (int comp)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetNormalComponentNormalizeFlag (int comp)` - Define the component(s) of the field to be used for the normal components. Note that the parameter comp must lie between (0,3). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `obj.SetTensorComponent (int comp, string arrayName, int arrayComp, int min, int max, int normalize)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `obj.SetTensorComponent (int comp, string arrayName, int arrayComp)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `string = obj.GetTensorComponentArrayName (int comp)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTensorComponentArrayComponent (int comp)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTensorComponentMinRange (int comp)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTensorComponentMaxRange (int comp)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTensorComponentNormalizeFlag (int comp)` - Define the components of the field to be used for the tensor components. Note that the parameter comp must lie between (0,9). To define

the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.

- `obj.SetTCoordComponent (int comp, string arrayName, int arrayComp, int min, int max, int normalize)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `obj.SetTCoordComponent (int comp, string arrayName, int arrayComp)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `string = obj.GetTCoordComponentArrayName (int comp)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTCoordComponentArrayComponent (int comp)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTCoordComponentMinRange (int comp)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTCoordComponentMaxRange (int comp)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `int = obj.GetTCoordComponentNormalizeFlag (int comp)` - Define the components of the field to be used for the cell texture coord components. Note that the parameter comp must lie between (0,9). To define the field component to use you specify an array name and the component in that array. The (min,max) values are the range of data in the component you wish to extract.
- `obj.SetDefaultNormalize (int )` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetScalarComponents).
- `int = obj.GetDefaultNormalize ()` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetScalarComponents).
- `obj.DefaultNormalizeOn ()` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetScalarComponents).
- `obj.DefaultNormalizeOff ()` - Set the default Normalize() flag for those methods setting a default Normalize value (e.g., SetScalarComponents).

33.93 vtkFillHolesFilter

33.93.1 Usage

vtkFillHolesFilter is a filter that identifies and fills holes in input vtkPolyData meshes. Holes are identified by locating boundary edges, linking them together into loops, and then triangulating the resulting loops. Note that you can specify an approximate limit to the size of the hole that can be filled.

To create an instance of class vtkFillHolesFilter, simply invoke its constructor as follows

```
obj = vtkFillHolesFilter
```

33.93.2 Methods

The class vtkFillHolesFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFillHolesFilter class.

- `string = obj.GetClassName ()` - Standard methods for instantiation, type information and printing.
- `int = obj.IsA (string name)` - Standard methods for instantiation, type information and printing.
- `vtkFillHolesFilter = obj.NewInstance ()` - Standard methods for instantiation, type information and printing.
- `vtkFillHolesFilter = obj.SafeDownCast (vtkObject o)` - Standard methods for instantiation, type information and printing.
- `obj.SetHoleSize (double )` - Specify the maximum hole size to fill. This is represented as a radius to the bounding circumsphere containing the hole. Note that this is an approximate area; the actual area cannot be computed without first triangulating the hole.
- `double = obj.GetHoleSizeMinValue ()` - Specify the maximum hole size to fill. This is represented as a radius to the bounding circumsphere containing the hole. Note that this is an approximate area; the actual area cannot be computed without first triangulating the hole.
- `double = obj.GetHoleSizeMaxValue ()` - Specify the maximum hole size to fill. This is represented as a radius to the bounding circumsphere containing the hole. Note that this is an approximate area; the actual area cannot be computed without first triangulating the hole.
- `double = obj.GetHoleSize ()` - Specify the maximum hole size to fill. This is represented as a radius to the bounding circumsphere containing the hole. Note that this is an approximate area; the actual area cannot be computed without first triangulating the hole.

33.94 vtkFrustumSource

33.94.1 Usage

vtkFrustumSource creates a frustum defines by a set of planes. The frustum is represented with four-sided polygons. It is possible to specify extra lines to better visualize the field of view.

.SECTION Usage Typical use consists of 3 steps: 1. get the planes coefficients from a vtkCamera with vtkCamera::GetFrustumPlanes() 2. initialize the planes with vtkPlanes::SetFrustumPlanes() with the planes coefficients 3. pass the vtkPlanes to a vtkFrustumSource.

To create an instance of class vtkFrustumSource, simply invoke its constructor as follows

```
obj = vtkFrustumSource
```

33.94.2 Methods

The class vtkFrustumSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFrustumSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkFrustumSource = obj.NewInstance ()`
- `vtkFrustumSource = obj.SafeDownCast (vtkObject o)`
- `vtkPlanes = obj.GetPlanes ()` - Return the 6 planes defining the frustum. Initial value is NULL. The 6 planes are defined in this order: left,right,bottom,top,far,near. If Planes==NULL or if Planes-¿GetNumberOfPlanes()!=6 when RequestData() is called, an error message will be emitted and RequestData() will return right away.
- `obj.SetPlanes (vtkPlanes planes)` - Set the 6 planes defining the frustum.
- `bool = obj.GetShowLines ()` - Tells if some extra lines will be generated. Initial value is true.
- `obj.SetShowLines (bool )` - Tells if some extra lines will be generated. Initial value is true.
- `obj.ShowLinesOn ()` - Tells if some extra lines will be generated. Initial value is true.
- `obj.ShowLinesOff ()` - Tells if some extra lines will be generated. Initial value is true.
- `double = obj.GetLinesLength ()` - Length of the extra lines. This a stricly positive value. Initial value is 1.0.
- `obj.SetLinesLength (double )` - Length of the extra lines. This a stricly positive value. Initial value is 1.0.
- `long = obj.GetMTime ()` - Modified GetMTime because of Planes.

33.95 vtkGeodesicPath

33.95.1 Usage

Serves as a base class for algorithms that trace a geodesic path on a polygonal dataset.

To create an instance of class vtkGeodesicPath, simply invoke its constructor as follows

```
obj = vtkGeodesicPath
```

33.95.2 Methods

The class vtkGeodesicPath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeodesicPath class.

- `string = obj.GetClassName ()` - Standard methids for printing and determining type information.
- `int = obj.IsA (string name)` - Standard methids for printing and determining type information.
- `vtkGeodesicPath = obj.NewInstance ()` - Standard methids for printing and determining type information.
- `vtkGeodesicPath = obj.SafeDownCast (vtkObject o)` - Standard methids for printing and determining type information.
- `double = obj.GetGeodesicLength ()`

33.96 vtkGeometryFilter

33.96.1 Usage

vtkGeometryFilter is a general-purpose filter to extract geometry (and associated data) from any type of dataset. Geometry is obtained as follows: all 0D, 1D, and 2D cells are extracted. All 2D faces that are used by only one 3D cell (i.e., boundary faces) are extracted. It also is possible to specify conditions on point ids, cell ids, and on bounding box (referred to as "Extent") to control the extraction process.

This filter also may be used to convert any type of data to polygonal type. The conversion process may be less than satisfactory for some 3D datasets. For example, this filter will extract the outer surface of a volume or structured grid dataset. (For structured data you may want to use vtkImageDataGeometryFilter, vtkStructuredGridGeometryFilter, vtkExtractUnstructuredGrid, vtkRectilinearGridGeometryFilter, or vtkExtractVOI.)

To create an instance of class vtkGeometryFilter, simply invoke its constructor as follows

```
obj = vtkGeometryFilter
```

33.96.2 Methods

The class vtkGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeometryFilter = obj.NewInstance ()`
- `vtkGeometryFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointClipping (int )` - Turn on/off selection of geometry by point id.
- `int = obj.GetPointClipping ()` - Turn on/off selection of geometry by point id.
- `obj.PointClippingOn ()` - Turn on/off selection of geometry by point id.
- `obj.PointClippingOff ()` - Turn on/off selection of geometry by point id.
- `obj.SetCellClipping (int )` - Turn on/off selection of geometry by cell id.
- `int = obj.GetCellClipping ()` - Turn on/off selection of geometry by cell id.
- `obj.CellClippingOn ()` - Turn on/off selection of geometry by cell id.
- `obj.CellClippingOff ()` - Turn on/off selection of geometry by cell id.
- `obj.SetExtentClipping (int )` - Turn on/off selection of geometry via bounding box.
- `int = obj.GetExtentClipping ()` - Turn on/off selection of geometry via bounding box.
- `obj.ExtentClippingOn ()` - Turn on/off selection of geometry via bounding box.
- `obj.ExtentClippingOff ()` - Turn on/off selection of geometry via bounding box.
- `obj.SetPointMinimum (vtkIdType )` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimumMinValue ()` - Specify the minimum point id for point id selection.

- `vtkIdType = obj.GetPointMinimumMaxValue ()` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimum ()` - Specify the minimum point id for point id selection.
- `obj.SetPointMaximum (vtkIdType )` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximumMinValue ()` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximumMaxValue ()` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximum ()` - Specify the maximum point id for point id selection.
- `obj.SetCellMinimum (vtkIdType )` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimumMinValue ()` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimumMaxValue ()` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimum ()` - Specify the minimum cell id for point id selection.
- `obj.SetCellMaximum (vtkIdType )` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximumMinValue ()` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximumMaxValue ()` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximum ()` - Specify the maximum cell id for point id selection.
- `obj.SetExtent (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)` - Specify a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `obj.SetExtent (double extent[6])` - Set / get a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `double = obj.GetExtent ()` - Set / get a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `obj.SetMerging (int )` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `int = obj.GetMerging ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOn ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOff ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.
- `long = obj.GetMTime ()` - Return the MTime also considering the locator.

33.97 vtkGlyph2D

33.97.1 Usage

This subclass of vtkGlyph3D is a specialization to 2D. Transformations (i.e., translation, scaling, and rotation) are constrained to the plane. For example, rotations due to a vector are computed from the x-y coordinates of the vector only, and are assumed to occur around the z-axis. (See vtkGlyph3D for documentation on the interface to this class.)

To create an instance of class vtkGlyph2D, simply invoke its constructor as follows

```
obj = vtkGlyph2D
```

33.97.2 Methods

The class vtkGlyph2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGlyph2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGlyph2D = obj.NewInstance ()`
- `vtkGlyph2D = obj.SafeDownCast (vtkObject o)`

33.98 vtkGlyph3D

33.98.1 Usage

vtkGlyph3D is a filter that copies a geometric representation (called a glyph) to every point in the input dataset. The glyph is defined with polygonal data from a source filter input. The glyph may be oriented along the input vectors or normals, and it may be scaled according to scalar data or vector magnitude. More than one glyph may be used by creating a table of source objects, each defining a different glyph. If a table of glyphs is defined, then the table can be indexed into by using either scalar value or vector magnitude.

To use this object you'll have to provide an input dataset and a source to define the glyph. Then decide whether you want to scale the glyph and how to scale the glyph (using scalar value or vector magnitude). Next decide whether you want to orient the glyph, and whether to use the vector data or normal data to orient it. Finally, decide whether to use a table of glyphs, or just a single glyph. If you use a table of glyphs, you'll have to decide whether to index into it with scalar value or with vector magnitude.

To create an instance of class vtkGlyph3D, simply invoke its constructor as follows

```
obj = vtkGlyph3D
```

33.98.2 Methods

The class vtkGlyph3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGlyph3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGlyph3D = obj.NewInstance ()`
- `vtkGlyph3D = obj.SafeDownCast (vtkObject o)`

- `obj.SetSource (vtkPolyData pd)` - Set the source to use for he glyph. Old style. See SetSourceConnection.
- `obj.SetSource (int id, vtkPolyData pd)` - Specify a source object at a specified table location. Old style. See SetSourceConnection.
- `obj.SetSourceConnection (int id, vtkAlgorithmOutput algOutput)` - Specify a source object at a specified table location. New style. Source connection is stored in port 1. This method is equivalent to SetInputConnection(1, id, outputPort).
- `obj.SetSourceConnection (vtkAlgorithmOutput algOutput)` - Get a pointer to a source object at a specified table location.
- `vtkPolyData = obj.GetSource (int id)` - Get a pointer to a source object at a specified table location.
- `obj.SetScaling (int )` - Turn on/off scaling of source geometry.
- `obj.ScalingOn ()` - Turn on/off scaling of source geometry.
- `obj.ScalingOff ()` - Turn on/off scaling of source geometry.
- `int = obj.GetScaling ()` - Turn on/off scaling of source geometry.
- `obj.SetScaleMode (int )` - Either scale by scalar or by vector/normal magnitude.
- `int = obj.GetScaleMode ()` - Either scale by scalar or by vector/normal magnitude.
- `obj.SetScaleModeToScaleByScalar ()` - Either scale by scalar or by vector/normal magnitude.
- `obj.SetScaleModeToScaleByVector ()` - Either scale by scalar or by vector/normal magnitude.
- `obj.SetScaleModeToScaleByVectorComponents ()` - Either scale by scalar or by vector/normal magnitude.
- `obj.SetScaleModeToDataScalingOff ()` - Either scale by scalar or by vector/normal magnitude.
- `string = obj.GetScaleModeAsString ()` - Either scale by scalar or by vector/normal magnitude.
- `obj.SetColorMode (int )` - Either color by scale, scalar or by vector/normal magnitude.
- `int = obj.GetColorMode ()` - Either color by scale, scalar or by vector/normal magnitude.
- `obj.SetColorModeToColorByScale ()` - Either color by scale, scalar or by vector/normal magnitude.
- `obj.SetColorModeToColorByScalar ()` - Either color by scale, scalar or by vector/normal magnitude.
- `obj.SetColorModeToColorByVector ()` - Either color by scale, scalar or by vector/normal magnitude.
- `string = obj.GetColorModeAsString ()` - Either color by scale, scalar or by vector/normal magnitude.
- `obj.SetScaleFactor (double )` - Specify scale factor to scale object by.
- `double = obj.GetScaleFactor ()` - Specify scale factor to scale object by.
- `obj.SetRange (double , double )` - Specify range to map scalar values into.
- `obj.SetRange (double  a[2])` - Specify range to map scalar values into.
- `double = obj. GetRange ()` - Specify range to map scalar values into.
- `obj.SetOrient (int )` - Turn on/off orienting of input geometry along vector/normal.

- `obj.OrientOn ()` - Turn on/off orienting of input geometry along vector/normal.
- `obj.OrientOff ()` - Turn on/off orienting of input geometry along vector/normal.
- `int = obj.GetOrient ()` - Turn on/off orienting of input geometry along vector/normal.
- `obj.SetClamping (int )` - Turn on/off clamping of "scalar" values to range. (Scalar value may be vector magnitude if ScaleByVector() is enabled.)
- `obj.ClampingOn ()` - Turn on/off clamping of "scalar" values to range. (Scalar value may be vector magnitude if ScaleByVector() is enabled.)
- `obj.ClampingOff ()` - Turn on/off clamping of "scalar" values to range. (Scalar value may be vector magnitude if ScaleByVector() is enabled.)
- `int = obj.GetClamping ()` - Turn on/off clamping of "scalar" values to range. (Scalar value may be vector magnitude if ScaleByVector() is enabled.)
- `obj.SetVectorMode (int )` - Specify whether to use vector or normal to perform vector operations.
- `int = obj.GetVectorMode ()` - Specify whether to use vector or normal to perform vector operations.
- `obj.SetVectorModeToUseVector ()` - Specify whether to use vector or normal to perform vector operations.
- `obj.SetVectorModeToUseNormal ()` - Specify whether to use vector or normal to perform vector operations.
- `obj.SetVectorModeToVectorRotationOff ()` - Specify whether to use vector or normal to perform vector operations.
- `string = obj.GetVectorModeAsString ()` - Specify whether to use vector or normal to perform vector operations.
- `obj.SetIndexMode (int )` - Index into table of sources by scalar, by vector/normal magnitude, or no indexing. If indexing is turned off, then the first source glyph in the table of glyphs is used. Note that indexing mode will only use the InputScalarsSelection array and not the InputColorScalarsSelection as the scalar source if an array is specified.
- `int = obj.GetIndexMode ()` - Index into table of sources by scalar, by vector/normal magnitude, or no indexing. If indexing is turned off, then the first source glyph in the table of glyphs is used. Note that indexing mode will only use the InputScalarsSelection array and not the InputColorScalarsSelection as the scalar source if an array is specified.
- `obj.SetIndexModeToScalar ()` - Index into table of sources by scalar, by vector/normal magnitude, or no indexing. If indexing is turned off, then the first source glyph in the table of glyphs is used. Note that indexing mode will only use the InputScalarsSelection array and not the InputColorScalarsSelection as the scalar source if an array is specified.
- `obj.SetIndexModeToVector ()` - Index into table of sources by scalar, by vector/normal magnitude, or no indexing. If indexing is turned off, then the first source glyph in the table of glyphs is used. Note that indexing mode will only use the InputScalarsSelection array and not the InputColorScalarsSelection as the scalar source if an array is specified.
- `obj.SetIndexModeToOff ()` - Index into table of sources by scalar, by vector/normal magnitude, or no indexing. If indexing is turned off, then the first source glyph in the table of glyphs is used. Note that indexing mode will only use the InputScalarsSelection array and not the InputColorScalarsSelection as the scalar source if an array is specified.

- `string = obj.GetIndexModeAsString ()` - Index into table of sources by scalar, by vector/normal magnitude, or no indexing. If indexing is turned off, then the first source glyph in the table of glyphs is used. Note that indexing mode will only use the InputScalarsSelection array and not the InputColorScalarsSelection as the scalar source if an array is specified.

- `obj.SetGeneratePointIds (int )` - Enable/disable the generation of point ids as part of the output. The point ids are the id of the input generating point. The point ids are stored in the output point field data and named "InputPointIds". Point generation is useful for debugging and pick operations.

- `int = obj.GetGeneratePointIds ()` - Enable/disable the generation of point ids as part of the output. The point ids are the id of the input generating point. The point ids are stored in the output point field data and named "InputPointIds". Point generation is useful for debugging and pick operations.

- `obj.GeneratePointIdsOn ()` - Enable/disable the generation of point ids as part of the output. The point ids are the id of the input generating point. The point ids are stored in the output point field data and named "InputPointIds". Point generation is useful for debugging and pick operations.

- `obj.GeneratePointIdsOff ()` - Enable/disable the generation of point ids as part of the output. The point ids are the id of the input generating point. The point ids are stored in the output point field data and named "InputPointIds". Point generation is useful for debugging and pick operations.

- `obj.SetPointIdsName (string )` - Set/Get the name of the PointIds array if generated. By default the Ids are named "InputPointIds", but this can be changed with this function.

- `string = obj.GetPointIdsName ()` - Set/Get the name of the PointIds array if generated. By default the Ids are named "InputPointIds", but this can be changed with this function.

- `obj.SetFillCellData (int )` - Enable/disable the generation of cell data as part of the output. The cell data at each cell will match the point data of the input at the glyphed point.

- `int = obj.GetFillCellData ()` - Enable/disable the generation of cell data as part of the output. The cell data at each cell will match the point data of the input at the glyphed point.

- `obj.FillCellDataOn ()` - Enable/disable the generation of cell data as part of the output. The cell data at each cell will match the point data of the input at the glyphed point.

- `obj.FillCellDataOff ()` - Enable/disable the generation of cell data as part of the output. The cell data at each cell will match the point data of the input at the glyphed point.

- `int = obj.IsPointVisible (vtkDataSet , vtkIdType )` - This can be overwritten by subclass to return 0 when a point is blanked. Default implementation is to always return 1;

33.99 vtkGlyphSource2D

33.99.1 Usage

vtkGlyphSource2D can generate a family of 2D glyphs each of which lies in the x-y plane (i.e., the z-coordinate is zero). The class is a helper class to be used with vtkGlyph2D and vtkXYPlotActor.

To use this class, specify the glyph type to use and its attributes. Attributes include its position (i.e., center point), scale, color, and whether the symbol is filled or not (a polygon or closed line sequence). You can also put a short line through the glyph running from -x to +x (the glyph looks like it's on a line), or a cross.

To create an instance of class vtkGlyphSource2D, simply invoke its constructor as follows

```
obj = vtkGlyphSource2D
```

33.99.2 Methods

The class vtkGlyphSource2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGlyphSource2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGlyphSource2D = obj.NewInstance ()`
- `vtkGlyphSource2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetCenter (double , double , double )` - Set the center of the glyph. By default the center is (0,0,0).
- `obj.SetCenter (double  a[3])` - Set the center of the glyph. By default the center is (0,0,0).
- `double = obj. GetCenter ()` - Set the center of the glyph. By default the center is (0,0,0).
- `obj.SetScale (double )` - Set the scale of the glyph. Note that the glyphs are designed to fit in the (1,1) rectangle.
- `double = obj.GetScaleMinValue ()` - Set the scale of the glyph. Note that the glyphs are designed to fit in the (1,1) rectangle.
- `double = obj.GetScaleMaxValue ()` - Set the scale of the glyph. Note that the glyphs are designed to fit in the (1,1) rectangle.
- `double = obj.GetScale ()` - Set the scale of the glyph. Note that the glyphs are designed to fit in the (1,1) rectangle.
- `obj.SetScale2 (double )` - Set the scale of optional portions of the glyph (e.g., the dash and cross is DashOn() and CrossOn()).
- `double = obj.GetScale2MinValue ()` - Set the scale of optional portions of the glyph (e.g., the dash and cross is DashOn() and CrossOn()).
- `double = obj.GetScale2MaxValue ()` - Set the scale of optional portions of the glyph (e.g., the dash and cross is DashOn() and CrossOn()).
- `double = obj.GetScale2 ()` - Set the scale of optional portions of the glyph (e.g., the dash and cross is DashOn() and CrossOn()).
- `obj.SetColor (double , double , double )` - Set the color of the glyph. The default color is white.
- `obj.SetColor (double  a[3])` - Set the color of the glyph. The default color is white.
- `double = obj. GetColor ()` - Set the color of the glyph. The default color is white.
- `obj.SetFilled (int )` - Specify whether the glyph is filled (a polygon) or not (a closed polygon defined by line segments). This only applies to 2D closed glyphs.
- `int = obj.GetFilled ()` - Specify whether the glyph is filled (a polygon) or not (a closed polygon defined by line segments). This only applies to 2D closed glyphs.
- `obj.FilledOn ()` - Specify whether the glyph is filled (a polygon) or not (a closed polygon defined by line segments). This only applies to 2D closed glyphs.
- `obj.FilledOff ()` - Specify whether the glyph is filled (a polygon) or not (a closed polygon defined by line segments). This only applies to 2D closed glyphs.

- `obj.SetDash (int )` - Specify whether a short line segment is drawn through the glyph. (This is in addition to the glyph. If the glyph type is set to "Dash" there is no need to enable this flag.)
- `int = obj.GetDash ()` - Specify whether a short line segment is drawn through the glyph. (This is in addition to the glyph. If the glyph type is set to "Dash" there is no need to enable this flag.)
- `obj.DashOn ()` - Specify whether a short line segment is drawn through the glyph. (This is in addition to the glyph. If the glyph type is set to "Dash" there is no need to enable this flag.)
- `obj.DashOff ()` - Specify whether a short line segment is drawn through the glyph. (This is in addition to the glyph. If the glyph type is set to "Dash" there is no need to enable this flag.)
- `obj.SetCross (int )` - Specify whether a cross is drawn as part of the glyph. (This is in addition to the glyph. If the glyph type is set to "Cross" there is no need to enable this flag.)
- `int = obj.GetCross ()` - Specify whether a cross is drawn as part of the glyph. (This is in addition to the glyph. If the glyph type is set to "Cross" there is no need to enable this flag.)
- `obj.CrossOn ()` - Specify whether a cross is drawn as part of the glyph. (This is in addition to the glyph. If the glyph type is set to "Cross" there is no need to enable this flag.)
- `obj.CrossOff ()` - Specify whether a cross is drawn as part of the glyph. (This is in addition to the glyph. If the glyph type is set to "Cross" there is no need to enable this flag.)
- `obj.SetRotationAngle (double )` - Specify an angle (in degrees) to rotate the glyph around the z-axis. Using this ivar, it is possible to generate rotated glyphs (e.g., crosses, arrows, etc.)
- `double = obj.GetRotationAngle ()` - Specify an angle (in degrees) to rotate the glyph around the z-axis. Using this ivar, it is possible to generate rotated glyphs (e.g., crosses, arrows, etc.)
- `obj.SetGlyphType (int )` - Specify the type of glyph to generate.
- `int = obj.GetGlyphTypeMinValue ()` - Specify the type of glyph to generate.
- `int = obj.GetGlyphTypeMaxValue ()` - Specify the type of glyph to generate.
- `int = obj.GetGlyphType ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToNone ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToVertex ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToDash ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToCross ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToThickCross ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToTriangle ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToSquare ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToCircle ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToDiamond ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToArrow ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToThickArrow ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToHookedArrow ()` - Specify the type of glyph to generate.
- `obj.SetGlyphTypeToEdgeArrow ()`

33.100 vtkGradientFilter

33.100.1 Usage

Estimates the gradient of a field in a data set. The gradient calculation is dependent on the input dataset type. The created gradient array is of the same type as the array it is calculated from (e.g. point data or cell data) as well as data type (e.g. float, double). At the boundary the gradient is not central differencing. The output array has 3*number of components of the input data array. The ordering for the output tuple will be du/dx, du/dy, du/dz, dv/dx, dv/dy, dv/dz, dw/dx, dw/dy, dw/dz for an input array u, v, w.

To create an instance of class vtkGradientFilter, simply invoke its constructor as follows

```
obj = vtkGradientFilter
```

33.100.2 Methods

The class vtkGradientFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGradientFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGradientFilter = obj.NewInstance ()`
- `vtkGradientFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInputScalars (int fieldAssociation, string name)` - These are basically a convenience method that calls SetInputArrayToProcess to set the array used as the input scalars. The fieldAssociation comes from the vtkDataObject::FieldAssocations enum. The fieldAttributeType comes from the vtkDataSetAttributes::AttributeTypes enum.
- `obj.SetInputScalars (int fieldAssociation, int fieldAttributeType)` - These are basically a convenience method that calls SetInputArrayToProcess to set the array used as the input scalars. The fieldAssociation comes from the vtkDataObject::FieldAssocations enum. The fieldAttributeType comes from the vtkDataSetAttributes::AttributeTypes enum.
- `string = obj.GetResultArrayName ()` - Get/Set the name of the resulting array to create. If NULL (the default) then the output array will be named "Gradients".
- `obj.SetResultArrayName (string )` - Get/Set the name of the resulting array to create. If NULL (the default) then the output array will be named "Gradients".
- `int = obj.GetFasterApproximation ()` - When this flag is on (default is off), the gradient filter will provide a less accurate (but close) algorithm that performs fewer derivative calculations (and is therefore faster). The error contains some smoothing of the output data and some possible errors on the boundary. This parameter has no effect when performing the gradient of cell data. This only applies if the input grid is a vtkUnstructuredGrid or a vtkPolyData.
- `obj.SetFasterApproximation (int )` - When this flag is on (default is off), the gradient filter will provide a less accurate (but close) algorithm that performs fewer derivative calculations (and is therefore faster). The error contains some smoothing of the output data and some possible errors on the boundary. This parameter has no effect when performing the gradient of cell data. This only applies if the input grid is a vtkUnstructuredGrid or a vtkPolyData.

- `obj.FasterApproximationOn ()` - When this flag is on (default is off), the gradient filter will provide a less accurate (but close) algorithm that performs fewer derivative calculations (and is therefore faster). The error contains some smoothing of the output data and some possible errors on the boundary. This parameter has no effect when performing the gradient of cell data. This only applies if the input grid is a vtkUnstructuredGrid or a vtkPolyData.
- `obj.FasterApproximationOff ()` - When this flag is on (default is off), the gradient filter will provide a less accurate (but close) algorithm that performs fewer derivative calculations (and is therefore faster). The error contains some smoothing of the output data and some possible errors on the boundary. This parameter has no effect when performing the gradient of cell data. This only applies if the input grid is a vtkUnstructuredGrid or a vtkPolyData.
- `obj.SetComputeVorticity (int )` - Set the resultant array to be vorticity/curl of the input array. The input array must have 3 components.
- `int = obj.GetComputeVorticity ()` - Set the resultant array to be vorticity/curl of the input array. The input array must have 3 components.
- `obj.ComputeVorticityOn ()` - Set the resultant array to be vorticity/curl of the input array. The input array must have 3 components.
- `obj.ComputeVorticityOff ()` - Set the resultant array to be vorticity/curl of the input array. The input array must have 3 components.

33.101 vtkGraphGeodesicPath

33.101.1 Usage

Serves as a base class for algorithms that trace a geodesic on a polygonal dataset treating it as a graph. ie points connecting the vertices of the graph

To create an instance of class vtkGraphGeodesicPath, simply invoke its constructor as follows

```
obj = vtkGraphGeodesicPath
```

33.101.2 Methods

The class vtkGraphGeodesicPath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphGeodesicPath class.

- `string = obj.GetClassName ()` - Standard methids for printing and determining type information.
- `int = obj.IsA (string name)` - Standard methids for printing and determining type information.
- `vtkGraphGeodesicPath = obj.NewInstance ()` - Standard methids for printing and determining type information.
- `vtkGraphGeodesicPath = obj.SafeDownCast (vtkObject o)` - Standard methids for printing and determining type information.
- `vtkIdType = obj.GetStartVertex ()` - The vertex at the start of the shortest path
- `obj.SetStartVertex (vtkIdType )` - The vertex at the start of the shortest path
- `vtkIdType = obj.GetEndVertex ()` - The vertex at the end of the shortest path
- `obj.SetEndVertex (vtkIdType )` - The vertex at the end of the shortest path

33.102 vtkGraphLayoutFilter

33.102.1 Usage

vtkGraphLayoutFilter will reposition a network of nodes, connected by lines or polylines, into a more pleasing arrangement. The class implements a simple force-directed placement algorithm (Fruchterman & Reingold "Graph Drawing by Force-directed Placement" Software-Practice and Experience 21(11) 1991).

The input to the filter is a vtkPolyData representing the undirected graphs. A graph is represented by a set of polylines and/or lines. The output is also a vtkPolyData, where the point positions have been modified. To use the filter, specify whether you wish the layout to occur in 2D or 3D; the bounds in which the graph should lie (note that you can just use automatic bounds computation); and modify the cool down rate (controls the final process of simulated annealing).

To create an instance of class vtkGraphLayoutFilter, simply invoke its constructor as follows

```
obj = vtkGraphLayoutFilter
```

33.102.2 Methods

The class vtkGraphLayoutFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphLayoutFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphLayoutFilter = obj.NewInstance ()`
- `vtkGraphLayoutFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraphBounds (double , double , double , double , double , double )` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `obj.SetGraphBounds (double a[6])` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `double = obj. GetGraphBounds ()` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `obj.SetAutomaticBoundsComputation (int )` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `int = obj.GetAutomaticBoundsComputation ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.AutomaticBoundsComputationOn ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.AutomaticBoundsComputationOff ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified.

- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified.
- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified.
- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified.
- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.
- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.
- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.
- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.
- `obj.SetThreeDimensionalLayout (int )`
- `int = obj.GetThreeDimensionalLayout ()`
- `obj.ThreeDimensionalLayoutOn ()`
- `obj.ThreeDimensionalLayoutOff ()`

33.103 vtkGraphToPoints

33.103.1 Usage

Converts a vtkGraph to a vtkPolyData containing a set of points. This assumes that the points of the graph have already been filled (perhaps by vtkGraphLayout). The vertex data is passed along to the point data.

To create an instance of class vtkGraphToPoints, simply invoke its constructor as follows

```
obj = vtkGraphToPoints
```

33.103.2 Methods

The class vtkGraphToPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphToPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphToPoints = obj.NewInstance ()`
- `vtkGraphToPoints = obj.SafeDownCast (vtkObject o)`

33.104 vtkGraphToPolyData

33.104.1 Usage

Converts a vtkGraph to a vtkPolyData. This assumes that the points of the graph have already been filled (perhaps by vtkGraphLayout), and coverts all the edge of the graph into lines in the polydata. The vertex data is passed along to the point data, and the edge data is passed along to the cell data.

Only the owned graph edges (i.e. edges with ghost level 0) are copied into the vtkPolyData.

To create an instance of class vtkGraphToPolyData, simply invoke its constructor as follows

```
obj = vtkGraphToPolyData
```

33.104.2 Methods

The class vtkGraphToPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphToPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphToPolyData = obj.NewInstance ()`
- `vtkGraphToPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetEdgeGlyphOutput (bool )` - Create a second output containing points and orientation vectors for drawing arrows or other glyphs on edges. This output should be set as the first input to vtkGlyph3D to place glyphs on the edges. vtkGlyphSource2D's VTK_EDGEARROW_GLYPH provides a good glyph for drawing arrows. Default value is off.
- `bool = obj.GetEdgeGlyphOutput ()` - Create a second output containing points and orientation vectors for drawing arrows or other glyphs on edges. This output should be set as the first input to vtkGlyph3D to place glyphs on the edges. vtkGlyphSource2D's VTK_EDGEARROW_GLYPH provides a good glyph for drawing arrows. Default value is off.
- `obj.EdgeGlyphOutputOn ()` - Create a second output containing points and orientation vectors for drawing arrows or other glyphs on edges. This output should be set as the first input to vtkGlyph3D to place glyphs on the edges. vtkGlyphSource2D's VTK_EDGEARROW_GLYPH provides a good glyph for drawing arrows. Default value is off.
- `obj.EdgeGlyphOutputOff ()` - Create a second output containing points and orientation vectors for drawing arrows or other glyphs on edges. This output should be set as the first input to vtkGlyph3D to place glyphs on the edges. vtkGlyphSource2D's VTK_EDGEARROW_GLYPH provides a good glyph for drawing arrows. Default value is off.
- `obj.SetEdgeGlyphPosition (double )` - The position of the glyph point along the edge. 0 puts a glyph point at the source of each edge. 1 puts a glyph point at the target of each edge. An intermediate value will place the glyph point between the source and target. The default value is 1.
- `double = obj.GetEdgeGlyphPosition ()` - The position of the glyph point along the edge. 0 puts a glyph point at the source of each edge. 1 puts a glyph point at the target of each edge. An intermediate value will place the glyph point between the source and target. The default value is 1.

33.105 vtkGridSynchronizedTemplates3D

33.105.1 Usage

vtkGridSynchronizedTemplates3D is a 3D implementation of the synchronized template algorithm.

To create an instance of class vtkGridSynchronizedTemplates3D, simply invoke its constructor as follows

```
obj = vtkGridSynchronizedTemplates3D
```

33.105.2 Methods

The class vtkGridSynchronizedTemplates3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGridSynchronizedTemplates3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGridSynchronizedTemplates3D = obj.NewInstance ()`
- `vtkGridSynchronizedTemplates3D = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Because we delegate to vtkContourValues
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.

- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Needed by templated functions.
- `int = obj.GetExecuteExtent ()` - Needed by templated functions.
- `obj.SetInputMemoryLimit (long limit)` - This filter will initiate streaming so that no piece requested from the input will be larger than this value (KiloBytes).

33.106 vtkHedgeHog

33.106.1 Usage

vtkHedgeHog creates oriented lines from the input data set. Line length is controlled by vector (or normal) magnitude times scale factor. If VectorMode is UseNormal, normals determine the orientation of the lines. Lines are colored by scalar data, if available.

To create an instance of class vtkHedgeHog, simply invoke its constructor as follows

```
obj = vtkHedgeHog
```

33.106.2 Methods

The class vtkHedgeHog has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHedgeHog class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHedgeHog = obj.NewInstance ()`
- `vtkHedgeHog = obj.SafeDownCast (vtkObject o)`
- `obj.SetScaleFactor (double )` - Set scale factor to control size of oriented lines.

- `double = obj.GetScaleFactor ()` - Set scale factor to control size of oriented lines.
- `obj.SetVectorMode (int )` - Specify whether to use vector or normal to perform vector operations.
- `int = obj.GetVectorMode ()` - Specify whether to use vector or normal to perform vector operations.
- `obj.SetVectorModeToUseVector ()` - Specify whether to use vector or normal to perform vector operations.
- `obj.SetVectorModeToUseNormal ()` - Specify whether to use vector or normal to perform vector operations.
- `string = obj.GetVectorModeAsString ()` - Specify whether to use vector or normal to perform vector operations.

33.107 vtkHierarchicalDataExtractDataSets

33.107.1 Usage

Legacy class. Use vtkExtractDataSets instead.

To create an instance of class vtkHierarchicalDataExtractDataSets, simply invoke its constructor as follows

```
obj = vtkHierarchicalDataExtractDataSets
```

33.107.2 Methods

The class vtkHierarchicalDataExtractDataSets has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalDataExtractDataSets class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalDataExtractDataSets = obj.NewInstance ()`
- `vtkHierarchicalDataExtractDataSets = obj.SafeDownCast (vtkObject o)`

33.108 vtkHierarchicalDataExtractLevel

33.108.1 Usage

Legacy class. Use vtkExtractLevel instead.

To create an instance of class vtkHierarchicalDataExtractLevel, simply invoke its constructor as follows

```
obj = vtkHierarchicalDataExtractLevel
```

33.108.2 Methods

The class vtkHierarchicalDataExtractLevel has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalDataExtractLevel class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkHierarchicalDataExtractLevel = obj.NewInstance ()`
- `vtkHierarchicalDataExtractLevel = obj.SafeDownCast (vtkObject o)`

33.109 vtkHierarchicalDataLevelFilter

33.109.1 Usage

Legacy class. Use vtkLevelIdScalars instead.

To create an instance of class vtkHierarchicalDataLevelFilter, simply invoke its constructor as follows

```
obj = vtkHierarchicalDataLevelFilter
```

33.109.2 Methods

The class vtkHierarchicalDataLevelFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalDataLevelFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalDataLevelFilter = obj.NewInstance ()`
- `vtkHierarchicalDataLevelFilter = obj.SafeDownCast (vtkObject o)`

33.110 vtkHierarchicalDataSetGeometryFilter

33.110.1 Usage

Legacy class. Use vtkCompositeDataGeometryFilter instead.

To create an instance of class vtkHierarchicalDataSetGeometryFilter, simply invoke its constructor as follows

```
obj = vtkHierarchicalDataSetGeometryFilter
```

33.110.2 Methods

The class vtkHierarchicalDataSetGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalDataSetGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalDataSetGeometryFilter = obj.NewInstance ()`
- `vtkHierarchicalDataSetGeometryFilter = obj.SafeDownCast (vtkObject o)`

33.111 vtkHull

33.111.1 Usage

vtkHull is a filter which will produce an n-sided convex hull given a set of n planes. (The convex hull bounds the input polygonal data.) The hull is generated by squeezing the planes towards the input vtkPolyData, until the planes just touch the vtkPolyData. Then, the resulting planes are used to generate a polyhedron (i.e., hull) that is represented by triangles.

The n planes can be defined in a number of ways including 1) manually specifying each plane; 2) choosing the six face planes of the input's bounding box; 3) choosing the eight vertex planes of the input's bounding box; 4) choosing the twelve edge planes of the input's bounding box; and/or 5) using a recursively subdivided octahedron. Note that when specifying planes, the plane normals should point outside of the convex region.

The output of this filter can be used in combination with vtkLODActor to represent a levels-of-detail in the LOD hierarchy. Another use of this class is to manually specify the planes, and then generate the polyhedron from the planes (without squeezing the planes towards the input). The method GenerateHull() is used to do this.

To create an instance of class vtkHull, simply invoke its constructor as follows

```
obj = vtkHull
```

33.111.2 Methods

The class vtkHull has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHull class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHull = obj.NewInstance ()`
- `vtkHull = obj.SafeDownCast (vtkObject o)`
- `obj.RemoveAllPlanes (void )` - Remove all planes from the current set of planes.
- `int = obj.AddPlane (double A, double B, double C)` - Add a plane to the current set of planes. It will be added at the end of the list, and an index that can later be used to set this plane's normal will be returned. The values A, B, C are from the plane equation Ax + By + Cz + D = 0. This vector does not have to have unit length (but it must have a non-zero length!). If a value 0 ¿ i ¿= -NumberOfPlanes is returned, then the plane is parallel with a previously inserted plane, and —-i-1— is the index of the plane that was previously inserted. If a value i ¡ -NumberOfPlanes is returned, then the plane normal is zero length.
- `int = obj.AddPlane (double plane[3])` - Add a plane to the current set of planes. It will be added at the end of the list, and an index that can later be used to set this plane's normal will be returned. The values A, B, C are from the plane equation Ax + By + Cz + D = 0. This vector does not have to have unit length (but it must have a non-zero length!). If a value 0 ¿ i ¿= -NumberOfPlanes is returned, then the plane is parallel with a previously inserted plane, and —-i-1— is the index of the plane that was previously inserted. If a value i ¡ -NumberOfPlanes is returned, then the plane normal is zero length.
- `obj.SetPlane (int i, double A, double B, double C)` - Set the normal values for plane i. This is a plane that was already added to the current set of planes with AddPlane(), and is now being modified. The values A, B, C are from the plane equation Ax + By + Cz + D = 0. This vector does not have to have unit length. Note that D is set to zero, except in the case of the method taking a vtkPlanes* argument, where it is set to the D value defined there.

- `obj.SetPlane (int i, double plane[3])` - Set the normal values for plane i. This is a plane that was already added to the current set of planes with AddPlane(), and is now being modified. The values A, B, C are from the plane equation Ax + By + Cz + D = 0. This vector does not have to have unit length. Note that D is set to zero, except in the case of the method taking a vtkPlanes* argument, where it is set to the D value defined there.

- `int = obj.AddPlane (double A, double B, double C, double D)` - Variations of AddPlane()/SetPlane() that allow D to be set. These methods are used when GenerateHull() is used.

- `int = obj.AddPlane (double plane[3], double D)` - Variations of AddPlane()/SetPlane() that allow D to be set. These methods are used when GenerateHull() is used.

- `obj.SetPlane (int i, double A, double B, double C, double D)` - Variations of AddPlane()/SetPlane() that allow D to be set. These methods are used when GenerateHull() is used.

- `obj.SetPlane (int i, double plane[3], double D)` - Variations of AddPlane()/SetPlane() that allow D to be set. These methods are used when GenerateHull() is used.

- `obj.SetPlanes (vtkPlanes planes)` - Set all the planes at once using a vtkPlanes implicit function. This also sets the D value, so it can be used with GenerateHull().

- `int = obj.GetNumberOfPlanes ()` - Get the number of planes in the current set of planes.

- `obj.AddCubeVertexPlanes ()` - Add the 8 planes that represent the vertices of a cube - the combination of the three face planes connecting to a vertex - (1,1,1), (1,1,-1), (1,-1,1), (1,-1,1), (-1,1,1), (-1,1,-1), (-1,-1,1), (-1,-1-1).

- `obj.AddCubeEdgePlanes ()` - Add the 12 planes that represent the edges of a cube - halfway between the two connecting face planes - (1,1,0), (-1,-1,0), (-1,1,0), (1,-1,0), (0,1,1), (0,-1,-1), (0,1,-1), (0,-1,1), (1,0,1), (-1,0,-1), (1,0,-1), (-1,0,1)

- `obj.AddCubeFacePlanes ()` - Add the six planes that make up the faces of a cube - (1,0,0), (-1, 0, 0), (0,1,0), (0,-1,0), (0,0,1), (0,0,-1)

- `obj.AddRecursiveSpherePlanes (int level)` - Add the planes that represent the normals of the vertices of a polygonal sphere formed by recursively subdividing the triangles in an octahedron. Each triangle is subdivided by connecting the midpoints of the edges thus forming 4 smaller triangles. The level indicates how many subdivisions to do with a level of 0 used to add the 6 planes from the original octahedron, level 1 will add 18 planes, and so on.

- `obj.GenerateHull (vtkPolyData pd, double bounds)` - A special method that is used to generate a polyhedron directly from a set of n planes. The planes that are supplied by the user are not squeezed towards the input data (in fact the user need not specify an input). To use this method, you must provide an instance of vtkPolyData into which the points and cells defining the polyhedron are placed. You must also provide a bounding box where you expect the resulting polyhedron to lie. This can be a very generous fit, it's only used to create the initial polygons that are eventually clipped.

- `obj.GenerateHull (vtkPolyData pd, double xmin, double xmax, double ymin, double ymax, double zmin,` - A special method that is used to generate a polyhedron directly from a set of n planes. The planes that are supplied by the user are not squeezed towards the input data (in fact the user need not specify an input). To use this method, you must provide an instance of vtkPolyData into which the points and cells defining the polyhedron are placed. You must also provide a bounding box where you expect the resulting polyhedron to lie. This can be a very generous fit, it's only used to create the initial polygons that are eventually clipped.

33.112 vtkHyperOctreeContourFilter

33.112.1 Usage

vtkContourFilter is a filter that takes as input any dataset and generates on output isosurfaces and/or isolines. The exact form of the output depends upon the dimensionality of the input data. Data consisting of 3D cells will generate isosurfaces, data consisting of 2D cells will generate isolines, and data with 1D or 0D cells will generate isopoints. Combinations of output type are possible if the input dimension is mixed.

To use this filter you must specify one or more contour values. You can either use the method SetValue() to specify each contour value, or use GenerateValues() to generate a series of evenly spaced contours. It is also possible to accelerate the operation of this filter (at the cost of extra memory) by using a vtkScalarTree. A scalar tree is used to quickly locate cells that contain a contour surface. This is especially effective if multiple contours are being extracted. If you want to use a scalar tree, invoke the method UseScalarTreeOn().

To create an instance of class vtkHyperOctreeContourFilter, simply invoke its constructor as follows

```
obj = vtkHyperOctreeContourFilter
```

33.112.2 Methods

The class vtkHyperOctreeContourFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeContourFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeContourFilter = obj.NewInstance ()`
- `vtkHyperOctreeContourFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Modified GetMTime Because we delegate to vtkContourValues
- `long = obj.GetMTime ()` - Modified GetMTime Because we delegate to vtkContourValues
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.113 vtkHyperOctreeCutter

33.113.1 Usage

vtkHyperOctreeCutter is a filter to cut through data using any subclass of vtkImplicitFunction. That is, a polygonal surface is created corresponding to the implicit function F(x,y,z) = value(s), where you can specify one or more values used to cut with.

In VTK, cutting means reducing a cell of dimension N to a cut surface of dimension N-1. For example, a tetrahedron when cut by a plane (i.e., vtkPlane implicit function) will generate triangles. (In comparison, clipping takes a N dimensional cell and creates N dimension primitives.)

vtkHyperOctreeCutter is generally used to "slice-through" a dataset, generating a surface that can be visualized. It is also possible to use vtkHyperOctreeCutter to do a form of volume rendering. vtkHyperOctreeCutter does this by generating multiple cut surfaces (usually planes) which are ordered (and rendered) from back-to-front. The surfaces are set translucent to give a volumetric rendering effect.

Note that data can be cut using either 1) the scalar values associated with the dataset or 2) an implicit function associated with this class. By default, if an implicit function is set it is used to cut the data set, otherwise the dataset scalars are used to perform the cut.

To create an instance of class vtkHyperOctreeCutter, simply invoke its constructor as follows

```
obj = vtkHyperOctreeCutter
```

33.113.2 Methods

The class vtkHyperOctreeCutter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeCutter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeCutter = obj.NewInstance ()`
- `vtkHyperOctreeCutter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Override GetMTime because we delegate to vtkContourValues and refer to vtkImplicitFunction.
- `long = obj.GetMTime ()` - Override GetMTime because we delegate to vtkContourValues and refer to vtkImplicitFunction.
- `obj.SetCutFunction (vtkImplicitFunction )`

- `vtkImplicitFunction = obj.GetCutFunction ()`
- `obj.SetGenerateCutScalars (int )` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `int = obj.GetGenerateCutScalars ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `obj.GenerateCutScalarsOn ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `obj.GenerateCutScalarsOff ()` - If this flag is enabled, then the output scalar values will be interpolated from the implicit function values, and not the input scalar data.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.SetSortBy (int )` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `int = obj.GetSortByMinValue ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `int = obj.GetSortByMaxValue ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `int = obj.GetSortBy ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

  Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.
- `obj.SetSortByToSortByValue ()` - Set the sorting order for the generated polydata. There are two possibilities: Sort by value = 0 - This is the most efficient sort. For each cell, all contour values are processed. This is the default. Sort by cell = 1 - For each contour value, all cells are processed. This order should be used if the extracted polygons must be rendered in a back-to-front or front-to-back order. This is very problem dependent. For most applications, the default order is fine (and faster).

Sort by cell is going to have a problem if the input has 2D and 3D cells. Cell data will be scrambled becauses with vtkPolyData output, verts and lines have lower cell ids than triangles.

- `obj.SetSortByToSortByCell ()` - Return the sorting procedure as a descriptive character string.
- `string = obj.GetSortByAsString ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.114 vtkHyperOctreeDepth

33.114.1 Usage

This filter returns a shallow copy of its input HyperOctree with a new data attribute field containing the depth of each cell.

To create an instance of class vtkHyperOctreeDepth, simply invoke its constructor as follows

```
obj = vtkHyperOctreeDepth
```

33.114.2 Methods

The class vtkHyperOctreeDepth has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeDepth class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeDepth = obj.NewInstance ()`
- `vtkHyperOctreeDepth = obj.SafeDownCast (vtkObject o)`

33.115 vtkHyperOctreeDualGridContourFilter

33.115.1 Usage

use of unsigned short to hold level index limits tree depth to 16.

To use this filter you must specify one or more contour values. You can either use the method SetValue() to specify each contour value, or use GenerateValues() to generate a series of evenly spaced contours. It is also possible to accelerate the operation of this filter (at the cost of extra memory) by using a vtkScalarTree. A scalar tree is used to quickly locate cells that contain a contour surface. This is especially effective if multiple contours are being extracted. If you want to use a scalar tree, invoke the method UseScalarTreeOn().

To create an instance of class vtkHyperOctreeDualGridContourFilter, simply invoke its constructor as follows

```
obj = vtkHyperOctreeDualGridContourFilter
```

33.115.2 Methods

The class vtkHyperOctreeDualGridContourFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeDualGridContourFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeDualGridContourFilter = obj.NewInstance ()`
- `vtkHyperOctreeDualGridContourFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Modified GetMTime Because we delegate to vtkContourValues
- `long = obj.GetMTime ()` - Modified GetMTime Because we delegate to vtkContourValues
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.116 vtkHyperOctreeFractalSource

33.116.1 Usage

To create an instance of class vtkHyperOctreeFractalSource, simply invoke its constructor as follows

```
obj = vtkHyperOctreeFractalSource
```

33.116.2 Methods

The class vtkHyperOctreeFractalSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeFractalSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeFractalSource = obj.NewInstance ()`
- `vtkHyperOctreeFractalSource = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetMaximumLevel ()` - Return the maximum number of levels of the hyperoctree.
- `obj.SetMaximumLevel (int levels)` - Set the maximum number of levels of the hyperoctree. If GetMinLevels()¿=levels, GetMinLevels() is changed to levels-1.
- `obj.SetMinimumLevel (int level)` - Return the minimal number of levels of systematic subdivision.
- `int = obj.GetMinimumLevel ()` - Return the minimal number of levels of systematic subdivision.
- `obj.SetProjectionAxes (int x, int y, int z)` - Set the projection from the 4D space (4 parameters / 2 imaginary numbers) to the axes of the 3D Volume. 0=C_Real, 1=C_Imaginary, 2=X_Real, 4=X_Imaginary
- `obj.SetProjectionAxes (int a[3])` - Set the projection from the 4D space (4 parameters / 2 imaginary numbers) to the axes of the 3D Volume. 0=C_Real, 1=C_Imaginary, 2=X_Real, 4=X_Imaginary
- `int = obj. GetProjectionAxes ()` - Set the projection from the 4D space (4 parameters / 2 imaginary numbers) to the axes of the 3D Volume. 0=C_Real, 1=C_Imaginary, 2=X_Real, 4=X_Imaginary
- `obj.SetOriginCX (double , double , double , double )` - Imaginary and real value for C (constant in equation) and X (initial value).
- `obj.SetOriginCX (double a[4])` - Imaginary and real value for C (constant in equation) and X (initial value).
- `double = obj. GetOriginCX ()` - Imaginary and real value for C (constant in equation) and X (initial value).
- `obj.SetSizeCX (double , double , double , double )` - Just a different way of setting the sample. This sets the size of the 4D volume. SampleCX is computed from size and extent. Size is ignored when a dimension i 0 (collapsed).
- `obj.SetSizeCX (double a[4])` - Just a different way of setting the sample. This sets the size of the 4D volume. SampleCX is computed from size and extent. Size is ignored when a dimension i 0 (collapsed).
- `double = obj. GetSizeCX ()` - Just a different way of setting the sample. This sets the size of the 4D volume. SampleCX is computed from size and extent. Size is ignored when a dimension i 0 (collapsed).
- `obj.SetMaximumNumberOfIterations (short )` - The maximum number of cycles run to see if the value goes over 2
- `GetMaximumNumberOfIterationsMinValue = obj.()` - The maximum number of cycles run to see if the value goes over 2
- `GetMaximumNumberOfIterationsMaxValue = obj.()` - The maximum number of cycles run to see if the value goes over 2

- `char = obj.GetMaximumNumberOfIterations ()` - The maximum number of cycles run to see if the value goes over 2
- `obj.SetDimension (int )` - Create a 2D or 3D fractal.
- `int = obj.GetDimensionMinValue ()` - Create a 2D or 3D fractal.
- `int = obj.GetDimensionMaxValue ()` - Create a 2D or 3D fractal.
- `int = obj.GetDimension ()` - Create a 2D or 3D fractal.
- `obj.SetSpanThreshold (double )` - Controls when a leaf gets subdivided. If the corner values span a larger range than this value, the leaf is subdivided. This defaults to 2.
- `double = obj.GetSpanThreshold ()` - Controls when a leaf gets subdivided. If the corner values span a larger range than this value, the leaf is subdivided. This defaults to 2.

33.117 vtkHyperOctreeLimiter

33.117.1 Usage

This filter returns a lower resolution copy of its input vtkHyperOctree. It does a length/area/volume weighted averaging to obtain data at each cut point. Above the cut level, leaf attribute data is simply copied.

To create an instance of class vtkHyperOctreeLimiter, simply invoke its constructor as follows

```
obj = vtkHyperOctreeLimiter
```

33.117.2 Methods

The class vtkHyperOctreeLimiter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeLimiter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeLimiter = obj.NewInstance ()`
- `vtkHyperOctreeLimiter = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetMaximumLevel ()` - Return the maximum number of levels of the hyperoctree.
- `obj.SetMaximumLevel (int levels)` - Set the maximum number of levels of the hyperoctree.

33.118 vtkHyperOctreeSampleFunction

33.118.1 Usage

vtkHyperOctreeSampleFunction is a source object that evaluates an implicit function to drive the subdivision process. The user can specify the threshold over which a subdivision occurs, the maximum and minimum level of subdivisions and the dimension of the hyperoctree.

To create an instance of class vtkHyperOctreeSampleFunction, simply invoke its constructor as follows

```
obj = vtkHyperOctreeSampleFunction
```

33.118.2 Methods

The class vtkHyperOctreeSampleFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeSampleFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeSampleFunction = obj.NewInstance ()`
- `vtkHyperOctreeSampleFunction = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetLevels ()` - Return the maximum number of levels of the hyperoctree.
- `obj.SetLevels (int levels)` - Set the maximum number of levels of the hyperoctree. If GetMinLevels()¿=levels, GetMinLevels() is changed to levels-1.
- `int = obj.GetMinLevels ()` - Return the minimal number of levels of systematic subdivision.
- `obj.SetMinLevels (int minLevels)` - Set the minimal number of levels of systematic subdivision.
- `double = obj.GetThreshold ()` - Return the threshold over which a subdivision is required.
- `obj.SetThreshold (double threshold)` - Set the threshold over which a subdivision is required.
- `int = obj.GetDimension ()` - Return the dimension of the tree (1D:binary tree(2 children), 2D:quadtree(4 children), 3D:octree (8 children))
- `obj.SetDimension (int dim)`
- `obj.SetSize (double , double , double )` - Set the size on each axis.
- `obj.SetSize (double  a[3])` - Set the size on each axis.
- `double = obj. GetSize ()` - Return the size on each axis.
- `obj.SetOrigin (double , double , double )` - Set the origin (position of corner (0,0,0) of the root.
- `obj.SetOrigin (double  a[3])` - Set the origin (position of corner (0,0,0) of the root.
- `double = obj. GetOrigin ()` - Set the origin (position of corner (0,0,0) of the root. Return the origin (position of corner (0,0,0)) of the root.
- `double = obj.GetWidth ()` - Return the length along the x-axis.
- `obj.SetWidth (double width)` - Set the length along the x-axis.
- `double = obj.GetHeight ()` - Return the length along the y-axis. Relevant only if GetDimension()¿=2
- `obj.SetHeight (double height)` - Set the length along the y-axis. Relevant only if GetDimension()¿=2
- `double = obj.GetDepth ()` - Return the length along the z-axis. Relevant only if GetDimension()¿=3
- `obj.SetDepth (double depth)` - Return the length along the z-axis. Relevant only if GetDimension()¿=3
- `obj.SetImplicitFunction (vtkImplicitFunction )` - Specify the implicit function to use to generate data.

- `vtkImplicitFunction = obj.GetImplicitFunction ()` - Specify the implicit function to use to generate data.
- `obj.SetOutputScalarType (int )` - Set what type of scalar data this source should generate.
- `int = obj.GetOutputScalarType ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToDouble ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToFloat ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToLong ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToInt ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToShort ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToChar ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedChar ()` - Return the MTime also considering the implicit function.
- `long = obj.GetMTime ()` - Return the MTime also considering the implicit function.

33.119 vtkHyperOctreeSurfaceFilter

33.119.1 Usage

vtkHyperOctreeSurfaceFilter extracts the surface of an hyperoctree.

To create an instance of class vtkHyperOctreeSurfaceFilter, simply invoke its constructor as follows

```
obj = vtkHyperOctreeSurfaceFilter
```

33.119.2 Methods

The class vtkHyperOctreeSurfaceFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeSurfaceFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeSurfaceFilter = obj.NewInstance ()`
- `vtkHyperOctreeSurfaceFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetMerging (int )` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.

- `int = obj.GetMerging ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOn ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOff ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `long = obj.GetMTime ()` - Return the MTime also considering the locator.
- `obj.SetPassThroughCellIds (int )` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory.
- `int = obj.GetPassThroughCellIds ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory.
- `obj.PassThroughCellIdsOn ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory.
- `obj.PassThroughCellIdsOff ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for cell picking. The default is off to conserve memory.

33.120 vtkHyperOctreeToUniformGridFilter

33.120.1 Usage

vtkHyperOctreeToUniformGridFilter creates a uniform grid with a resolution based on the number of levels of the hyperoctree. Then, it copies celldata in each cell of the uniform grid that belongs to an actual leaf of the hyperoctree.

To create an instance of class vtkHyperOctreeToUniformGridFilter, simply invoke its constructor as follows

```
obj = vtkHyperOctreeToUniformGridFilter
```

33.120.2 Methods

The class vtkHyperOctreeToUniformGridFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeToUniformGridFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeToUniformGridFilter = obj.NewInstance ()`
- `vtkHyperOctreeToUniformGridFilter = obj.SafeDownCast (vtkObject o)`

33.121 vtkHyperStreamline

33.121.1 Usage

vtkHyperStreamline is a filter that integrates through a tensor field to generate a hyperstreamline. The integration is along the maximum eigenvector and the cross section of the hyperstreamline is defined by the two other eigenvectors. Thus the shape of the hyperstreamline is "tube-like", with the cross section being elliptical. Hyperstreamlines are used to visualize tensor fields.

The starting point of a hyperstreamline can be defined in one of two ways. First, you may specify an initial position. This is a x-y-z global coordinate. The second option is to specify a starting location. This is cellId, subId, and cell parametric coordinates.

The integration of the hyperstreamline occurs through the major eigenvector field. IntegrationStepLength controls the step length within each cell (i.e., this is the fraction of the cell length). The length of the hyperstreamline is controlled by MaximumPropagationDistance. This parameter is the length of the hyperstreamline in units of distance. The tube itself is composed of many small sub-tubes - NumberOfSides controls the number of sides in the tube, and StepLength controls the length of the sub-tubes.

Because hyperstreamlines are often created near regions of singularities, it is possible to control the scaling of the tube cross section by using a logarithmic scale. Use LogScalingOn to turn this capability on. The Radius value controls the initial radius of the tube.

To create an instance of class vtkHyperStreamline, simply invoke its constructor as follows

```
obj = vtkHyperStreamline
```

33.121.2 Methods

The class vtkHyperStreamline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperStreamline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperStreamline = obj.NewInstance ()`
- `vtkHyperStreamline = obj.SafeDownCast (vtkObject o)`
- `obj.SetStartLocation (vtkIdType cellId, int subId, double pcoords[3])` - Specify the start of the hyperstreamline in the cell coordinate system. That is, cellId and subId (if composite cell), and parametric coordinates.
- `obj.SetStartLocation (vtkIdType cellId, int subId, double r, double s, double t)` - Specify the start of the hyperstreamline in the cell coordinate system. That is, cellId and subId (if composite cell), and parametric coordinates.
- `obj.SetStartPosition (double x[3])` - Specify the start of the hyperstreamline in the global coordinate system. Starting from position implies that a search must be performed to find initial cell to start integration from.
- `obj.SetStartPosition (double x, double y, double z)` - Specify the start of the hyperstreamline in the global coordinate system. Starting from position implies that a search must be performed to find initial cell to start integration from.
- `double = obj.GetStartPosition ()` - Get the start position of the hyperstreamline in global x-y-z coordinates.
- `obj.SetMaximumPropagationDistance (double )` - Set / get the maximum length of the hyperstreamline expressed as absolute distance (i.e., arc length) value.

- `double = obj.GetMaximumPropagationDistanceMinValue ()` - Set / get the maximum length of the hyperstreamline expressed as absolute distance (i.e., arc length) value.
- `double = obj.GetMaximumPropagationDistanceMaxValue ()` - Set / get the maximum length of the hyperstreamline expressed as absolute distance (i.e., arc length) value.
- `double = obj.GetMaximumPropagationDistance ()` - Set / get the maximum length of the hyperstreamline expressed as absolute distance (i.e., arc length) value.
- `obj.SetIntegrationEigenvector (int )` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `int = obj.GetIntegrationEigenvectorMinValue ()` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `int = obj.GetIntegrationEigenvectorMaxValue ()` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `int = obj.GetIntegrationEigenvector ()` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `obj.SetIntegrationEigenvectorToMajor ()` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `obj.SetIntegrationEigenvectorToMedium ()` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `obj.SetIntegrationEigenvectorToMinor ()` - Set / get the eigenvector field through which to ingrate. It is possible to integrate using the major, medium or minor eigenvector field. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `obj.IntegrateMajorEigenvector ()` - Use the major eigenvector field as the vector field through which to integrate. The major eigenvector is the eigenvector whose corresponding eigenvalue is closest to positive infinity.

- `obj.IntegrateMediumEigenvector ()` - Use the medium eigenvector field as the vector field through which to integrate. The medium eigenvector is the eigenvector whose corresponding eigenvalue is between the major and minor eigenvalues.
- `obj.IntegrateMinorEigenvector ()` - Use the minor eigenvector field as the vector field through which to integrate. The minor eigenvector is the eigenvector whose corresponding eigenvalue is closest to negative infinity.
- `obj.SetIntegrationStepLength (double )` - Set / get a nominal integration step size (expressed as a fraction of the size of each cell).
- `double = obj.GetIntegrationStepLengthMinValue ()` - Set / get a nominal integration step size (expressed as a fraction of the size of each cell).
- `double = obj.GetIntegrationStepLengthMaxValue ()` - Set / get a nominal integration step size (expressed as a fraction of the size of each cell).
- `double = obj.GetIntegrationStepLength ()` - Set / get a nominal integration step size (expressed as a fraction of the size of each cell).
- `obj.SetStepLength (double )` - Set / get the length of a tube segment composing the hyperstreamline. The length is specified as a fraction of the diagonal length of the input bounding box.
- `double = obj.GetStepLengthMinValue ()` - Set / get the length of a tube segment composing the hyperstreamline. The length is specified as a fraction of the diagonal length of the input bounding box.
- `double = obj.GetStepLengthMaxValue ()` - Set / get the length of a tube segment composing the hyperstreamline. The length is specified as a fraction of the diagonal length of the input bounding box.
- `double = obj.GetStepLength ()` - Set / get the length of a tube segment composing the hyperstreamline. The length is specified as a fraction of the diagonal length of the input bounding box.
- `obj.SetIntegrationDirection (int )` - Specify the direction in which to integrate the hyperstreamline.
- `int = obj.GetIntegrationDirectionMinValue ()` - Specify the direction in which to integrate the hyperstreamline.
- `int = obj.GetIntegrationDirectionMaxValue ()` - Specify the direction in which to integrate the hyperstreamline.
- `int = obj.GetIntegrationDirection ()` - Specify the direction in which to integrate the hyperstreamline.
- `obj.SetIntegrationDirectionToForward ()` - Specify the direction in which to integrate the hyperstreamline.
- `obj.SetIntegrationDirectionToBackward ()` - Specify the direction in which to integrate the hyperstreamline.
- `obj.SetIntegrationDirectionToIntegrateBothDirections ()` - Specify the direction in which to integrate the hyperstreamline.
- `obj.SetTerminalEigenvalue (double )` - Set/get terminal eigenvalue. If major eigenvalue falls below this value, hyperstreamline terminates propagation.
- `double = obj.GetTerminalEigenvalueMinValue ()` - Set/get terminal eigenvalue. If major eigenvalue falls below this value, hyperstreamline terminates propagation.

- `double = obj.GetTerminalEigenvalueMaxValue ()` - Set/get terminal eigenvalue. If major eigenvalue falls below this value, hyperstreamline terminates propagation.
- `double = obj.GetTerminalEigenvalue ()` - Set/get terminal eigenvalue. If major eigenvalue falls below this value, hyperstreamline terminates propagation.
- `obj.SetNumberOfSides (int )` - Set / get the number of sides for the hyperstreamlines. At a minimum, number of sides is 3.
- `int = obj.GetNumberOfSidesMinValue ()` - Set / get the number of sides for the hyperstreamlines. At a minimum, number of sides is 3.
- `int = obj.GetNumberOfSidesMaxValue ()` - Set / get the number of sides for the hyperstreamlines. At a minimum, number of sides is 3.
- `int = obj.GetNumberOfSides ()` - Set / get the number of sides for the hyperstreamlines. At a minimum, number of sides is 3.
- `obj.SetRadius (double )` - Set / get the initial tube radius. This is the maximum "elliptical" radius at the beginning of the tube. Radius varies based on ratio of eigenvalues. Note that tube section is actually elliptical and may become a point or line in cross section in some cases.
- `double = obj.GetRadiusMinValue ()` - Set / get the initial tube radius. This is the maximum "elliptical" radius at the beginning of the tube. Radius varies based on ratio of eigenvalues. Note that tube section is actually elliptical and may become a point or line in cross section in some cases.
- `double = obj.GetRadiusMaxValue ()` - Set / get the initial tube radius. This is the maximum "elliptical" radius at the beginning of the tube. Radius varies based on ratio of eigenvalues. Note that tube section is actually elliptical and may become a point or line in cross section in some cases.
- `double = obj.GetRadius ()` - Set / get the initial tube radius. This is the maximum "elliptical" radius at the beginning of the tube. Radius varies based on ratio of eigenvalues. Note that tube section is actually elliptical and may become a point or line in cross section in some cases.
- `obj.SetLogScaling (int )` - Turn on/off logarithmic scaling. If scaling is on, the log base 10 of the computed eigenvalues are used to scale the cross section radii.
- `int = obj.GetLogScaling ()` - Turn on/off logarithmic scaling. If scaling is on, the log base 10 of the computed eigenvalues are used to scale the cross section radii.
- `obj.LogScalingOn ()` - Turn on/off logarithmic scaling. If scaling is on, the log base 10 of the computed eigenvalues are used to scale the cross section radii.
- `obj.LogScalingOff ()` - Turn on/off logarithmic scaling. If scaling is on, the log base 10 of the computed eigenvalues are used to scale the cross section radii.

33.122 vtkIconGlyphFilter

33.122.1 Usage

vtkIconGlyphFilter takes in a vtkPointSet where each point corresponds to the center of an icon. Scalar integer data must also be set to give each point an icon index. This index is a zero based row major index into an image that contains a grid of icons. You must also set pixel Size of the icon image and the size of a particular icon.

To create an instance of class vtkIconGlyphFilter, simply invoke its constructor as follows

```
obj = vtkIconGlyphFilter
```

33.122.2 Methods

The class vtkIconGlyphFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIconGlyphFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIconGlyphFilter = obj.NewInstance ()`
- `vtkIconGlyphFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetIconSize (int , int )` - Specify the Width and Height, in pixels, of an icon in the icon sheet
- `obj.SetIconSize (int  a[2])` - Specify the Width and Height, in pixels, of an icon in the icon sheet
- `int = obj. GetIconSize ()` - Specify the Width and Height, in pixels, of an icon in the icon sheet
- `obj.SetIconSheetSize (int , int )` - Specify the Width and Height, in pixels, of an icon in the icon sheet
- `obj.SetIconSheetSize (int  a[2])` - Specify the Width and Height, in pixels, of an icon in the icon sheet
- `int = obj. GetIconSheetSize ()` - Specify the Width and Height, in pixels, of an icon in the icon sheet
- `obj.SetUseIconSize (bool b)` - Specify whether the Quad generated to place the icon on will be either 1 x 1 or the dimensions specified by IconSize.
- `bool = obj.GetUseIconSize ()` - Specify whether the Quad generated to place the icon on will be either 1 x 1 or the dimensions specified by IconSize.
- `obj.UseIconSizeOn ()` - Specify whether the Quad generated to place the icon on will be either 1 x 1 or the dimensions specified by IconSize.
- `obj.UseIconSizeOff ()` - Specify whether the Quad generated to place the icon on will be either 1 x 1 or the dimensions specified by IconSize.
- `obj.SetGravity (int )` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `int = obj.GetGravity ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToTopRight ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToTopCenter ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToTopLeft ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.

- `obj.SetGravityToCenterRight ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToCenterCenter ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToCenterLeft ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToBottomRight ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToBottomCenter ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.
- `obj.SetGravityToBottomLeft ()` - Specify if the input points define the center of the icon quad or one of top right corner, top center, top left corner, center right, center, center center left, bottom right corner, bottom center or bottom left corner.

33.123 vtkIdFilter

33.123.1 Usage

vtkIdFilter is a filter to that generates scalars or field data using cell and point ids. That is, the point attribute data scalars or field data are generated from the point ids, and the cell attribute data scalars or field data are generated from the the cell ids.

Typically this filter is used with vtkLabeledDataMapper (and possibly vtkSelectVisiblePoints) to create labels for points and cells, or labels for the point or cell data scalar values.

To create an instance of class vtkIdFilter, simply invoke its constructor as follows

```
obj = vtkIdFilter
```

33.123.2 Methods

The class vtkIdFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIdFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIdFilter = obj.NewInstance ()`
- `vtkIdFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointIds (int )` - Enable/disable the generation of point ids. Default is on.
- `int = obj.GetPointIds ()` - Enable/disable the generation of point ids. Default is on.
- `obj.PointIdsOn ()` - Enable/disable the generation of point ids. Default is on.
- `obj.PointIdsOff ()` - Enable/disable the generation of point ids. Default is on.

- `obj.SetCellIds (int )` - Enable/disable the generation of point ids. Default is on.
- `int = obj.GetCellIds ()` - Enable/disable the generation of point ids. Default is on.
- `obj.CellIdsOn ()` - Enable/disable the generation of point ids. Default is on.
- `obj.CellIdsOff ()` - Enable/disable the generation of point ids. Default is on.
- `obj.SetFieldData (int )` - Set/Get the flag which controls whether to generate scalar data or field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Default is off.
- `int = obj.GetFieldData ()` - Set/Get the flag which controls whether to generate scalar data or field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Default is off.
- `obj.FieldDataOn ()` - Set/Get the flag which controls whether to generate scalar data or field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Default is off.
- `obj.FieldDataOff ()` - Set/Get the flag which controls whether to generate scalar data or field data. If this flag is off, scalar data is generated. Otherwise, field data is generated. Default is off.
- `obj.SetIdsArrayName (string )` - Set/Get the name of the Ids array if generated. By default the Ids are named "vtkIdFilter_Ids", but this can be changed with this function.
- `string = obj.GetIdsArrayName ()` - Set/Get the name of the Ids array if generated. By default the Ids are named "vtkIdFilter_Ids", but this can be changed with this function.

33.124 vtkImageDataGeometryFilter

33.124.1 Usage

vtkImageDataGeometryFilter is a filter that extracts geometry from a structured points dataset. By specifying appropriate i-j-k indices (via the "Extent" instance variable), it is possible to extract a point, a line, a plane (i.e., image), or a "volume" from dataset. (Since the output is of type polydata, the volume is actually a (n x m x o) region of points.)

The extent specification is zero-offset. That is, the first k-plane in a 50x50x50 volume is given by (0,49, 0,49, 0,0).

To create an instance of class vtkImageDataGeometryFilter, simply invoke its constructor as follows

```
obj = vtkImageDataGeometryFilter
```

33.124.2 Methods

The class vtkImageDataGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDataGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDataGeometryFilter = obj.NewInstance ()`
- `vtkImageDataGeometryFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetExtent (int extent[6])` - Set / get the extent (imin,imax, jmin,jmax, kmin,kmax) indices.
- `obj.SetExtent (int iMin, int iMax, int jMin, int jMax, int kMin, int kMax)` - Set / get the extent (imin,imax, jmin,jmax, kmin,kmax) indices.

- `obj.SetThresholdCells (int )` - Set ThresholdCells to true if you wish to skip any voxel/pixels which have scalar values less than the specified threshold. Currently this functionality is only implemented for 2D imagedata
- `int = obj.GetThresholdCells ()` - Set ThresholdCells to true if you wish to skip any voxel/pixels which have scalar values less than the specified threshold. Currently this functionality is only implemented for 2D imagedata
- `obj.ThresholdCellsOn ()` - Set ThresholdCells to true if you wish to skip any voxel/pixels which have scalar values less than the specified threshold. Currently this functionality is only implemented for 2D imagedata
- `obj.ThresholdCellsOff ()` - Set ThresholdCells to true if you wish to skip any voxel/pixels which have scalar values less than the specified threshold. Currently this functionality is only implemented for 2D imagedata
- `obj.SetThresholdValue (double )` - Set ThresholdValue to the scalar value by which to threshhold cells when extracting geometry when ThresholdCells is true. Cells with scalar values greater than the threshold will be output.
- `double = obj.GetThresholdValue ()` - Set ThresholdValue to the scalar value by which to threshhold cells when extracting geometry when ThresholdCells is true. Cells with scalar values greater than the threshold will be output.
- `obj.ThresholdValueOn ()` - Set ThresholdValue to the scalar value by which to threshhold cells when extracting geometry when ThresholdCells is true. Cells with scalar values greater than the threshold will be output.
- `obj.ThresholdValueOff ()` - Set ThresholdValue to the scalar value by which to threshhold cells when extracting geometry when ThresholdCells is true. Cells with scalar values greater than the threshold will be output.
- `obj.SetOutputTriangles (int )` - Set OutputTriangles to true if you wish to generate triangles instead of quads when extracting cells from 2D imagedata Currently this functionality is only implemented for 2D imagedata
- `int = obj.GetOutputTriangles ()` - Set OutputTriangles to true if you wish to generate triangles instead of quads when extracting cells from 2D imagedata Currently this functionality is only implemented for 2D imagedata
- `obj.OutputTrianglesOn ()` - Set OutputTriangles to true if you wish to generate triangles instead of quads when extracting cells from 2D imagedata Currently this functionality is only implemented for 2D imagedata
- `obj.OutputTrianglesOff ()` - Set OutputTriangles to true if you wish to generate triangles instead of quads when extracting cells from 2D imagedata Currently this functionality is only implemented for 2D imagedata

33.125 vtkImageMarchingCubes

33.125.1 Usage

vtkImageMarchingCubes is a filter that takes as input images (e.g., 3D image region) and generates on output one or more isosurfaces. One or more contour values must be specified to generate the isosurfaces. Alternatively, you can specify a min/max scalar range and the number of contours to generate a series of evenly spaced contour values. This filter can stream, so that the entire volume need not be loaded at once. Streaming is controlled using the instance variable InputMemoryLimit, which has units KBytes.

To create an instance of class vtkImageMarchingCubes, simply invoke its constructor as follows

```
obj = vtkImageMarchingCubes
```

33.125.2 Methods

The class vtkImageMarchingCubes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMarchingCubes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMarchingCubes = obj.NewInstance ()`
- `vtkImageMarchingCubes = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Methods to set contour values
- `double = obj.GetValue (int i)` - Methods to set contour values
- `obj.GetValues (double contourValues)` - Methods to set contour values
- `obj.SetNumberOfContours (int number)` - Methods to set contour values
- `int = obj.GetNumberOfContours ()` - Methods to set contour values
- `obj.GenerateValues (int numContours, double range[2])` - Methods to set contour values
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Methods to set contour values
- `long = obj.GetMTime ()` - Because we delegate to vtkContourValues & refer to vtkImplicitFunction
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.

- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetLocatorPoint (int cellX, int cellY, int edge)`
- `obj.AddLocatorPoint (int cellX, int cellY, int edge, int ptId)`
- `obj.IncrementLocatorZ ()`
- `obj.SetInputMemoryLimit (int )` - The InputMemoryLimit determines the chunk size (the number of slices requested at each iteration). The units of this limit is KiloBytes. For now, only the Z axis is split.
- `int = obj.GetInputMemoryLimit ()` - The InputMemoryLimit determines the chunk size (the number of slices requested at each iteration). The units of this limit is KiloBytes. For now, only the Z axis is split.

33.126 vtkImplicitTextureCoords

33.126.1 Usage

vtkImplicitTextureCoords is a filter to generate 1D, 2D, or 3D texture coordinates from one, two, or three implicit functions, respectively. In combinations with a vtkBooleanTexture map (or another texture map of your own creation), the texture coordinates can be used to highlight (via color or intensity) or cut (via transparency) dataset geometry without any complex geometric processing. (Note: the texture coordinates are referred to as r-s-t coordinates.)

The texture coordinates are automatically normalized to lie between (0,1). Thus, no matter what the implicit functions evaluate to, the resulting texture coordinates lie between (0,1), with the zero implicit function value mapped to the 0.5 texture coordinates value. Depending upon the maximum negative/positive implicit function values, the full (0,1) range may not be occupied (i.e., the positive/negative ranges are mapped using the same scale factor).

A boolean variable InvertTexture is available to flip the texture coordinates around 0.5 (value 1.0 becomes 0.0, 0.25-¿0.75). This is equivalent to flipping the texture map (but a whole lot easier).

To create an instance of class vtkImplicitTextureCoords, simply invoke its constructor as follows

```
obj = vtkImplicitTextureCoords
```

33.126.2 Methods

The class vtkImplicitTextureCoords has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitTextureCoords class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkImplicitTextureCoords = obj.NewInstance ()`
- `vtkImplicitTextureCoords = obj.SafeDownCast (vtkObject o)`
- `obj.SetRFunction (vtkImplicitFunction )` - Specify an implicit function to compute the r texture coordinate.
- `vtkImplicitFunction = obj.GetRFunction ()` - Specify an implicit function to compute the r texture coordinate.
- `obj.SetSFunction (vtkImplicitFunction )` - Specify an implicit function to compute the s texture coordinate.
- `vtkImplicitFunction = obj.GetSFunction ()` - Specify an implicit function to compute the s texture coordinate.
- `obj.SetTFunction (vtkImplicitFunction )` - Specify an implicit function to compute the t texture coordinate.
- `vtkImplicitFunction = obj.GetTFunction ()` - Specify an implicit function to compute the t texture coordinate.
- `obj.SetFlipTexture (int )` - If enabled, this will flip the sense of inside and outside the implicit function (i.e., a rotation around the r-s-t=0.5 axis).
- `int = obj.GetFlipTexture ()` - If enabled, this will flip the sense of inside and outside the implicit function (i.e., a rotation around the r-s-t=0.5 axis).
- `obj.FlipTextureOn ()` - If enabled, this will flip the sense of inside and outside the implicit function (i.e., a rotation around the r-s-t=0.5 axis).
- `obj.FlipTextureOff ()` - If enabled, this will flip the sense of inside and outside the implicit function (i.e., a rotation around the r-s-t=0.5 axis).

33.127 vtkInterpolateDataSetAttributes

33.127.1 Usage

vtkInterpolateDataSetAttributes is a filter that interpolates data set attribute values between input data sets. The input to the filter must be datasets of the same type, same number of cells, and same number of points. The output of the filter is a data set of the same type as the input dataset and whose attribute values have been interpolated at the parametric value specified.

The filter is used by specifying two or more input data sets (total of N), and a parametric value t (0 ¡= t ¡= N-1). The output will contain interpolated data set attributes common to all input data sets. (For example, if one input has scalars and vectors, and another has just scalars, then only scalars will be interpolated and output.)

To create an instance of class vtkInterpolateDataSetAttributes, simply invoke its constructor as follows

```
obj = vtkInterpolateDataSetAttributes
```

33.127.2 Methods

The class vtkInterpolateDataSetAttributes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInterpolateDataSetAttributes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInterpolateDataSetAttributes = obj.NewInstance ()`
- `vtkInterpolateDataSetAttributes = obj.SafeDownCast (vtkObject o)`
- `vtkDataSetCollection = obj.GetInputList ()` - Return the list of inputs to this filter.
- `obj.SetT (double )` - Specify interpolation parameter t.
- `double = obj.GetTMinValue ()` - Specify interpolation parameter t.
- `double = obj.GetTMaxValue ()` - Specify interpolation parameter t.
- `double = obj.GetT ()` - Specify interpolation parameter t.

33.128 vtkInterpolatingSubdivisionFilter

33.128.1 Usage

vtkInterpolatingSubdivisionFilter is an abstract class that defines the protocol for interpolating subdivision surface filters.

To create an instance of class vtkInterpolatingSubdivisionFilter, simply invoke its constructor as follows

```
obj = vtkInterpolatingSubdivisionFilter
```

33.128.2 Methods

The class vtkInterpolatingSubdivisionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInterpolatingSubdivisionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInterpolatingSubdivisionFilter = obj.NewInstance ()`
- `vtkInterpolatingSubdivisionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfSubdivisions (int )` - Set/get the number of subdivisions.
- `int = obj.GetNumberOfSubdivisions ()` - Set/get the number of subdivisions.

33.129 vtkKdTreeSelector

33.129.1 Usage

If SetKdTree is used, the filter ignores the input and selects based on that kd-tree. If SetKdTree is not used, the filter builds a kd-tree using the input point set and uses that tree for selection. The output is a vtkSelection containing the ids found in the kd-tree using the specified bounds.

To create an instance of class vtkKdTreeSelector, simply invoke its constructor as follows

```
obj = vtkKdTreeSelector
```

33.129.2 Methods

The class vtkKdTreeSelector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKdTreeSelector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKdTreeSelector = obj.NewInstance ()`
- `vtkKdTreeSelector = obj.SafeDownCast (vtkObject o)`
- `obj.SetKdTree (vtkKdTree tree)` - The kd-tree to use to find selected ids. The kd-tree must be initialized with the desired set of points. When this is set, the optional input is ignored.
- `vtkKdTree = obj.GetKdTree ()` - The kd-tree to use to find selected ids. The kd-tree must be initialized with the desired set of points. When this is set, the optional input is ignored.
- `obj.SetSelectionBounds (double , double , double , double , double , double )` - The bounds of the form (xmin,xmax,ymin,ymax,zmin,zmax). To perform a search in 2D, use the bounds (xmin,xmax,ymin,ymax,VTI
- `obj.SetSelectionBounds (double a[6])` - The bounds of the form (xmin,xmax,ymin,ymax,zmin,zmax). To perform a search in 2D, use the bounds (xmin,xmax,ymin,ymax,VTK_DOUBLE_MIN,VTK_DOUBLE_MAX).
- `double = obj. GetSelectionBounds ()` - The bounds of the form (xmin,xmax,ymin,ymax,zmin,zmax). To perform a search in 2D, use the bounds (xmin,xmax,ymin,ymax,VTK_DOUBLE_MIN,VTK_DOUBLE_MAX).
- `obj.SetSelectionFieldName (string )` - The field name to use when generating the selection. If set, creates a VALUES selection. If not set (or is set to NULL), creates a INDICES selection. By default this is not set.
- `string = obj.GetSelectionFieldName ()` - The field name to use when generating the selection. If set, creates a VALUES selection. If not set (or is set to NULL), creates a INDICES selection. By default this is not set.
- `obj.SetSelectionAttribute (int )` - The field attribute to use when generating the selection. If set, creates a PEDIGREEIDS or GLOBALIDS selection. If not set (or is set to -1), creates a INDICES selection. By default this is not set. NOTE: This should be set a constant in vtkDataSetAttributes, not vtkSelection.
- `int = obj.GetSelectionAttribute ()` - The field attribute to use when generating the selection. If set, creates a PEDIGREEIDS or GLOBALIDS selection. If not set (or is set to -1), creates a INDICES selection. By default this is not set. NOTE: This should be set a constant in vtkDataSetAttributes, not vtkSelection.
- `obj.SetSingleSelection (bool )` - Whether to only allow up to one value in the result. The item selected is closest to the center of the bounds, if there are any points within the selection threshold. Default is off.
- `bool = obj.GetSingleSelection ()` - Whether to only allow up to one value in the result. The item selected is closest to the center of the bounds, if there are any points within the selection threshold. Default is off.
- `obj.SingleSelectionOn ()` - Whether to only allow up to one value in the result. The item selected is closest to the center of the bounds, if there are any points within the selection threshold. Default is off.

- `obj.SingleSelectionOff ()` - Whether to only allow up to one value in the result. The item selected is closest to the center of the bounds, if there are any points within the selection threshold. Default is off.
- `obj.SetSingleSelectionThreshold (double )` - The threshold for the single selection. A single point is added to the selection if it is within this threshold from the bounds center. Default is 1.
- `double = obj.GetSingleSelectionThreshold ()` - The threshold for the single selection. A single point is added to the selection if it is within this threshold from the bounds center. Default is 1.
- `long = obj.GetMTime ()`

33.130 vtkLevelIdScalars

33.130.1 Usage

vtkLevelIdScalars is a filter that generates scalars using the level number for each level. Note that all datasets within a level get the same scalar. The new scalars array is named ĻevelIdScalars.

To create an instance of class vtkLevelIdScalars, simply invoke its constructor as follows

```
obj = vtkLevelIdScalars
```

33.130.2 Methods

The class vtkLevelIdScalars has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLevelIdScalars class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLevelIdScalars = obj.NewInstance ()`
- `vtkLevelIdScalars = obj.SafeDownCast (vtkObject o)`

33.131 vtkLinearExtrusionFilter

33.131.1 Usage

vtkLinearExtrusionFilter is a modeling filter. It takes polygonal data as input and generates polygonal data on output. The input dataset is swept according to some extrusion function and creates new polygonal primitives. These primitives form a "skirt" or swept surface. For example, sweeping a line results in a quadrilateral, and sweeping a triangle creates a "wedge".

There are a number of control parameters for this filter. You can control whether the sweep of a 2D object (i.e., polygon or triangle strip) is capped with the generating geometry via the "Capping" ivar. Also, you can extrude in the direction of a user specified vector, towards a point, or in the direction of vertex normals (normals must be provided - use vtkPolyDataNormals if necessary). The amount of extrusion is controlled by the "ScaleFactor" instance variable.

The skirt is generated by locating certain topological features. Free edges (edges of polygons or triangle strips only used by one polygon or triangle strips) generate surfaces. This is true also of lines or polylines. Vertices generate lines.

This filter can be used to create 3D fonts, 3D irregular bar charts, or to model 2 1/2D objects like punched plates. It also can be used to create solid objects from 2D polygonal meshes.

To create an instance of class vtkLinearExtrusionFilter, simply invoke its constructor as follows

```
obj = vtkLinearExtrusionFilter
```

33.131.2 Methods

The class vtkLinearExtrusionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLinearExtrusionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLinearExtrusionFilter = obj.NewInstance ()`
- `vtkLinearExtrusionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetExtrusionType (int )` - Set/Get the type of extrusion.
- `int = obj.GetExtrusionTypeMinValue ()` - Set/Get the type of extrusion.
- `int = obj.GetExtrusionTypeMaxValue ()` - Set/Get the type of extrusion.
- `int = obj.GetExtrusionType ()` - Set/Get the type of extrusion.
- `obj.SetExtrusionTypeToVectorExtrusion ()` - Set/Get the type of extrusion.
- `obj.SetExtrusionTypeToNormalExtrusion ()` - Set/Get the type of extrusion.
- `obj.SetExtrusionTypeToPointExtrusion ()` - Set/Get the type of extrusion.
- `obj.SetCapping (int )` - Turn on/off the capping of the skirt.
- `int = obj.GetCapping ()` - Turn on/off the capping of the skirt.
- `obj.CappingOn ()` - Turn on/off the capping of the skirt.
- `obj.CappingOff ()` - Turn on/off the capping of the skirt.
- `obj.SetScaleFactor (double )` - Set/Get extrusion scale factor,
- `double = obj.GetScaleFactor ()` - Set/Get extrusion scale factor,
- `obj.SetVector (double , double , double )` - Set/Get extrusion vector. Only needs to be set if VectorExtrusion is turned on.
- `obj.SetVector (double a[3])` - Set/Get extrusion vector. Only needs to be set if VectorExtrusion is turned on.
- `double = obj. GetVector ()` - Set/Get extrusion vector. Only needs to be set if VectorExtrusion is turned on.
- `obj.SetExtrusionPoint (double , double , double )` - Set/Get extrusion point. Only needs to be set if PointExtrusion is turned on. This is the point towards which extrusion occurs.
- `obj.SetExtrusionPoint (double a[3])` - Set/Get extrusion point. Only needs to be set if PointExtrusion is turned on. This is the point towards which extrusion occurs.
- `double = obj. GetExtrusionPoint ()` - Set/Get extrusion point. Only needs to be set if PointExtrusion is turned on. This is the point towards which extrusion occurs.

33.132 vtkLinearSubdivisionFilter

33.132.1 Usage

vtkLinearSubdivisionFilter is a filter that generates output by subdividing its input polydata. Each subdivision iteration create 4 new triangles for each triangle in the polydata.

To create an instance of class vtkLinearSubdivisionFilter, simply invoke its constructor as follows

```
obj = vtkLinearSubdivisionFilter
```

33.132.2 Methods

The class vtkLinearSubdivisionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLinearSubdivisionFilter class.

- `string = obj.GetClassName ()` - Construct object with NumberOfSubdivisions set to 1.
- `int = obj.IsA (string name)` - Construct object with NumberOfSubdivisions set to 1.
- `vtkLinearSubdivisionFilter = obj.NewInstance ()` - Construct object with NumberOfSubdivisions set to 1.
- `vtkLinearSubdivisionFilter = obj.SafeDownCast (vtkObject o)` - Construct object with NumberOfSubdivisions set to 1.

33.133 vtkLineSource

33.133.1 Usage

vtkLineSource is a source object that creates a polyline defined by two endpoints. The number of segments composing the polyline is controlled by setting the object resolution.

To create an instance of class vtkLineSource, simply invoke its constructor as follows

```
obj = vtkLineSource
```

33.133.2 Methods

The class vtkLineSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLineSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLineSource = obj.NewInstance ()`
- `vtkLineSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetPoint1 (double , double , double )` - Set position of first end point.
- `obj.SetPoint1 (double  a[3])` - Set position of first end point.
- `double = obj. GetPoint1 ()` - Set position of first end point.
- `obj.SetPoint2 (double , double , double )` - Set position of other end point.

- `obj.SetPoint2 (double  a[3])` - Set position of other end point.
- `double = obj. GetPoint2 ()` - Set position of other end point.
- `obj.SetResolution (int )` - Divide line into resolution number of pieces.
- `int = obj.GetResolutionMinValue ()` - Divide line into resolution number of pieces.
- `int = obj.GetResolutionMaxValue ()` - Divide line into resolution number of pieces.
- `int = obj.GetResolution ()` - Divide line into resolution number of pieces.

33.134 vtkLinkEdgels

33.134.1 Usage

vtkLinkEdgels links edgels into digital curves which are then stored as polylines. The algorithm works one pixel at a time only looking at its immediate neighbors. There is a GradientThreshold that can be set that eliminates any pixels with a smaller gradient value. This can be used as the lower threshold of a two value edgel thresholding.

For the remaining edgels, links are first tried for the four connected neighbors. A successful neighbor will satisfy three tests. First both edgels must be above the gradient threshold. Second, the difference between the orientation between the two edgels (Alpha) and each edgels orientation (Phi) must be less than LinkThreshold. Third, the difference between the two edgels Phi values must be less than PhiThreshold. The most successful link is selected. The measure is simply the sum of the three angle differences (actually stored as the sum of the cosines). If none of the four connect neighbors succeeds, then the eight connect neighbors are examined using the same method.

This filter requires gradient information so you will need to use a vtkImageGradient at some point prior to this filter. Typically a vtkNonMaximumSuppression filter is also used. vtkThresholdEdgels can be used to complete the two value edgel thresholding as used in a Canny edge detector. The vtkSubpixelPositionEdgels filter can also be used after this filter to adjust the edgel locations.

To create an instance of class vtkLinkEdgels, simply invoke its constructor as follows

```
obj = vtkLinkEdgels
```

33.134.2 Methods

The class vtkLinkEdgels has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLinkEdgels class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLinkEdgels = obj.NewInstance ()`
- `vtkLinkEdgels = obj.SafeDownCast (vtkObject o)`
- `obj.SetLinkThreshold (double )` - Set/Get the threshold for Phi vs. Alpha link thresholding.
- `double = obj.GetLinkThreshold ()` - Set/Get the threshold for Phi vs. Alpha link thresholding.
- `obj.SetPhiThreshold (double )` - Set/get the threshold for Phi vs. Phi link thresholding.
- `double = obj.GetPhiThreshold ()` - Set/get the threshold for Phi vs. Phi link thresholding.
- `obj.SetGradientThreshold (double )` - Set/Get the threshold for image gradient thresholding.
- `double = obj.GetGradientThreshold ()` - Set/Get the threshold for image gradient thresholding.

33.135 vtkLoopSubdivisionFilter

33.135.1 Usage

vtkLoopSubdivisionFilter is an approximating subdivision scheme that creates four new triangles for each triangle in the mesh. The user can specify the NumberOfSubdivisions. Loop's subdivision scheme is described in: Loop, C., "Smooth Subdivision surfaces based on triangles,", Masters Thesis, University of Utah, August 1987. For a nice summary of the technique see, Hoppe, H., et. al, "Piecewise Smooth Surface Reconstruction,:, Proceedings of Siggraph 94 (Orlando, Florida, July 24-29, 1994). In COmputer Graphics Proceedings, Annual COnference Series, 1994, ACM SIGGRAPH, pp. 295-302. ¡P¿ The filter only operates on triangles. Users should use the vtkTriangleFilter to triangulate meshes that contain polygons or triangle strips. ¡P¿ The filter approximates point data using the same scheme. New triangles create at a subdivision step will have the cell data of their parent cell.

To create an instance of class vtkLoopSubdivisionFilter, simply invoke its constructor as follows

```
obj = vtkLoopSubdivisionFilter
```

33.135.2 Methods

The class vtkLoopSubdivisionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLoopSubdivisionFilter class.

- `string = obj.GetClassName ()` - Construct object with NumberOfSubdivisions set to 1.
- `int = obj.IsA (string name)` - Construct object with NumberOfSubdivisions set to 1.
- `vtkLoopSubdivisionFilter = obj.NewInstance ()` - Construct object with NumberOfSubdivisions set to 1.
- `vtkLoopSubdivisionFilter = obj.SafeDownCast (vtkObject o)` - Construct object with NumberOfSubdivisions set to 1.

33.136 vtkMarchingContourFilter

33.136.1 Usage

vtkMarchingContourFilter is a filter that takes as input any dataset and generates on output isosurfaces and/or isolines. The exact form of the output depends upon the dimensionality of the input data. Data consisting of 3D cells will generate isosurfaces, data consisting of 2D cells will generate isolines, and data with 1D or 0D cells will generate isopoints. Combinations of output type are possible if the input dimension is mixed.

This filter will identify special dataset types (e.g., structured points) and use the appropriate specialized filter to process the data. For examples, if the input dataset type is a volume, this filter will create an internal vtkMarchingCubes instance and use it. This gives much better performance.

To use this filter you must specify one or more contour values. You can either use the method SetValue() to specify each contour value, or use GenerateValues() to generate a series of evenly spaced contours. It is also possible to accelerate the operation of this filter (at the cost of extra memory) by using a vtkScalarTree. A scalar tree is used to quickly locate cells that contain a contour surface. This is especially effective if multiple contours are being extracted. If you want to use a scalar tree, invoke the method UseScalarTreeOn().

To create an instance of class vtkMarchingContourFilter, simply invoke its constructor as follows

```
obj = vtkMarchingContourFilter
```

33.136.2 Methods

The class vtkMarchingContourFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMarchingContourFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMarchingContourFilter = obj.NewInstance ()`
- `vtkMarchingContourFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Methods to set / get contour values.
- `double = obj.GetValue (int i)` - Methods to set / get contour values.
- `obj.GetValues (double contourValues)` - Methods to set / get contour values.
- `obj.SetNumberOfContours (int number)` - Methods to set / get contour values.
- `int = obj.GetNumberOfContours ()` - Methods to set / get contour values.
- `obj.GenerateValues (int numContours, double range[2])` - Methods to set / get contour values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Methods to set / get contour values.
- `long = obj.GetMTime ()` - Modified GetMTime Because we delegate to vtkContourValues
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.

- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.
- `obj.SetUseScalarTree (int )` - Enable the use of a scalar tree to accelerate contour extraction.
- `int = obj.GetUseScalarTree ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.UseScalarTreeOn ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.UseScalarTreeOff ()` - Enable the use of a scalar tree to accelerate contour extraction.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.137 vtkMarchingCubes

33.137.1 Usage

vtkMarchingCubes is a filter that takes as input a volume (e.g., 3D structured point set) and generates on output one or more isosurfaces. One or more contour values must be specified to generate the isosurfaces. Alternatively, you can specify a min/max scalar range and the number of contours to generate a series of evenly spaced contour values.

To create an instance of class vtkMarchingCubes, simply invoke its constructor as follows

```
obj = vtkMarchingCubes
```

33.137.2 Methods

The class vtkMarchingCubes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMarchingCubes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMarchingCubes = obj.NewInstance ()`
- `vtkMarchingCubes = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)`
- `double = obj.GetValue (int i)`

- `obj.GetValues (double contourValues)`
- `obj.SetNumberOfContours (int number)`
- `int = obj.GetNumberOfContours ()`
- `obj.GenerateValues (int numContours, double range[2])`
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)`
- `long = obj.GetMTime ()`
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Overide the default locator. Useful for changing the number of bins for performance or specifying a more aggressive locator.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Overide the default locator. Useful for changing the number of bins for performance or specifying a more aggressive locator.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.138 vtkMarchingSquares

33.138.1 Usage

vtkMarchingSquares is a filter that takes as input a structured points set and generates on output one or more isolines. One or more contour values must be specified to generate the isolines. Alternatively, you can specify a min/max scalar range and the number of contours to generate a series of evenly spaced contour values.

To generate contour lines the input data must be of topological dimension 2 (i.e., an image). If not, you can use the ImageRange ivar to select an image plane from an input volume. This avoids having to extract a plane first (using vtkExtractSubVolume). The filter deals with this by first trying to use the input data directly, and if not a 2D image, then uses the ImageRange ivar to reduce it to an image.

To create an instance of class vtkMarchingSquares, simply invoke its constructor as follows

```
obj = vtkMarchingSquares
```

33.138.2 Methods

The class vtkMarchingSquares has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMarchingSquares class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMarchingSquares = obj.NewInstance ()`
- `vtkMarchingSquares = obj.SafeDownCast (vtkObject o)`
- `obj.SetImageRange (int [6])` - Set/Get the i-j-k index range which define a plane on which to generate contour lines. Using this ivar it is possible to input a 3D volume directly and then generate contour lines on one of the i-j-k planes, or a portion of a plane.
- `int = obj. GetImageRange ()` - Set/Get the i-j-k index range which define a plane on which to generate contour lines. Using this ivar it is possible to input a 3D volume directly and then generate contour lines on one of the i-j-k planes, or a portion of a plane.
- `obj.SetImageRange (int imin, int imax, int jmin, int jmax, int kmin, int kmax)` - Set/Get the i-j-k index range which define a plane on which to generate contour lines. Using this ivar it is possible to input a 3D volume directly and then generate contour lines on one of the i-j-k planes, or a portion of a plane.
- `obj.SetValue (int i, double value)` - Methods to set contour values
- `double = obj.GetValue (int i)` - Methods to set contour values
- `obj.GetValues (double contourValues)` - Methods to set contour values
- `obj.SetNumberOfContours (int number)` - Methods to set contour values
- `int = obj.GetNumberOfContours ()` - Methods to set contour values
- `obj.GenerateValues (int numContours, double range[2])` - Methods to set contour values
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Methods to set contour values
- `long = obj.GetMTime ()` - Because we delegate to vtkContourValues

- `obj.SetLocator (vtkIncrementalPointLocator locator)`
- `vtkIncrementalPointLocator = obj.GetLocator ()`
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified. The locator is used to merge coincident points.

33.139 vtkMaskFields

33.139.1 Usage

vtkMaskFields is used to mark which fields in the input dataset get copied to the output. The output will contain only those fields marked as on by the filter.

To create an instance of class vtkMaskFields, simply invoke its constructor as follows

```
obj = vtkMaskFields
```

33.139.2 Methods

The class vtkMaskFields has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMaskFields class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMaskFields = obj.NewInstance ()`
- `vtkMaskFields = obj.SafeDownCast (vtkObject o)`
- `obj.CopyFieldOn (int fieldLocation, string name)` - Turn on/off the copying of the field or specified by name. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array A field name and a location must be specified. For example: @verbatim maskFields-¿CopyFieldOff(vtkMaskFields::CELL_DATA, "foo"); @endverbatim causes the field "foo" on the input cell data to not get copied to the output.
- `obj.CopyFieldOff (int fieldLocation, string name)` - Turn on/off the copying of the attribute or specified by vtkDataSetAttributes:AttributeTypes. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array An attribute type and a location must be specified. For example: @verbatim maskFields-¿CopyAttributeOff(vtkMaskFields::POINT_DATA, vtkDataSetAttributes::SCALARS); @endverbatim causes the scalars on the input point data to not get copied to the output.
- `obj.CopyAttributeOn (int attributeLocation, int attributeType)` - Turn on/off the copying of the attribute or specified by vtkDataSetAttributes:AttributeTypes. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array An attribute type and a location must be specified. For example: @verbatim maskFields-¿CopyAttributeOff(vtkMaskFields::POINT_DATA, vtkDataSetAttributes::SCALARS); @endverbatim causes the scalars on the input point data to not get copied to the output.
- `obj.CopyAttributeOff (int attributeLocation, int attributeType)` - Convenience methods which operate on all field data or attribute data. More specific than CopyAllOn or CopyAllOff

- `obj.CopyFieldsOff ()` - Convenience methods which operate on all field data or attribute data. More specific than CopyAllOn or CopyAllOff
- `obj.CopyAttributesOff ()`
- `obj.CopyFieldsOn ()`
- `obj.CopyAttributesOn ()` - Helper methods used by other language bindings. Allows the caller to specify arguments as strings instead of enums.
- `obj.CopyAttributeOn (string attributeLoc, string attributeType)` - Helper methods used by other language bindings. Allows the caller to specify arguments as strings instead of enums.
- `obj.CopyAttributeOff (string attributeLoc, string attributeType)` - Helper methods used by other language bindings. Allows the caller to specify arguments as strings instead of enums.
- `obj.CopyFieldOn (string fieldLoc, string name)` - Helper methods used by other language bindings. Allows the caller to specify arguments as strings instead of enums.
- `obj.CopyFieldOff (string fieldLoc, string name)` - Helper methods used by other language bindings. Allows the caller to specify arguments as strings instead of enums.
- `obj.CopyAllOn ()` - Turn on copying of all data. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array
- `obj.CopyAllOff ()` - Turn off copying of all data. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

33.140 vtkMaskPoints

33.140.1 Usage

vtkMaskPoints is a filter that passes through points and point attributes from input dataset. (Other geometry is not passed through.) It is possible to mask every nth point, and to specify an initial offset to begin masking from. A special random mode feature enables random selection of points. The filter can also generate vertices (topological primitives) as well as points. This is useful because vertices are rendered while points are not.

To create an instance of class vtkMaskPoints, simply invoke its constructor as follows

```
obj = vtkMaskPoints
```

33.140.2 Methods

The class vtkMaskPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMaskPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMaskPoints = obj.NewInstance ()`
- `vtkMaskPoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetOnRatio (int )` - Turn on every nth point.
- `int = obj.GetOnRatioMinValue ()` - Turn on every nth point.

- `int = obj.GetOnRatioMaxValue ()` - Turn on every nth point.
- `int = obj.GetOnRatio ()` - Turn on every nth point.
- `obj.SetMaximumNumberOfPoints (vtkIdType )` - Limit the number of points that can be passed through.
- `vtkIdType = obj.GetMaximumNumberOfPointsMinValue ()` - Limit the number of points that can be passed through.
- `vtkIdType = obj.GetMaximumNumberOfPointsMaxValue ()` - Limit the number of points that can be passed through.
- `vtkIdType = obj.GetMaximumNumberOfPoints ()` - Limit the number of points that can be passed through.
- `obj.SetOffset (vtkIdType )` - Start with this point.
- `vtkIdType = obj.GetOffsetMinValue ()` - Start with this point.
- `vtkIdType = obj.GetOffsetMaxValue ()` - Start with this point.
- `vtkIdType = obj.GetOffset ()` - Start with this point.
- `obj.SetRandomMode (int )` - Special flag causes randomization of point selection. If this mode is on, statistically every nth point (i.e., OnRatio) will be displayed.
- `int = obj.GetRandomMode ()` - Special flag causes randomization of point selection. If this mode is on, statistically every nth point (i.e., OnRatio) will be displayed.
- `obj.RandomModeOn ()` - Special flag causes randomization of point selection. If this mode is on, statistically every nth point (i.e., OnRatio) will be displayed.
- `obj.RandomModeOff ()` - Special flag causes randomization of point selection. If this mode is on, statistically every nth point (i.e., OnRatio) will be displayed.
- `obj.SetGenerateVertices (int )` - Generate output polydata vertices as well as points. A useful convenience method because vertices are drawn (they are topology) while points are not (they are geometry). By default this method is off.
- `int = obj.GetGenerateVertices ()` - Generate output polydata vertices as well as points. A useful convenience method because vertices are drawn (they are topology) while points are not (they are geometry). By default this method is off.
- `obj.GenerateVerticesOn ()` - Generate output polydata vertices as well as points. A useful convenience method because vertices are drawn (they are topology) while points are not (they are geometry). By default this method is off.
- `obj.GenerateVerticesOff ()` - Generate output polydata vertices as well as points. A useful convenience method because vertices are drawn (they are topology) while points are not (they are geometry). By default this method is off.
- `obj.SetSingleVertexPerCell (int )` - When vertex generation is enabled, by default vertices are produced as multi-vertex cells (more than one per cell), if you wish to have a single vertex per cell, enable this flag.
- `int = obj.GetSingleVertexPerCell ()` - When vertex generation is enabled, by default vertices are produced as multi-vertex cells (more than one per cell), if you wish to have a single vertex per cell, enable this flag.

- `obj.SingleVertexPerCellOn ()` - When vertex generation is enabled, by default vertices are produced as multi-vertex cells (more than one per cell), if you wish to have a single vertex per cell, enable this flag.
- `obj.SingleVertexPerCellOff ()` - When vertex generation is enabled, by default vertices are produced as multi-vertex cells (more than one per cell), if you wish to have a single vertex per cell, enable this flag.

33.141 vtkMaskPolyData

33.141.1 Usage

vtkMaskPolyData is a filter that sub-samples the cells of input polygonal data. The user specifies every nth item, with an initial offset to begin sampling.

To create an instance of class vtkMaskPolyData, simply invoke its constructor as follows

```
obj = vtkMaskPolyData
```

33.141.2 Methods

The class vtkMaskPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMaskPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMaskPolyData = obj.NewInstance ()`
- `vtkMaskPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetOnRatio (int )` - Turn on every nth entity (cell).
- `int = obj.GetOnRatioMinValue ()` - Turn on every nth entity (cell).
- `int = obj.GetOnRatioMaxValue ()` - Turn on every nth entity (cell).
- `int = obj.GetOnRatio ()` - Turn on every nth entity (cell).
- `obj.SetOffset (vtkIdType )` - Start with this entity (cell).
- `vtkIdType = obj.GetOffsetMinValue ()` - Start with this entity (cell).
- `vtkIdType = obj.GetOffsetMaxValue ()` - Start with this entity (cell).
- `vtkIdType = obj.GetOffset ()` - Start with this entity (cell).

33.142 vtkMassProperties

33.142.1 Usage

vtkMassProperties estimates the volume, the surface area, and the normalized shape index of a triangle mesh. The algorithm implemented here is based on the discrete form of the divergence theorem. The general assumption here is that the model is of closed surface. For more details see the following reference (Alyassin A.M. et al, "Evaluation of new algorithms for the interactive measurement of surface area and volume", Med Phys 21(6) 1994.).

To create an instance of class vtkMassProperties, simply invoke its constructor as follows

```
obj = vtkMassProperties
```

33.142.2 Methods

The class vtkMassProperties has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMassProperties class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMassProperties = obj.NewInstance ()`
- `vtkMassProperties = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetVolume ()` - Compute and return the projected volume. Typically you should compare this volume to the value returned by GetVolume if you get an error (GetVolume()-GetVolumeProjected())*10000 that is greater than GetVolume() this should identify a problem: * Either the polydata is not closed * Or the polydata contains triangle that are flipped
- `double = obj.GetVolumeProjected ()` - Compute and return the volume projected on to each axis aligned plane.
- `double = obj.GetVolumeX ()` - Compute and return the volume projected on to each axis aligned plane.
- `double = obj.GetVolumeY ()` - Compute and return the volume projected on to each axis aligned plane.
- `double = obj.GetVolumeZ ()` - Compute and return the weighting factors for the maximum unit normal component (MUNC).
- `double = obj.GetKx ()` - Compute and return the weighting factors for the maximum unit normal component (MUNC).
- `double = obj.GetKy ()` - Compute and return the weighting factors for the maximum unit normal component (MUNC).
- `double = obj.GetKz ()` - Compute and return the area.
- `double = obj.GetSurfaceArea ()` - Compute and return the min cell area.
- `double = obj.GetMinCellArea ()` - Compute and return the max cell area.
- `double = obj.GetMaxCellArea ()` - Compute and return the normalized shape index. This characterizes the deviation of the shape of an object from a sphere. A sphere's NSI is one. This number is always ¿= 1.0.
- `double = obj.GetNormalizedShapeIndex ()`

33.143 vtkMergeCells

33.143.1 Usage

Designed to work with distributed vtkDataSets, this class will take vtkDataSets and merge them back into a single vtkUnstructuredGrid.

The vtkPoints object of the unstructured grid will have data type VTK_FLOAT, regardless of the data type of the points of the input vtkDataSets. If this is a problem, someone must let me know.

It is assumed the different DataSets have the same field arrays. If the name of a global point ID array is provided, this class will refrain from including duplicate points in the merged Ugrid. This class differs

from vtkAppendFilter in these ways: (1) it uses less memory than that class (which uses memory equal to twice the size of the final Ugrid) but requires that you know the size of the final Ugrid in advance (2) this class assumes the individual DataSets have the same field arrays, while vtkAppendFilter intersects the field arrays (3) this class knows duplicate points may be appearing in the DataSets and can filter those out, (4) this class is not a filter.

To create an instance of class vtkMergeCells, simply invoke its constructor as follows

```
obj = vtkMergeCells
```

33.143.2 Methods

The class vtkMergeCells has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeCells class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergeCells = obj.NewInstance ()`
- `vtkMergeCells = obj.SafeDownCast (vtkObject o)`
- `obj.SetUnstructuredGrid (vtkUnstructuredGrid )`
- `vtkUnstructuredGrid = obj.GetUnstructuredGrid ()`
- `obj.SetTotalNumberOfCells (vtkIdType )`
- `vtkIdType = obj.GetTotalNumberOfCells ()`
- `obj.SetTotalNumberOfPoints (vtkIdType )`
- `vtkIdType = obj.GetTotalNumberOfPoints ()`
- `obj.SetUseGlobalIds (int )`
- `int = obj.GetUseGlobalIds ()`
- `obj.SetPointMergeTolerance (float )`
- `float = obj.GetPointMergeToleranceMinValue ()`
- `float = obj.GetPointMergeToleranceMaxValue ()`
- `float = obj.GetPointMergeTolerance ()`
- `obj.SetUseGlobalCellIds (int )`
- `int = obj.GetUseGlobalCellIds ()`
- `obj.SetMergeDuplicatePoints (int )`
- `int = obj.GetMergeDuplicatePoints ()`
- `obj.MergeDuplicatePointsOn ()`
- `obj.MergeDuplicatePointsOff ()`
- `obj.SetTotalNumberOfDataSets (int )`
- `int = obj.GetTotalNumberOfDataSets ()`
- `int = obj.MergeDataSet (vtkDataSet set)`
- `obj.Finish ()`

33.144 vtkMergeDataObjectFilter

33.144.1 Usage

vtkMergeDataObjectFilter is a filter that merges the field from a vtkDataObject with a vtkDataSet. The resulting combined dataset can then be processed by other filters (e.g., vtkFieldDataToAttributeDataFilter) to create attribute data like scalars, vectors, etc.

The filter operates as follows. The field data from the vtkDataObject is merged with the input's vtkDataSet and then placed in the output. You can choose to place the field data into the cell data field, the point data field, or the datasets field (i.e., the one inherited from vtkDataSet's superclass vtkDataObject). All this data shuffling occurs via reference counting, therefore memory is not copied.

One of the uses of this filter is to allow you to read/generate the structure of a dataset independent of the attributes. So, for example, you could store the dataset geometry/topology in one file, and field data in another. Then use this filter in combination with vtkFieldDataToAttributeData to create a dataset ready for processing in the visualization pipeline.

To create an instance of class vtkMergeDataObjectFilter, simply invoke its constructor as follows

```
obj = vtkMergeDataObjectFilter
```

33.144.2 Methods

The class vtkMergeDataObjectFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeDataObjectFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergeDataObjectFilter = obj.NewInstance ()`
- `vtkMergeDataObjectFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataObject (vtkDataObject object)` - Specify the data object to merge with the input dataset.
- `vtkDataObject = obj.GetDataObject ()` - Specify the data object to merge with the input dataset.
- `obj.SetOutputField (int )` - Specify where to place the field data during the merge process. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `int = obj.GetOutputField ()` - Specify where to place the field data during the merge process. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetOutputFieldToDataObjectField ()` - Specify where to place the field data during the merge process. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetOutputFieldToPointDataField ()` - Specify where to place the field data during the merge process. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.
- `obj.SetOutputFieldToCellDataField ()` - Specify where to place the field data during the merge process. There are three choices: the field data associated with the vtkDataObject superclass; the point field attribute data; and the cell field attribute data.

33.145 vtkMergeFields

33.145.1 Usage

vtkMergeFields is used to merge mutliple field into one. The new field is put in the same field data as the original field. For example @verbatim mf-¿SetOutputField("foo", vtkMergeFields::POINT_DATA); mf-¿SetNumberOfComponents(2); mf-¿Merge(0, "array1", 1); mf-¿Merge(1, "array2", 0); @endverbatim will tell vtkMergeFields to use the 2nd component of array1 and the 1st component of array2 to create a 2 component field called foo. The same can be done using Tcl: @verbatim mf SetOutputField foo POINT_DATA mf Merge 0 array1 1 mf Merge 1 array2 0

Field locations: DATA_OBJECT, POINT_DATA, CELL_DATA @endverbatim

To create an instance of class vtkMergeFields, simply invoke its constructor as follows

```
obj = vtkMergeFields
```

33.145.2 Methods

The class vtkMergeFields has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeFields class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergeFields = obj.NewInstance ()`
- `vtkMergeFields = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputField (string name, int fieldLoc)` - The output field will have the given name and it will be in fieldLoc (the input fields also have to be in fieldLoc).
- `obj.SetOutputField (string name, string fieldLoc)` - Helper method used by the other language bindings. Allows the caller to specify arguments as strings instead of enums.Returns an operation id which can later be used to remove the operation.
- `obj.Merge (int component, string arrayName, int sourceComp)` - Add a component (arrayName,sourceComp) to the output field.
- `obj.SetNumberOfComponents (int )` - Set the number of the components in the output field. This has to be set before execution. Default value is 0.
- `int = obj.GetNumberOfComponents ()` - Set the number of the components in the output field. This has to be set before execution. Default value is 0.

33.146 vtkMergeFilter

33.146.1 Usage

vtkMergeFilter is a filter that extracts separate components of data from different datasets and merges them into a single dataset. The output from this filter is of the same type as the input (i.e., vtkDataSet.) It treats both cell and point data set attributes.

To create an instance of class vtkMergeFilter, simply invoke its constructor as follows

```
obj = vtkMergeFilter
```

33.146.2 Methods

The class vtkMergeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergeFilter = obj.NewInstance ()`
- `vtkMergeFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetGeometry (vtkDataSet input)` - Specify object from which to extract geometry information. Old style. Use SetGeometryConnection() instead.
- `vtkDataSet = obj.GetGeometry ()` - Specify object from which to extract geometry information. Old style. Use SetGeometryConnection() instead.
- `obj.SetGeometryConnection (vtkAlgorithmOutput algOutput)` - Specify object from which to extract scalar information. Old style. Use SetScalarsConnection() instead.
- `obj.SetScalars (vtkDataSet )` - Specify object from which to extract scalar information. Old style. Use SetScalarsConnection() instead.
- `vtkDataSet = obj.GetScalars ()` - Specify object from which to extract scalar information. Old style. Use SetScalarsConnection() instead.
- `obj.SetScalarsConnection (vtkAlgorithmOutput algOutput)` - Set / get the object from which to extract vector information. Old style. Use SetVectorsConnection() instead.
- `obj.SetVectors (vtkDataSet )` - Set / get the object from which to extract vector information. Old style. Use SetVectorsConnection() instead.
- `vtkDataSet = obj.GetVectors ()` - Set / get the object from which to extract vector information. Old style. Use SetVectorsConnection() instead.
- `obj.SetVectorsConnection (vtkAlgorithmOutput algOutput)` - Set / get the object from which to extract normal information. Old style. Use SetNormalsConnection() instead.
- `obj.SetNormals (vtkDataSet )` - Set / get the object from which to extract normal information. Old style. Use SetNormalsConnection() instead.
- `vtkDataSet = obj.GetNormals ()` - Set / get the object from which to extract normal information. Old style. Use SetNormalsConnection() instead.
- `obj.SetNormalsConnection (vtkAlgorithmOutput algOutput)` - Set / get the object from which to extract texture coordinates information. Old style. Use SetTCoordsConnection() instead.
- `obj.SetTCoords (vtkDataSet )` - Set / get the object from which to extract texture coordinates information. Old style. Use SetTCoordsConnection() instead.
- `vtkDataSet = obj.GetTCoords ()` - Set / get the object from which to extract texture coordinates information. Old style. Use SetTCoordsConnection() instead.
- `obj.SetTCoordsConnection (vtkAlgorithmOutput algOutput)` - Set / get the object from which to extract tensor data. Old style. Use SetTensorsConnection() instead.
- `obj.SetTensors (vtkDataSet )` - Set / get the object from which to extract tensor data. Old style. Use SetTensorsConnection() instead.

- `vtkDataSet = obj.GetTensors ()` - Set / get the object from which to extract tensor data. Old style. Use SetTensorsConnection() instead.
- `obj.SetTensorsConnection (vtkAlgorithmOutput algOutput)` - Set the object from which to extract a field and the name of the field. Note that this does not create pipeline connectivity.
- `obj.AddField (string name, vtkDataSet input)` - Set the object from which to extract a field and the name of the field. Note that this does not create pipeline connectivity.

33.147 vtkMeshQuality

33.147.1 Usage

vtkMeshQuality computes one or more functions of (geometric) quality for each 2-D and 3-D cell (triangle, quadrilateral, tetrahedron, or hexahedron) of a mesh. These functions of quality are then averaged over the entire mesh. The minimum, average, maximum, and unbiased variance of quality for each type of cell is stored in the output mesh's FieldData. The FieldData arrays are named "Mesh Triangle Quality," "Mesh Quadrilateral Quality," "Mesh Tetrahedron Quality," and "Mesh Hexahedron Quality." Each array has a single tuple with 5 components. The first 4 components are the quality statistics mentioned above; the final value is the number of cells of the given type. This final component makes aggregation of statistics for distributed mesh data possible.

By default, the per-cell quality is added to the mesh's cell data, in an array named "Quality." Cell types not supported by this filter will have an entry of 0. Use SaveCellQualityOff() to store only the final statistics.

This version of the filter written by Philippe Pebay and David Thompson overtakes an older version written by Leila Baghdadi, Hanif Ladak, and David Steinman at the Imaging Research Labs, Robarts Research Institute. That version only supported tetrahedral radius ratio. See the CompatibilityModeOn() member for information on how to make this filter behave like the previous implementation. For more information on the triangle quality functions of this class, cf. Pebay & Baker 2003, Analysis of triangle quality measures, Math Comp 72:244. For more information on the quadrangle quality functions of this class, cf. Pebay 2004, Planar Quadrangle Quality Measures, Eng Comp 20:2.

To create an instance of class vtkMeshQuality, simply invoke its constructor as follows

```
obj = vtkMeshQuality
```

33.147.2 Methods

The class vtkMeshQuality has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMeshQuality class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMeshQuality = obj.NewInstance ()`
- `vtkMeshQuality = obj.SafeDownCast (vtkObject o)`
- `obj.SetSaveCellQuality (int )` - This variable controls whether or not cell quality is stored as cell data in the resulting mesh or discarded (leaving only the aggregate quality average of the entire mesh, recorded in the FieldData).
- `int = obj.GetSaveCellQuality ()` - This variable controls whether or not cell quality is stored as cell data in the resulting mesh or discarded (leaving only the aggregate quality average of the entire mesh, recorded in the FieldData).

- `obj.SaveCellQualityOn ()` - This variable controls whether or not cell quality is stored as cell data in the resulting mesh or discarded (leaving only the aggregate quality average of the entire mesh, recorded in the FieldData).

- `obj.SaveCellQualityOff ()` - This variable controls whether or not cell quality is stored as cell data in the resulting mesh or discarded (leaving only the aggregate quality average of the entire mesh, recorded in the FieldData).

- `obj.SetTriangleQualityMeasure (int )` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `int = obj.GetTriangleQualityMeasure ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTriangleQualityMeasureToArea ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTriangleQualityMeasureToEdgeRatio ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTriangleQualityMeasureToAspectRatio ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RAT VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTriangleQualityMeasureToRadiusRatio ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RAT VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTriangleQualityMeasureToAspectFrobenius ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_C VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTriangleQualityMeasureToMinAngle ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToMaxAngle ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToCondition ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToScaledJacobian ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_C VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToRelativeSizeSquared ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_C VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToShape ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToShapeAndSize ()` - Set/Get the particular estimator used to function the quality of triangles. The default is VTK_QUALITY_RADIUS_RATIO and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, and VTK_QUALITY_EDGE_RAT VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_CONDITION, VTK_QUALITY_SC VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetTriangleQualityMeasureToDistortion ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasure (int )` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `int = obj.GetQuadQualityMeasure ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToEdgeRatio ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToAspectRatio ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToRadiusRatio ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO

VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToMedAspectFrobenius ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RA VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToMaxAspectFrobenius ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RA VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToMaxEdgeRatios ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToSkew ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToTaper ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToWarpage ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToArea ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToStretch ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToMinAngle ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO

VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToMaxAngle ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToOddy ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToCondition ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToJacobian ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToScaledJacobian ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToShear ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToShape ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToRelativeSizeSquared ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RA VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToShapeAndSize ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO

VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToShearAndSize ()` - Set/Get the particular estimator used to measure the quality of quadrilaterals. The default is VTK_QUALITY_EDGE_RATIO and valid values also include VTK_QUALITY_RADIUS_RATIO, VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_MAX_EDGE_RATIO VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_WARPAGE, VTK_QUALITY_AREA, VTK_QUALITY_STRETCH, VTK_QUALITY_MIN_ANGLE, VTK_QUALITY_MAX_ANGLE, VTK_QUALITY_ODD VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

  Scope: Except for VTK_QUALITY_EDGE_RATIO, these estimators are intended for planar quadrilaterals only; use at your own risk if you really want to assess non-planar quadrilateral quality with those.

- `obj.SetQuadQualityMeasureToDistortion ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasure (int )` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `int = obj.GetTetQualityMeasure ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToEdgeRatio ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToAspectRatio ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS,

VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToRadiusRatio ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToAspectFrobenius ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBE VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToMinAngle ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToCollapseRatio ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENI VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToAspectBeta ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToAspectGamma ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToVolume ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA,

VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J
VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED,
VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToCondition ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToJacobian ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToScaledJacobian ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENI VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToShape ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENIUS, VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToRelativeSizeSquared ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FR VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToShapeAndSize ()` - Set/Get the particular estimator used to measure the quality of tetrahedra. The default is VTK_QUALITY_RADIUS_RATIO (identical to Verdict's aspect ratio beta) and valid values also include VTK_QUALITY_ASPECT_RATIO, VTK_QUALITY_ASPECT_FROBENI VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_COLLAPSE_RATIO, VTK_QUALITY_ASPECT_BETA, VTK_QUALITY_ASPECT_GAMMA, VTK_QUALITY_VOLUME, VTK_QUALITY_CONDITION, VTK_QUALITY_J VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetTetQualityMeasureToDistortion ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY

VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasure (int )` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RAT VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `int = obj.GetHexQualityMeasure ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToEdgeRatio ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToMedAspectFrobenius ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToMaxAspectFrobenius ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToMaxEdgeRatios ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToSkew ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToTaper ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDG VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToVolume ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDG VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToStretch ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToDiagonal ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToDimension ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.
- `obj.SetHexQualityMeasureToOddy ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE

VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToCondition ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToJacobian ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToScaledJacobian ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToShear ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDG VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToShape ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDG VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUME, VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY, VTK_QUALITY_CONDITIO VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SH VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToRelativeSizeSquared ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY

VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToShapeAndSize ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToShearAndSize ()` - Set/Get the particular estimator used to measure the quality of hexahedra. The default is VTK_QUALITY_MAX_ASPECT_FROBENIUS and valid values also include VTK_QUALITY_EDGE_RATIO, VTK_QUALITY_MAX_ASPECT_FROBENIUS, VTK_QUALITY_MAX_EDGE_RATIO, VTK_QUALITY_SKEW, VTK_QUALITY_TAPER, VTK_QUALITY_VOLUM VTK_QUALITY_STRETCH, VTK_QUALITY_DIAGONAL, VTK_QUALITY_DIMENSION, VTK_QUALITY_ODDY VTK_QUALITY_CONDITION, VTK_QUALITY_JACOBIAN, VTK_QUALITY_SCALED_JACOBIAN, VTK_QUALITY_SHEAR, VTK_QUALITY_SHAPE, VTK_QUALITY_RELATIVE_SIZE_SQUARED, VTK_QUALITY_SHAPE_AND_SIZE, VTK_QUALITY_SHEAR_AND_SIZE, and VTK_QUALITY_DISTORTION.

- `obj.SetHexQualityMeasureToDistortion ()` - This is a static function used to calculate the area of a triangle. It assumes that you pass the correct type of cell – no type checking is performed because this method is called from the inner loop of the Execute() member function.

- `obj.SetRatio (int r)` - These methods are deprecated. Use Get/SetSaveCellQuality() instead.

  Formerly, SetRatio could be used to disable computation of the tetrahedral radius ratio so that volume alone could be computed. Now, cell quality is always computed, but you may decide not to store the result for each cell. This allows average cell quality of a mesh to be calculated without requiring per-cell storage.

- `int = obj.GetRatio ()` - These methods are deprecated. Use Get/SetSaveCellQuality() instead.

  Formerly, SetRatio could be used to disable computation of the tetrahedral radius ratio so that volume alone could be computed. Now, cell quality is always computed, but you may decide not to store the result for each cell. This allows average cell quality of a mesh to be calculated without requiring per-cell storage.

- `obj.RatioOn ()` - These methods are deprecated. Use Get/SetSaveCellQuality() instead.

  Formerly, SetRatio could be used to disable computation of the tetrahedral radius ratio so that volume alone could be computed. Now, cell quality is always computed, but you may decide not to store the result for each cell. This allows average cell quality of a mesh to be calculated without requiring per-cell storage.

- `obj.RatioOff ()` - These methods are deprecated. Use Get/SetSaveCellQuality() instead.

  Formerly, SetRatio could be used to disable computation of the tetrahedral radius ratio so that volume alone could be computed. Now, cell quality is always computed, but you may decide not to store the result for each cell. This allows average cell quality of a mesh to be calculated without requiring per-cell storage.

- `obj.SetVolume (int cv)` - These methods are deprecated. The functionality of computing cell volume is being removed until it can be computed for any 3D cell. (The previous implementation only worked for tetrahedra.)

  For now, turning on the volume computation will put this filter into "compatibility mode," where tetrahedral cell volume is stored in first component of each output tuple and the radius ratio is stored

in the second component. You may also use CompatibilityModeOn()/Off() to enter this mode. In this mode, cells other than tetrahedra will have report a volume of 0.0 (if volume computation is enabled).

By default, volume computation is disabled and compatibility mode is off, since it does not make a lot of sense for meshes with non-tetrahedral cells.

- `int = obj.GetVolume ()` - These methods are deprecated. The functionality of computing cell volume is being removed until it can be computed for any 3D cell. (The previous implementation only worked for tetrahedra.)

  For now, turning on the volume computation will put this filter into "compatibility mode," where tetrahedral cell volume is stored in first component of each output tuple and the radius ratio is stored in the second component. You may also use CompatibilityModeOn()/Off() to enter this mode. In this mode, cells other than tetrahedra will have report a volume of 0.0 (if volume computation is enabled).

  By default, volume computation is disabled and compatibility mode is off, since it does not make a lot of sense for meshes with non-tetrahedral cells.

- `obj.VolumeOn ()` - These methods are deprecated. The functionality of computing cell volume is being removed until it can be computed for any 3D cell. (The previous implementation only worked for tetrahedra.)

  For now, turning on the volume computation will put this filter into "compatibility mode," where tetrahedral cell volume is stored in first component of each output tuple and the radius ratio is stored in the second component. You may also use CompatibilityModeOn()/Off() to enter this mode. In this mode, cells other than tetrahedra will have report a volume of 0.0 (if volume computation is enabled).

  By default, volume computation is disabled and compatibility mode is off, since it does not make a lot of sense for meshes with non-tetrahedral cells.

- `obj.VolumeOff ()` - These methods are deprecated. The functionality of computing cell volume is being removed until it can be computed for any 3D cell. (The previous implementation only worked for tetrahedra.)

  For now, turning on the volume computation will put this filter into "compatibility mode," where tetrahedral cell volume is stored in first component of each output tuple and the radius ratio is stored in the second component. You may also use CompatibilityModeOn()/Off() to enter this mode. In this mode, cells other than tetrahedra will have report a volume of 0.0 (if volume computation is enabled).

  By default, volume computation is disabled and compatibility mode is off, since it does not make a lot of sense for meshes with non-tetrahedral cells.

- `obj.SetCompatibilityMode (int cm)` - CompatibilityMode governs whether, when both a quality function and cell volume are to be stored as cell data, the two values are stored in a single array. When compatibility mode is off (the default), two separate arrays are used – one labeled "Quality" and the other labeled "Volume". When compatibility mode is on, both values are stored in a single array, with volume as the first component and quality as the second component.

  Enabling CompatibilityMode changes the default tetrahedral quality function to VTK_QUALITY_RADIUS_RATIO and turns volume computation on. (This matches the default behavior of the initial implementation of vtkMeshQuality.) You may change quality function and volume computation without leaving compatibility mode.

  Disabling compatibility mode does not affect the current volume computation or tetrahedral quality function settings.

  The final caveat to CompatibilityMode is that regardless of its setting, the resulting array will be of type vtkDoubleArray rather than the original vtkFloatArray. This is a safety function to keep the authors from diving off of the Combinatorial Coding Cliff into Certain Insanity.

- `int = obj.GetCompatibilityMode ()` - CompatibilityMode governs whether, when both a quality function and cell volume are to be stored as cell data, the two values are stored in a single array. When compatibility mode is off (the default), two separate arrays are used – one labeled "Quality" and the

other labeled "Volume". When compatibility mode is on, both values are stored in a single array, with volume as the first component and quality as the second component.

Enabling CompatibilityMode changes the default tetrahedral quality function to VTK_QUALITY_RADIUS_RATIO and turns volume computation on. (This matches the default behavior of the initial implementation of vtkMeshQuality.) You may change quality function and volume computation without leaving compatibility mode.

Disabling compatibility mode does not affect the current volume computation or tetrahedral quality function settings.

The final caveat to CompatibilityMode is that regardless of its setting, the resulting array will be of type vtkDoubleArray rather than the original vtkFloatArray. This is a safety function to keep the authors from diving off of the Combinatorial Coding Cliff into Certain Insanity.

- `obj.CompatibilityModeOn ()` - CompatibilityMode governs whether, when both a quality function and cell volume are to be stored as cell data, the two values are stored in a single array. When compatibility mode is off (the default), two separate arrays are used – one labeled "Quality" and the other labeled "Volume". When compatibility mode is on, both values are stored in a single array, with volume as the first component and quality as the second component.

  Enabling CompatibilityMode changes the default tetrahedral quality function to VTK_QUALITY_RADIUS_RATIO and turns volume computation on. (This matches the default behavior of the initial implementation of vtkMeshQuality.) You may change quality function and volume computation without leaving compatibility mode.

  Disabling compatibility mode does not affect the current volume computation or tetrahedral quality function settings.

  The final caveat to CompatibilityMode is that regardless of its setting, the resulting array will be of type vtkDoubleArray rather than the original vtkFloatArray. This is a safety function to keep the authors from diving off of the Combinatorial Coding Cliff into Certain Insanity.

- `obj.CompatibilityModeOff ()` - CompatibilityMode governs whether, when both a quality function and cell volume are to be stored as cell data, the two values are stored in a single array. When compatibility mode is off (the default), two separate arrays are used – one labeled "Quality" and the other labeled "Volume". When compatibility mode is on, both values are stored in a single array, with volume as the first component and quality as the second component.

  Enabling CompatibilityMode changes the default tetrahedral quality function to VTK_QUALITY_RADIUS_RATIO and turns volume computation on. (This matches the default behavior of the initial implementation of vtkMeshQuality.) You may change quality function and volume computation without leaving compatibility mode.

  Disabling compatibility mode does not affect the current volume computation or tetrahedral quality function settings.

  The final caveat to CompatibilityMode is that regardless of its setting, the resulting array will be of type vtkDoubleArray rather than the original vtkFloatArray. This is a safety function to keep the authors from diving off of the Combinatorial Coding Cliff into Certain Insanity.

33.148 vtkModelMetadata

33.148.1 Usage

This class is inspired by the Exodus II file format, but because this class does not depend on the Exodus library, it should be possible to use it to represent metadata for other dataset file formats. Sandia Labs uses it in their Exodus II reader, their Exodus II writer and their EnSight writer. vtkDistributedDataFilter looks for metadata attached to it's input and redistributes the metadata with the grid.

The fields in this class are those described in the document "EXODUS II: A Finite Element Data Model", SAND92-2137, November 1995.

Element and node IDs stored in this object must be global IDs, in the event that the original dataset was partitioned across many files.

One way to initialize this object is by using vtkExodusModel (a Sandia class used by the Sandia Exodus reader). That class will take an open Exodus II file and a vtkUnstructuredGrid drawn from it and will set the required fields.

Alternatively, you can use all the Set* methods to set the individual fields. This class does not copy the data, it simply uses your pointer. This class will free the storage associated with your pointer when the class is deleted. Most fields have sensible defaults. The only requirement is that if you are using this ModelMetadata to write out an Exodus or EnSight file in parallel, you must SetBlockIds and SetBlockIdArrayName. Your vtkUnstructuredGrid must have a cell array giving the block ID for each cell.

To create an instance of class vtkModelMetadata, simply invoke its constructor as follows

```
obj = vtkModelMetadata
```

33.148.2 Methods

The class vtkModelMetadata has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkModelMetadata class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkModelMetadata = obj.NewInstance ()`
- `vtkModelMetadata = obj.SafeDownCast (vtkObject o)`
- `obj.PrintGlobalInformation ()`
- `obj.PrintLocalInformation ()`
- `obj.SetTitle (string )` - The title of the dataset.
- `obj.AddInformationLine (string info)` - Add an information line.
- `obj.AddQARecord (string name, string version, string date, string time)` - Add a QA record. They fields are: The code name The code version number The date (MM/DD/YY or NULL for today) The time (HH:MM:SS or NULL for right now)
- `obj.SetTimeStepIndex (int )` - Set the index of the time step represented by the results data in the file attached to this ModelMetadata object. Time step indices start at 0 in this file, they start at 1 in an Exodus file.
- `obj.SetTimeSteps (int numberOfTimeSteps, float timeStepValues)` - Set the total number of time steps in the file, and the value at each time step. We use your time step value array and delete it when we're done.
- `obj.SetNumberOfBlocks (int )` - The number of blocks in the file. Set this before setting any of the block arrays.
- `obj.SetBlockIds (int )` - An arbitrary integer ID for each block. We use your pointer, and free the memory when the object is freed.
- `int = obj.SetBlockNumberOfElements (int nelts)` - Set or get a pointer to a list of the number of elements in each block. We use your pointers, and free the memory when the object is freed.
- `obj.SetBlockNodesPerElement (int )` - Set or get a pointer to a list of the number of nodes in the elements of each block. We use your pointers, and free the memory when the object is freed.

- `obj.SetBlockElementIdList (int )` - Set or get a pointer to a list global element IDs for the elements in each block. We use your pointers, and free the memory when the object is freed.
- `int = obj.SetBlockNumberOfAttributesPerElement (int natts)` - Set or get a pointer to a list of the number of attributes stored for the elements in each block. We use your pointers, and free the memory when the object is freed.
- `obj.SetBlockAttributes (float )` - Set or get a pointer to a list of the attributes for all blocks. The order of the list should be by block, by element within the block, by attribute. Omit blocks that don't have element attributes.
- `obj.SetNumberOfNodeSets (int )` - The number of node sets in the file. Set this value before setting the various node set arrays.
- `obj.SetNodeSetIds (int )` - Set or get the list the IDs for each node set. Length of list is the number of node sets. We use your pointer, and free the memory when the object is freed.
- `int = obj.SetNodeSetSize (int )` - Set or get a pointer to a list of the number of nodes in each node set. We use your pointer, and free the memory when the object is freed.
- `obj.SetNodeSetNodeIdList (int )` - Set or get a pointer to a concatenated list of the IDs of all nodes in each node set. First list all IDs in node set 0, then all IDs in node set 1, and so on. We use your pointer, and free the memory when the object is freed.
- `int = obj.SetNodeSetNumberOfDistributionFactors (int )` - Set or get a list of the number of distribution factors stored by each node set. This is either 0 or equal to the number of nodes in the node set. Length of list is number of node sets. We use your pointer, and free the memory when the object is freed.
- `obj.SetNodeSetDistributionFactors (float )` - Set or get a list of the distribution factors for the node sets. The list is organized by node set, and within node set by node. We use your pointer, and free the memory when the object is freed.
- `obj.SetNumberOfSideSets (int )` - Set or get the number of side sets. Set this value before setting any of the other side set arrays.
- `obj.SetSideSetIds (int )` - Set or get a pointer to a list giving the ID of each side set. We use your pointer, and free the memory when the object is freed.
- `int = obj.SetSideSetSize (int sizes)` - Set or get a pointer to a list of the number of sides in each side set. We use your pointer, and free the memory when the object is freed.
- `int = obj.SetSideSetNumberOfDistributionFactors (int df)` - Set or get a pointer to a list of the number of distribution factors stored by each side set. Each side set has either no distribution factors, or 1 per node in the side set. We use your pointer, and free the memory when the object is freed.
- `obj.SetSideSetElementList (int )` - Set or get a pointer to a list of the elements containing each side in each side set. The list is organized by side set, and within side set by element. We use your pointer, and free the memory when the object is freed.
- `obj.SetSideSetSideList (int )` - Set or get a pointer to the element side for each side in the side set. (See the manual for the convention for numbering sides in different types of cells.) Side Ids are arranged by side set and within side set by side, and correspond to the SideSetElementList. We use your pointer, and free the memory when the object is freed.
- `obj.SetSideSetNumDFPerSide (int numNodes)` - Set or get a pointer to a list of the number of nodes in each side of each side set. This list is organized by side set, and within side set by side. We use your pointer, and free the memory when the object is freed.

- `obj.SetSideSetDistributionFactors (float )` - Set or get a pointer to a list of all the distribution factors. For every side set that has distribution factors, the number of factors per node was given in the SideSetNumberOfDistributionFactors array. If this number for a given side set is N, then for that side set we have N floating point values for each node for each side in the side set. If nodes are repeated in more than one side, we repeat the distribution factors. So this list is in order by side set, by node. We use your pointer, and free the memory when the object is freed.
- `obj.SetBlockPropertyValue (int )` - Set or get value for each variable for each block. List the integer values in order by variable and within variable by block.
- `obj.SetNodeSetPropertyValue (int )` - Set or get value for each variable for each node set. List the integer values in order by variable and within variable by node set.
- `obj.SetSideSetPropertyValue (int )` - Set or get value for each variable for each side set. List the integer values in order by variable and within variable by side set.
- `obj.SetGlobalVariableValue (float f)` - Set or get the values of the global variables at the current time step.
- `obj.SetElementVariableTruthTable (int )` - A truth table indicating which element variables are defined for which blocks. The variables are all the original element variables that were in the file. The table is by block ID and within block ID by variable.
- `obj.SetAllVariablesDefinedInAllBlocks (int )` - Instead of a truth table of all "1"s, you can set this instance variable to indicate that all variables are defined in all blocks.
- `obj.AllVariablesDefinedInAllBlocksOn ()` - Instead of a truth table of all "1"s, you can set this instance variable to indicate that all variables are defined in all blocks.
- `obj.AllVariablesDefinedInAllBlocksOff ()` - Instead of a truth table of all "1"s, you can set this instance variable to indicate that all variables are defined in all blocks.
- `int = obj.ElementVariableIsDefinedInBlock (string varname, int blockId)` - If the element variable named is defined for the block Id provided (in the element variable truth table) return a 1, otherwise return a 0. If the variable name or block Id are unrecognized, the default value of 1 is returned. (This is an "original" variable name, from the file, not a name created for the vtkUnstructuredGrid. Use FindOriginal*VariableName to map between the two.)
- `string = obj.FindOriginalElementVariableName (string name, int component)` - Given the name of an element variable the vtkUnstructuredGrid described by this ModelMetadata, and a component number, give the name of the scalar array in the original file that turned into that component when the file was read into VTK.
- `string = obj.FindOriginalNodeVariableName (string name, int component)` - Given the name of an node variable the vtkUnstructuredGrid described by this ModelMetadata, and a component number, give the name of the scalar array in the original file that turned into that component when the file was read into VTK.
- `obj.Pack (vtkDataSet ugrid)` - Pack this object's metadata into a field array of a dataset.
- `int = obj.Unpack (vtkDataSet ugrid, int deleteIt)` - Unpack the metadata stored in a dataset, and initialize this object with it. Return 1 if there's no metadata packed into the grid, 0 if OK. If deleteIt is ON, then delete the grid's packed data after unpacking it into the object.
- `int = obj.AddUGridElementVariable (string ugridVarName, string origName, int numComponents)` - In order to write Exodus files from vtkUnstructuredGrid objects that were read from Exodus files, we need to know the mapping from variable names in the UGrid to variable names in the Exodus file. (The Exodus reader combines scalar variables with similar names into vectors in the UGrid.) When building the UGrid to which this ModelMetadata refers, add each element and node variable name

with this call, including the name of original variable that yielded it's first component, and the number of components. If a variable is removed from the UGrid, remove it from the ModelMetadata. (If this information is missing or incomplete, the ExodusIIWriter can still do something sensible in creating names for variables.)

- `int = obj.RemoveUGridElementVariable (string ugridVarName)` - In order to write Exodus files from vtkUnstructuredGrid objects that were read from Exodus files, we need to know the mapping from variable names in the UGrid to variable names in the Exodus file. (The Exodus reader combines scalar variables with similar names into vectors in the UGrid.) When building the UGrid to which this ModelMetadata refers, add each element and node variable name with this call, including the name of original variable that yielded it's first component, and the number of components. If a variable is removed from the UGrid, remove it from the ModelMetadata. (If this information is missing or incomplete, the ExodusIIWriter can still do something sensible in creating names for variables.)
- `int = obj.AddUGridNodeVariable (string ugridVarName, string origName, int numComponents)`
- `int = obj.RemoveUGridNodeVariable (string ugridVarName)`
- `int = obj.MergeModelMetadata (vtkModelMetadata em)` - In VTK we take vtkUnstructuredGrids and perform operations on them, including subsetting and merging grids. We need to modify the metadata object when this happens. MergeModelMetadata merges the supplied model (both global and local metadata) into this model. The models must be from the same file set.

  MergeModelMetadata assumes that no element in one metadata object appears in the other. (It doesn't test for duplicate elements when merging the two metadata objects.)
- `int = obj.MergeGlobalInformation (vtkModelMetadata em)` - The metadata is divided into global metadata and local metadata. MergeGlobalInformation merges just the global metadata of the supplied object into the global metadata of this object.
- `vtkModelMetadata = obj.ExtractModelMetadata (vtkIdTypeArray globalCellIdList, vtkDataSet grid)` - Create and return a new metadata object which contains the information for the subset of global cell IDs provided. We need the grid containing the cells so we can find point Ids as well, and also the name of the global cell ID array and the name of the global point ID array.
- `vtkModelMetadata = obj.ExtractGlobalMetadata ()` - Create and return a new metadata object containing only the global metadata of this metadata object.
- `obj.FreeAllGlobalData ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.
- `obj.FreeAllLocalData ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.
- `obj.FreeBlockDependentData ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.FreeOriginalElementVariableNames ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.FreeOriginalNodeVariableNames ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.FreeUsedElementVariableNames ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.FreeUsedNodeVariableNames ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.FreeUsedElementVariables ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.FreeUsedNodeVariables ()` - Free selected portions of the metadata when updating values in the vtkModelMetadata object. Resetting a particular field, (i.e. SetNodeSetIds) frees the previous setting, but if you are not setting every field, you may want to do a wholesale "Free" first.

  FreeAllGlobalData frees all the fields which don't depend on which time step, which blocks, or which variables are in the input. FreeAllLocalData frees all the fields which do depend on which time step, blocks or variables are in the input. FreeBlockDependentData frees all metadata fields which depend on which blocks were read in.

- `obj.Reset ()` - Set the object back to it's initial state

- `int = obj.GetBlockLocalIndex (int id)` - Block information is stored in arrays. This method returns the array index for a given block ID.

33.149 vtkMultiBlockDataGroupFilter

33.149.1 Usage

vtkMultiBlockDataGroupFilter is an M to 1 filter that merges multiple input into one multi-group dataset. It will assign each input to one group of the multi-group dataset and will assign each update piece as a sub-block. For example, if there are two inputs and four update pieces, the output contains two groups with four datasets each.

To create an instance of class vtkMultiBlockDataGroupFilter, simply invoke its constructor as follows

```
obj = vtkMultiBlockDataGroupFilter
```

33.149.2 Methods

The class vtkMultiBlockDataGroupFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiBlockDataGroupFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiBlockDataGroupFilter = obj.NewInstance ()`
- `vtkMultiBlockDataGroupFilter = obj.SafeDownCast (vtkObject o)`
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

33.150 vtkMultiBlockMergeFilter

33.150.1 Usage

vtkMultiBlockMergeFilter is an M to 1 filter similar to vtkMultiBlockDataGroupFilter. However where as that class creates N groups in the output for N inputs, this creates 1 group in the output with N datasets inside it. In actuality if the inputs have M blocks, this will produce M blocks, each of which has N datasets. Inside the merged group, the i'th data set comes from the i'th data set in the i'th input.

To create an instance of class vtkMultiBlockMergeFilter, simply invoke its constructor as follows

```
obj = vtkMultiBlockMergeFilter
```

33.150.2 Methods

The class vtkMultiBlockMergeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiBlockMergeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiBlockMergeFilter = obj.NewInstance ()`
- `vtkMultiBlockMergeFilter = obj.SafeDownCast (vtkObject o)`
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

33.151 vtkMultiThreshold

33.151.1 Usage

This filter can be substituted for a chain of several vtkThreshold filters and can also perform more sophisticated subsetting operations. It generates a vtkMultiBlockDataSet as its output. This multiblock dataset contains a vtkUnstructuredGrid for each thresholded subset you request. A thresholded subset can be a set defined by an interval over a point or cell attribute of the mesh; these subsets are called IntervalSets. A thresholded subset can also be a boolean combination of one or more IntervalSets; these subsets are called BooleanSets. BooleanSets allow complex logic since their output can depend on multiple intervals over multiple variables defined on the input mesh. This is useful because it eliminates the need for thresholding several times and then appending the results, as can be required with vtkThreshold when one wants to remove some range of values (e.g., a notch filter). Cells are not repeated when they belong to more than one interval unless those intervals have different output grids.

Another advantage this filter provides over vtkThreshold is the ability to threshold on non-scalar (i.e., vector, tensor, etc.) attributes without first computing an array containing some norm of the desired attribute. vtkMultiThreshold provides L_1, L_2, and L_∞ norms.

This filter makes a distinction between intermediate subsets and subsets that will be output to a grid. Each intermediate subset you create with AddIntervalSet or AddBooleanSet is given a unique integer identifier (via the return values of these member functions). If you wish for a given set to be output, you must call OutputSet and pass it one of these identifiers. The return of OutputSet is the integer index of the output set in the multiblock dataset created by this filter.

For example, if an input mesh defined three attributes T, P, and s, one might wish to find cells that satisfy "T ¡ 320 [K] && (P ¿ 101 [kPa] —— s ¡ 0.1 [kJ/kg/K])". To accomplish this with a vtkMultiThreshold filter,

```
vtkMultiThreshold* thr;
int intervalSets[3];

intervalSets[0] = thr->AddIntervalSet( vtkMath::NegInf(), 320., vtkMultiThreshold::CLOSED, vtkMultiThr
    vtkDataObject::FIELD\_ASSOCIATION\_POINTS, ''T'', 0, 1 );
intervalSets[1] = thr->AddIntervalSet( 101., vtkMath::Inf(), vtkMultiThreshold::OPEN, vtkMultiThreshol
    vtkDataObject::FIELD\_ASSOCIATION\_CELLS, ''P'', 0, 1 );
intervalSets[2] = thr->AddIntervalSet( vtkMath::NegInf(), 0.1, vtkMultiThreshold::CLOSED, vtkMultiThres
    vtkDataObject::FIELD\_ASSOCIATION\_POINTS, ''s'', 0, 1 );

int intermediate = thr->AddBooleanSet( vtkMultiThreshold::OR, 2, \&intervalSets[1] );

int intersection[2];
intersection[0] = intervalSets[0];
```

```
intersection[1] = intermediate;
int outputSet = thr->AddBooleanSet( vtkMultiThreshold::AND, 2, intersection );

int outputGridIndex = thr->OutputSet( outputSet );
thr->Update();
```

The result of this filter will be a multiblock dataset that contains a single child with the desired cells. If we had also called ¡code¿thr-¿OutputSet(intervalSets[0]);¡/code¿, there would be two child meshes and one would contain all cells with T ¡ 320 [K]. In that case, the output can be represented by this graph

```
digraph MultiThreshold {
  set0 [shape=rect,style=filled,label=''point T(0) in [-Inf,320['']
  set1 [shape=rect,label=''cell P(0) in ]101,Inf]'']
  set2 [shape=rect,label=''point s(0) in [-Inf,0.1['']
  set3 [shape=rect,label=''OR'']
  set4 [shape=rect,style=filled,label=''AND'']
  set0 -> set4
  set1 -> set3
  set2 -> set3
  set3 -> set4
}
```

The filled rectangles represent sets that are output.

To create an instance of class vtkMultiThreshold, simply invoke its constructor as follows

```
obj = vtkMultiThreshold
```

33.151.2 Methods

The class vtkMultiThreshold has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiThreshold class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiThreshold = obj.NewInstance ()`
- `vtkMultiThreshold = obj.SafeDownCast (vtkObject o)`
- `int = obj.AddIntervalSet (double xmin, double xmax, int omin, int omax, int assoc, string arrayName`
  - Add a mesh subset to be computed by thresholding an attribute of the input mesh. The subset can then be added to an output mesh with OuputSet() or combined with other sets using AddBooleanSet. If you wish to include all cells with values below some number a, call with xmin set to vtkMath::NegInf() and xmax set to a. Similarly, if you wish to include all cells with values above some number a, call with xmin set to a and xmax set to vtkMath::Inf(). When specifying Inf() or NegInf() for an endpoint, it does not matter whether you specify and open or closed endpoint.

  When creating intervals, any integers can be used for the IDs of output meshes. All that matters is that the same ID be used if intervals should output to the same mesh. The outputs are ordered with ascending IDs in output block 0.

  It is possible to specify an invalid interval, in which case these routines will return -1. Invalid intervals occur when - an array does not exist, - center is invalid, - xmin == xmax and omin and/or omax are vtkMultiThreshold::OPEN, or - xmin ¿ xmax. - xmin or xmax is not a number (i.e., IEEE NaN).

Having both xmin and xmax equal NaN is allowed. vtkMath provides a portable way to specify IEEE infinities and Nan. Note that specifying an interval completely out of the bounds of an attribute is considered valid. In fact, it is occasionally useful to create a closed interval with both endpoints set to ∞ or both endpoints set to $-\infty$ in order to locate cells with problematic values.

@param xmin The minimum attribute value @param xmax The maximum attribute value @param omin Whether the interval should be open or closed at xmin. Use vtkMultiThreshold::OPEN or vtkMultiThreshold::CLOSED. @param omax Whether the interval should be open or closed at xmax. Use vtkMultiThreshold::OPEN or vtkMultiThreshold::CLOSED. @param assoc One of vtkDataObject::FIELD_ASSOCIATION_CELLS or vtkDataObject::FIELD_ASSOCIATION_POINTS indicating whether a point or cell array should be used. @param arrayName The name of the array to use for thresholding @param attribType The attribute to use for thresholding. One of vtkDataSetAttributes::SCALARS, VECTORS, TENSORS, NORMALS, TCOORDS, or GLOBALIDS. @param component The number of the component to threshold on or one of the following enumerants for norms: LINFINITY_NORM, L2_NORM, L1_NORM. @param allScalars When center is vtkDataObject::FIELD_ASSOCIATION must all scalars be in the interval for the cell to be passed to the output, or just a single point's scalar? @return An index used to identify the cells selected by the interval or -1 if the interval specification was invalid. If a valid value is returned, you may pass it to OutputSet().

- `int = obj.AddIntervalSet (double xmin, double xmax, int omin, int omax, int assoc, int attribType,` - Add a mesh subset to be computed by thresholding an attribute of the input mesh. The subset can then be added to an output mesh with OuputSet() or combined with other sets using AddBooleanSet. If you wish to include all cells with values below some number a, call with xmin set to vtkMath::NegInf() and xmax set to a. Similarly, if you wish to include all cells with values above some number a, call with xmin set to a and xmax set to vtkMath::Inf(). When specifying Inf() or NegInf() for an endpoint, it does not matter whether you specify and open or closed endpoint.

  When creating intervals, any integers can be used for the IDs of output meshes. All that matters is that the same ID be used if intervals should output to the same mesh. The outputs are ordered with ascending IDs in output block 0.

  It is possible to specify an invalid interval, in which case these routines will return -1. Invalid intervals occur when - an array does not exist, - center is invalid, - xmin == xmax and omin and/or omax are vtkMultiThreshold::OPEN, or - xmin ¿ xmax. - xmin or xmax is not a number (i.e., IEEE NaN). Having both xmin and xmax equal NaN is allowed. vtkMath provides a portable way to specify IEEE infinities and Nan. Note that specifying an interval completely out of the bounds of an attribute is considered valid. In fact, it is occasionally useful to create a closed interval with both endpoints set to ∞ or both endpoints set to $-\infty$ in order to locate cells with problematic values.

  @param xmin The minimum attribute value @param xmax The maximum attribute value @param omin Whether the interval should be open or closed at xmin. Use vtkMultiThreshold::OPEN or vtkMultiThreshold::CLOSED. @param omax Whether the interval should be open or closed at xmax. Use vtkMultiThreshold::OPEN or vtkMultiThreshold::CLOSED. @param assoc One of vtkDataObject::FIELD_ASSOCIATION_CELLS or vtkDataObject::FIELD_ASSOCIATION_POINTS indicating whether a point or cell array should be used. @param arrayName The name of the array to use for thresholding @param attribType The attribute to use for thresholding. One of vtkDataSetAttributes::SCALARS, VECTORS, TENSORS, NORMALS, TCOORDS, or GLOBALIDS. @param component The number of the component to threshold on or one of the following enumerants for norms: LINFINITY_NORM, L2_NORM, L1_NORM. @param allScalars When center is vtkDataObject::FIELD_ASSOCIATION must all scalars be in the interval for the cell to be passed to the output, or just a single point's scalar? @return An index used to identify the cells selected by the interval or -1 if the interval specification was invalid. If a valid value is returned, you may pass it to OutputSet().

- `int = obj.AddLowpassIntervalSet (double xmax, int assoc, string arrayName, int component, int allSc` - These convenience members make it easy to insert closed intervals. The "notch" interval is accomplished by creating a bandpass interval and applying a NAND operation. In this case, the set ID returned in the NAND operation set ID. Note that you can pass xmin == xmax when creating a

bandpass threshold to retrieve elements matching exactly one value (since the intervals created by these routines are closed).

- `int = obj.AddHighpassIntervalSet (double xmin, int assoc, string arrayName, int component, int allS` - These convenience members make it easy to insert closed intervals. The "notch" interval is accomplished by creating a bandpass interval and applying a NAND operation. In this case, the set ID returned in the NAND operation set ID. Note that you can pass xmin == xmax when creating a bandpass threshold to retrieve elements matching exactly one value (since the intervals created by these routines are closed).
- `int = obj.AddBandpassIntervalSet (double xmin, double xmax, int assoc, string arrayName, int compor` - These convenience members make it easy to insert closed intervals. The "notch" interval is accomplished by creating a bandpass interval and applying a NAND operation. In this case, the set ID returned in the NAND operation set ID. Note that you can pass xmin == xmax when creating a bandpass threshold to retrieve elements matching exactly one value (since the intervals created by these routines are closed).
- `int = obj.AddNotchIntervalSet (double xlo, double xhi, int assoc, string arrayName, int component,` - These convenience members make it easy to insert closed intervals. The "notch" interval is accomplished by creating a bandpass interval and applying a NAND operation. In this case, the set ID returned in the NAND operation set ID. Note that you can pass xmin == xmax when creating a bandpass threshold to retrieve elements matching exactly one value (since the intervals created by these routines are closed).
- `int = obj.AddBooleanSet (int operation, int numInputs, int inputs)` - Create a new mesh subset using boolean operations on pre-existing sets.
- `int = obj.OutputSet (int setId)` - Create an output mesh containing a boolean or interval subset of the input mesh.
- `obj.Reset ()` - Remove all the intervals currently defined.

33.152 vtkOBBDicer

33.152.1 Usage

vtkOBBDicer separates the cells of a dataset into spatially aggregated pieces using a Oriented Bounding Box (OBB). These pieces can then be operated on by other filters (e.g., vtkThreshold). One application is to break very large polygonal models into pieces and performing viewing and occlusion culling on the pieces.

Refer to the superclass documentation (vtkDicer) for more information.

To create an instance of class vtkOBBDicer, simply invoke its constructor as follows

```
obj = vtkOBBDicer
```

33.152.2 Methods

The class vtkOBBDicer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOBBDicer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOBBDicer = obj.NewInstance ()`
- `vtkOBBDicer = obj.SafeDownCast (vtkObject o)`

33.153 vtkOBBTree

33.153.1 Usage

vtkOBBTree is an object to generate oriented bounding box (OBB) trees. An oriented bounding box is a bounding box that does not necessarily line up along coordinate axes. The OBB tree is a hierarchical tree structure of such boxes, where deeper levels of OBB confine smaller regions of space.

To build the OBB, a recursive, top-down process is used. First, the root OBB is constructed by finding the mean and covariance matrix of the cells (and their points) that define the dataset. The eigenvectors of the covariance matrix are extracted, giving a set of three orthogonal vectors that define the tightest-fitting OBB. To create the two children OBB's, a split plane is found that (approximately) divides the number cells in half. These are then assigned to the children OBB's. This process then continues until the MaxLevel ivar limits the recursion, or no split plane can be found.

A good reference for OBB-trees is Gottschalk & Manocha in Proceedings of Siggraph '96.

To create an instance of class vtkOBBTree, simply invoke its constructor as follows

```
obj = vtkOBBTree
```

33.153.2 Methods

The class vtkOBBTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOBBTree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOBBTree = obj.NewInstance ()`
- `vtkOBBTree = obj.SafeDownCast (vtkObject o)`
- `int = obj.IntersectWithLine (double a0[3], double a1[3], vtkPoints points, vtkIdList cellIds)` - Take the passed line segment and intersect it with the data set. This method assumes that the data set is a vtkPolyData that describes a closed surface, and the intersection points that are returned in 'points' alternate between entrance points and exit points. The return value of the function is 0 if no intersections were found, -1 if point 'a0' lies inside the closed surface, or +1 if point 'a0' lies outside the closed surface. Either 'points' or 'cellIds' can be set to NULL if you don't want to receive that information.
- `obj.ComputeOBB (vtkDataSet input, double corner[3], double max[3], double mid[3], double min[3], do` - Compute an OBB for the input dataset using the cells in the data. Return the corner point and the three axes defining the orientation of the OBB. Also return a sorted list of relative "sizes" of axes for comparison purposes.
- `int = obj.InsideOrOutside (double point[3])` - Determine whether a point is inside or outside the data used to build this OBB tree. The data must be a closed surface vtkPolyData data set. The return value is +1 if outside, -1 if inside, and 0 if undecided.
- `obj.FreeSearchStructure ()` - Satisfy locator's abstract interface, see vtkLocator.
- `obj.BuildLocator ()` - Satisfy locator's abstract interface, see vtkLocator.
- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - Create polygonal representation for OBB tree at specified level. If level ¡ 0, then the leaf OBB nodes will be gathered. The aspect ratio (ar) and line diameter (d) are used to control the building of the representation. If a OBB node edge ratio's are greater than ar, then the dimension of the OBB is collapsed (OBB-¿plane-¿line). A "line" OBB will be represented either as two crossed polygons, or as a line, depending on the relative diameter of the OBB compared to the diameter (d).

33.154 vtkOutlineCornerFilter

33.154.1 Usage

vtkOutlineCornerFilter is a filter that generates wireframe outline corners of any data set. The outline consists of the eight corners of the dataset bounding box.

To create an instance of class vtkOutlineCornerFilter, simply invoke its constructor as follows

```
obj = vtkOutlineCornerFilter
```

33.154.2 Methods

The class vtkOutlineCornerFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutlineCornerFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutlineCornerFilter = obj.NewInstance ()`
- `vtkOutlineCornerFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetCornerFactor (double )` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactorMinValue ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactorMaxValue ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactor ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds

33.155 vtkOutlineCornerSource

33.155.1 Usage

vtkOutlineCornerSource creates wireframe outline corners around a user-specified bounding box.

To create an instance of class vtkOutlineCornerSource, simply invoke its constructor as follows

```
obj = vtkOutlineCornerSource
```

33.155.2 Methods

The class vtkOutlineCornerSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutlineCornerSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutlineCornerSource = obj.NewInstance ()`
- `vtkOutlineCornerSource = obj.SafeDownCast (vtkObject o)`

- `obj.SetCornerFactor (double )` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactorMinValue ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactorMaxValue ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactor ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds

33.156 vtkOutlineFilter

33.156.1 Usage

vtkOutlineFilter is a filter that generates a wireframe outline of any data set. The outline consists of the twelve edges of the dataset bounding box.

To create an instance of class vtkOutlineFilter, simply invoke its constructor as follows

```
obj = vtkOutlineFilter
```

33.156.2 Methods

The class vtkOutlineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutlineFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutlineFilter = obj.NewInstance ()`
- `vtkOutlineFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetGenerateFaces (int )` - Generate solid faces for the box. This is off by default.
- `obj.GenerateFacesOn ()` - Generate solid faces for the box. This is off by default.
- `obj.GenerateFacesOff ()` - Generate solid faces for the box. This is off by default.
- `int = obj.GetGenerateFaces ()` - Generate solid faces for the box. This is off by default.

33.157 vtkOutlineSource

33.157.1 Usage

vtkOutlineSource creates a wireframe outline around a user-specified bounding box. The outline may be created aligned with the x,y,z axis - in which case it is defined by the 6 bounds xmin,xmax,ymin,ymax,zmin,zmax via SetBounds(). Alternatively, the box may be arbitrarily aligned, in which case it should be set via the SetCorners() member.

To create an instance of class vtkOutlineSource, simply invoke its constructor as follows

```
obj = vtkOutlineSource
```

33.157.2 Methods

The class vtkOutlineSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutlineSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutlineSource = obj.NewInstance ()`
- `vtkOutlineSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetBoxType (int )` - Set box type to AxisAligned (default) or Oriented. Use the method SetBounds() with AxisAligned mode, and SetCorners() with Oriented mode.
- `int = obj.GetBoxType ()` - Set box type to AxisAligned (default) or Oriented. Use the method SetBounds() with AxisAligned mode, and SetCorners() with Oriented mode.
- `obj.SetBoxTypeToAxisAligned ()` - Set box type to AxisAligned (default) or Oriented. Use the method SetBounds() with AxisAligned mode, and SetCorners() with Oriented mode.
- `obj.SetBoxTypeToOriented ()` - Specify the bounds of the box to be used in Axis Aligned mode.
- `obj.SetBounds (double , double , double , double , double , double )` - Specify the bounds of the box to be used in Axis Aligned mode.
- `obj.SetBounds (double a[6])` - Specify the bounds of the box to be used in Axis Aligned mode.
- `double = obj. GetBounds ()` - Specify the bounds of the box to be used in Axis Aligned mode.
- `obj.SetCorners (double [24])` - Specify the corners of the outline when in Oriented mode, the values are supplied as 8*3 double values The correct corner ordering is using x,y,z convention for the unit cube as follows: 0,0,0,1,0,0,0,1,0,1,1,0,0,0,1,1,0,1,0,1,1,1,1,1.
- `double = obj. GetCorners ()` - Specify the corners of the outline when in Oriented mode, the values are supplied as 8*3 double values The correct corner ordering is using x,y,z convention for the unit cube as follows: 0,0,0,1,0,0,0,1,0,1,1,0,0,0,1,1,0,1,0,1,1,1,1,1.
- `obj.SetGenerateFaces (int )` - Generate solid faces for the box. This is off by default.
- `obj.GenerateFacesOn ()` - Generate solid faces for the box. This is off by default.
- `obj.GenerateFacesOff ()` - Generate solid faces for the box. This is off by default.
- `int = obj.GetGenerateFaces ()` - Generate solid faces for the box. This is off by default.

33.158 vtkParametricFunctionSource

33.158.1 Usage

This class tessellates parametric functions. The user must specify how many points in the parametric coordinate directions are required (i.e., the resolution), and the mode to use to generate scalars.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricFunctionSource, simply invoke its constructor as follows

```
obj = vtkParametricFunctionSource
```

33.158.2 Methods

The class vtkParametricFunctionSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricFunctionSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricFunctionSource = obj.NewInstance ()`
- `vtkParametricFunctionSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetParametricFunction (vtkParametricFunction )` - Specify the parametric function to use to generate the tessellation.
- `vtkParametricFunction = obj.GetParametricFunction ()` - Specify the parametric function to use to generate the tessellation.
- `obj.SetUResolution (int )` - Set/Get the number of subdivisions / tessellations in the u parametric direction. Note that the number of tessellant points in the u direction is the UResolution + 1.
- `int = obj.GetUResolution ()` - Set/Get the number of subdivisions / tessellations in the u parametric direction. Note that the number of tessellant points in the u direction is the UResolution + 1.
- `obj.SetVResolution (int )` - Set/Get the number of subdivisions / tessellations in the v parametric direction. Note that the number of tessellant points in the v direction is the VResolution + 1.
- `int = obj.GetVResolution ()` - Set/Get the number of subdivisions / tessellations in the v parametric direction. Note that the number of tessellant points in the v direction is the VResolution + 1.
- `obj.SetWResolution (int )` - Set/Get the number of subdivisions / tessellations in the w parametric direction. Note that the number of tessellant points in the w direction is the WResolution + 1.
- `int = obj.GetWResolution ()` - Set/Get the number of subdivisions / tessellations in the w parametric direction. Note that the number of tessellant points in the w direction is the WResolution + 1.
- `obj.GenerateTextureCoordinatesOn ()` - Set/Get the generation of texture coordinates. This is off by default. Note that this is only applicable to parametric surfaces whose parametric dimension is 2. Note that texturing may fail in some cases.
- `obj.GenerateTextureCoordinatesOff ()` - Set/Get the generation of texture coordinates. This is off by default. Note that this is only applicable to parametric surfaces whose parametric dimension is 2. Note that texturing may fail in some cases.
- `obj.SetGenerateTextureCoordinates (int )` - Set/Get the generation of texture coordinates. This is off by default. Note that this is only applicable to parametric surfaces whose parametric dimension is 2. Note that texturing may fail in some cases.
- `int = obj.GetGenerateTextureCoordinates ()` - Set/Get the generation of texture coordinates. This is off by default. Note that this is only applicable to parametric surfaces whose parametric dimension is 2. Note that texturing may fail in some cases.

- `obj.SetScalarMode (int )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().
- `int = obj.GetScalarModeMinValue ()` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().
- `int = obj.GetScalarModeMaxValue ()` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().
- `int = obj.GetScalarMode ()` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().
- `obj.SetScalarModeToNone (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg,

0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToU (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToV (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToU0 (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToV0 (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending

upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToU0V0 (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToModulus (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToPhase (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToQuadrant (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToX (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToY (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToZ (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToDistance (void )` - Get/Set the mode used for the scalar data. The options are: SCALAR_NONE, (default) scalars are not generated. SCALAR_U, the scalar is set to the u-value. SCALAR_V, the scalar is set to the v-value. SCALAR_U0, the scalar is set to 1 if u = (u_max - u_min)/2 = u_avg, 0 otherwise. SCALAR_V0, the scalar is set to 1 if v = (v_max - v_min)/2 = v_avg, 0 otherwise. SCALAR_U0V0, the scalar is set to 1 if u == u_avg, 2 if v == v_avg, 3 if u = u_avg && v = v_avg, 0 otherwise. SCALAR_MODULUS, the scalar is set to (sqrt(u*u+v*v)), this is measured relative to (u_avg,v_avg). SCALAR_PHASE, the scalar is set to (atan2(v,u)) (in degrees, 0 to 360), this is measured relative to (u_avg,v_avg). SCALAR_QUADRANT, the scalar is set to 1, 2, 3 or 4 depending upon the quadrant of the point (u,v). SCALAR_X, the scalar is set to the x-value. SCALAR_Y, the scalar is set to the y-value. SCALAR_Z, the scalar is set to the z-value. SCALAR_DISTANCE, the scalar is set to (sqrt(x*x+y*y+z*z)). I.e. distance from the origin. SCALAR_FUNCTION_DEFINED, the scalar is set to the value returned from EvaluateScalar().

- `obj.SetScalarModeToFunctionDefined (void )` - Return the MTime also considering the parametric function.

- `long = obj.GetMTime ()` - Return the MTime also considering the parametric function.

33.159 vtkPlaneSource

33.159.1 Usage

vtkPlaneSource creates an m x n array of quadrilaterals arranged as a regular tiling in a plane. The plane is defined by specifying an origin point, and then two other points that, together with the origin, define two axes for the plane. These axes do not have to be orthogonal - so you can create a parallelogram. (The axes must not be parallel.) The resolution of the plane (i.e., number of subdivisions) is controlled by the ivars XResolution and YResolution.

By default, the plane is centered at the origin and perpendicular to the z-axis, with width and height of length 1 and resolutions set to 1.

There are three convenience methods that allow you to easily move the plane. The first, SetNormal(), allows you to specify the plane normal. The effect of this method is to rotate the plane around the center of the plane, aligning the plane normal with the specified normal. The rotation is about the axis defined by the cross product of the current normal with the new normal. The second, SetCenter(), translates the center of the plane to the specified center point. The third method, Push(), allows you to translate the plane along the plane normal by the distance specified. (Negative Push values translate the plane in the negative normal direction.) Note that the SetNormal(), SetCenter() and Push() methods modify the Origin, Point1, and/or Point2 instance variables.

To create an instance of class vtkPlaneSource, simply invoke its constructor as follows

```
obj = vtkPlaneSource
```

33.159.2 Methods

The class vtkPlaneSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlaneSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPlaneSource = obj.NewInstance ()`
- `vtkPlaneSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetXResolution (int )` - Specify the resolution of the plane along the first axes.
- `int = obj.GetXResolution ()` - Specify the resolution of the plane along the first axes.
- `obj.SetYResolution (int )` - Specify the resolution of the plane along the second axes.
- `int = obj.GetYResolution ()` - Specify the resolution of the plane along the second axes.
- `obj.SetResolution (int xR, int yR)` - Set the number of x-y subdivisions in the plane.
- `obj.SetOrigin (double , double , double )` - Specify a point defining the origin of the plane.
- `obj.SetOrigin (double  a[3])` - Specify a point defining the origin of the plane.
- `double = obj. GetOrigin ()` - Specify a point defining the origin of the plane.
- `obj.SetPoint1 (double x, double y, double z)` - Specify a point defining the first axis of the plane.
- `obj.SetPoint1 (double pnt[3])` - Specify a point defining the first axis of the plane.
- `double = obj. GetPoint1 ()` - Specify a point defining the first axis of the plane.

- `obj.SetPoint2 (double x, double y, double z)` - Specify a point defining the second axis of the plane.
- `obj.SetPoint2 (double pnt[3])` - Specify a point defining the second axis of the plane.
- `double = obj. GetPoint2 ()` - Specify a point defining the second axis of the plane.
- `obj.SetCenter (double x, double y, double z)` - Set/Get the center of the plane. Works in conjunction with the plane normal to position the plane. Don't use this method to define the plane. Instead, use it to move the plane to a new center point.
- `obj.SetCenter (double center[3])` - Set/Get the center of the plane. Works in conjunction with the plane normal to position the plane. Don't use this method to define the plane. Instead, use it to move the plane to a new center point.
- `double = obj. GetCenter ()` - Set/Get the center of the plane. Works in conjunction with the plane normal to position the plane. Don't use this method to define the plane. Instead, use it to move the plane to a new center point.
- `obj.SetNormal (double nx, double ny, double nz)` - Set/Get the plane normal. Works in conjunction with the plane center to orient the plane. Don't use this method to define the plane. Instead, use it to rotate the plane around the current center point.
- `obj.SetNormal (double n[3])` - Set/Get the plane normal. Works in conjunction with the plane center to orient the plane. Don't use this method to define the plane. Instead, use it to rotate the plane around the current center point.
- `double = obj. GetNormal ()` - Set/Get the plane normal. Works in conjunction with the plane center to orient the plane. Don't use this method to define the plane. Instead, use it to rotate the plane around the current center point.
- `obj.Push (double distance)` - Translate the plane in the direction of the normal by the distance specified. Negative values move the plane in the opposite direction.

33.160 vtkPlatonicSolidSource

33.160.1 Usage

vtkPlatonicSolidSource can generate each of the five Platonic solids: tetrahedron, cube, octahedron, icosahedron, and dodecahedron. Each of the solids is placed inside a sphere centered at the origin with radius 1.0. To use this class, simply specify the solid to create. Note that this source object creates cell scalars that are (integral value) face numbers.

To create an instance of class vtkPlatonicSolidSource, simply invoke its constructor as follows

```
obj = vtkPlatonicSolidSource
```

33.160.2 Methods

The class vtkPlatonicSolidSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlatonicSolidSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPlatonicSolidSource = obj.NewInstance ()`

- `vtkPlatonicSolidSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetSolidType (int )` - Specify the type of PlatonicSolid solid to create.
- `int = obj.GetSolidTypeMinValue ()` - Specify the type of PlatonicSolid solid to create.
- `int = obj.GetSolidTypeMaxValue ()` - Specify the type of PlatonicSolid solid to create.
- `int = obj.GetSolidType ()` - Specify the type of PlatonicSolid solid to create.
- `obj.SetSolidTypeToTetrahedron ()` - Specify the type of PlatonicSolid solid to create.
- `obj.SetSolidTypeToCube ()` - Specify the type of PlatonicSolid solid to create.
- `obj.SetSolidTypeToOctahedron ()` - Specify the type of PlatonicSolid solid to create.
- `obj.SetSolidTypeToIcosahedron ()` - Specify the type of PlatonicSolid solid to create.
- `obj.SetSolidTypeToDodecahedron ()`

33.161 vtkPointDataToCellData

33.161.1 Usage

vtkPointDataToCellData is a filter that transforms point data (i.e., data specified per point) into cell data (i.e., data specified per cell). The method of transformation is based on averaging the data values of all points defining a particular cell. Optionally, the input point data can be passed through to the output as well.

To create an instance of class vtkPointDataToCellData, simply invoke its constructor as follows

```
obj = vtkPointDataToCellData
```

33.161.2 Methods

The class vtkPointDataToCellData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointDataToCellData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointDataToCellData = obj.NewInstance ()`
- `vtkPointDataToCellData = obj.SafeDownCast (vtkObject o)`
- `obj.SetPassPointData (int )` - Control whether the input point data is to be passed to the output. If on, then the input point data is passed through to the output; otherwise, only generated point data is placed into the output.
- `int = obj.GetPassPointData ()` - Control whether the input point data is to be passed to the output. If on, then the input point data is passed through to the output; otherwise, only generated point data is placed into the output.
- `obj.PassPointDataOn ()` - Control whether the input point data is to be passed to the output. If on, then the input point data is passed through to the output; otherwise, only generated point data is placed into the output.
- `obj.PassPointDataOff ()` - Control whether the input point data is to be passed to the output. If on, then the input point data is passed through to the output; otherwise, only generated point data is placed into the output.

33.162 vtkPointSource

33.162.1 Usage

vtkPointSource is a source object that creates a user-specified number of points within a specified radius about a specified center point. By default location of the points is random within the sphere. It is also possible to generate random points only on the surface of the sphere.

To create an instance of class vtkPointSource, simply invoke its constructor as follows

```
obj = vtkPointSource
```

33.162.2 Methods

The class vtkPointSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointSource = obj.NewInstance ()`
- `vtkPointSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPoints (vtkIdType )` - Set the number of points to generate.
- `vtkIdType = obj.GetNumberOfPointsMinValue ()` - Set the number of points to generate.
- `vtkIdType = obj.GetNumberOfPointsMaxValue ()` - Set the number of points to generate.
- `vtkIdType = obj.GetNumberOfPoints ()` - Set the number of points to generate.
- `obj.SetCenter (double , double , double )` - Set the center of the point cloud.
- `obj.SetCenter (double  a[3])` - Set the center of the point cloud.
- `double = obj. GetCenter ()` - Set the center of the point cloud.
- `obj.SetRadius (double )` - Set the radius of the point cloud. If you are generating a Gaussian distribution, then this is the standard deviation for each of x, y, and z.
- `double = obj.GetRadiusMinValue ()` - Set the radius of the point cloud. If you are generating a Gaussian distribution, then this is the standard deviation for each of x, y, and z.
- `double = obj.GetRadiusMaxValue ()` - Set the radius of the point cloud. If you are generating a Gaussian distribution, then this is the standard deviation for each of x, y, and z.
- `double = obj.GetRadius ()` - Set the radius of the point cloud. If you are generating a Gaussian distribution, then this is the standard deviation for each of x, y, and z.
- `obj.SetDistribution (int )` - Specify the distribution to use. The default is a uniform distribution. The shell distribution produces random points on the surface of the sphere, none in the interior.
- `obj.SetDistributionToUniform ()` - Specify the distribution to use. The default is a uniform distribution. The shell distribution produces random points on the surface of the sphere, none in the interior.
- `obj.SetDistributionToShell ()` - Specify the distribution to use. The default is a uniform distribution. The shell distribution produces random points on the surface of the sphere, none in the interior.
- `int = obj.GetDistribution ()` - Specify the distribution to use. The default is a uniform distribution. The shell distribution produces random points on the surface of the sphere, none in the interior.

33.163 vtkPolyDataConnectivityFilter

33.163.1 Usage

vtkPolyDataConnectivityFilter is a filter that extracts cells that share common points and/or satisfy a scalar threshold criterion. (Such a group of cells is called a region.) The filter works in one of six ways: 1) extract the largest connected region in the dataset; 2) extract specified region numbers; 3) extract all regions sharing specified point ids; 4) extract all regions sharing specified cell ids; 5) extract the region closest to the specified point; or 6) extract all regions (used to color regions).

This filter is specialized for polygonal data. This means it runs a bit faster and is easier to construct visualization networks that process polygonal data.

The behavior of vtkPolyDataConnectivityFilter can be modified by turning on the boolean ivar ScalarConnectivity. If this flag is on, the connectivity algorithm is modified so that cells are considered connected only if 1) they are geometrically connected (share a point) and 2) the scalar values of one of the cell's points falls in the scalar range specified. This use of ScalarConnectivity is particularly useful for selecting cells for later processing.

To create an instance of class vtkPolyDataConnectivityFilter, simply invoke its constructor as follows

```
obj = vtkPolyDataConnectivityFilter
```

33.163.2 Methods

The class vtkPolyDataConnectivityFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataConnectivityFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataConnectivityFilter = obj.NewInstance ()`
- `vtkPolyDataConnectivityFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetScalarConnectivity (int )` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `int = obj.GetScalarConnectivity ()` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `obj.ScalarConnectivityOn ()` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `obj.ScalarConnectivityOff ()` - Turn on/off connectivity based on scalar value. If on, cells are connected only if they share points AND one of the cells scalar values falls in the scalar range specified.
- `obj.SetScalarRange (double , double )` - Set the scalar range to use to extract cells based on scalar connectivity.
- `obj.SetScalarRange (double  a[2])` - Set the scalar range to use to extract cells based on scalar connectivity.
- `double = obj. GetScalarRange ()` - Set the scalar range to use to extract cells based on scalar connectivity.
- `obj.SetExtractionMode (int )` - Control the extraction of connected surfaces.
- `int = obj.GetExtractionModeMinValue ()` - Control the extraction of connected surfaces.

- `int = obj.GetExtractionModeMaxValue ()` - Control the extraction of connected surfaces.
- `int = obj.GetExtractionMode ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToPointSeededRegions ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToCellSeededRegions ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToLargestRegion ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToSpecifiedRegions ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToClosestPointRegion ()` - Control the extraction of connected surfaces.
- `obj.SetExtractionModeToAllRegions ()` - Control the extraction of connected surfaces.
- `string = obj.GetExtractionModeAsString ()` - Control the extraction of connected surfaces.
- `obj.InitializeSeedList ()` - Initialize list of point ids/cell ids used to seed regions.
- `obj.AddSeed (int id)` - Add a seed id (point or cell id). Note: ids are 0-offset.
- `obj.DeleteSeed (int id)` - Delete a seed id (point or cell id). Note: ids are 0-offset.
- `obj.InitializeSpecifiedRegionList ()` - Initialize list of region ids to extract.
- `obj.AddSpecifiedRegion (int id)` - Add a region id to extract. Note: ids are 0-offset.
- `obj.DeleteSpecifiedRegion (int id)` - Delete a region id to extract. Note: ids are 0-offset.
- `obj.SetClosestPoint (double , double , double )` - Use to specify x-y-z point coordinates when extracting the region closest to a specified point.
- `obj.SetClosestPoint (double a[3])` - Use to specify x-y-z point coordinates when extracting the region closest to a specified point.
- `double = obj. GetClosestPoint ()` - Use to specify x-y-z point coordinates when extracting the region closest to a specified point.
- `int = obj.GetNumberOfExtractedRegions ()` - Obtain the number of connected regions.
- `obj.SetColorRegions (int )` - Turn on/off the coloring of connected regions.
- `int = obj.GetColorRegions ()` - Turn on/off the coloring of connected regions.
- `obj.ColorRegionsOn ()` - Turn on/off the coloring of connected regions.
- `obj.ColorRegionsOff ()` - Turn on/off the coloring of connected regions.

33.164 vtkPolyDataNormals

33.164.1 Usage

vtkPolyDataNormals is a filter that computes point normals for a polygonal mesh. The filter can reorder polygons to insure consistent orientation across polygon neighbors. Sharp edges can be split and points duplicated with separate normals to give crisp (rendered) surface definition. It is also possible to globally flip the normal orientation.

The algorithm works by determining normals for each polygon and then averaging them at shared points. When sharp edges are present, the edges are split and new points generated to prevent blurry edges (due to Gouraud shading).

To create an instance of class vtkPolyDataNormals, simply invoke its constructor as follows

```
obj = vtkPolyDataNormals
```

33.164.2 Methods

The class vtkPolyDataNormals has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataNormals class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataNormals = obj.NewInstance ()`
- `vtkPolyDataNormals = obj.SafeDownCast (vtkObject o)`
- `obj.SetFeatureAngle (double )` - Specify the angle that defines a sharp edge. If the difference in angle across neighboring polygons is greater than this value, the shared edge is considered "sharp".
- `double = obj.GetFeatureAngleMinValue ()` - Specify the angle that defines a sharp edge. If the difference in angle across neighboring polygons is greater than this value, the shared edge is considered "sharp".
- `double = obj.GetFeatureAngleMaxValue ()` - Specify the angle that defines a sharp edge. If the difference in angle across neighboring polygons is greater than this value, the shared edge is considered "sharp".
- `double = obj.GetFeatureAngle ()` - Specify the angle that defines a sharp edge. If the difference in angle across neighboring polygons is greater than this value, the shared edge is considered "sharp".
- `obj.SetSplitting (int )` - Turn on/off the splitting of sharp edges.
- `int = obj.GetSplitting ()` - Turn on/off the splitting of sharp edges.
- `obj.SplittingOn ()` - Turn on/off the splitting of sharp edges.
- `obj.SplittingOff ()` - Turn on/off the splitting of sharp edges.
- `obj.SetConsistency (int )` - Turn on/off the enforcement of consistent polygon ordering.
- `int = obj.GetConsistency ()` - Turn on/off the enforcement of consistent polygon ordering.
- `obj.ConsistencyOn ()` - Turn on/off the enforcement of consistent polygon ordering.
- `obj.ConsistencyOff ()` - Turn on/off the enforcement of consistent polygon ordering.
- `obj.SetAutoOrientNormals (int )` - Turn on/off the automatic determination of correct normal orientation. NOTE: This assumes a completely closed surface (i.e. no boundary edges) and no non-manifold edges. If these constraints do not hold, all bets are off. This option adds some computational complexity, and is useful if you don't want to have to inspect the rendered image to determine whether to turn on the FlipNormals flag. However, this flag can work with the FlipNormals flag, and if both are set, all the normals in the output will point "inward".
- `int = obj.GetAutoOrientNormals ()` - Turn on/off the automatic determination of correct normal orientation. NOTE: This assumes a completely closed surface (i.e. no boundary edges) and no non-manifold edges. If these constraints do not hold, all bets are off. This option adds some computational complexity, and is useful if you don't want to have to inspect the rendered image to determine whether to turn on the FlipNormals flag. However, this flag can work with the FlipNormals flag, and if both are set, all the normals in the output will point "inward".

- `obj.AutoOrientNormalsOn ()` - Turn on/off the automatic determination of correct normal orientation. NOTE: This assumes a completely closed surface (i.e. no boundary edges) and no non-manifold edges. If these constraints do not hold, all bets are off. This option adds some computational complexity, and is useful if you don't want to have to inspect the rendered image to determine whether to turn on the FlipNormals flag. However, this flag can work with the FlipNormals flag, and if both are set, all the normals in the output will point "inward".

- `obj.AutoOrientNormalsOff ()` - Turn on/off the automatic determination of correct normal orientation. NOTE: This assumes a completely closed surface (i.e. no boundary edges) and no non-manifold edges. If these constraints do not hold, all bets are off. This option adds some computational complexity, and is useful if you don't want to have to inspect the rendered image to determine whether to turn on the FlipNormals flag. However, this flag can work with the FlipNormals flag, and if both are set, all the normals in the output will point "inward".

- `obj.SetComputePointNormals (int )` - Turn on/off the computation of point normals.

- `int = obj.GetComputePointNormals ()` - Turn on/off the computation of point normals.

- `obj.ComputePointNormalsOn ()` - Turn on/off the computation of point normals.

- `obj.ComputePointNormalsOff ()` - Turn on/off the computation of point normals.

- `obj.SetComputeCellNormals (int )` - Turn on/off the computation of cell normals.

- `int = obj.GetComputeCellNormals ()` - Turn on/off the computation of cell normals.

- `obj.ComputeCellNormalsOn ()` - Turn on/off the computation of cell normals.

- `obj.ComputeCellNormalsOff ()` - Turn on/off the computation of cell normals.

- `obj.SetFlipNormals (int )` - Turn on/off the global flipping of normal orientation. Flipping reverves the meaning of front and back for Frontface and Backface culling in vtkProperty. Flipping modifies both the normal direction and the order of a cell's points.

- `int = obj.GetFlipNormals ()` - Turn on/off the global flipping of normal orientation. Flipping reverves the meaning of front and back for Frontface and Backface culling in vtkProperty. Flipping modifies both the normal direction and the order of a cell's points.

- `obj.FlipNormalsOn ()` - Turn on/off the global flipping of normal orientation. Flipping reverves the meaning of front and back for Frontface and Backface culling in vtkProperty. Flipping modifies both the normal direction and the order of a cell's points.

- `obj.FlipNormalsOff ()` - Turn on/off the global flipping of normal orientation. Flipping reverves the meaning of front and back for Frontface and Backface culling in vtkProperty. Flipping modifies both the normal direction and the order of a cell's points.

- `obj.SetNonManifoldTraversal (int )` - Turn on/off traversal across non-manifold edges. This will prevent problems where the consistency of polygonal ordering is corrupted due to topological loops.

- `int = obj.GetNonManifoldTraversal ()` - Turn on/off traversal across non-manifold edges. This will prevent problems where the consistency of polygonal ordering is corrupted due to topological loops.

- `obj.NonManifoldTraversalOn ()` - Turn on/off traversal across non-manifold edges. This will prevent problems where the consistency of polygonal ordering is corrupted due to topological loops.

- `obj.NonManifoldTraversalOff ()` - Turn on/off traversal across non-manifold edges. This will prevent problems where the consistency of polygonal ordering is corrupted due to topological loops.

33.165 vtkPolyDataPointSampler

33.165.1 Usage

vtkPolyDataPointSampler generates points from input vtkPolyData. The points are placed approximately a specified distance apart.

This filter functions as follows. First, it regurgitates all input points, then samples all lines, plus edges associated with the input polygons and triangle strips to produce edge points. Finally, the interiors of polygons and triangle strips are subsampled to produce points. All of these functiona can be enabled or disabled separately. Note that this algorithm only approximately generates points the specified distance apart. Generally the point density is finer than requested.

To create an instance of class vtkPolyDataPointSampler, simply invoke its constructor as follows

```
obj = vtkPolyDataPointSampler
```

33.165.2 Methods

The class vtkPolyDataPointSampler has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataPointSampler class.

- `string = obj.GetClassName ()` - Standard macros for type information and printing.
- `int = obj.IsA (string name)` - Standard macros for type information and printing.
- `vtkPolyDataPointSampler = obj.NewInstance ()` - Standard macros for type information and printing.
- `vtkPolyDataPointSampler = obj.SafeDownCast (vtkObject o)` - Standard macros for type information and printing.
- `obj.SetDistance (double )` - Set/Get the approximate distance between points. This is an absolute distance measure. The default is 0.01.
- `double = obj.GetDistanceMinValue ()` - Set/Get the approximate distance between points. This is an absolute distance measure. The default is 0.01.
- `double = obj.GetDistanceMaxValue ()` - Set/Get the approximate distance between points. This is an absolute distance measure. The default is 0.01.
- `double = obj.GetDistance ()` - Set/Get the approximate distance between points. This is an absolute distance measure. The default is 0.01.
- `int = obj.GetGenerateVertexPoints ()` - Specify/retrieve a boolean flag indicating whether cell vertex points should be output.
- `obj.SetGenerateVertexPoints (int )` - Specify/retrieve a boolean flag indicating whether cell vertex points should be output.
- `obj.GenerateVertexPointsOn ()` - Specify/retrieve a boolean flag indicating whether cell vertex points should be output.
- `obj.GenerateVertexPointsOff ()` - Specify/retrieve a boolean flag indicating whether cell vertex points should be output.
- `int = obj.GetGenerateEdgePoints ()` - Specify/retrieve a boolean flag indicating whether cell edges should be sampled to produce output points. The default is true.

- `obj.SetGenerateEdgePoints (int )` - Specify/retrieve a boolean flag indicating whether cell edges should be sampled to produce output points. The default is true.
- `obj.GenerateEdgePointsOn ()` - Specify/retrieve a boolean flag indicating whether cell edges should be sampled to produce output points. The default is true.
- `obj.GenerateEdgePointsOff ()` - Specify/retrieve a boolean flag indicating whether cell edges should be sampled to produce output points. The default is true.
- `int = obj.GetGenerateInteriorPoints ()` - Specify/retrieve a boolean flag indicating whether cell interiors should be sampled to produce output points. The default is true.
- `obj.SetGenerateInteriorPoints (int )` - Specify/retrieve a boolean flag indicating whether cell interiors should be sampled to produce output points. The default is true.
- `obj.GenerateInteriorPointsOn ()` - Specify/retrieve a boolean flag indicating whether cell interiors should be sampled to produce output points. The default is true.
- `obj.GenerateInteriorPointsOff ()` - Specify/retrieve a boolean flag indicating whether cell interiors should be sampled to produce output points. The default is true.
- `int = obj.GetGenerateVertices ()` - Specify/retrieve a boolean flag indicating whether cell vertices should be generated. Cell vertices are useful if you actually want to display the points (that is, for each point generated, a vertex is generated). Recall that VTK only renders vertices and not points. The default is true.
- `obj.SetGenerateVertices (int )` - Specify/retrieve a boolean flag indicating whether cell vertices should be generated. Cell vertices are useful if you actually want to display the points (that is, for each point generated, a vertex is generated). Recall that VTK only renders vertices and not points. The default is true.
- `obj.GenerateVerticesOn ()` - Specify/retrieve a boolean flag indicating whether cell vertices should be generated. Cell vertices are useful if you actually want to display the points (that is, for each point generated, a vertex is generated). Recall that VTK only renders vertices and not points. The default is true.
- `obj.GenerateVerticesOff ()` - Specify/retrieve a boolean flag indicating whether cell vertices should be generated. Cell vertices are useful if you actually want to display the points (that is, for each point generated, a vertex is generated). Recall that VTK only renders vertices and not points. The default is true.

33.166 vtkPolyDataStreamer

33.166.1 Usage

vtkPolyDataStreamer initiates streaming by requesting pieces from its single input it appends these pieces it to the requested output. Note that since vtkPolyDataStreamer uses an append filter, all the polygons generated have to be kept in memory before rendering. If these do not fit in the memory, it is possible to make the vtkPolyDataMapper stream. Since the mapper will render each piece separately, all the polygons do not have to stored in memory. .SECTION Note The output may be slightly different if the pipeline does not handle ghost cells properly (i.e. you might see seames between the pieces).

To create an instance of class vtkPolyDataStreamer, simply invoke its constructor as follows

```
obj = vtkPolyDataStreamer
```

33.166.2 Methods

The class vtkPolyDataStreamer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataStreamer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataStreamer = obj.NewInstance ()`
- `vtkPolyDataStreamer = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfStreamDivisions (int num)` - Set the number of pieces to divide the problem into.
- `int = obj.GetNumberOfStreamDivisions ()` - Set the number of pieces to divide the problem into.
- `obj.SetColorByPiece (int )` - By default, this option is off. When it is on, cell scalars are generated based on which piece they are in.
- `int = obj.GetColorByPiece ()` - By default, this option is off. When it is on, cell scalars are generated based on which piece they are in.
- `obj.ColorByPieceOn ()` - By default, this option is off. When it is on, cell scalars are generated based on which piece they are in.
- `obj.ColorByPieceOff ()` - By default, this option is off. When it is on, cell scalars are generated based on which piece they are in.

33.167 vtkProbeFilter

33.167.1 Usage

vtkProbeFilter is a filter that computes point attributes (e.g., scalars, vectors, etc.) at specified point positions. The filter has two inputs: the Input and Source. The Input geometric structure is passed through the filter. The point attributes are computed at the Input point positions by interpolating into the source data. For example, we can compute data values on a plane (plane specified as Input) from a volume (Source). The cell data of the source data is copied to the output based on in which source cell each input point is. If an array of the same name exists both in source's point and cell data, only the one from the point data is probed.

This filter can be used to resample data, or convert one dataset form into another. For example, an unstructured grid (vtkUnstructuredGrid) can be probed with a volume (three-dimensional vtkImageData), and then volume rendering techniques can be used to visualize the results. Another example: a line or curve can be used to probe data to produce x-y plots along that line or curve.

To create an instance of class vtkProbeFilter, simply invoke its constructor as follows

```
obj = vtkProbeFilter
```

33.167.2 Methods

The class vtkProbeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProbeFilter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkProbeFilter = obj.NewInstance ()`
- `vtkProbeFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetSource (vtkDataObject source)` - Specify the point locations used to probe input. Any geometry can be used. Old style. Do not use unless for backwards compatibility.
- `vtkDataObject = obj.GetSource ()` - Specify the point locations used to probe input. Any geometry can be used. Old style. Do not use unless for backwards compatibility.
- `obj.SetSourceConnection (vtkAlgorithmOutput algOutput)` - Specify the point locations used to probe input. Any geometry can be used. New style. Equivalent to SetInputConnection(1, algOutput).
- `obj.SetSpatialMatch (int )` - This flag is used only when a piece is requested to update. By default the flag is off. Because no spatial correspondence between input pieces and source pieces is known, all of the source has to be requested no matter what piece of the output is requested. When there is a spatial correspondence, the user/application can set this flag. This hint allows the breakup of the probe operation to be much more efficient. When piece m of n is requested for update by the user, then only n of m needs to be requested of the source.
- `int = obj.GetSpatialMatch ()` - This flag is used only when a piece is requested to update. By default the flag is off. Because no spatial correspondence between input pieces and source pieces is known, all of the source has to be requested no matter what piece of the output is requested. When there is a spatial correspondence, the user/application can set this flag. This hint allows the breakup of the probe operation to be much more efficient. When piece m of n is requested for update by the user, then only n of m needs to be requested of the source.
- `obj.SpatialMatchOn ()` - This flag is used only when a piece is requested to update. By default the flag is off. Because no spatial correspondence between input pieces and source pieces is known, all of the source has to be requested no matter what piece of the output is requested. When there is a spatial correspondence, the user/application can set this flag. This hint allows the breakup of the probe operation to be much more efficient. When piece m of n is requested for update by the user, then only n of m needs to be requested of the source.
- `obj.SpatialMatchOff ()` - This flag is used only when a piece is requested to update. By default the flag is off. Because no spatial correspondence between input pieces and source pieces is known, all of the source has to be requested no matter what piece of the output is requested. When there is a spatial correspondence, the user/application can set this flag. This hint allows the breakup of the probe operation to be much more efficient. When piece m of n is requested for update by the user, then only n of m needs to be requested of the source.
- `vtkIdTypeArray = obj.GetValidPoints ()` - Get the list of point ids in the output that contain attribute data interpolated from the source.
- `obj.SetValidPointMaskArrayName (string )` - Returns the name of the char array added to the output with values 1 for valid points and 0 for invalid points. Set to "vtkValidPointMask" by default.
- `string = obj.GetValidPointMaskArrayName ()` - Returns the name of the char array added to the output with values 1 for valid points and 0 for invalid points. Set to "vtkValidPointMask" by default.

33.168 vtkProbeSelectedLocations

33.168.1 Usage

vtkProbeSelectedLocations is similar to vtkExtractSelectedLocations except that it interpolates the point attributes at the probe location. This is equivalent to the vtkProbeFilter except that the probe locations

are provided by a vtkSelection. The FieldType of the input vtkSelection is immaterial and is ignored. The ContentType of the input vtkSelection must be vtkSelection::LOCATIONS.

To create an instance of class vtkProbeSelectedLocations, simply invoke its constructor as follows

```
obj = vtkProbeSelectedLocations
```

33.168.2 Methods

The class vtkProbeSelectedLocations has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProbeSelectedLocations class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProbeSelectedLocations = obj.NewInstance ()`
- `vtkProbeSelectedLocations = obj.SafeDownCast (vtkObject o)`

33.169 vtkProgrammableAttributeDataFilter

33.169.1 Usage

vtkProgrammableAttributeDataFilter is a filter that allows you to write a custom procedure to manipulate attribute data - either point or cell data. For example, you could generate scalars based on a complex formula; convert vectors to normals; compute scalar values as a function of vectors, texture coords, and/or any other point data attribute; and so on. The filter takes multiple inputs (input plus an auxiliary input list), so you can write procedures that combine several dataset point attributes. Note that the output of the filter is the same type (topology/geometry) as the input.

The filter works as follows. It operates like any other filter (i.e., checking and managing modified and execution times, processing Update() and Execute() methods, managing release of data, etc.), but the difference is that the Execute() method simply invokes a user-specified function with an optional (void *) argument (typically the "this" pointer in C++). It is also possible to specify a function to delete the argument via ExecuteMethodArgDelete().

To use the filter, you write a procedure to process the input datasets, process the data, and generate output data. Typically, this means grabbing the input point or cell data (using GetInput() and maybe GetInputList()), operating on it (creating new point and cell attributes such as scalars, vectors, etc.), and then setting the point and/or cell attributes in the output dataset (you'll need to use GetOutput() to access the output). (Note: besides C++, it is possible to do the same thing in Tcl, Java, or other languages that wrap the C++ core.) Remember, proper filter protocol requires that you don't modify the input data - you create new output data from the input.

To create an instance of class vtkProgrammableAttributeDataFilter, simply invoke its constructor as follows

```
obj = vtkProgrammableAttributeDataFilter
```

33.169.2 Methods

The class vtkProgrammableAttributeDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProgrammableAttributeDataFilter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkProgrammableAttributeDataFilter = obj.NewInstance ()`
- `vtkProgrammableAttributeDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.AddInput (vtkDataSet in)` - Add a dataset to the list of data to process.
- `obj.RemoveInput (vtkDataSet in)` - Remove a dataset from the list of data to process.
- `vtkDataSetCollection = obj.GetInputList ()` - Return the list of inputs.

33.170 vtkProgrammableDataObjectSource

33.170.1 Usage

vtkProgrammableDataObjectSource is a source object that is programmable by the user. The output of the filter is a data object (vtkDataObject) which represents data via an instance of field data. To use this object, you must specify a function that creates the output.

Example use of this filter includes reading tabular data and encoding it as vtkFieldData. You can then use filters like vtkDataObjectToDataSetFilter to convert the data object to a dataset and then visualize it. Another important use of this class is that it allows users of interpreters (e.g., Tcl or Java) the ability to write source objects without having to recompile C++ code or generate new libraries.

To create an instance of class vtkProgrammableDataObjectSource, simply invoke its constructor as follows

```
obj = vtkProgrammableDataObjectSource
```

33.170.2 Methods

The class vtkProgrammableDataObjectSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProgrammableDataObjectSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProgrammableDataObjectSource = obj.NewInstance ()`
- `vtkProgrammableDataObjectSource = obj.SafeDownCast (vtkObject o)`

33.171 vtkProgrammableFilter

33.171.1 Usage

vtkProgrammableFilter is a filter that can be programmed by the user. To use the filter you define a function that retrieves input of the correct type, creates data, and then manipulates the output of the filter. Using this filter avoids the need for subclassing - and the function can be defined in an interpreter wrapper language such as Tcl or Java.

The trickiest part of using this filter is that the input and output methods are unusual and cannot be compile-time type checked. Instead, as a user of this filter it is your responsibility to set and get the correct input and output types.

To create an instance of class vtkProgrammableFilter, simply invoke its constructor as follows

```
obj = vtkProgrammableFilter
```

33.171.2 Methods

The class vtkProgrammableFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProgrammableFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProgrammableFilter = obj.NewInstance ()`
- `vtkProgrammableFilter = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetPolyDataInput ()` - Get the input as a concrete type. This method is typically used by the writer of the filter function to get the input as a particular type (i.e., it essentially does type casting). It is the users responsibility to know the correct type of the input data.
- `vtkStructuredPoints = obj.GetStructuredPointsInput ()` - Get the input as a concrete type.
- `vtkStructuredGrid = obj.GetStructuredGridInput ()` - Get the input as a concrete type.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridInput ()` - Get the input as a concrete type.
- `vtkRectilinearGrid = obj.GetRectilinearGridInput ()` - Get the input as a concrete type.
- `vtkGraph = obj.GetGraphInput ()` - Get the input as a concrete type.
- `vtkTable = obj.GetTableInput ()` - Get the input as a concrete type.
- `obj.SetCopyArrays (bool )` - When CopyArrays is true, all arrays are copied to the output iff input and output are of the same type. False by default.
- `bool = obj.GetCopyArrays ()` - When CopyArrays is true, all arrays are copied to the output iff input and output are of the same type. False by default.
- `obj.CopyArraysOn ()` - When CopyArrays is true, all arrays are copied to the output iff input and output are of the same type. False by default.
- `obj.CopyArraysOff ()` - When CopyArrays is true, all arrays are copied to the output iff input and output are of the same type. False by default.

33.172 vtkProgrammableGlyphFilter

33.172.1 Usage

vtkProgrammableGlyphFilter is a filter that allows you to place a glyph at each input point in the dataset. In addition, the filter is programmable which means the user has control over the generation of the glyph. The glyphs can be controlled via the point data attributes (e.g., scalars, vectors, etc.) or any other information in the input dataset.

This is the way the filter works. You must define an input dataset which at a minimum contains points with associated attribute values. Also, the Source instance variable must be set which is of type vtkPolyData. Then, for each point in the input, the PointId is set to the current point id, and a user-defined function is called (i.e., GlyphMethod). In this method you can manipulate the Source data (including changing to a different Source object). After the GlyphMethod is called, vtkProgrammableGlyphFilter will invoke an Update() on its Source object, and then copy its data to the output of the vtkProgrammableGlyphFilter. Therefore the output of this filter is of type vtkPolyData.

Another option to this filter is the way you color the glyphs. You can use the scalar data from the input or the source. The instance variable ColorMode controls this behavior.

To create an instance of class vtkProgrammableGlyphFilter, simply invoke its constructor as follows

```
obj = vtkProgrammableGlyphFilter
```

33.172.2 Methods

The class vtkProgrammableGlyphFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProgrammableGlyphFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProgrammableGlyphFilter = obj.NewInstance ()`
- `vtkProgrammableGlyphFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetSource (vtkPolyData source)` - Set/Get the source to use for this glyph. Note: you can change the source during execution of this filter.
- `vtkPolyData = obj.GetSource ()` - Set/Get the source to use for this glyph. Note: you can change the source during execution of this filter.
- `vtkIdType = obj.GetPointId ()` - Get the current point id during processing. Value only valid during the Execute() method of this filter. (Meant to be called by the GlyphMethod().)
- `double = obj. GetPoint ()` - Get the current point coordinates during processing. Value only valid during the Execute() method of this filter. (Meant to be called by the GlyphMethod().)
- `vtkPointData = obj.GetPointData ()` - Get the set of point data attributes for the input. A convenience to the programmer to be used in the GlyphMethod(). Only valid during the Execute() method of this filter.
- `obj.SetColorMode (int )` - Either color by the input or source scalar data.
- `int = obj.GetColorMode ()` - Either color by the input or source scalar data.
- `obj.SetColorModeToColorByInput ()` - Either color by the input or source scalar data.
- `obj.SetColorModeToColorBySource ()` - Either color by the input or source scalar data.
- `string = obj.GetColorModeAsString ()` - Either color by the input or source scalar data.

33.173 vtkProgrammableSource

33.173.1 Usage

vtkProgrammableSource is a source object that is programmable by the user. To use this object, you must specify a function that creates the output. It is possible to generate an output dataset of any (concrete) type; it is up to the function to properly initialize and define the output. Typically, you use one of the methods to get a concrete output type (e.g., GetPolyDataOutput() or GetStructuredPointsOutput()), and then manipulate the output in the user-specified function.

Example use of this include writing a function to read a data file or interface to another system. (You might want to do this in favor of deriving a new class.) Another important use of this class is that it allows users of interpreters (e.g., Tcl or Java) the ability to write source objects without having to recompile C++ code or generate new libraries.

To create an instance of class vtkProgrammableSource, simply invoke its constructor as follows

```
obj = vtkProgrammableSource
```

33.173.2 Methods

The class vtkProgrammableSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProgrammableSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProgrammableSource = obj.NewInstance ()`
- `vtkProgrammableSource = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as a concrete type. This method is typically used by the writer of the source function to get the output as a particular type (i.e., it essentially does type casting). It is the users responsibility to know the correct type of the output data.
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output as a concrete type.
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as a concrete type.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as a concrete type.
- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output as a concrete type.

33.174 vtkProjectedTexture

33.174.1 Usage

vtkProjectedTexture assigns texture coordinates to a dataset as if the texture was projected from a slide projected located somewhere in the scene. Methods are provided to position the projector and aim it at a location, to set the width of the projector's frustum, and to set the range of texture coordinates assigned to the dataset.

Objects in the scene that appear behind the projector are also assigned texture coordinates; the projected image is left-right and top-bottom flipped, much as a lens' focus flips the rays of light that pass through it. A warning is issued if a point in the dataset falls at the focus of the projector.

To create an instance of class vtkProjectedTexture, simply invoke its constructor as follows

```
obj = vtkProjectedTexture
```

33.174.2 Methods

The class vtkProjectedTexture has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProjectedTexture class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProjectedTexture = obj.NewInstance ()`
- `vtkProjectedTexture = obj.SafeDownCast (vtkObject o)`
- `obj.SetPosition (double , double , double )` - Set/Get the position of the focus of the projector.

- `obj.SetPosition (double  a[3])` - Set/Get the position of the focus of the projector.
- `double = obj. GetPosition ()` - Set/Get the position of the focus of the projector.
- `obj.SetFocalPoint (double focalPoint[3])` - Set/Get the focal point of the projector (a point that lies along the center axis of the projector's frustum).
- `obj.SetFocalPoint (double x, double y, double z)` - Set/Get the focal point of the projector (a point that lies along the center axis of the projector's frustum).
- `double = obj. GetFocalPoint ()` - Set/Get the focal point of the projector (a point that lies along the center axis of the projector's frustum).
- `obj.SetCameraMode (int )` - Set/Get the camera mode of the projection – pinhole projection or two mirror projection.
- `int = obj.GetCameraMode ()` - Set/Get the camera mode of the projection – pinhole projection or two mirror projection.
- `obj.SetCameraModeToPinhole ()` - Set/Get the camera mode of the projection – pinhole projection or two mirror projection.
- `obj.SetCameraModeToTwoMirror ()` - Set/Get the mirror separation for the two mirror system.
- `obj.SetMirrorSeparation (double )` - Set/Get the mirror separation for the two mirror system.
- `double = obj.GetMirrorSeparation ()` - Set/Get the mirror separation for the two mirror system.
- `double = obj. GetOrientation ()` - Get the normalized orientation vector of the projector.
- `obj.SetUp (double , double , double )`
- `obj.SetUp (double  a[3])`
- `double = obj. GetUp ()`
- `obj.SetAspectRatio (double , double , double )`
- `obj.SetAspectRatio (double  a[3])`
- `double = obj. GetAspectRatio ()`
- `obj.SetSRange (double , double )` - Specify s-coordinate range for texture s-t coordinate pair.
- `obj.SetSRange (double  a[2])` - Specify s-coordinate range for texture s-t coordinate pair.
- `double = obj. GetSRange ()` - Specify s-coordinate range for texture s-t coordinate pair.
- `obj.SetTRange (double , double )` - Specify t-coordinate range for texture s-t coordinate pair.
- `obj.SetTRange (double  a[2])` - Specify t-coordinate range for texture s-t coordinate pair.
- `double = obj. GetTRange ()` - Specify t-coordinate range for texture s-t coordinate pair.

33.175 vtkQuadraturePointInterpolator

33.175.1 Usage

Interpolates each scalar/vector field in a vtkUnstrcturedGrid on its input to a specific set of quadrature points. The set of quadrature points is specified per array via a dictionary (ie an instance of vtkInformationQuadratureSchemeDefinitionVectorKey). contained in the array. The interpolated fields are placed in FieldData along with a set of per cell indexes, that allow random access to a given cells quadrature points.

To create an instance of class vtkQuadraturePointInterpolator, simply invoke its constructor as follows

```
obj = vtkQuadraturePointInterpolator
```

33.175.2 Methods

The class vtkQuadraturePointInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraturePointInterpolator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraturePointInterpolator = obj.NewInstance ()`
- `vtkQuadraturePointInterpolator = obj.SafeDownCast (vtkObject o)`

33.176 vtkQuadraturePointsGenerator

33.176.1 Usage

Create a vtkPolyData on its output containing the vertices for the quadrature points for one of the vtkDataArrays present on its input vtkUnstructuredGrid. If the input data set has has FieldData generated by vtkQuadraturePointInterpolator then this will be set as point data. Note: Point sets are generated per field array. This is because each field array may contain its own dictionary.

.SECTION See also vtkQuadraturePointInterpolator, vtkQuadratureSchemeDefinition, vtkInformationQuadratureSchemeDefinitionVectorKey

To create an instance of class vtkQuadraturePointsGenerator, simply invoke its constructor as follows

```
obj = vtkQuadraturePointsGenerator
```

33.176.2 Methods

The class vtkQuadraturePointsGenerator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraturePointsGenerator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraturePointsGenerator = obj.NewInstance ()`
- `vtkQuadraturePointsGenerator = obj.SafeDownCast (vtkObject o)`

33.177 vtkQuadratureSchemeDictionaryGenerator

33.177.1 Usage

Given an unstructured grid on its input this filter generates for each data array in point data dictionary (ie an instance of vtkInformationQuadratureSchemeDefinitionVectorKey). This filter has been introduced to facilitate testing of the vtkQuadrature* classes as these cannot operate with the dictionary. This class is for testing and should not be used for application development.

.SECTION See also vtkQuadraturePointInterpolator, vtkQuadraturePointsGenerator, vtkQuadratureSchemeDefinition

To create an instance of class vtkQuadratureSchemeDictionaryGenerator, simply invoke its constructor as follows

```
obj = vtkQuadratureSchemeDictionaryGenerator
```

33.177.2 Methods

The class vtkQuadratureSchemeDictionaryGenerator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadratureSchemeDictionaryGenerator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadratureSchemeDictionaryGenerator = obj.NewInstance ()`
- `vtkQuadratureSchemeDictionaryGenerator = obj.SafeDownCast (vtkObject o)`

33.178 vtkQuadricClustering

33.178.1 Usage

vtkQuadricClustering is a filter to reduce the number of triangles in a triangle mesh, forming a good approximation to the original geometry. The input to vtkQuadricClustering is a vtkPolyData object, and all types of polygonal data are handled.

The algorithm used is the one described by Peter Lindstrom in his Siggraph 2000 paper, "Out-of-Core Simplification of Large Polygonal Models." The general approach of the algorithm is to cluster vertices in a uniform binning of space, accumulating the quadric of each triangle (pushed out to the triangles vertices) within each bin, and then determining an optimal position for a single vertex in a bin by using the accumulated quadric. In more detail, the algorithm first gets the bounds of the input poly data. It then breaks this bounding volume into a user-specified number of spatial bins. It then reads each triangle from the input and hashes its vertices into these bins. (If this is the first time a bin has been visited, initialize its quadric to the 0 matrix.) The algorithm computes the error quadric for this triangle and adds it to the existing quadric of the bin in which each vertex is contained. Then, if 2 or more vertices of the triangle fall in the same bin, the triangle is dicarded. If the triangle is not discarded, it adds the triangle to the list of output triangles as a list of vertex identifiers. (There is one vertex id per bin.) After all the triangles have been read, the representative vertex for each bin is computed (an optimal location is found) using the quadric for that bin. This determines the spatial location of the vertices of each of the triangles in the output.

To use this filter, specify the divisions defining the spatial subdivision in the x, y, and z directions. You must also specify an input vtkPolyData. Then choose to either 1) use the original points that minimize the quadric error to produce the output triangles or 2) compute an optimal position in each bin to produce the output triangles (recommended and default behavior).

This filter can take multiple inputs. To do this, the user must explicity call StartAppend, Append (once for each input), and EndAppend. StartAppend sets up the data structure to hold the quadric matrices. Append processes each triangle in the input poly data it was called on, hashes its vertices to the appropriate bins, determines whether to keep this triangle, and updates the appropriate quadric matrices. EndAppend determines the spatial location of each of the representative vertices for the visited bins. While this approach does not fit into the visualization architecture and requires manual control, it has the advantage that extremely large data can be processed in pieces and appended to the filter piece-by-piece.

To create an instance of class vtkQuadricClustering, simply invoke its constructor as follows

```
obj = vtkQuadricClustering
```

33.178.2 Methods

The class vtkQuadricClustering has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadricClustering class.

- `string = obj.GetClassName ()` - Standard instantition, type and print methods.
- `int = obj.IsA (string name)` - Standard instantition, type and print methods.
- `vtkQuadricClustering = obj.NewInstance ()` - Standard instantition, type and print methods.
- `vtkQuadricClustering = obj.SafeDownCast (vtkObject o)` - Standard instantition, type and print methods.
- `obj.SetNumberOfXDivisions (int num)` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `obj.SetNumberOfYDivisions (int num)` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `obj.SetNumberOfZDivisions (int num)` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `int = obj.GetNumberOfXDivisions ()` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `int = obj.GetNumberOfYDivisions ()` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `int = obj.GetNumberOfZDivisions ()` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `obj.SetNumberOfDivisions (int div[3])` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `obj.SetNumberOfDivisions (int div0, int div1, int div2)` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `int = obj.GetNumberOfDivisions ()` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.
- `obj.GetNumberOfDivisions (int div[3])` - Set/Get the number of divisions along each axis for the spatial bins. The number of spatial bins is NumberOfXDivisions*NumberOfYDivisions* NumberOfZDivisions. The filter may choose to ignore large numbers of divisions if the input has few points and AutoAdjustNumberOfDivisions is enabled.

- `obj.SetAutoAdjustNumberOfDivisions (int )` - Enable automatic adjustment of number of divisions. If off, the number of divisions specified by the user is always used (as long as it is valid). The default is On

- `int = obj.GetAutoAdjustNumberOfDivisions ()` - Enable automatic adjustment of number of divisions. If off, the number of divisions specified by the user is always used (as long as it is valid). The default is On

- `obj.AutoAdjustNumberOfDivisionsOn ()` - Enable automatic adjustment of number of divisions. If off, the number of divisions specified by the user is always used (as long as it is valid). The default is On

- `obj.AutoAdjustNumberOfDivisionsOff ()` - Enable automatic adjustment of number of divisions. If off, the number of divisions specified by the user is always used (as long as it is valid). The default is On

- `obj.SetDivisionOrigin (double x, double y, double z)` - This is an alternative way to set up the bins. If you are trying to match boundaries between pieces, then you should use these methods rather than SetNumberOfDivisions. To use these methods, specify the origin and spacing of the spatial binning.

- `obj.SetDivisionOrigin (double o[3])` - This is an alternative way to set up the bins. If you are trying to match boundaries between pieces, then you should use these methods rather than SetNumberOfDivisions. To use these methods, specify the origin and spacing of the spatial binning.

- `double = obj. GetDivisionOrigin ()` - This is an alternative way to set up the bins. If you are trying to match boundaries between pieces, then you should use these methods rather than SetNumberOfDivisions. To use these methods, specify the origin and spacing of the spatial binning.

- `obj.SetDivisionSpacing (double x, double y, double z)` - This is an alternative way to set up the bins. If you are trying to match boundaries between pieces, then you should use these methods rather than SetNumberOfDivisions. To use these methods, specify the origin and spacing of the spatial binning.

- `obj.SetDivisionSpacing (double s[3])` - This is an alternative way to set up the bins. If you are trying to match boundaries between pieces, then you should use these methods rather than SetNumberOfDivisions. To use these methods, specify the origin and spacing of the spatial binning.

- `double = obj. GetDivisionSpacing ()` - This is an alternative way to set up the bins. If you are trying to match boundaries between pieces, then you should use these methods rather than SetNumberOfDivisions. To use these methods, specify the origin and spacing of the spatial binning.

- `obj.SetUseInputPoints (int )` - Normally the point that minimizes the quadric error function is used as the output of the bin. When this flag is on, the bin point is forced to be one of the points from the input (the one with the smallest error). This option does not work (i.e., input points cannot be used) when the append methods (StartAppend(), Append(), EndAppend()) are being called directly.

- `int = obj.GetUseInputPoints ()` - Normally the point that minimizes the quadric error function is used as the output of the bin. When this flag is on, the bin point is forced to be one of the points from the input (the one with the smallest error). This option does not work (i.e., input points cannot be used) when the append methods (StartAppend(), Append(), EndAppend()) are being called directly.

- `obj.UseInputPointsOn ()` - Normally the point that minimizes the quadric error function is used as the output of the bin. When this flag is on, the bin point is forced to be one of the points from the input (the one with the smallest error). This option does not work (i.e., input points cannot be used) when the append methods (StartAppend(), Append(), EndAppend()) are being called directly.

- `obj.UseInputPointsOff ()` - Normally the point that minimizes the quadric error function is used as the output of the bin. When this flag is on, the bin point is forced to be one of the points from the input (the one with the smallest error). This option does not work (i.e., input points cannot be used) when the append methods (StartAppend(), Append(), EndAppend()) are being called directly.

- `obj.SetUseFeatureEdges (int )` - By default, this flag is off. When "UseFeatureEdges" is on, then quadrics are computed for boundary edges/feature edges. They influence the quadrics (position of points), but not the mesh. Which features to use can be controlled by the filter "FeatureEdges".

- `int = obj.GetUseFeatureEdges ()` - By default, this flag is off. When "UseFeatureEdges" is on, then quadrics are computed for boundary edges/feature edges. They influence the quadrics (position of points), but not the mesh. Which features to use can be controlled by the filter "FeatureEdges".

- `obj.UseFeatureEdgesOn ()` - By default, this flag is off. When "UseFeatureEdges" is on, then quadrics are computed for boundary edges/feature edges. They influence the quadrics (position of points), but not the mesh. Which features to use can be controlled by the filter "FeatureEdges".

- `obj.UseFeatureEdgesOff ()` - By default, this flag is off. When "UseFeatureEdges" is on, then quadrics are computed for boundary edges/feature edges. They influence the quadrics (position of points), but not the mesh. Which features to use can be controlled by the filter "FeatureEdges".

- `vtkFeatureEdges = obj.GetFeatureEdges ()` - By default, this flag is off. It only has an effect when "UseFeatureEdges" is also on. When "UseFeaturePoints" is on, then quadrics are computed for boundary / feature points used in the boundary / feature edges. They influence the quadrics (position of points), but not the mesh.

- `obj.SetUseFeaturePoints (int )` - By default, this flag is off. It only has an effect when "UseFeatureEdges" is also on. When "UseFeaturePoints" is on, then quadrics are computed for boundary / feature points used in the boundary / feature edges. They influence the quadrics (position of points), but not the mesh.

- `int = obj.GetUseFeaturePoints ()` - By default, this flag is off. It only has an effect when "UseFeatureEdges" is also on. When "UseFeaturePoints" is on, then quadrics are computed for boundary / feature points used in the boundary / feature edges. They influence the quadrics (position of points), but not the mesh.

- `obj.UseFeaturePointsOn ()` - By default, this flag is off. It only has an effect when "UseFeatureEdges" is also on. When "UseFeaturePoints" is on, then quadrics are computed for boundary / feature points used in the boundary / feature edges. They influence the quadrics (position of points), but not the mesh.

- `obj.UseFeaturePointsOff ()` - By default, this flag is off. It only has an effect when "UseFeatureEdges" is also on. When "UseFeaturePoints" is on, then quadrics are computed for boundary / feature points used in the boundary / feature edges. They influence the quadrics (position of points), but not the mesh.

- `obj.SetFeaturePointsAngle (double )` - Set/Get the angle to use in determining whether a point on a boundary / feature edge is a feature point.

- `double = obj.GetFeaturePointsAngleMinValue ()` - Set/Get the angle to use in determining whether a point on a boundary / feature edge is a feature point.

- `double = obj.GetFeaturePointsAngleMaxValue ()` - Set/Get the angle to use in determining whether a point on a boundary / feature edge is a feature point.

- `double = obj.GetFeaturePointsAngle ()` - Set/Get the angle to use in determining whether a point on a boundary / feature edge is a feature point.

- `obj.SetUseInternalTriangles (int )` - When this flag is on (and it is on by default), then triangles that are completely contained in a bin are added to the bin quadrics. When the the flag is off the filter operates faster, but the surface may not be as well behaved.
- `int = obj.GetUseInternalTriangles ()` - When this flag is on (and it is on by default), then triangles that are completely contained in a bin are added to the bin quadrics. When the the flag is off the filter operates faster, but the surface may not be as well behaved.
- `obj.UseInternalTrianglesOn ()` - When this flag is on (and it is on by default), then triangles that are completely contained in a bin are added to the bin quadrics. When the the flag is off the filter operates faster, but the surface may not be as well behaved.
- `obj.UseInternalTrianglesOff ()` - When this flag is on (and it is on by default), then triangles that are completely contained in a bin are added to the bin quadrics. When the the flag is off the filter operates faster, but the surface may not be as well behaved.
- `obj.StartAppend (double bounds)` - These methods provide an alternative way of executing the filter. PolyData can be added to the result in pieces (append). In this mode, the user must specify the bounds of the entire model as an argument to the "StartAppend" method.
- `obj.StartAppend (double x0, double x1, double y0, double y1, double z0, double z1)` - These methods provide an alternative way of executing the filter. PolyData can be added to the result in pieces (append). In this mode, the user must specify the bounds of the entire model as an argument to the "StartAppend" method.
- `obj.Append (vtkPolyData piece)` - These methods provide an alternative way of executing the filter. PolyData can be added to the result in pieces (append). In this mode, the user must specify the bounds of the entire model as an argument to the "StartAppend" method.
- `obj.EndAppend ()` - These methods provide an alternative way of executing the filter. PolyData can be added to the result in pieces (append). In this mode, the user must specify the bounds of the entire model as an argument to the "StartAppend" method.
- `obj.SetCopyCellData (int )` - This flag makes the filter copy cell data from input to output (the best it can). It uses input cells that trigger the addition of output cells (no averaging). This is off by default, and does not work when append is being called explicitely (non-pipeline usage).
- `int = obj.GetCopyCellData ()` - This flag makes the filter copy cell data from input to output (the best it can). It uses input cells that trigger the addition of output cells (no averaging). This is off by default, and does not work when append is being called explicitely (non-pipeline usage).
- `obj.CopyCellDataOn ()` - This flag makes the filter copy cell data from input to output (the best it can). It uses input cells that trigger the addition of output cells (no averaging). This is off by default, and does not work when append is being called explicitely (non-pipeline usage).
- `obj.CopyCellDataOff ()` - This flag makes the filter copy cell data from input to output (the best it can). It uses input cells that trigger the addition of output cells (no averaging). This is off by default, and does not work when append is being called explicitely (non-pipeline usage).
- `obj.SetPreventDuplicateCells (int )` - Specify a boolean indicating whether to remove duplicate cells (i.e. triangles). This is a little slower, and takes more memory, but in some cases can reduce the number of cells produced by an order of magnitude. By default, this flag is true.
- `int = obj.GetPreventDuplicateCells ()` - Specify a boolean indicating whether to remove duplicate cells (i.e. triangles). This is a little slower, and takes more memory, but in some cases can reduce the number of cells produced by an order of magnitude. By default, this flag is true.
- `obj.PreventDuplicateCellsOn ()` - Specify a boolean indicating whether to remove duplicate cells (i.e. triangles). This is a little slower, and takes more memory, but in some cases can reduce the number of cells produced by an order of magnitude. By default, this flag is true.

- `obj.PreventDuplicateCellsOff ()` - Specify a boolean indicating whether to remove duplicate cells (i.e. triangles). This is a little slower, and takes more memory, but in some cases can reduce the number of cells produced by an order of magnitude. By default, this flag is true.

33.179 vtkQuadricDecimation

33.179.1 Usage

vtkQuadricDecimation is a filter to reduce the number of triangles in a triangle mesh, forming a good approximation to the original geometry. The input to vtkQuadricDecimation is a vtkPolyData object, and only triangles are treated. If you desire to decimate polygonal meshes, first triangulate the polygons with vtkTriangleFilter.

The algorithm is based on repeated edge collapses until the requested mesh reduction is achieved. Edges are placed in a priority queue based on the "cost" to delete the edge. The cost is an approximate measure of error (distance to the original surface)–described by the so-called quadric error measure. The quadric error measure is associated with each vertex of the mesh and represents a matrix of planes incident on that vertex. The distance of the planes to the vertex is the error in the position of the vertex (originally the vertex error iz zero). As edges are deleted, the quadric error measure associated with the two end points of the edge are summed (this combines the plane equations) and an optimal collapse point can be computed. Edges connected to the collapse point are then reinserted into the queue after computing the new cost to delete them. The process continues until the desired reduction level is reached or topological constraints prevent further reduction. Note that this basic algorithm can be extended to higher dimensions by taking into account variation in attributes (i.e., scalars, vectors, and so on).

This paper is based on the work of Garland and Heckbert who first presented the quadric error measure at Siggraph '97 "Surface Simplification Using Quadric Error Metrics". For details of the algorithm Michael Garland's Ph.D. thesis is also recommended. Hughues Hoppe's Vis '99 paper, "New Quadric Metric for Simplifying Meshes with Appearance Attributes" is also a good take on the subject especially as it pertains to the error metric applied to attributes.

.SECTION Thanks Thanks to Bradley Lowekamp of the National Library of Medicine/NIH for contributing this class.

To create an instance of class vtkQuadricDecimation, simply invoke its constructor as follows

```
obj = vtkQuadricDecimation
```

33.179.2 Methods

The class vtkQuadricDecimation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadricDecimation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadricDecimation = obj.NewInstance ()`
- `vtkQuadricDecimation = obj.SafeDownCast (vtkObject o)`
- `obj.SetTargetReduction (double )` - Set/Get the desired reduction (expressed as a fraction of the original number of triangles). The actual reduction may be less depending on triangulation and topological constraints.
- `double = obj.GetTargetReductionMinValue ()` - Set/Get the desired reduction (expressed as a fraction of the original number of triangles). The actual reduction may be less depending on triangulation and topological constraints.

- `double = obj.GetTargetReductionMaxValue ()` - Set/Get the desired reduction (expressed as a fraction of the original number of triangles). The actual reduction may be less depending on triangulation and topological constraints.

- `double = obj.GetTargetReduction ()` - Set/Get the desired reduction (expressed as a fraction of the original number of triangles). The actual reduction may be less depending on triangulation and topological constraints.

- `obj.SetAttributeErrorMetric (int )` - Decide whether to include data attributes in the error metric. If off, then only geometric error is used to control the decimation. By default the attribute errors are off.

- `int = obj.GetAttributeErrorMetric ()` - Decide whether to include data attributes in the error metric. If off, then only geometric error is used to control the decimation. By default the attribute errors are off.

- `obj.AttributeErrorMetricOn ()` - Decide whether to include data attributes in the error metric. If off, then only geometric error is used to control the decimation. By default the attribute errors are off.

- `obj.AttributeErrorMetricOff ()` - Decide whether to include data attributes in the error metric. If off, then only geometric error is used to control the decimation. By default the attribute errors are off.

- `obj.SetScalarsAttribute (int )` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `int = obj.GetScalarsAttribute ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `obj.ScalarsAttributeOn ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `obj.ScalarsAttributeOff ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `obj.SetVectorsAttribute (int )` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `int = obj.GetVectorsAttribute ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `obj.VectorsAttributeOn ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `obj.VectorsAttributeOff ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `obj.SetNormalsAttribute (int )` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.

- `int = obj.GetNormalsAttribute ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.NormalsAttributeOn ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.NormalsAttributeOff ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.SetTCoordsAttribute (int )` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `int = obj.GetTCoordsAttribute ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.TCoordsAttributeOn ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.TCoordsAttributeOff ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.SetTensorsAttribute (int )` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `int = obj.GetTensorsAttribute ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.TensorsAttributeOn ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.TensorsAttributeOff ()` - If attribute errors are to be included in the metric (i.e., AttributeErrorMetric is on), then the following flags control which attributes are to be included in the error calculation. By default all of these are on.
- `obj.SetScalarsWeight (double )` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `obj.SetVectorsWeight (double )` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `obj.SetNormalsWeight (double )` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `obj.SetTCoordsWeight (double )` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `obj.SetTensorsWeight (double )` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.

- `double = obj.GetScalarsWeight ()` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `double = obj.GetVectorsWeight ()` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `double = obj.GetNormalsWeight ()` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `double = obj.GetTCoordsWeight ()` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `double = obj.GetTensorsWeight ()` - Set/Get the scaling weight contribution of the attribute. These values are used to weight the contribution of the attributes towards the error metric.
- `double = obj.GetActualReduction ()` - Get the actual reduction. This value is only valid after the filter has executed.

33.180 vtkQuantizePolyDataPoints

33.180.1 Usage

vtkQuantizePolyDataPoints is a subclass of vtkCleanPolyData and inherits the functionality of vtkCleanPolyData with the addition that it quantizes the point coordinates before inserting into the point list. The user should set QFactor to a positive value (0.25 by default) and all x,y,z coordinates will be quantized to that grain size.

A tolerance of zero is expected, though positive values may be used, the quantization will take place before the tolerance is applied.

To create an instance of class vtkQuantizePolyDataPoints, simply invoke its constructor as follows

```
obj = vtkQuantizePolyDataPoints
```

33.180.2 Methods

The class vtkQuantizePolyDataPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuantizePolyDataPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuantizePolyDataPoints = obj.NewInstance ()`
- `vtkQuantizePolyDataPoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetQFactor (double )` - Specify quantization grain size. Default is 0.25
- `double = obj.GetQFactorMinValue ()` - Specify quantization grain size. Default is 0.25
- `double = obj.GetQFactorMaxValue ()` - Specify quantization grain size. Default is 0.25
- `double = obj.GetQFactor ()` - Specify quantization grain size. Default is 0.25
- `obj.OperateOnPoint (double in[3], double out[3])` - Perform quantization on a point
- `obj.OperateOnBounds (double in[6], double out[6])` - Perform quantization on bounds

33.181 vtkRandomAttributeGenerator

33.181.1 Usage

vtkRandomAttributeGenerator is a filter that creates random attributes including scalars, vectors, normals, tensors, texture coordinates and/or general data arrays. These attributes can be generated as point data, cell data or general field data. The generation of each component is normalized between a user-specified minimum and maximum value.

This filter provides that capability to specify the data type of the attributes, the range for each of the components, and the number of components. Note, however, that this flexibility only goes so far because some attributes (e.g., normals, vectors and tensors) are fixed in the number of components, and in the case of normals and tensors, are constrained in the values that some of the components can take (i.e., normals have magnitude one, and tensors are symmetric).

To create an instance of class vtkRandomAttributeGenerator, simply invoke its constructor as follows

```
obj = vtkRandomAttributeGenerator
```

33.181.2 Methods

The class vtkRandomAttributeGenerator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRandomAttributeGenerator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRandomAttributeGenerator = obj.NewInstance ()`
- `vtkRandomAttributeGenerator = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataType (int )` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToBit ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToChar ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToUnsignedChar ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToShort ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToUnsignedShort ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToInt ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToUnsignedInt ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.
- `obj.SetDataTypeToLong ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.

- `obj.SetDataTypeToUnsignedLong ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.

- `obj.SetDataTypeToFloat ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.

- `obj.SetDataTypeToDouble ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.

- `int = obj.GetDataType ()` - Specify the type of array to create (all components of this array are of this type). This holds true for all arrays that are created.

- `obj.SetNumberOfComponents (int )` - Specify the number of components to generate. This value only applies to those attribute types that take a variable number of components. For example, a vector is only three components so the number of components is not applicable; whereas a scalar may support multiple, varying number of components.

- `int = obj.GetNumberOfComponentsMinValue ()` - Specify the number of components to generate. This value only applies to those attribute types that take a variable number of components. For example, a vector is only three components so the number of components is not applicable; whereas a scalar may support multiple, varying number of components.

- `int = obj.GetNumberOfComponentsMaxValue ()` - Specify the number of components to generate. This value only applies to those attribute types that take a variable number of components. For example, a vector is only three components so the number of components is not applicable; whereas a scalar may support multiple, varying number of components.

- `int = obj.GetNumberOfComponents ()` - Specify the number of components to generate. This value only applies to those attribute types that take a variable number of components. For example, a vector is only three components so the number of components is not applicable; whereas a scalar may support multiple, varying number of components.

- `obj.SetMinimumComponentValue (double )` - Set the minimum component value. This applies to all data that is generated, although normals and tensors have internal constraints that must be observed.

- `double = obj.GetMinimumComponentValue ()` - Set the minimum component value. This applies to all data that is generated, although normals and tensors have internal constraints that must be observed.

- `obj.SetMaximumComponentValue (double )` - Set the maximum component value. This applies to all data that is generated, although normals and tensors have internal constraints that must be observed.

- `double = obj.GetMaximumComponentValue ()` - Set the maximum component value. This applies to all data that is generated, although normals and tensors have internal constraints that must be observed.

- `obj.SetNumberOfTuples (vtkIdType )` - Specify the number of tuples to generate. This value only applies when creating general field data. In all other cases (i.e., point data or cell data), the number of tuples is controlled by the number of points and cells, respectively.

- `vtkIdType = obj.GetNumberOfTuplesMinValue ()` - Specify the number of tuples to generate. This value only applies when creating general field data. In all other cases (i.e., point data or cell data), the number of tuples is controlled by the number of points and cells, respectively.

- `vtkIdType = obj.GetNumberOfTuplesMaxValue ()` - Specify the number of tuples to generate. This value only applies when creating general field data. In all other cases (i.e., point data or cell data), the number of tuples is controlled by the number of points and cells, respectively.

- `vtkIdType = obj.GetNumberOfTuples ()` - Specify the number of tuples to generate. This value only applies when creating general field data. In all other cases (i.e., point data or cell data), the number of tuples is controlled by the number of points and cells, respectively.
- `obj.SetGeneratePointScalars (int )` - Indicate that point scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `int = obj.GetGeneratePointScalars ()` - Indicate that point scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GeneratePointScalarsOn ()` - Indicate that point scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GeneratePointScalarsOff ()` - Indicate that point scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `obj.SetGeneratePointVectors (int )` - Indicate that point vectors are to be generated. Note that the number of components is always equal to three.
- `int = obj.GetGeneratePointVectors ()` - Indicate that point vectors are to be generated. Note that the number of components is always equal to three.
- `obj.GeneratePointVectorsOn ()` - Indicate that point vectors are to be generated. Note that the number of components is always equal to three.
- `obj.GeneratePointVectorsOff ()` - Indicate that point vectors are to be generated. Note that the number of components is always equal to three.
- `obj.SetGeneratePointNormals (int )` - Indicate that point normals are to be generated. Note that the number of components is always equal to three.
- `int = obj.GetGeneratePointNormals ()` - Indicate that point normals are to be generated. Note that the number of components is always equal to three.
- `obj.GeneratePointNormalsOn ()` - Indicate that point normals are to be generated. Note that the number of components is always equal to three.
- `obj.GeneratePointNormalsOff ()` - Indicate that point normals are to be generated. Note that the number of components is always equal to three.
- `obj.SetGeneratePointTensors (int )` - Indicate that point tensors are to be generated. Note that the number of components is always equal to nine.
- `int = obj.GetGeneratePointTensors ()` - Indicate that point tensors are to be generated. Note that the number of components is always equal to nine.
- `obj.GeneratePointTensorsOn ()` - Indicate that point tensors are to be generated. Note that the number of components is always equal to nine.
- `obj.GeneratePointTensorsOff ()` - Indicate that point tensors are to be generated. Note that the number of components is always equal to nine.
- `obj.SetGeneratePointTCoords (int )` - Indicate that point texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `int = obj.GetGeneratePointTCoords ()` - Indicate that point texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).

- `obj.GeneratePointTCoordsOn ()` - Indicate that point texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `obj.GeneratePointTCoordsOff ()` - Indicate that point texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `obj.SetGeneratePointArray (int )` - Indicate that an arbitrary point array is to be generated. Note that the specified number of components is used to create the array.
- `int = obj.GetGeneratePointArray ()` - Indicate that an arbitrary point array is to be generated. Note that the specified number of components is used to create the array.
- `obj.GeneratePointArrayOn ()` - Indicate that an arbitrary point array is to be generated. Note that the specified number of components is used to create the array.
- `obj.GeneratePointArrayOff ()` - Indicate that an arbitrary point array is to be generated. Note that the specified number of components is used to create the array.
- `obj.SetGenerateCellScalars (int )` - Indicate that cell scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `int = obj.GetGenerateCellScalars ()` - Indicate that cell scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GenerateCellScalarsOn ()` - Indicate that cell scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GenerateCellScalarsOff ()` - Indicate that cell scalars are to be generated. Note that the specified number of components is used to create the scalar.
- `obj.SetGenerateCellVectors (int )` - Indicate that cell vectors are to be generated. Note that the number of components is always equal to three.
- `int = obj.GetGenerateCellVectors ()` - Indicate that cell vectors are to be generated. Note that the number of components is always equal to three.
- `obj.GenerateCellVectorsOn ()` - Indicate that cell vectors are to be generated. Note that the number of components is always equal to three.
- `obj.GenerateCellVectorsOff ()` - Indicate that cell vectors are to be generated. Note that the number of components is always equal to three.
- `obj.SetGenerateCellNormals (int )` - Indicate that cell normals are to be generated. Note that the number of components is always equal to three.
- `int = obj.GetGenerateCellNormals ()` - Indicate that cell normals are to be generated. Note that the number of components is always equal to three.
- `obj.GenerateCellNormalsOn ()` - Indicate that cell normals are to be generated. Note that the number of components is always equal to three.
- `obj.GenerateCellNormalsOff ()` - Indicate that cell normals are to be generated. Note that the number of components is always equal to three.
- `obj.SetGenerateCellTensors (int )` - Indicate that cell tensors are to be generated. Note that the number of components is always equal to nine.
- `int = obj.GetGenerateCellTensors ()` - Indicate that cell tensors are to be generated. Note that the number of components is always equal to nine.

- `obj.GenerateCellTensorsOn ()` - Indicate that cell tensors are to be generated. Note that the number of components is always equal to nine.
- `obj.GenerateCellTensorsOff ()` - Indicate that cell tensors are to be generated. Note that the number of components is always equal to nine.
- `obj.SetGenerateCellTCoords (int )` - Indicate that cell texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `int = obj.GetGenerateCellTCoords ()` - Indicate that cell texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `obj.GenerateCellTCoordsOn ()` - Indicate that cell texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `obj.GenerateCellTCoordsOff ()` - Indicate that cell texture coordinates are to be generated. Note that the specified number of components is used to create the texture coordinates (but must range between one and three).
- `obj.SetGenerateCellArray (int )` - Indicate that an arbitrary cell array is to be generated. Note that the specified number of components is used to create the array.
- `int = obj.GetGenerateCellArray ()` - Indicate that an arbitrary cell array is to be generated. Note that the specified number of components is used to create the array.
- `obj.GenerateCellArrayOn ()` - Indicate that an arbitrary cell array is to be generated. Note that the specified number of components is used to create the array.
- `obj.GenerateCellArrayOff ()` - Indicate that an arbitrary cell array is to be generated. Note that the specified number of components is used to create the array.
- `obj.SetGenerateFieldArray (int )` - Indicate that an arbitrary field data array is to be generated. Note that the specified number of components is used to create the scalar.
- `int = obj.GetGenerateFieldArray ()` - Indicate that an arbitrary field data array is to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GenerateFieldArrayOn ()` - Indicate that an arbitrary field data array is to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GenerateFieldArrayOff ()` - Indicate that an arbitrary field data array is to be generated. Note that the specified number of components is used to create the scalar.
- `obj.GenerateAllPointDataOn ()` - Convenience methods for generating data: all data, all point data, or all cell data. For example, if all data is enabled, then all point, cell and field data is generated. If all point data is enabled, then point scalars, vectors, normals, tensors, tcoords, and a data array are produced.
- `obj.GenerateAllPointDataOff ()` - Convenience methods for generating data: all data, all point data, or all cell data. For example, if all data is enabled, then all point, cell and field data is generated. If all point data is enabled, then point scalars, vectors, normals, tensors, tcoords, and a data array are produced.
- `obj.GenerateAllCellDataOn ()` - Convenience methods for generating data: all data, all point data, or all cell data. For example, if all data is enabled, then all point, cell and field data is generated. If all point data is enabled, then point scalars, vectors, normals, tensors, tcoords, and a data array are produced.

- `obj.GenerateAllCellDataOff ()` - Convenience methods for generating data: all data, all point data, or all cell data. For example, if all data is enabled, then all point, cell and field data is generated. If all point data is enabled, then point scalars, vectors, normals, tensors, tcoords, and a data array are produced.
- `obj.GenerateAllDataOn ()` - Convenience methods for generating data: all data, all point data, or all cell data. For example, if all data is enabled, then all point, cell and field data is generated. If all point data is enabled, then point scalars, vectors, normals, tensors, tcoords, and a data array are produced.
- `obj.GenerateAllDataOff ()`

33.182 vtkRearrangeFields

33.182.1 Usage

vtkRearrangeFields is used to copy/move fields (vtkDataArrays) between data object's field data, point data and cell data. To specify which fields are copied/moved, the user adds operations. There are two types of operations: 1. the type which copies/moves an attribute's data (i.e. the field will be copied but will not be an attribute in the target), 2. the type which copies/moves fields by name. For example: @verbatim rf-¿AddOperation(vtkRearrangeFields::COPY, "foo", vtkRearrangeFields::DATA_OBJECT, vtkRearrangeFields::POINT_DATA); @endverbatim adds an operation which copies a field (data array) called foo from the data object's field data to point data. From Tcl, the same operation can be added as follows: @verbatim rf AddOperation COPY foo DATA_OBJECT POINT_DATA @endverbatim The same can be done using Python and Java bindings by passing strings as arguments. @verbatim Operation types: COPY, MOVE AttributeTypes: SCALARS, VECTORS, NORMALS, TCOORDS, TENSORS Field data locations: DATA_OBJECT, POINT_DATA, CELL_DATA @endverbatim

To create an instance of class vtkRearrangeFields, simply invoke its constructor as follows

```
obj = vtkRearrangeFields
```

33.182.2 Methods

The class vtkRearrangeFields has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRearrangeFields class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRearrangeFields = obj.NewInstance ()`
- `vtkRearrangeFields = obj.SafeDownCast (vtkObject o)`
- `int = obj.AddOperation (int operationType, int attributeType, int fromFieldLoc, int toFieldLoc)` - Add an operation which copies an attribute's field (data array) from one field data to another. Returns an operation id which can later be used to remove the operation.
- `int = obj.AddOperation (int operationType, string name, int fromFieldLoc, int toFieldLoc)` - Add an operation which copies a field (data array) from one field data to another. Returns an operation id which can later be used to remove the operation.
- `int = obj.AddOperation (string operationType, string attributeType, string fromFieldLoc, string toF` - Helper method used by other language bindings. Allows the caller to specify arguments as strings instead of enums.Returns an operation id which can later be used to remove the operation.

- `int = obj.RemoveOperation (int operationId)` - Remove an operation with the given id.
- `int = obj.RemoveOperation (int operationType, int attributeType, int fromFieldLoc, int toFieldLoc)` - Remove an operation with the given signature. See AddOperation for details.
- `int = obj.RemoveOperation (int operationType, string name, int fromFieldLoc, int toFieldLoc)` - Remove an operation with the given signature. See AddOperation for details.
- `int = obj.RemoveOperation (string operationType, string attributeType, string fromFieldLoc, string` - Remove an operation with the given signature. See AddOperation for details.
- `obj.RemoveAllOperations ()`

33.183 vtkRectangularButtonSource

33.183.1 Usage

vtkRectangularButtonSource creates a rectangular shaped button with texture coordinates suitable for application of a texture map. This provides a way to make nice looking 3D buttons. The buttons are represented as vtkPolyData that includes texture coordinates and normals. The button lies in the x-y plane.

To use this class you must define its width, height and length. These measurements are all taken with respect to the shoulder of the button. The shoulder is defined as follows. Imagine a box sitting on the floor. The distance from the floor to the top of the box is the depth; the other directions are the length (x-direction) and height (y-direction). In this particular widget the box can have a smaller bottom than top. The ratio in size between bottom and top is called the box ratio (by default=1.0). The ratio of the texture region to the shoulder region is the texture ratio. And finally the texture region may be out of plane compared to the shoulder. The texture height ratio controls this.

To create an instance of class vtkRectangularButtonSource, simply invoke its constructor as follows

```
obj = vtkRectangularButtonSource
```

33.183.2 Methods

The class vtkRectangularButtonSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectangularButtonSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectangularButtonSource = obj.NewInstance ()`
- `vtkRectangularButtonSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetWidth (double )` - Set/Get the width of the button.
- `double = obj.GetWidthMinValue ()` - Set/Get the width of the button.
- `double = obj.GetWidthMaxValue ()` - Set/Get the width of the button.
- `double = obj.GetWidth ()` - Set/Get the width of the button.
- `obj.SetHeight (double )` - Set/Get the height of the button.
- `double = obj.GetHeightMinValue ()` - Set/Get the height of the button.
- `double = obj.GetHeightMaxValue ()` - Set/Get the height of the button.

- `double = obj.GetHeight ()` - Set/Get the height of the button.
- `obj.SetDepth (double )` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `double = obj.GetDepthMinValue ()` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `double = obj.GetDepthMaxValue ()` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `double = obj.GetDepth ()` - Set/Get the depth of the button (the z-eliipsoid axis length).
- `obj.SetBoxRatio (double )` - Set/Get the ratio of the bottom of the button with the shoulder region. Numbers greater than one produce buttons with a wider bottom than shoulder; ratios less than one produce buttons that have a wider shoulder than bottom.
- `double = obj.GetBoxRatioMinValue ()` - Set/Get the ratio of the bottom of the button with the shoulder region. Numbers greater than one produce buttons with a wider bottom than shoulder; ratios less than one produce buttons that have a wider shoulder than bottom.
- `double = obj.GetBoxRatioMaxValue ()` - Set/Get the ratio of the bottom of the button with the shoulder region. Numbers greater than one produce buttons with a wider bottom than shoulder; ratios less than one produce buttons that have a wider shoulder than bottom.
- `double = obj.GetBoxRatio ()` - Set/Get the ratio of the bottom of the button with the shoulder region. Numbers greater than one produce buttons with a wider bottom than shoulder; ratios less than one produce buttons that have a wider shoulder than bottom.
- `obj.SetTextureRatio (double )` - Set/Get the ratio of the texture region to the shoulder region. This number must be 0¡=tr¡=1. If the texture style is to fit the image, then satisfying the texture ratio may only be possible in one of the two directions (length or width) depending on the dimensions of the texture.
- `double = obj.GetTextureRatioMinValue ()` - Set/Get the ratio of the texture region to the shoulder region. This number must be 0¡=tr¡=1. If the texture style is to fit the image, then satisfying the texture ratio may only be possible in one of the two directions (length or width) depending on the dimensions of the texture.
- `double = obj.GetTextureRatioMaxValue ()` - Set/Get the ratio of the texture region to the shoulder region. This number must be 0¡=tr¡=1. If the texture style is to fit the image, then satisfying the texture ratio may only be possible in one of the two directions (length or width) depending on the dimensions of the texture.
- `double = obj.GetTextureRatio ()` - Set/Get the ratio of the texture region to the shoulder region. This number must be 0¡=tr¡=1. If the texture style is to fit the image, then satisfying the texture ratio may only be possible in one of the two directions (length or width) depending on the dimensions of the texture.
- `obj.SetTextureHeightRatio (double )` - Set/Get the ratio of the height of the texture region to the shoulder height. Values greater than 1.0 yield convex buttons with the texture region raised above the shoulder. Values less than 1.0 yield concave buttons with the texture region below the shoulder.
- `double = obj.GetTextureHeightRatioMinValue ()` - Set/Get the ratio of the height of the texture region to the shoulder height. Values greater than 1.0 yield convex buttons with the texture region raised above the shoulder. Values less than 1.0 yield concave buttons with the texture region below the shoulder.
- `double = obj.GetTextureHeightRatioMaxValue ()` - Set/Get the ratio of the height of the texture region to the shoulder height. Values greater than 1.0 yield convex buttons with the texture region raised above the shoulder. Values less than 1.0 yield concave buttons with the texture region below the shoulder.

- `double = obj.GetTextureHeightRatio ()` - Set/Get the ratio of the height of the texture region to the shoulder height. Values greater than 1.0 yield convex buttons with the texture region raised above the shoulder. Values less than 1.0 yield concave buttons with the texture region below the shoulder.

33.184 vtkRectilinearGridClip

33.184.1 Usage

vtkRectilinearGridClip will make an image smaller. The output must have an image extent which is the subset of the input. The filter has two modes of operation: 1: By default, the data is not copied in this filter. Only the whole extent is modified. 2: If ClipDataOn is set, then you will get no more that the clipped extent.

To create an instance of class vtkRectilinearGridClip, simply invoke its constructor as follows

```
obj = vtkRectilinearGridClip
```

33.184.2 Methods

The class vtkRectilinearGridClip has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridClip class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridClip = obj.NewInstance ()`
- `vtkRectilinearGridClip = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputWholeExtent (int extent[6], vtkInformation outInfo)` - The whole extent of the output has to be set explicitly.
- `obj.SetOutputWholeExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - The whole extent of the output has to be set explicitly.
- `obj.GetOutputWholeExtent (int extent[6])` - The whole extent of the output has to be set explicitly.
- `obj.ResetOutputWholeExtent ()`
- `obj.SetClipData (int )` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `int = obj.GetClipData ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.ClipDataOn ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.ClipDataOff ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.SetOutputWholeExtent (int piece, int numPieces)` - Hack set output by piece

33.185 vtkRectilinearGridGeometryFilter

33.185.1 Usage

vtkRectilinearGridGeometryFilter is a filter that extracts geometry from a rectilinear grid. By specifying appropriate i-j-k indices, it is possible to extract a point, a curve, a surface, or a "volume". The volume is actually a (n x m x o) region of points.

The extent specification is zero-offset. That is, the first k-plane in a 50x50x50 rectilinear grid is given by (0,49, 0,49, 0,0).

To create an instance of class vtkRectilinearGridGeometryFilter, simply invoke its constructor as follows

```
obj = vtkRectilinearGridGeometryFilter
```

33.185.2 Methods

The class vtkRectilinearGridGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridGeometryFilter = obj.NewInstance ()`
- `vtkRectilinearGridGeometryFilter = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetExtent ()` - Get the extent in topological coordinate range (imin,imax, jmin,jmax, kmin,kmax).
- `obj.SetExtent (int iMin, int iMax, int jMin, int jMax, int kMin, int kMax)` - Specify (imin,imax, jmin,jmax, kmin,kmax) indices.
- `obj.SetExtent (int extent[6])` - Specify (imin,imax, jmin,jmax, kmin,kmax) indices in array form.

33.186 vtkRectilinearGridToTetrahedra

33.186.1 Usage

vtkRectilinearGridToTetrahedra forms a mesh of Tetrahedra from a vtkRectilinearGrid. The tetrahedra can be 5 per cell, 6 per cell, or a mixture of 5 or 12 per cell. The resulting mesh is consistent, meaning that there are no edge crossings and that each tetrahedron face is shared by two tetrahedra, except those tetrahedra on the boundary. All tetrahedra are right handed.

Note that 12 tetrahedra per cell means adding a point in the center of the cell.

In order to subdivide some cells into 5 and some cells into 12 tetrahedra: SetTetraPerCellTo5And12(); Set the Scalars of the Input RectilinearGrid to be 5 or 12 depending on what you want per cell of the RectilinearGrid.

If you set RememberVoxelId, the scalars of the tetrahedron will be set to the Id of the Cell in the RectilinearGrid from which the tetrahedron came.

.SECTION Thanks This class was developed by Samson J. Timoner of the MIT Artificial Intelligence Laboratory

To create an instance of class vtkRectilinearGridToTetrahedra, simply invoke its constructor as follows

```
obj = vtkRectilinearGridToTetrahedra
```

33.186.2 Methods

The class vtkRectilinearGridToTetrahedra has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridToTetrahedra class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridToTetrahedra = obj.NewInstance ()`
- `vtkRectilinearGridToTetrahedra = obj.SafeDownCast (vtkObject o)`
- `obj.SetTetraPerCellTo5 ()` - Set the method to divide each cell (voxel) in the RectilinearGrid into tetrahedra.
- `obj.SetTetraPerCellTo6 ()` - Set the method to divide each cell (voxel) in the RectilinearGrid into tetrahedra.
- `obj.SetTetraPerCellTo12 ()` - Set the method to divide each cell (voxel) in the RectilinearGrid into tetrahedra.
- `obj.SetTetraPerCellTo5And12 ()` - Set the method to divide each cell (voxel) in the RectilinearGrid into tetrahedra.
- `obj.SetTetraPerCell (int )` - Set the method to divide each cell (voxel) in the RectilinearGrid into tetrahedra.
- `int = obj.GetTetraPerCell ()` - Set the method to divide each cell (voxel) in the RectilinearGrid into tetrahedra.
- `obj.SetRememberVoxelId (int )` - Should the tetrahedra have scalar data indicating which Voxel they came from in the vtkRectilinearGrid?
- `int = obj.GetRememberVoxelId ()` - Should the tetrahedra have scalar data indicating which Voxel they came from in the vtkRectilinearGrid?
- `obj.RememberVoxelIdOn ()` - Should the tetrahedra have scalar data indicating which Voxel they came from in the vtkRectilinearGrid?
- `obj.RememberVoxelIdOff ()` - Should the tetrahedra have scalar data indicating which Voxel they came from in the vtkRectilinearGrid?
- `obj.SetInput (double Extent[3], double Spacing[3], double tol)` - This function for convenience for creating a Rectilinear Grid If Spacing does not fit evenly into extent, the last cell will have a different width (or height or depth). If Extent[i]/Spacing[i] is within tol of an integer, then assume the programmer meant an integer for direction i.
- `obj.SetInput (double ExtentX, double ExtentY, double ExtentZ, double SpacingX, double SpacingY, dou` - This version of the function for the wrappers

33.187 vtkRectilinearSynchronizedTemplates

33.187.1 Usage

vtkRectilinearSynchronizedTemplates is a 3D implementation (for rectilinear grids) of the synchronized template algorithm. Note that vtkContourFilter will automatically use this class when appropriate.

To create an instance of class vtkRectilinearSynchronizedTemplates, simply invoke its constructor as follows

```
obj = vtkRectilinearSynchronizedTemplates
```

33.187.2 Methods

The class vtkRectilinearSynchronizedTemplates has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearSynchronizedTemplates class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearSynchronizedTemplates = obj.NewInstance ()`
- `vtkRectilinearSynchronizedTemplates = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Because we delegate to vtkContourValues
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.

- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Needed by templated functions.
- `obj.SetArrayComponent (int )` - Set/get which component of the scalar array to contour on; defaults to 0.
- `int = obj.GetArrayComponent ()` - Set/get which component of the scalar array to contour on; defaults to 0.
- `obj.ComputeSpacing (vtkRectilinearGrid data, int i, int j, int k, int extent[6], double spacing[6])` - Compute the spacing between this point and its 6 neighbors. This method needs to be public so it can be accessed from a templated function.

33.188 vtkRecursiveDividingCubes

33.188.1 Usage

vtkRecursiveDividingCubes is a filter that generates points lying on a surface of constant scalar value (i.e., an isosurface). Dense point clouds (i.e., at screen resolution) will appear as a surface. Less dense clouds can be used as a source to generate streamlines or to generate "transparent" surfaces.

This implementation differs from vtkDividingCubes in that it uses a recursive procedure. In many cases this can result in generating more points than the procedural implementation of vtkDividingCubes. This is because the recursive procedure divides voxels by multiples of powers of two. This can over-constrain subdivision. One of the advantages of the recursive technique is that the recursion is terminated earlier, which in some cases can be more efficient.

To create an instance of class vtkRecursiveDividingCubes, simply invoke its constructor as follows

```
obj = vtkRecursiveDividingCubes
```

33.188.2 Methods

The class vtkRecursiveDividingCubes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRecursiveDividingCubes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRecursiveDividingCubes = obj.NewInstance ()`

- `vtkRecursiveDividingCubes = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (double )` - Set isosurface value.
- `double = obj.GetValue ()` - Set isosurface value.
- `obj.SetDistance (double )` - Specify sub-voxel size at which to generate point.
- `double = obj.GetDistanceMinValue ()` - Specify sub-voxel size at which to generate point.
- `double = obj.GetDistanceMaxValue ()` - Specify sub-voxel size at which to generate point.
- `double = obj.GetDistance ()` - Specify sub-voxel size at which to generate point.
- `obj.SetIncrement (int )` - Every "Increment" point is added to the list of points. This parameter, if set to a large value, can be used to limit the number of points while retaining good accuracy.
- `int = obj.GetIncrementMinValue ()` - Every "Increment" point is added to the list of points. This parameter, if set to a large value, can be used to limit the number of points while retaining good accuracy.
- `int = obj.GetIncrementMaxValue ()` - Every "Increment" point is added to the list of points. This parameter, if set to a large value, can be used to limit the number of points while retaining good accuracy.
- `int = obj.GetIncrement ()` - Every "Increment" point is added to the list of points. This parameter, if set to a large value, can be used to limit the number of points while retaining good accuracy.

33.189 vtkReflectionFilter

33.189.1 Usage

The vtkReflectionFilter reflects a data set across one of the planes formed by the data set's bounding box. Since it converts data sets into unstructured grids, it is not effeicient for structured data sets.

To create an instance of class vtkReflectionFilter, simply invoke its constructor as follows

```
obj = vtkReflectionFilter
```

33.189.2 Methods

The class vtkReflectionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkReflectionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkReflectionFilter = obj.NewInstance ()`
- `vtkReflectionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPlane (int )` - Set the normal of the plane to use as mirror.
- `int = obj.GetPlaneMinValue ()` - Set the normal of the plane to use as mirror.
- `int = obj.GetPlaneMaxValue ()` - Set the normal of the plane to use as mirror.
- `int = obj.GetPlane ()` - Set the normal of the plane to use as mirror.

- `obj.SetPlaneToX ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToY ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToZ ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToXMin ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToYMin ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToZMin ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToXMax ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToYMax ()` - Set the normal of the plane to use as mirror.
- `obj.SetPlaneToZMax ()` - Set the normal of the plane to use as mirror.
- `obj.SetCenter (double )` - If the reflection plane is set to X, Y or Z, this variable is use to set the position of the plane.
- `double = obj.GetCenter ()` - If the reflection plane is set to X, Y or Z, this variable is use to set the position of the plane.
- `obj.SetCopyInput (int )` - If on (the default), copy the input geometry to the output. If off, the output will only contain the reflection.
- `int = obj.GetCopyInput ()` - If on (the default), copy the input geometry to the output. If off, the output will only contain the reflection.
- `obj.CopyInputOn ()` - If on (the default), copy the input geometry to the output. If off, the output will only contain the reflection.
- `obj.CopyInputOff ()` - If on (the default), copy the input geometry to the output. If off, the output will only contain the reflection.

33.190 vtkRegularPolygonSource

33.190.1 Usage

vtkRegularPolygonSource is a source object that creates a single n-sided polygon and/or polyline. The polygon is centered at a specified point, orthogonal to a specified normal, and with a circumscribing radius set by the user. The user can also specify the number of sides of the polygon ranging from [3,N].

This object can be used for seeding streamlines or defining regions for clipping/cutting.

To create an instance of class vtkRegularPolygonSource, simply invoke its constructor as follows

```
obj = vtkRegularPolygonSource
```

33.190.2 Methods

The class vtkRegularPolygonSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRegularPolygonSource class.

- `string = obj.GetClassName ()` - Standard methods for instantiation, obtaining type and printing instance values.
- `int = obj.IsA (string name)` - Standard methods for instantiation, obtaining type and printing instance values.

- `vtkRegularPolygonSource = obj.NewInstance ()` - Standard methods for instantiation, obtaining type and printing instance values.
- `vtkRegularPolygonSource = obj.SafeDownCast (vtkObject o)` - Standard methods for instantiation, obtaining type and printing instance values.
- `obj.SetNumberOfSides (int )` - Set/Get the number of sides of the polygon. By default, the number of sides is set to six.
- `int = obj.GetNumberOfSidesMinValue ()` - Set/Get the number of sides of the polygon. By default, the number of sides is set to six.
- `int = obj.GetNumberOfSidesMaxValue ()` - Set/Get the number of sides of the polygon. By default, the number of sides is set to six.
- `int = obj.GetNumberOfSides ()` - Set/Get the number of sides of the polygon. By default, the number of sides is set to six.
- `obj.SetCenter (double , double , double )` - Set/Get the center of the polygon. By default, the center is set at the origin (0,0,0).
- `obj.SetCenter (double  a[3])` - Set/Get the center of the polygon. By default, the center is set at the origin (0,0,0).
- `double = obj. GetCenter ()` - Set/Get the center of the polygon. By default, the center is set at the origin (0,0,0).
- `obj.SetNormal (double , double , double )` - Set/Get the normal to the polygon. The ordering of the polygon will be counter-clockwise around the normal (i.e., using the right-hand rule). By default, the normal is set to (0,0,1).
- `obj.SetNormal (double  a[3])` - Set/Get the normal to the polygon. The ordering of the polygon will be counter-clockwise around the normal (i.e., using the right-hand rule). By default, the normal is set to (0,0,1).
- `double = obj. GetNormal ()` - Set/Get the normal to the polygon. The ordering of the polygon will be counter-clockwise around the normal (i.e., using the right-hand rule). By default, the normal is set to (0,0,1).
- `obj.SetRadius (double )` - Set/Get the radius of the polygon. By default, the radius is set to 0.5.
- `double = obj.GetRadius ()` - Set/Get the radius of the polygon. By default, the radius is set to 0.5.
- `obj.SetGeneratePolygon (int )` - Control whether a polygon is produced. By default, GeneratePolygon is enabled.
- `int = obj.GetGeneratePolygon ()` - Control whether a polygon is produced. By default, GeneratePolygon is enabled.
- `obj.GeneratePolygonOn ()` - Control whether a polygon is produced. By default, GeneratePolygon is enabled.
- `obj.GeneratePolygonOff ()` - Control whether a polygon is produced. By default, GeneratePolygon is enabled.
- `obj.SetGeneratePolyline (int )` - Control whether a polyline is produced. By default, GeneratePolyline is enabled.
- `int = obj.GetGeneratePolyline ()` - Control whether a polyline is produced. By default, GeneratePolyline is enabled.

- `obj.GeneratePolylineOn ()` - Control whether a polyline is produced. By default, GeneratePolyline is enabled.
- `obj.GeneratePolylineOff ()` - Control whether a polyline is produced. By default, GeneratePolyline is enabled.

33.191 vtkReverseSense

33.191.1 Usage

vtkReverseSense is a filter that reverses the order of polygonal cells and/or reverses the direction of point and cell normals. Two flags are used to control these operations. Cell reversal means reversing the order of indices in the cell connectivity list. Normal reversal means multiplying the normal vector by -1 (both point and cell normals, if present).

To create an instance of class vtkReverseSense, simply invoke its constructor as follows

```
obj = vtkReverseSense
```

33.191.2 Methods

The class vtkReverseSense has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkReverseSense class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkReverseSense = obj.NewInstance ()`
- `vtkReverseSense = obj.SafeDownCast (vtkObject o)`
- `obj.SetReverseCells (int )` - Flag controls whether to reverse cell ordering.
- `int = obj.GetReverseCells ()` - Flag controls whether to reverse cell ordering.
- `obj.ReverseCellsOn ()` - Flag controls whether to reverse cell ordering.
- `obj.ReverseCellsOff ()` - Flag controls whether to reverse cell ordering.
- `obj.SetReverseNormals (int )` - Flag controls whether to reverse normal orientation.
- `int = obj.GetReverseNormals ()` - Flag controls whether to reverse normal orientation.
- `obj.ReverseNormalsOn ()` - Flag controls whether to reverse normal orientation.
- `obj.ReverseNormalsOff ()` - Flag controls whether to reverse normal orientation.

33.192 vtkRibbonFilter

33.192.1 Usage

vtkRibbonFilter is a filter to create oriented ribbons from lines defined in polygonal dataset. The orientation of the ribbon is along the line segments and perpendicular to "projected" line normals. Projected line normals are the original line normals projected to be perpendicular to the local line segment. An offset angle can be specified to rotate the ribbon with respect to the normal.

To create an instance of class vtkRibbonFilter, simply invoke its constructor as follows

```
obj = vtkRibbonFilter
```

33.192.2 Methods

The class vtkRibbonFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRibbonFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRibbonFilter = obj.NewInstance ()`
- `vtkRibbonFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetWidth (double )` - Set the "half" width of the ribbon. If the width is allowed to vary, this is the minimum width. The default is 0.5
- `double = obj.GetWidthMinValue ()` - Set the "half" width of the ribbon. If the width is allowed to vary, this is the minimum width. The default is 0.5
- `double = obj.GetWidthMaxValue ()` - Set the "half" width of the ribbon. If the width is allowed to vary, this is the minimum width. The default is 0.5
- `double = obj.GetWidth ()` - Set the "half" width of the ribbon. If the width is allowed to vary, this is the minimum width. The default is 0.5
- `obj.SetAngle (double )` - Set the offset angle of the ribbon from the line normal. (The angle is expressed in degrees.) The default is 0.0
- `double = obj.GetAngleMinValue ()` - Set the offset angle of the ribbon from the line normal. (The angle is expressed in degrees.) The default is 0.0
- `double = obj.GetAngleMaxValue ()` - Set the offset angle of the ribbon from the line normal. (The angle is expressed in degrees.) The default is 0.0
- `double = obj.GetAngle ()` - Set the offset angle of the ribbon from the line normal. (The angle is expressed in degrees.) The default is 0.0
- `obj.SetVaryWidth (int )` - Turn on/off the variation of ribbon width with scalar value. The default is Off
- `int = obj.GetVaryWidth ()` - Turn on/off the variation of ribbon width with scalar value. The default is Off
- `obj.VaryWidthOn ()` - Turn on/off the variation of ribbon width with scalar value. The default is Off
- `obj.VaryWidthOff ()` - Turn on/off the variation of ribbon width with scalar value. The default is Off
- `obj.SetWidthFactor (double )` - Set the maximum ribbon width in terms of a multiple of the minimum width. The default is 2.0
- `double = obj.GetWidthFactor ()` - Set the maximum ribbon width in terms of a multiple of the minimum width. The default is 2.0
- `obj.SetDefaultNormal (double , double , double )` - Set the default normal to use if no normals are supplied, and DefaultNormalOn is set. The default is (0,0,1)
- `obj.SetDefaultNormal (double  a[3])` - Set the default normal to use if no normals are supplied, and DefaultNormalOn is set. The default is (0,0,1)

- `double = obj. GetDefaultNormal ()` - Set the default normal to use if no normals are supplied, and DefaultNormalOn is set. The default is (0,0,1)
- `obj.SetUseDefaultNormal (int )` - Set a boolean to control whether to use default normals. The default is Off
- `int = obj.GetUseDefaultNormal ()` - Set a boolean to control whether to use default normals. The default is Off
- `obj.UseDefaultNormalOn ()` - Set a boolean to control whether to use default normals. The default is Off
- `obj.UseDefaultNormalOff ()` - Set a boolean to control whether to use default normals. The default is Off
- `obj.SetGenerateTCoords (int )` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `int = obj.GetGenerateTCoordsMinValue ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `int = obj.GetGenerateTCoordsMaxValue ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `int = obj.GetGenerateTCoords ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `obj.SetGenerateTCoordsToOff ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `obj.SetGenerateTCoordsToNormalizedLength ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `obj.SetGenerateTCoordsToUseLength ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `obj.SetGenerateTCoordsToUseScalars ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `string = obj.GetGenerateTCoordsAsString ()` - Control whether and how texture coordinates are produced. This is useful for striping the ribbon with time textures, etc.
- `obj.SetTextureLength (double )` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space. The default is 1.0
- `double = obj.GetTextureLengthMinValue ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space. The default is 1.0
- `double = obj.GetTextureLengthMaxValue ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space. The default is 1.0
- `double = obj.GetTextureLength ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space. The default is 1.0

33.193 vtkRotationalExtrusionFilter

33.193.1 Usage

vtkRotationalExtrusionFilter is a modeling filter. It takes polygonal data as input and generates polygonal data on output. The input dataset is swept around the z-axis to create new polygonal primitives. These primitives form a "skirt" or swept surface. For example, sweeping a line results in a cylindrical shell, and sweeping a circle creates a torus.

There are a number of control parameters for this filter. You can control whether the sweep of a 2D object (i.e., polygon or triangle strip) is capped with the generating geometry via the "Capping" instance variable. Also, you can control the angle of rotation, and whether translation along the z-axis is performed along with the rotation. (Translation is useful for creating "springs".) You also can adjust the radius of the generating geometry using the "DeltaRotation" instance variable.

The skirt is generated by locating certain topological features. Free edges (edges of polygons or triangle strips only used by one polygon or triangle strips) generate surfaces. This is true also of lines or polylines. Vertices generate lines.

This filter can be used to model axisymmetric objects like cylinders, bottles, and wine glasses; or translational/rotational symmetric objects like springs or corkscrews.

To create an instance of class vtkRotationalExtrusionFilter, simply invoke its constructor as follows

```
obj = vtkRotationalExtrusionFilter
```

33.193.2 Methods

The class vtkRotationalExtrusionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRotationalExtrusionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRotationalExtrusionFilter = obj.NewInstance ()`
- `vtkRotationalExtrusionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetResolution (int )` - Set/Get resolution of sweep operation. Resolution controls the number of intermediate node points.
- `int = obj.GetResolutionMinValue ()` - Set/Get resolution of sweep operation. Resolution controls the number of intermediate node points.
- `int = obj.GetResolutionMaxValue ()` - Set/Get resolution of sweep operation. Resolution controls the number of intermediate node points.
- `int = obj.GetResolution ()` - Set/Get resolution of sweep operation. Resolution controls the number of intermediate node points.
- `obj.SetCapping (int )` - Turn on/off the capping of the skirt.
- `int = obj.GetCapping ()` - Turn on/off the capping of the skirt.
- `obj.CappingOn ()` - Turn on/off the capping of the skirt.
- `obj.CappingOff ()` - Turn on/off the capping of the skirt.
- `obj.SetAngle (double )` - Set/Get angle of rotation.
- `double = obj.GetAngle ()` - Set/Get angle of rotation.

- `obj.SetTranslation (double )` - Set/Get total amount of translation along the z-axis.
- `double = obj.GetTranslation ()` - Set/Get total amount of translation along the z-axis.
- `obj.SetDeltaRadius (double )` - Set/Get change in radius during sweep process.
- `double = obj.GetDeltaRadius ()` - Set/Get change in radius during sweep process.

33.194 vtkRotationFilter

33.194.1 Usage

The vtkRotationFilter duplicates a data set by rotation about one of the 3 axis of the dataset's reference. Since it converts data sets into unstructured grids, it is not efficient for structured data sets.

.SECTION Thanks Theophane Foggia of The Swiss National Supercomputing Centre (CSCS) for creating and contributing this filter

To create an instance of class vtkRotationFilter, simply invoke its constructor as follows

```
obj = vtkRotationFilter
```

33.194.2 Methods

The class vtkRotationFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRotationFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRotationFilter = obj.NewInstance ()`
- `vtkRotationFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetAxis (int )` - Set the axis of rotation to use. It is set by default to Z.
- `int = obj.GetAxisMinValue ()` - Set the axis of rotation to use. It is set by default to Z.
- `int = obj.GetAxisMaxValue ()` - Set the axis of rotation to use. It is set by default to Z.
- `int = obj.GetAxis ()` - Set the axis of rotation to use. It is set by default to Z.
- `obj.SetAxisToX ()` - Set the axis of rotation to use. It is set by default to Z.
- `obj.SetAxisToY ()` - Set the axis of rotation to use. It is set by default to Z.
- `obj.SetAxisToZ ()` - Set the axis of rotation to use. It is set by default to Z.
- `obj.SetAngle (double )` - Set the rotation angle to use.
- `double = obj.GetAngle ()` - Set the rotation angle to use.
- `obj.SetCenter (double , double , double )` - Set the rotation center coordinates.
- `obj.SetCenter (double  a[3])` - Set the rotation center coordinates.
- `double = obj. GetCenter ()` - Set the rotation center coordinates.
- `obj.SetNumberOfCopies (int )` - Set the number of copies to create. The source will be rotated N times and a new polydata copy of the original created at each angular position All copies will be appended to form a single output

- `int = obj.GetNumberOfCopies ()` - Set the number of copies to create. The source will be rotated N times and a new polydata copy of the original created at each angular position All copies will be appended to form a single output
- `obj.SetCopyInput (int )` - If on (the default), copy the input geometry to the output. If off, the output will only contain the rotation.
- `int = obj.GetCopyInput ()` - If on (the default), copy the input geometry to the output. If off, the output will only contain the rotation.
- `obj.CopyInputOn ()` - If on (the default), copy the input geometry to the output. If off, the output will only contain the rotation.
- `obj.CopyInputOff ()` - If on (the default), copy the input geometry to the output. If off, the output will only contain the rotation.

33.195 vtkRuledSurfaceFilter

33.195.1 Usage

vtkRuledSurfaceFilter is a filter that generates a surface from a set of lines. The lines are assumed to be "parallel" in the sense that they do not intersect and remain somewhat close to one another. A surface is generated by connecting the points defining each pair of lines with straight lines. This creates a strip for each pair of lines (i.e., a triangulation is created from two generating lines). The filter can handle an arbitrary number of lines, with lines i and i+1 assumed connected. Note that there are several different approaches for creating the ruled surface, the method for creating the surface can either use the input points or resample from the polylines (using a user-specified resolution).

This filter offers some other important features. A DistanceFactor ivar is used to decide when two lines are too far apart to connect. (The factor is a multiple of the distance between the first two points of the two lines defining the strip.) If the distance between the two generating lines becomes too great, then the surface is not generated in that region. (Note: if the lines separate and then merge, then a hole can be generated in the surface.) In addition, the Offset and OnRation ivars can be used to create nifty striped surfaces. Closed surfaces (e.g., tubes) can be created by setting the CloseSurface ivar. (The surface can be closed in the other direction by repeating the first and last point in the polylines defining the surface.)

An important use of this filter is to combine it with vtkStreamLine to generate stream surfaces. It can also be used to create surfaces from contours.

To create an instance of class vtkRuledSurfaceFilter, simply invoke its constructor as follows

```
obj = vtkRuledSurfaceFilter
```

33.195.2 Methods

The class vtkRuledSurfaceFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRuledSurfaceFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRuledSurfaceFilter = obj.NewInstance ()`
- `vtkRuledSurfaceFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetDistanceFactor (double )` - Set/Get the factor that controls tearing of the surface.

- `double = obj.GetDistanceFactorMinValue ()` - Set/Get the factor that controls tearing of the surface.
- `double = obj.GetDistanceFactorMaxValue ()` - Set/Get the factor that controls tearing of the surface.
- `double = obj.GetDistanceFactor ()` - Set/Get the factor that controls tearing of the surface.
- `obj.SetOnRatio (int )` - Control the striping of the ruled surface. If OnRatio is greater than 1, then every nth strip is turned on, beginning with the Offset strip.
- `int = obj.GetOnRatioMinValue ()` - Control the striping of the ruled surface. If OnRatio is greater than 1, then every nth strip is turned on, beginning with the Offset strip.
- `int = obj.GetOnRatioMaxValue ()` - Control the striping of the ruled surface. If OnRatio is greater than 1, then every nth strip is turned on, beginning with the Offset strip.
- `int = obj.GetOnRatio ()` - Control the striping of the ruled surface. If OnRatio is greater than 1, then every nth strip is turned on, beginning with the Offset strip.
- `obj.SetOffset (int )` - Control the striping of the ruled surface. The offset sets the first stripe that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `int = obj.GetOffsetMinValue ()` - Control the striping of the ruled surface. The offset sets the first stripe that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `int = obj.GetOffsetMaxValue ()` - Control the striping of the ruled surface. The offset sets the first stripe that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `int = obj.GetOffset ()` - Control the striping of the ruled surface. The offset sets the first stripe that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `obj.SetCloseSurface (int )` - Indicate whether the surface is to be closed. If this boolean is on, then the first and last polyline are used to generate a stripe that closes the surface. (Note: to close the surface in the other direction, repeat the first point in the polyline as the last point in the polyline.)
- `int = obj.GetCloseSurface ()` - Indicate whether the surface is to be closed. If this boolean is on, then the first and last polyline are used to generate a stripe that closes the surface. (Note: to close the surface in the other direction, repeat the first point in the polyline as the last point in the polyline.)
- `obj.CloseSurfaceOn ()` - Indicate whether the surface is to be closed. If this boolean is on, then the first and last polyline are used to generate a stripe that closes the surface. (Note: to close the surface in the other direction, repeat the first point in the polyline as the last point in the polyline.)
- `obj.CloseSurfaceOff ()` - Indicate whether the surface is to be closed. If this boolean is on, then the first and last polyline are used to generate a stripe that closes the surface. (Note: to close the surface in the other direction, repeat the first point in the polyline as the last point in the polyline.)
- `obj.SetRuledMode (int )` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.
- `int = obj.GetRuledModeMinValue ()` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.

- `int = obj.GetRuledModeMaxValue ()` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.
- `int = obj.GetRuledMode ()` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.
- `obj.SetRuledModeToResample ()` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.
- `obj.SetRuledModeToPointWalk ()` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.
- `string = obj.GetRuledModeAsString ()` - Set the mode by which to create the ruled surface. (Dramatically different results are possible depending on the chosen mode.) The resample mode evenly resamples the polylines (based on length) and generates triangle strips. The point walk mode uses the existing points and walks around the polyline using existing points.
- `obj.SetResolution (int , int )` - If the ruled surface generation mode is RESAMPLE, then these parameters are used to determine the resample rate. Resolution[0] defines the resolution in the direction of the polylines; Resolution[1] defines the resolution across the polylines (i.e., direction orthogonal to Resolution[0]).
- `obj.SetResolution (int a[2])` - If the ruled surface generation mode is RESAMPLE, then these parameters are used to determine the resample rate. Resolution[0] defines the resolution in the direction of the polylines; Resolution[1] defines the resolution across the polylines (i.e., direction orthogonal to Resolution[0]).
- `int = obj. GetResolution ()` - If the ruled surface generation mode is RESAMPLE, then these parameters are used to determine the resample rate. Resolution[0] defines the resolution in the direction of the polylines; Resolution[1] defines the resolution across the polylines (i.e., direction orthogonal to Resolution[0]).
- `obj.SetPassLines (int )` - Indicate whether the generating lines are to be passed to the output. By defualt lines are not passed to the output.
- `int = obj.GetPassLines ()` - Indicate whether the generating lines are to be passed to the output. By defualt lines are not passed to the output.
- `obj.PassLinesOn ()` - Indicate whether the generating lines are to be passed to the output. By defualt lines are not passed to the output.
- `obj.PassLinesOff ()` - Indicate whether the generating lines are to be passed to the output. By defualt lines are not passed to the output.
- `obj.SetOrientLoops (int )` - Indicate whether the starting points of the loops need to be determined. If set to 0, then its assumes that the 0th point of each loop should be always connected By defualt the loops are not oriented.
- `int = obj.GetOrientLoops ()` - Indicate whether the starting points of the loops need to be determined. If set to 0, then its assumes that the 0th point of each loop should be always connected By defualt the loops are not oriented.

- `obj.OrientLoopsOn ()` - Indicate whether the starting points of the loops need to be determined. If set to 0, then its assumes that the 0th point of each loop should be always connected By defualt the loops are not oriented.
- `obj.OrientLoopsOff ()` - Indicate whether the starting points of the loops need to be determined. If set to 0, then its assumes that the 0th point of each loop should be always connected By defualt the loops are not oriented.

33.196 vtkSectorSource

33.196.1 Usage

vtkSectorSource creates a sector of a polygonal disk. The disk has zero height. The user can specify the inner and outer radius of the disk, the z-coordinate, and the radial and circumferential resolution of the polygonal representation.

To create an instance of class vtkSectorSource, simply invoke its constructor as follows

```
obj = vtkSectorSource
```

33.196.2 Methods

The class vtkSectorSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSectorSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSectorSource = obj.NewInstance ()`
- `vtkSectorSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetInnerRadius (double )` - Specify inner radius of the sector.
- `double = obj.GetInnerRadiusMinValue ()` - Specify inner radius of the sector.
- `double = obj.GetInnerRadiusMaxValue ()` - Specify inner radius of the sector.
- `double = obj.GetInnerRadius ()` - Specify inner radius of the sector.
- `obj.SetOuterRadius (double )` - Specify outer radius of the sector.
- `double = obj.GetOuterRadiusMinValue ()` - Specify outer radius of the sector.
- `double = obj.GetOuterRadiusMaxValue ()` - Specify outer radius of the sector.
- `double = obj.GetOuterRadius ()` - Specify outer radius of the sector.
- `obj.SetZCoord (double )` - Specify the z coordinate of the sector.
- `double = obj.GetZCoordMinValue ()` - Specify the z coordinate of the sector.
- `double = obj.GetZCoordMaxValue ()` - Specify the z coordinate of the sector.
- `double = obj.GetZCoord ()` - Specify the z coordinate of the sector.
- `obj.SetRadialResolution (int )` - Set the number of points in radius direction.
- `int = obj.GetRadialResolutionMinValue ()` - Set the number of points in radius direction.

- `int = obj.GetRadialResolutionMaxValue ()` - Set the number of points in radius direction.
- `int = obj.GetRadialResolution ()` - Set the number of points in radius direction.
- `obj.SetCircumferentialResolution (int )` - Set the number of points in circumferential direction.
- `int = obj.GetCircumferentialResolutionMinValue ()` - Set the number of points in circumferential direction.
- `int = obj.GetCircumferentialResolutionMaxValue ()` - Set the number of points in circumferential direction.
- `int = obj.GetCircumferentialResolution ()` - Set the number of points in circumferential direction.
- `obj.SetStartAngle (double )` - Set the start angle of the sector.
- `double = obj.GetStartAngleMinValue ()` - Set the start angle of the sector.
- `double = obj.GetStartAngleMaxValue ()` - Set the start angle of the sector.
- `double = obj.GetStartAngle ()` - Set the start angle of the sector.
- `obj.SetEndAngle (double )` - Set the end angle of the sector.
- `double = obj.GetEndAngleMinValue ()` - Set the end angle of the sector.
- `double = obj.GetEndAngleMaxValue ()` - Set the end angle of the sector.
- `double = obj.GetEndAngle ()` - Set the end angle of the sector.

33.197 vtkSelectEnclosedPoints

33.197.1 Usage

vtkSelectEnclosedPoints is a filter that evaluates all the input points to determine whether they are in an enclosed surface. The filter produces a (0,1) mask (in the form of a vtkDataArray) that indicates whether points are outside (mask value=0) or inside (mask value=1) a provided surface. (The name of the output vtkDataArray is "SelectedPointsArray".)

After running the filter, it is possible to query it as to whether a point is inside/outside by invoking the IsInside(ptId) method.

To create an instance of class vtkSelectEnclosedPoints, simply invoke its constructor as follows

```
obj = vtkSelectEnclosedPoints
```

33.197.2 Methods

The class vtkSelectEnclosedPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSelectEnclosedPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSelectEnclosedPoints = obj.NewInstance ()`
- `vtkSelectEnclosedPoints = obj.SafeDownCast (vtkObject o)`

- `obj.SetSurface (vtkPolyData pd)` - Set the surface to be used to test for containment. Two methods are provided: one directly for vtkPolyData, and one for the output of a filter.
- `obj.SetSurfaceConnection (vtkAlgorithmOutput algOutput)` - Set the surface to be used to test for containment. Two methods are provided: one directly for vtkPolyData, and one for the output of a filter.
- `vtkPolyData = obj.GetSurface ()` - Return a pointer to the enclosing surface.
- `vtkPolyData = obj.GetSurface (vtkInformationVector sourceInfo)` - Return a pointer to the enclosing surface.
- `obj.SetInsideOut (int )` - By default, points inside the surface are marked inside or sent to the output. If InsideOut is on, then the points outside the surface are marked inside.
- `obj.InsideOutOn ()` - By default, points inside the surface are marked inside or sent to the output. If InsideOut is on, then the points outside the surface are marked inside.
- `obj.InsideOutOff ()` - By default, points inside the surface are marked inside or sent to the output. If InsideOut is on, then the points outside the surface are marked inside.
- `int = obj.GetInsideOut ()` - By default, points inside the surface are marked inside or sent to the output. If InsideOut is on, then the points outside the surface are marked inside.
- `obj.SetCheckSurface (int )` - Specify whether to check the surface for closure. If on, then the algorithm first checks to see if the surface is closed and manifold.
- `obj.CheckSurfaceOn ()` - Specify whether to check the surface for closure. If on, then the algorithm first checks to see if the surface is closed and manifold.
- `obj.CheckSurfaceOff ()` - Specify whether to check the surface for closure. If on, then the algorithm first checks to see if the surface is closed and manifold.
- `int = obj.GetCheckSurface ()` - Specify whether to check the surface for closure. If on, then the algorithm first checks to see if the surface is closed and manifold.
- `int = obj.IsInside (vtkIdType inputPtId)` - Query an input point id as to whether it is inside or outside. Note that the result requires that the filter execute first.
- `obj.SetTolerance (double )` - Specify the tolerance on the intersection. The tolerance is expressed as a fraction of the bounding box of the enclosing surface.
- `double = obj.GetToleranceMinValue ()` - Specify the tolerance on the intersection. The tolerance is expressed as a fraction of the bounding box of the enclosing surface.
- `double = obj.GetToleranceMaxValue ()` - Specify the tolerance on the intersection. The tolerance is expressed as a fraction of the bounding box of the enclosing surface.
- `double = obj.GetTolerance ()` - Specify the tolerance on the intersection. The tolerance is expressed as a fraction of the bounding box of the enclosing surface.
- `obj.Initialize (vtkPolyData surface)` - This is a backdoor that can be used to test many points for containment. First initialize the instance, then repeated calls to IsInsideSurface() can be used without rebuilding the search structures. The complete method releases memory.
- `int = obj.IsInsideSurface (double x, double y, double z)` - This is a backdoor that can be used to test many points for containment. First initialize the instance, then repeated calls to IsInsideSurface() can be used without rebuilding the search structures. The complete method releases memory.

- `int = obj.IsInsideSurface (double x[3])` - This is a backdoor that can be used to test many points for containment. First initialize the instance, then repeated calls to IsInsideSurface() can be used without rebuilding the search structures. The complete method releases memory.

- `obj.Complete ()` - This is a backdoor that can be used to test many points for containment. First initialize the instance, then repeated calls to IsInsideSurface() can be used without rebuilding the search structures. The complete method releases memory.

33.198 vtkSelectPolyData

33.198.1 Usage

vtkSelectPolyData is a filter that selects polygonal data based on defining a "loop" and indicating the region inside of the loop. The mesh within the loop consists of complete cells (the cells are not cut). Alternatively, this filter can be used to generate scalars. These scalar values, which are a distance measure to the loop, can be used to clip, contour. or extract data (i.e., anything that an implicit function can do).

The loop is defined by an array of x-y-z point coordinates. (Coordinates should be in the same coordinate space as the input polygonal data.) The loop can be concave and non-planar, but not self-intersecting. The input to the filter is a polygonal mesh (only surface primitives such as triangle strips and polygons); the output is either a) a portion of the original mesh laying within the selection loop (GenerateSelectionScalarsOff); or b) the same polygonal mesh with the addition of scalar values (GenerateSelectionScalarsOn).

The algorithm works as follows. For each point coordinate in the loop, the closest point in the mesh is found. The result is a loop of closest point ids from the mesh. Then, the edges in the mesh connecting the closest points (and laying along the lines forming the loop) are found. A greedy edge tracking procedure is used as follows. At the current point, the mesh edge oriented in the direction of and whose end point is closest to the line is chosen. The edge is followed to the new end point, and the procedure is repeated. This process continues until the entire loop has been created.

To determine what portion of the mesh is inside and outside of the loop, three options are possible. 1) the smallest connected region, 2) the largest connected region, and 3) the connected region closest to a user specified point. (Set the ivar SelectionMode.)

Once the loop is computed as above, the GenerateSelectionScalars controls the output of the filter. If on, then scalar values are generated based on distance to the loop lines. Otherwise, the cells laying inside the selection loop are output. By default, the mesh lying within the loop is output; however, if InsideOut is on, then the portion of the mesh lying outside of the loop is output.

The filter can be configured to generate the unselected portions of the mesh as output by setting GenerateUnselectedOutput. Use the method GetUnselectedOutput to access this output. (Note: this flag is pertinent only when GenerateSelectionScalars is off.)

To create an instance of class vtkSelectPolyData, simply invoke its constructor as follows

```
obj = vtkSelectPolyData
```

33.198.2 Methods

The class vtkSelectPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSelectPolyData class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkSelectPolyData = obj.NewInstance ()`

- `vtkSelectPolyData = obj.SafeDownCast (vtkObject o)`

- `obj.SetGenerateSelectionScalars (int )` - Set/Get the flag to control behavior of the filter. If GenerateSelectionScalars is on, then the output of the filter is the same as the input, except that scalars are generated. If off, the filter outputs the cells laying inside the loop, and does not generate scalars.
- `int = obj.GetGenerateSelectionScalars ()` - Set/Get the flag to control behavior of the filter. If GenerateSelectionScalars is on, then the output of the filter is the same as the input, except that scalars are generated. If off, the filter outputs the cells laying inside the loop, and does not generate scalars.
- `obj.GenerateSelectionScalarsOn ()` - Set/Get the flag to control behavior of the filter. If GenerateSelectionScalars is on, then the output of the filter is the same as the input, except that scalars are generated. If off, the filter outputs the cells laying inside the loop, and does not generate scalars.
- `obj.GenerateSelectionScalarsOff ()` - Set/Get the flag to control behavior of the filter. If GenerateSelectionScalars is on, then the output of the filter is the same as the input, except that scalars are generated. If off, the filter outputs the cells laying inside the loop, and does not generate scalars.
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. When off, the mesh within the loop is extracted. When on, the mesh outside the loop is extracted.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. When off, the mesh within the loop is extracted. When on, the mesh outside the loop is extracted.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. When off, the mesh within the loop is extracted. When on, the mesh outside the loop is extracted.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. When off, the mesh within the loop is extracted. When on, the mesh outside the loop is extracted.
- `obj.SetLoop (vtkPoints )` - Set/Get the array of point coordinates defining the loop. There must be at least three points used to define a loop.
- `vtkPoints = obj.GetLoop ()` - Set/Get the array of point coordinates defining the loop. There must be at least three points used to define a loop.
- `obj.SetSelectionMode (int )` - Control how inside/outside of loop is defined.
- `int = obj.GetSelectionModeMinValue ()` - Control how inside/outside of loop is defined.
- `int = obj.GetSelectionModeMaxValue ()` - Control how inside/outside of loop is defined.
- `int = obj.GetSelectionMode ()` - Control how inside/outside of loop is defined.
- `obj.SetSelectionModeToSmallestRegion ()` - Control how inside/outside of loop is defined.
- `obj.SetSelectionModeToLargestRegion ()` - Control how inside/outside of loop is defined.
- `obj.SetSelectionModeToClosestPointRegion ()` - Control how inside/outside of loop is defined.
- `string = obj.GetSelectionModeAsString ()` - Control how inside/outside of loop is defined.
- `obj.SetGenerateUnselectedOutput (int )` - Control whether a second output is generated. The second output contains the polygonal data that's not been selected.
- `int = obj.GetGenerateUnselectedOutput ()` - Control whether a second output is generated. The second output contains the polygonal data that's not been selected.
- `obj.GenerateUnselectedOutputOn ()` - Control whether a second output is generated. The second output contains the polygonal data that's not been selected.
- `obj.GenerateUnselectedOutputOff ()` - Control whether a second output is generated. The second output contains the polygonal data that's not been selected.

- `vtkPolyData = obj.GetUnselectedOutput ()` - Return output that hasn't been selected (if GenreateUnselectedOutput is enabled).
- `vtkPolyData = obj.GetSelectionEdges ()` - Return the (mesh) edges of the selection region.
- `long = obj.GetMTime ()`

33.199 vtkShrinkFilter

33.199.1 Usage

vtkShrinkFilter shrinks cells composing an arbitrary data set towards their centroid. The centroid of a cell is computed as the average position of the cell points. Shrinking results in disconnecting the cells from one another. The output of this filter is of general dataset type vtkUnstructuredGrid.

To create an instance of class vtkShrinkFilter, simply invoke its constructor as follows

```
obj = vtkShrinkFilter
```

33.199.2 Methods

The class vtkShrinkFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShrinkFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShrinkFilter = obj.NewInstance ()`
- `vtkShrinkFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetShrinkFactor (double )` - Get/Set the fraction of shrink for each cell. The default is 0.5.
- `double = obj.GetShrinkFactorMinValue ()` - Get/Set the fraction of shrink for each cell. The default is 0.5.
- `double = obj.GetShrinkFactorMaxValue ()` - Get/Set the fraction of shrink for each cell. The default is 0.5.
- `double = obj.GetShrinkFactor ()` - Get/Set the fraction of shrink for each cell. The default is 0.5.

33.200 vtkShrinkPolyData

33.200.1 Usage

vtkShrinkPolyData shrinks cells composing a polygonal dataset (e.g., vertices, lines, polygons, and triangle strips) towards their centroid. The centroid of a cell is computed as the average position of the cell points. Shrinking results in disconnecting the cells from one another. The output dataset type of this filter is polygonal data.

During execution the filter passes its input cell data to its output. Point data attributes are copied to the points created during the shrinking process.

To create an instance of class vtkShrinkPolyData, simply invoke its constructor as follows

```
obj = vtkShrinkPolyData
```

33.200.2 Methods

The class vtkShrinkPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShrinkPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShrinkPolyData = obj.NewInstance ()`
- `vtkShrinkPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetShrinkFactor (double )` - Set the fraction of shrink for each cell.
- `double = obj.GetShrinkFactorMinValue ()` - Set the fraction of shrink for each cell.
- `double = obj.GetShrinkFactorMaxValue ()` - Set the fraction of shrink for each cell.
- `double = obj.GetShrinkFactor ()` - Get the fraction of shrink for each cell.

33.201 vtkSimpleElevationFilter

33.201.1 Usage

vtkSimpleElevationFilter is a filter to generate scalar values from a dataset. The scalar values are generated by dotting a user-specified vector against a vector defined from the input dataset points to the origin.

To create an instance of class vtkSimpleElevationFilter, simply invoke its constructor as follows

```
obj = vtkSimpleElevationFilter
```

33.201.2 Methods

The class vtkSimpleElevationFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimpleElevationFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSimpleElevationFilter = obj.NewInstance ()`
- `vtkSimpleElevationFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetVector (double , double , double )` - Define one end of the line (small scalar values).
- `obj.SetVector (double  a[3])` - Define one end of the line (small scalar values).
- `double = obj. GetVector ()` - Define one end of the line (small scalar values).

33.202 vtkSliceCubes

33.202.1 Usage

vtkSliceCubes is a special version of the marching cubes filter. Instead of ingesting an entire volume at once it processes only four slices at a time. This way, it can generate isosurfaces from huge volumes. Also, the output of this object is written to a marching cubes triangle file. That way, output triangles do not need to be held in memory.

To use vtkSliceCubes you must specify an instance of vtkVolumeReader to read the data. Set this object up with the proper file prefix, image range, data origin, data dimensions, header size, data mask, and swap bytes flag. The vtkSliceCubes object will then take over and read slices as necessary. You also will need to specify the name of an output marching cubes triangle file.

To create an instance of class vtkSliceCubes, simply invoke its constructor as follows

```
obj = vtkSliceCubes
```

33.202.2 Methods

The class vtkSliceCubes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSliceCubes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSliceCubes = obj.NewInstance ()`
- `vtkSliceCubes = obj.SafeDownCast (vtkObject o)`
- `obj.Write ()`
- `obj.Update ()`
- `obj.SetReader (vtkVolumeReader )` - Set/get object to read slices.
- `vtkVolumeReader = obj.GetReader ()` - Set/get object to read slices.
- `obj.SetFileName (string )` - Specify file name of marching cubes output file.
- `string = obj.GetFileName ()` - Specify file name of marching cubes output file.
- `obj.SetValue (double )` - Set/get isosurface contour value.
- `double = obj.GetValue ()` - Set/get isosurface contour value.
- `obj.SetLimitsFileName (string )` - Specify file name of marching cubes limits file. The limits file speeds up subsequent reading of output triangle file.
- `string = obj.GetLimitsFileName ()` - Specify file name of marching cubes limits file. The limits file speeds up subsequent reading of output triangle file.

33.203 vtkSmoothPolyDataFilter

33.203.1 Usage

vtkSmoothPolyDataFilter is a filter that adjusts point coordinates using Laplacian smoothing. The effect is to "relax" the mesh, making the cells better shaped and the vertices more evenly distributed. Note that this filter operates on the lines, polygons, and triangle strips composing an instance of vtkPolyData. Vertex or poly-vertex cells are never modified.

The algorithm proceeds as follows. For each vertex v, a topological and geometric analysis is performed to determine which vertices are connected to v, and which cells are connected to v. Then, a connectivity array is constructed for each vertex. (The connectivity array is a list of lists of vertices that directly attach to each vertex.) Next, an iteration phase begins over all vertices. For each vertex v, the coordinates of v are modified according to an average of the connected vertices. (A relaxation factor is available to control the amount of displacement of v). The process repeats for each vertex. This pass over the list of vertices is a single iteration. Many iterations (generally around 20 or so) are repeated until the desired result is obtained.

There are some special instance variables used to control the execution of this filter. (These ivars basically control what vertices can be smoothed, and the creation of the connectivity array.) The BoundarySmoothing ivar enables/disables the smoothing operation on vertices that are on the "boundary" of the mesh. A boundary vertex is one that is surrounded by a semi-cycle of polygons (or used by a single line).

Another important ivar is FeatureEdgeSmoothing. If this ivar is enabled, then interior vertices are classified as either "simple", "interior edge", or "fixed", and smoothed differently. (Interior vertices are manifold vertices surrounded by a cycle of polygons; or used by two line cells.) The classification is based on the number of feature edges attached to v. A feature edge occurs when the angle between the two surface normals of a polygon sharing an edge is greater than the FeatureAngle ivar. Then, vertices used by no feature edges are classified "simple", vertices used by exactly two feature edges are classified "interior edge", and all others are "fixed" vertices.

Once the classification is known, the vertices are smoothed differently. Corner (i.e., fixed) vertices are not smoothed at all. Simple vertices are smoothed as before (i.e., average of connected vertex coordinates). Interior edge vertices are smoothed only along their two connected edges, and only if the angle between the edges is less than the EdgeAngle ivar.

The total smoothing can be controlled by using two ivars. The NumberOfIterations is a cap on the maximum number of smoothing passes. The Convergence ivar is a limit on the maximum point motion. If the maximum motion during an iteration is less than Convergence, then the smoothing process terminates. (Convergence is expressed as a fraction of the diagonal of the bounding box.)

There are two instance variables that control the generation of error data. If the ivar GenerateErrorScalars is on, then a scalar value indicating the distance of each vertex from its original position is computed. If the ivar GenerateErrorVectors is on, then a vector representing change in position is computed.

Optionally you can further control the smoothing process by defining a second input: the Source. If defined, the input mesh is constrained to lie on the surface defined by the Source ivar.

To create an instance of class vtkSmoothPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkSmoothPolyDataFilter
```

33.203.2 Methods

The class vtkSmoothPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSmoothPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSmoothPolyDataFilter = obj.NewInstance ()`
- `vtkSmoothPolyDataFilter = obj.SafeDownCast (vtkObject o)`

- `obj.SetConvergence (double )` - Specify a convergence criterion for the iteration process. Smaller numbers result in more smoothing iterations.
- `double = obj.GetConvergenceMinValue ()` - Specify a convergence criterion for the iteration process. Smaller numbers result in more smoothing iterations.
- `double = obj.GetConvergenceMaxValue ()` - Specify a convergence criterion for the iteration process. Smaller numbers result in more smoothing iterations.
- `double = obj.GetConvergence ()` - Specify a convergence criterion for the iteration process. Smaller numbers result in more smoothing iterations.
- `obj.SetNumberOfIterations (int )` - Specify the number of iterations for Laplacian smoothing,
- `int = obj.GetNumberOfIterationsMinValue ()` - Specify the number of iterations for Laplacian smoothing,
- `int = obj.GetNumberOfIterationsMaxValue ()` - Specify the number of iterations for Laplacian smoothing,
- `int = obj.GetNumberOfIterations ()` - Specify the number of iterations for Laplacian smoothing,
- `obj.SetRelaxationFactor (double )` - Specify the relaxation factor for Laplacian smoothing. As in all iterative methods, the stability of the process is sensitive to this parameter. In general, small relaxation factors and large numbers of iterations are more stable than larger relaxation factors and smaller numbers of iterations.
- `double = obj.GetRelaxationFactor ()` - Specify the relaxation factor for Laplacian smoothing. As in all iterative methods, the stability of the process is sensitive to this parameter. In general, small relaxation factors and large numbers of iterations are more stable than larger relaxation factors and smaller numbers of iterations.
- `obj.SetFeatureEdgeSmoothing (int )` - Turn on/off smoothing along sharp interior edges.
- `int = obj.GetFeatureEdgeSmoothing ()` - Turn on/off smoothing along sharp interior edges.
- `obj.FeatureEdgeSmoothingOn ()` - Turn on/off smoothing along sharp interior edges.
- `obj.FeatureEdgeSmoothingOff ()` - Turn on/off smoothing along sharp interior edges.
- `obj.SetFeatureAngle (double )` - Specify the feature angle for sharp edge identification.
- `double = obj.GetFeatureAngleMinValue ()` - Specify the feature angle for sharp edge identification.
- `double = obj.GetFeatureAngleMaxValue ()` - Specify the feature angle for sharp edge identification.
- `double = obj.GetFeatureAngle ()` - Specify the feature angle for sharp edge identification.
- `obj.SetEdgeAngle (double )` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `double = obj.GetEdgeAngleMinValue ()` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `double = obj.GetEdgeAngleMaxValue ()` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `double = obj.GetEdgeAngle ()` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `obj.SetBoundarySmoothing (int )` - Turn on/off the smoothing of vertices on the boundary of the mesh.

- `int = obj.GetBoundarySmoothing ()` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `obj.BoundarySmoothingOn ()` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `obj.BoundarySmoothingOff ()` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `obj.SetGenerateErrorScalars (int )` - Turn on/off the generation of scalar distance values.
- `int = obj.GetGenerateErrorScalars ()` - Turn on/off the generation of scalar distance values.
- `obj.GenerateErrorScalarsOn ()` - Turn on/off the generation of scalar distance values.
- `obj.GenerateErrorScalarsOff ()` - Turn on/off the generation of scalar distance values.
- `obj.SetGenerateErrorVectors (int )` - Turn on/off the generation of error vectors.
- `int = obj.GetGenerateErrorVectors ()` - Turn on/off the generation of error vectors.
- `obj.GenerateErrorVectorsOn ()` - Turn on/off the generation of error vectors.
- `obj.GenerateErrorVectorsOff ()` - Turn on/off the generation of error vectors.
- `obj.SetSource (vtkPolyData source)` - Specify the source object which is used to constrain smoothing. The source defines a surface that the input (as it is smoothed) is constrained to lie upon.
- `vtkPolyData = obj.GetSource ()` - Specify the source object which is used to constrain smoothing. The source defines a surface that the input (as it is smoothed) is constrained to lie upon.

33.204 vtkSpatialRepresentationFilter

33.204.1 Usage

vtkSpatialRepresentationFilter generates an polygonal representation of a spatial search (vtkLocator) object. The representation varies depending upon the nature of the spatial search object. For example, the representation for vtkOBBTree is a collection of oriented bounding boxes. Ths input to this filter is a dataset of any type, and the output is polygonal data. You must also specify the spatial search object to use.

Generally spatial search objects are used for collision detection and other geometric operations, but in this filter one or more levels of spatial searchers can be generated to form a geometric approximation to the input data. This is a form of data simplification, generally used to accelerate the rendering process. Or, this filter can be used as a debugging/ visualization aid for spatial search objects.

This filter can generate one or more output vtkPolyData corresponding to different levels in the spatial search tree. The output data is retrieved using the GetOutput(id) method, where id ranges from 0 (root level) to Level. Note that the output for level "id" is not computed unless a GetOutput(id) method is issued. Thus, if you desire three levels of output (say 2,4,7), you would have to invoke GetOutput(2), GetOutput(4), and GetOutput(7). (Also note that the Level ivar is computed automatically depending on the size and nature of the input data.) There is also another GetOutput() method that takes no parameters. This method returns the leafs of the spatial search tree, which may be at different levels.

To create an instance of class vtkSpatialRepresentationFilter, simply invoke its constructor as follows

```
obj = vtkSpatialRepresentationFilter
```

33.204.2 Methods

The class vtkSpatialRepresentationFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSpatialRepresentationFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSpatialRepresentationFilter = obj.NewInstance ()`
- `vtkSpatialRepresentationFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetSpatialRepresentation (vtkLocator )` - Set/Get the locator that will be used to generate the representation.
- `vtkLocator = obj.GetSpatialRepresentation ()` - Set/Get the locator that will be used to generate the representation.
- `int = obj.GetLevel ()` - Get the maximum number of outputs actually available.
- `vtkPolyData = obj.GetOutput (int level)` - A special form of the GetOutput() method that returns multiple outputs.
- `vtkPolyData = obj.GetOutput ()` - Output of terminal nodes/leaves.
- `obj.ResetOutput ()` - Reset requested output levels
- `obj.SetInput (vtkDataSet input)` - Set / get the input data or filter.
- `vtkDataSet = obj.GetInput ()` - Set / get the input data or filter.

33.205 vtkSpherePuzzle

33.205.1 Usage

vtkSpherePuzzle creates

To create an instance of class vtkSpherePuzzle, simply invoke its constructor as follows

```
obj = vtkSpherePuzzle
```

33.205.2 Methods

The class vtkSpherePuzzle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSpherePuzzle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSpherePuzzle = obj.NewInstance ()`
- `vtkSpherePuzzle = obj.SafeDownCast (vtkObject o)`
- `obj.Reset ()` - Reset the state of this puzzle back to its original state.

- `obj.MoveHorizontal (int section, int percentage, int rightFlag)` - Move the top/bottom half one segment either direction.

- `obj.MoveVertical (int section, int percentage, int rightFlag)` - Rotate vertical half of sphere along one of the longitude lines.

- `int = obj.SetPoint (double x, double y, double z)` - SetPoint will be called as the mouse moves over the screen. The output will change to indicate the pending move. SetPoint returns zero if move is not activated by point. Otherwise it encodes the move into a unique integer so that the caller can determine if the move state has changed. This will answer the question, "Should I render."

- `obj.MovePoint (int percentage)` - Move actually implements the pending move. When percentage is 100, the pending move becomes inactive, and SetPoint will have to be called again to setup another move.

33.206 vtkSpherePuzzleArrows

33.206.1 Usage

vtkSpherePuzzleArrows creates

To create an instance of class vtkSpherePuzzleArrows, simply invoke its constructor as follows

```
obj = vtkSpherePuzzleArrows
```

33.206.2 Methods

The class vtkSpherePuzzleArrows has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSpherePuzzleArrows class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkSpherePuzzleArrows = obj.NewInstance ()`

- `vtkSpherePuzzleArrows = obj.SafeDownCast (vtkObject o)`

- `obj.SetPermutation (int [32])` - Permutation is an array of puzzle piece ids. Arrows will be generated for any id that does not contain itself. Permutation[3] = 3 will produce no arrow. Permutation[3] = 10 will draw an arrow from location 3 to 10.

- `int = obj. GetPermutation ()` - Permutation is an array of puzzle piece ids. Arrows will be generated for any id that does not contain itself. Permutation[3] = 3 will produce no arrow. Permutation[3] = 10 will draw an arrow from location 3 to 10.

- `obj.SetPermutationComponent (int comp, int val)` - Permutation is an array of puzzle piece ids. Arrows will be generated for any id that does not contain itself. Permutation[3] = 3 will produce no arrow. Permutation[3] = 10 will draw an arrow from location 3 to 10.

- `obj.SetPermutation (vtkSpherePuzzle puz)` - Permutation is an array of puzzle piece ids. Arrows will be generated for any id that does not contain itself. Permutation[3] = 3 will produce no arrow. Permutation[3] = 10 will draw an arrow from location 3 to 10.

33.207 vtkSphereSource

33.207.1 Usage

vtkSphereSource creates a sphere (represented by polygons) of specified radius centered at the origin. The resolution (polygonal discretization) in both the latitude (phi) and longitude (theta) directions can be specified. It also is possible to create partial spheres by specifying maximum phi and theta angles. By default, the surface tessellation of the sphere uses triangles; however you can set LatLongTessellation to produce a tessellation using quadrilaterals.

To create an instance of class vtkSphereSource, simply invoke its constructor as follows

```
obj = vtkSphereSource
```

33.207.2 Methods

The class vtkSphereSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphereSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSphereSource = obj.NewInstance ()`
- `vtkSphereSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetRadius (double )` - Set radius of sphere. Default is .5.
- `double = obj.GetRadiusMinValue ()` - Set radius of sphere. Default is .5.
- `double = obj.GetRadiusMaxValue ()` - Set radius of sphere. Default is .5.
- `double = obj.GetRadius ()` - Set radius of sphere. Default is .5.
- `obj.SetCenter (double , double , double )` - Set the center of the sphere. Default is 0,0,0.
- `obj.SetCenter (double  a[3])` - Set the center of the sphere. Default is 0,0,0.
- `double = obj. GetCenter ()` - Set the center of the sphere. Default is 0,0,0.
- `obj.SetThetaResolution (int )` - Set the number of points in the longitude direction (ranging from StartTheta to EndTheta).
- `int = obj.GetThetaResolutionMinValue ()` - Set the number of points in the longitude direction (ranging from StartTheta to EndTheta).
- `int = obj.GetThetaResolutionMaxValue ()` - Set the number of points in the longitude direction (ranging from StartTheta to EndTheta).
- `int = obj.GetThetaResolution ()` - Set the number of points in the longitude direction (ranging from StartTheta to EndTheta).
- `obj.SetPhiResolution (int )` - Set the number of points in the latitude direction (ranging from StartPhi to EndPhi).
- `int = obj.GetPhiResolutionMinValue ()` - Set the number of points in the latitude direction (ranging from StartPhi to EndPhi).
- `int = obj.GetPhiResolutionMaxValue ()` - Set the number of points in the latitude direction (ranging from StartPhi to EndPhi).

- `int = obj.GetPhiResolution ()` - Set the number of points in the latitude direction (ranging from StartPhi to EndPhi).
- `obj.SetStartTheta (double )` - Set the starting longitude angle. By default StartTheta=0 degrees.
- `double = obj.GetStartThetaMinValue ()` - Set the starting longitude angle. By default StartTheta=0 degrees.
- `double = obj.GetStartThetaMaxValue ()` - Set the starting longitude angle. By default StartTheta=0 degrees.
- `double = obj.GetStartTheta ()` - Set the starting longitude angle. By default StartTheta=0 degrees.
- `obj.SetEndTheta (double )` - Set the ending longitude angle. By default EndTheta=360 degrees.
- `double = obj.GetEndThetaMinValue ()` - Set the ending longitude angle. By default EndTheta=360 degrees.
- `double = obj.GetEndThetaMaxValue ()` - Set the ending longitude angle. By default EndTheta=360 degrees.
- `double = obj.GetEndTheta ()` - Set the ending longitude angle. By default EndTheta=360 degrees.
- `obj.SetStartPhi (double )` - Set the starting latitude angle (0 is at north pole). By default StartPhi=0 degrees.
- `double = obj.GetStartPhiMinValue ()` - Set the starting latitude angle (0 is at north pole). By default StartPhi=0 degrees.
- `double = obj.GetStartPhiMaxValue ()` - Set the starting latitude angle (0 is at north pole). By default StartPhi=0 degrees.
- `double = obj.GetStartPhi ()` - Set the starting latitude angle (0 is at north pole). By default StartPhi=0 degrees.
- `obj.SetEndPhi (double )` - Set the ending latitude angle. By default EndPhi=180 degrees.
- `double = obj.GetEndPhiMinValue ()` - Set the ending latitude angle. By default EndPhi=180 degrees.
- `double = obj.GetEndPhiMaxValue ()` - Set the ending latitude angle. By default EndPhi=180 degrees.
- `double = obj.GetEndPhi ()` - Set the ending latitude angle. By default EndPhi=180 degrees.
- `obj.SetLatLongTessellation (int )` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.
- `int = obj.GetLatLongTessellation ()` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.

- `obj.LatLongTessellationOn ()` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.

- `obj.LatLongTessellationOff ()` - Cause the sphere to be tessellated with edges along the latitude and longitude lines. If off, triangles are generated at non-polar regions, which results in edges that are not parallel to latitude and longitude lines. If on, quadrilaterals are generated everywhere except at the poles. This can be useful for generating a wireframe sphere with natural latitude and longitude lines.

33.208 vtkSplineFilter

33.208.1 Usage

vtkSplineFilter is a filter that generates an output polylines from an input set of polylines. The polylines are uniformly subdivided and produced with the help of a vtkSpline class that the user can specify (by default a vtkCardinalSpline is used). The number of subdivisions of the line can be controlled in several ways. The user can either specify the number of subdivisions or a length of each subdivision can be provided (and the class will figure out how many subdivisions is required over the whole polyline). The maximum number of subdivisions can also be set.

The output of this filter is a polyline per input polyline (or line). New points and texture coordinates are created. Point data is interpolated and cell data passed on. Any polylines with less than two points, or who have coincident points, are ignored.

To create an instance of class vtkSplineFilter, simply invoke its constructor as follows

```
obj = vtkSplineFilter
```

33.208.2 Methods

The class vtkSplineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplineFilter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkSplineFilter = obj.NewInstance ()`

- `vtkSplineFilter = obj.SafeDownCast (vtkObject o)`

- `obj.SetMaximumNumberOfSubdivisions (int )` - Set the maximum number of subdivisions that are created for each polyline.

- `int = obj.GetMaximumNumberOfSubdivisionsMinValue ()` - Set the maximum number of subdivisions that are created for each polyline.

- `int = obj.GetMaximumNumberOfSubdivisionsMaxValue ()` - Set the maximum number of subdivisions that are created for each polyline.

- `int = obj.GetMaximumNumberOfSubdivisions ()` - Set the maximum number of subdivisions that are created for each polyline.

- `obj.SetSubdivide (int )` - Specify how the number of subdivisions is determined.

- `int = obj.GetSubdivideMinValue ()` - Specify how the number of subdivisions is determined.
- `int = obj.GetSubdivideMaxValue ()` - Specify how the number of subdivisions is determined.
- `int = obj.GetSubdivide ()` - Specify how the number of subdivisions is determined.
- `obj.SetSubdivideToSpecified ()` - Specify how the number of subdivisions is determined.
- `obj.SetSubdivideToLength ()` - Specify how the number of subdivisions is determined.
- `string = obj.GetSubdivideAsString ()` - Specify how the number of subdivisions is determined.
- `obj.SetNumberOfSubdivisions (int )` - Set the number of subdivisions that are created for the polyline. This method only has effect if Subdivisions is set to SetSubdivisionsToSpecify().
- `int = obj.GetNumberOfSubdivisionsMinValue ()` - Set the number of subdivisions that are created for the polyline. This method only has effect if Subdivisions is set to SetSubdivisionsToSpecify().
- `int = obj.GetNumberOfSubdivisionsMaxValue ()` - Set the number of subdivisions that are created for the polyline. This method only has effect if Subdivisions is set to SetSubdivisionsToSpecify().
- `int = obj.GetNumberOfSubdivisions ()` - Set the number of subdivisions that are created for the polyline. This method only has effect if Subdivisions is set to SetSubdivisionsToSpecify().
- `obj.SetLength (double )` - Control the number of subdivisions that are created for the polyline based on an absolute length. The length of the spline is divided by this length to determine the number of subdivisions.
- `double = obj.GetLengthMinValue ()` - Control the number of subdivisions that are created for the polyline based on an absolute length. The length of the spline is divided by this length to determine the number of subdivisions.
- `double = obj.GetLengthMaxValue ()` - Control the number of subdivisions that are created for the polyline based on an absolute length. The length of the spline is divided by this length to determine the number of subdivisions.
- `double = obj.GetLength ()` - Control the number of subdivisions that are created for the polyline based on an absolute length. The length of the spline is divided by this length to determine the number of subdivisions.
- `obj.SetSpline (vtkSpline )` - Specify an instance of vtkSpline to use to perform the interpolation.
- `vtkSpline = obj.GetSpline ()` - Specify an instance of vtkSpline to use to perform the interpolation.
- `obj.SetGenerateTCoords (int )` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.
- `int = obj.GetGenerateTCoordsMinValue ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.
- `int = obj.GetGenerateTCoordsMaxValue ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `int = obj.GetGenerateTCoords ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `obj.SetGenerateTCoordsToOff ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `obj.SetGenerateTCoordsToNormalizedLength ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `obj.SetGenerateTCoordsToUseLength ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `obj.SetGenerateTCoordsToUseScalars ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `string = obj.GetGenerateTCoordsAsString ()` - Control whether and how texture coordinates are produced. This is useful for striping the output polyline. The texture coordinates can be generated in three ways: a normalized (0,1) generation; based on the length (divided by the texture length); and by using the input scalar values.

- `obj.SetTextureLength (double )` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.

- `double = obj.GetTextureLengthMinValue ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.

- `double = obj.GetTextureLengthMaxValue ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.

- `double = obj.GetTextureLength ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.

33.209 vtkSplitField

33.209.1 Usage

vtkSplitField is used to split a multi-component field (vtkDataArray) into multiple single component fields. The new fields are put in the same field data as the original field. The output arrays are of the same type as the input array. Example: @verbatim sf-¿SetInputField("gradient", vtkSplitField::POINT_DATA); sf-¿Split(0, "firstcomponent"); @endverbatim tells vtkSplitField to extract the first component of the field called gradient and create an array called firstcomponent (the new field will be in the output's point data). The same can be done from Tcl: @verbatim sf SetInputField gradient POINT_DATA sf Split 0 firstcomponent

AttributeTypes: SCALARS, VECTORS, NORMALS, TCOORDS, TENSORS Field locations: DATA_OBJECT, POINT_DATA, CELL_DATA @endverbatim Note that, by default, the original array is also passed through.

To create an instance of class vtkSplitField, simply invoke its constructor as follows

```
obj = vtkSplitField
```

33.209.2 Methods

The class vtkSplitField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplitField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSplitField = obj.NewInstance ()`
- `vtkSplitField = obj.SafeDownCast (vtkObject o)`
- `obj.SetInputField (int attributeType, int fieldLoc)` - Use the given attribute in the field data given by fieldLoc as input.
- `obj.SetInputField (string name, int fieldLoc)` - Use the array with given name in the field data given by fieldLoc as input.
- `obj.SetInputField (string name, string fieldLoc)` - Helper method used by other language bindings. Allows the caller to specify arguments as strings instead of enums.
- `obj.Split (int component, string arrayName)` - Create a new array with the given component.

33.210 vtkStreamer

33.210.1 Usage

vtkStreamer is a filter that integrates a massless particle through a vector field. The integration is performed using second order Runge-Kutta method. vtkStreamer often serves as a base class for other classes that perform numerical integration through a vector field (e.g., vtkStreamLine).

Note that vtkStreamer can integrate both forward and backward in time, or in both directions. The length of the streamer is controlled by specifying an elapsed time. (The elapsed time is the time each particle travels.) Otherwise, the integration terminates after exiting the dataset or if the particle speed is reduced to a value less than the terminal speed.

vtkStreamer integrates through any type of dataset. As a result, if the dataset contains 2D cells such as polygons or triangles, the integration is constrained to lie on the surface defined by the 2D cells.

The starting point of streamers may be defined in three different ways. Starting from global x-y-z "position" allows you to start a single streamer at a specified x-y-z coordinate. Starting from "location" allows you to start at a specified cell, subId, and parametric coordinate. Finally, you may specify a source object to start multiple streamers. If you start streamers using a source object, for each point in the source that is inside the dataset a streamer is created.

vtkStreamer implements the integration process in the Integrate() method. Because vtkStreamer does not implement the Execute() method that its superclass (i.e., Filter) requires, it is an abstract class. Its subclasses implement the execute method and use the Integrate() method, and then build their own representation of the integration path (i.e., lines, dashed lines, points, etc.).

To create an instance of class vtkStreamer, simply invoke its constructor as follows

```
obj = vtkStreamer
```

33.210.2 Methods

The class vtkStreamer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamer = obj.NewInstance ()`
- `vtkStreamer = obj.SafeDownCast (vtkObject o)`
- `obj.SetStartLocation (vtkIdType cellId, int subId, double pcoords[3])` - Specify the start of the streamline in the cell coordinate system. That is, cellId and subId (if composite cell), and parametric coordinates.
- `obj.SetStartLocation (vtkIdType cellId, int subId, double r, double s, double t)` - Specify the start of the streamline in the cell coordinate system. That is, cellId and subId (if composite cell), and parametric coordinates.
- `obj.SetStartPosition (double x[3])` - Specify the start of the streamline in the global coordinate system. Search must be performed to find initial cell to start integration from.
- `obj.SetStartPosition (double x, double y, double z)` - Specify the start of the streamline in the global coordinate system. Search must be performed to find initial cell to start integration from.
- `double = obj.GetStartPosition ()` - Get the start position in global x-y-z coordinates.
- `obj.SetSource (vtkDataSet source)` - Specify the source object used to generate starting points.
- `vtkDataSet = obj.GetSource ()` - Specify the source object used to generate starting points.
- `obj.SetMaximumPropagationTime (double )` - Specify the maximum length of the Streamer expressed in elapsed time.
- `double = obj.GetMaximumPropagationTimeMinValue ()` - Specify the maximum length of the Streamer expressed in elapsed time.
- `double = obj.GetMaximumPropagationTimeMaxValue ()` - Specify the maximum length of the Streamer expressed in elapsed time.
- `double = obj.GetMaximumPropagationTime ()` - Specify the maximum length of the Streamer expressed in elapsed time.
- `obj.SetIntegrationDirection (int )` - Specify the direction in which to integrate the Streamer.
- `int = obj.GetIntegrationDirectionMinValue ()` - Specify the direction in which to integrate the Streamer.
- `int = obj.GetIntegrationDirectionMaxValue ()` - Specify the direction in which to integrate the Streamer.
- `int = obj.GetIntegrationDirection ()` - Specify the direction in which to integrate the Streamer.
- `obj.SetIntegrationDirectionToForward ()` - Specify the direction in which to integrate the Streamer.
- `obj.SetIntegrationDirectionToBackward ()` - Specify the direction in which to integrate the Streamer.
- `obj.SetIntegrationDirectionToIntegrateBothDirections ()` - Specify the direction in which to integrate the Streamer.

- `string = obj.GetIntegrationDirectionAsString ()` - Specify the direction in which to integrate the Streamer.
- `obj.SetIntegrationStepLength (double )` - Specify a nominal integration step size (expressed as a fraction of the size of each cell). This value can be larger than 1.
- `double = obj.GetIntegrationStepLengthMinValue ()` - Specify a nominal integration step size (expressed as a fraction of the size of each cell). This value can be larger than 1.
- `double = obj.GetIntegrationStepLengthMaxValue ()` - Specify a nominal integration step size (expressed as a fraction of the size of each cell). This value can be larger than 1.
- `double = obj.GetIntegrationStepLength ()` - Specify a nominal integration step size (expressed as a fraction of the size of each cell). This value can be larger than 1.
- `obj.SetSpeedScalars (int )` - Turn on/off the creation of scalar data from velocity magnitude. If off, and input dataset has scalars, input dataset scalars are used.
- `int = obj.GetSpeedScalars ()` - Turn on/off the creation of scalar data from velocity magnitude. If off, and input dataset has scalars, input dataset scalars are used.
- `obj.SpeedScalarsOn ()` - Turn on/off the creation of scalar data from velocity magnitude. If off, and input dataset has scalars, input dataset scalars are used.
- `obj.SpeedScalarsOff ()` - Turn on/off the creation of scalar data from velocity magnitude. If off, and input dataset has scalars, input dataset scalars are used.
- `obj.SetOrientationScalars (int )` - Turn on/off the creation of scalar data from vorticity information. The scalar information is currently the orientation value "theta" used in rotating stream tubes. If off, and input dataset has scalars, then input dataset scalars are used, unless SpeedScalars is also on. SpeedScalars takes precedence over OrientationScalars.
- `int = obj.GetOrientationScalars ()` - Turn on/off the creation of scalar data from vorticity information. The scalar information is currently the orientation value "theta" used in rotating stream tubes. If off, and input dataset has scalars, then input dataset scalars are used, unless SpeedScalars is also on. SpeedScalars takes precedence over OrientationScalars.
- `obj.OrientationScalarsOn ()` - Turn on/off the creation of scalar data from vorticity information. The scalar information is currently the orientation value "theta" used in rotating stream tubes. If off, and input dataset has scalars, then input dataset scalars are used, unless SpeedScalars is also on. SpeedScalars takes precedence over OrientationScalars.
- `obj.OrientationScalarsOff ()` - Turn on/off the creation of scalar data from vorticity information. The scalar information is currently the orientation value "theta" used in rotating stream tubes. If off, and input dataset has scalars, then input dataset scalars are used, unless SpeedScalars is also on. SpeedScalars takes precedence over OrientationScalars.
- `obj.SetTerminalSpeed (double )` - Set/get terminal speed (i.e., speed is velocity magnitude). Terminal speed is speed at which streamer will terminate propagation.
- `double = obj.GetTerminalSpeedMinValue ()` - Set/get terminal speed (i.e., speed is velocity magnitude). Terminal speed is speed at which streamer will terminate propagation.
- `double = obj.GetTerminalSpeedMaxValue ()` - Set/get terminal speed (i.e., speed is velocity magnitude). Terminal speed is speed at which streamer will terminate propagation.
- `double = obj.GetTerminalSpeed ()` - Set/get terminal speed (i.e., speed is velocity magnitude). Terminal speed is speed at which streamer will terminate propagation.

- `obj.SetVorticity (int )` - Turn on/off the computation of vorticity. Vorticity is an indication of the rotation of the flow. In combination with vtkStreamLine and vtkTubeFilter can be used to create rotated tubes. If vorticity is turned on, in the output, the velocity vectors are replaced by vorticity vectors.
- `int = obj.GetVorticity ()` - Turn on/off the computation of vorticity. Vorticity is an indication of the rotation of the flow. In combination with vtkStreamLine and vtkTubeFilter can be used to create rotated tubes. If vorticity is turned on, in the output, the velocity vectors are replaced by vorticity vectors.
- `obj.VorticityOn ()` - Turn on/off the computation of vorticity. Vorticity is an indication of the rotation of the flow. In combination with vtkStreamLine and vtkTubeFilter can be used to create rotated tubes. If vorticity is turned on, in the output, the velocity vectors are replaced by vorticity vectors.
- `obj.VorticityOff ()` - Turn on/off the computation of vorticity. Vorticity is an indication of the rotation of the flow. In combination with vtkStreamLine and vtkTubeFilter can be used to create rotated tubes. If vorticity is turned on, in the output, the velocity vectors are replaced by vorticity vectors.
- `obj.SetNumberOfThreads (int )`
- `int = obj.GetNumberOfThreads ()`
- `obj.SetSavePointInterval (double )`
- `double = obj.GetSavePointInterval ()`
- `obj.SetIntegrator (vtkInitialValueProblemSolver )` - Set/get the integrator type to be used in the stream line calculation. The object passed is not actually used but is cloned with NewInstance by each thread/process in the process of integration (prototype pattern). The default is 2nd order Runge Kutta.
- `vtkInitialValueProblemSolver = obj.GetIntegrator ()` - Set/get the integrator type to be used in the stream line calculation. The object passed is not actually used but is cloned with NewInstance by each thread/process in the process of integration (prototype pattern). The default is 2nd order Runge Kutta.
- `obj.SetEpsilon (double )` - A positive value, as small as possible for numerical comparison. The initial value is 1E-12.
- `double = obj.GetEpsilon ()` - A positive value, as small as possible for numerical comparison. The initial value is 1E-12.

33.211 vtkStreamingTessellator

33.211.1 Usage

This class is a simple algorithm that takes a single starting simplex – a tetrahedron, triangle, or line segment – and calls a function you pass it with (possibly many times) tetrahedra, triangles, or lines adaptively sampled from the one you specified. It uses an algorithm you specify to control the level of adaptivity.

This class does not create vtkUnstructuredGrid output because it is intended for use in mappers as well as filters. Instead, it calls the registered function with simplices as they are created.

The subdivision algorithm should change the vertex coordinates (it must change both geometric and, if desired, parametric coordinates) of the midpoint. These coordinates need not be changed unless the EvaluateEdge() member returns true. The vtkStreamingTessellator itself has no way of creating a more accurate midpoint vertex.

Here's how to use this class: - Call AdaptivelySample1Facet, AdaptivelySample2Facet, or AdaptivelySample3Facet, with an edge, triangle, or tetrahedron you want tessellated. - The adaptive tessellator classifies each edge by passing the midpoint values to the vtkEdgeSubdivisionCriterion. - After each edge is classified, the tessellator subdivides edges as required until the subdivision criterion is satisfied or the maximum subdivision depth has been reached. - Edges, triangles, or tetrahedra connecting the vertices generated by the subdivision algorithm are processed by calling the user-defined callback functions (set with SetTetrahedronCallback(), SetTriangleCallback(), or SetEdgeCallback()).

.SECTION Warning Note that the vertices passed to AdaptivelySample3Facet, AdaptivelySample2Facet, or AdaptivelySample1Facet must be at least 6, 5, or 4 entries long, respectively! This is because the <r,s,t>, <r,s>, or <r> parametric coordinates of the vertices are maintained as the facet is subdivided. This information is often required by the subdivision algorithm in order to compute an error metric. You may change the number of parametric coordinates associated with each vertex using vtkStreamingTessellator::SetEmbeddingDimension().

.SECTION Interpolating Field Values If you wish, you may also use vtkStreamingTessellator to interpolate field values at newly created vertices. Interpolated field values are stored just beyond the parametric coordinates associated with a vertex. They will always be double values; it does not make sense to interpolate a boolean or string value and your output and subdivision subroutines may always cast to a float or use floor() to truncate an interpolated value to an integer.

To create an instance of class vtkStreamingTessellator, simply invoke its constructor as follows

```
obj = vtkStreamingTessellator
```

33.211.2 Methods

The class vtkStreamingTessellator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamingTessellator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamingTessellator = obj.NewInstance ()`
- `vtkStreamingTessellator = obj.SafeDownCast (vtkObject o)`
- `obj.SetSubdivisionAlgorithm (vtkEdgeSubdivisionCriterion )` - Get/Set the algorithm used to determine whether an edge should be subdivided or left as-is. This is used once for each call to AdaptivelySample1Facet (which is recursive and will call itself resulting in additional edges to be checked) or three times for each call to AdaptivelySample2Facet (also recursive).
- `vtkEdgeSubdivisionCriterion = obj.GetSubdivisionAlgorithm ()` - Get/Set the algorithm used to determine whether an edge should be subdivided or left as-is. This is used once for each call to AdaptivelySample1Facet (which is recursive and will call itself resulting in additional edges to be checked) or three times for each call to AdaptivelySample2Facet (also recursive).
- `obj.SetEmbeddingDimension (int k, int d)` - Get/Set the number of parameter-space coordinates associated with each input and output point. The default is k for k -facets. You may specify a different dimension, d, for each type of k -facet to be processed. For example, SetEmbeddingDimension(2, 3) would associate r, s, and t coordinates with each input and output point generated by AdaptivelySample2Facet but does not say anything about input or output points generated by AdaptivelySample1Facet. Call SetEmbeddingDimension(-1, d) to specify the same dimension for all possible k values. d may not exceed 8, as that would be plain silly.
- `int = obj.GetEmbeddingDimension (int k) const` - Get/Set the number of parameter-space coordinates associated with each input and output point. The default is k for k -facets. You may specify

a different dimension, d, for each type of k -facet to be processed. For example, SetEmbeddingDimension(2, 3) would associate r, s, and t coordinates with each input and output point generated by AdaptivelySample2Facet but does not say anything about input or output points generated by AdaptivelySample1Facet. Call SetEmbeddingDimension(-1, d) to specify the same dimension for all possible k values. d may not exceed 8, as that would be plain silly.

- `obj.SetFieldSize (int k, int s)` - Get/Set the number of field value coordinates associated with each input and output point. The default is 0; no field values are interpolated. You may specify a different size, s, for each type of k -facet to be processed. For example, SetFieldSize(2, 3) would associate 3 field value coordinates with each input and output point of an AdaptivelySample2Facet call, but does not say anything about input or output points of AdaptivelySample1Facet. Call SetFieldSize(-1, s) to specify the same dimension for all possible k values. s may not exceed vtkStreamingTessellator::MaxFieldSize. This is a compile-time constant that defaults to 18, which is large enough for a scalar, vector, tensor, normal, and texture coordinate to be included at each point.

  Normally, you will not call SetFieldSize() directly; instead, subclasses of vtkEdgeSubdivisionCriterion, such as vtkShoeMeshSubdivisionAlgorithm, will call it for you.

  In any event, setting FieldSize to a non-zero value means you must pass field values to the AdaptivelySamplekFacet routines; For example, @verbatim vtkStreamingTessellator* t = vtkStreamingTessellator::New(); t-¿SetFieldSize(1, 3); t-¿SetEmbeddingDimension(1, 1); // not really required, this is the default double p0[3+1+3] = x0, y0, z0, r0, fx0, fy0, fz0 ; double p1[3+1+3] = x1, y1, z1, r1, fx1, fy1, fz1 ; t-¿AdaptivelySample1Facet(p0, p1); @endverbatim This would adaptively sample an curve (1-facet) with geometry and a vector field at every output point on the curve.

- `int = obj.GetFieldSize (int k) const` - Get/Set the number of field value coordinates associated with each input and output point. The default is 0; no field values are interpolated. You may specify a different size, s, for each type of k -facet to be processed. For example, SetFieldSize(2, 3) would associate 3 field value coordinates with each input and output point of an AdaptivelySample2Facet call, but does not say anything about input or output points of AdaptivelySample1Facet. Call SetFieldSize(-1, s) to specify the same dimension for all possible k values. s may not exceed vtkStreamingTessellator::MaxFieldSize. This is a compile-time constant that defaults to 18, which is large enough for a scalar, vector, tensor, normal, and texture coordinate to be included at each point.

  Normally, you will not call SetFieldSize() directly; instead, subclasses of vtkEdgeSubdivisionCriterion, such as vtkShoeMeshSubdivisionAlgorithm, will call it for you.

  In any event, setting FieldSize to a non-zero value means you must pass field values to the AdaptivelySamplekFacet routines; For example, @verbatim vtkStreamingTessellator* t = vtkStreamingTessellator::New(); t-¿SetFieldSize(1, 3); t-¿SetEmbeddingDimension(1, 1); // not really required, this is the default double p0[3+1+3] = x0, y0, z0, r0, fx0, fy0, fz0 ; double p1[3+1+3] = x1, y1, z1, r1, fx1, fy1, fz1 ; t-¿AdaptivelySample1Facet(p0, p1); @endverbatim This would adaptively sample an curve (1-facet) with geometry and a vector field at every output point on the curve.

- `obj.SetMaximumNumberOfSubdivisions (int num\_subdiv\_in)` - Get/Set the maximum number of subdivisions that may occur.

- `int = obj.GetMaximumNumberOfSubdivisions ()` - Get/Set the maximum number of subdivisions that may occur.

- `obj.AdaptivelySample3Facet (double v1, double v2, double v3, double v4) const` - This will adaptively subdivide the tetrahedron (3-facet), triangle (2-facet), or edge (1-facet) until the subdivision algorithm returns false for every edge or the maximum recursion depth is reached.

  Use SetMaximumNumberOfSubdivisions to change the maximum recursion depth.

  The AdaptivelySample0Facet method is provided as a convenience. Obviously, there is no way to adaptively subdivide a vertex. Instead the input vertex is passed unchanged to the output via a call to the registered VertexProcessorFunction callback.

.SECTION Warning This assumes that you have called SetSubdivisionAlgorithm(), SetEdgeCallback(), SetTriangleCallback(), and SetTetrahedronCallback() with valid values!

- `obj.AdaptivelySample2Facet (double v1, double v2, double v3) const` - This will adaptively subdivide the tetrahedron (3-facet), triangle (2-facet), or edge (1-facet) until the subdivision algorithm returns false for every edge or the maximum recursion depth is reached.

  Use SetMaximumNumberOfSubdivisions to change the maximum recursion depth.

  The AdaptivelySample0Facet method is provided as a convenience. Obviously, there is no way to adaptively subdivide a vertex. Instead the input vertex is passed unchanged to the output via a call to the registered VertexProcessorFunction callback.

  .SECTION Warning This assumes that you have called SetSubdivisionAlgorithm(), SetEdgeCallback(), SetTriangleCallback(), and SetTetrahedronCallback() with valid values!

- `obj.AdaptivelySample1Facet (double v1, double v2) const` - This will adaptively subdivide the tetrahedron (3-facet), triangle (2-facet), or edge (1-facet) until the subdivision algorithm returns false for every edge or the maximum recursion depth is reached.

  Use SetMaximumNumberOfSubdivisions to change the maximum recursion depth.

  The AdaptivelySample0Facet method is provided as a convenience. Obviously, there is no way to adaptively subdivide a vertex. Instead the input vertex is passed unchanged to the output via a call to the registered VertexProcessorFunction callback.

  .SECTION Warning This assumes that you have called SetSubdivisionAlgorithm(), SetEdgeCallback(), SetTriangleCallback(), and SetTetrahedronCallback() with valid values!

- `obj.ResetCounts ()` - Reset/access the histogram of subdivision cases encountered. The histogram may be used to examine coverage during testing as well as characterizing the tessellation algorithm's performance. You should call ResetCounts() once, at the beginning of a stream of tetrahedra. It must be called before AdaptivelySample3Facet() to prevent uninitialized memory reads.

  These functions have no effect (and return 0) when PARAVIEW_DEBUG_TESSELLATOR has not been defined. By default, PARAVIEW_DEBUG_TESSELLATOR is not defined, and your code will be fast and efficient. Really!

- `vtkIdType = obj.GetCaseCount (int c)` - Reset/access the histogram of subdivision cases encountered. The histogram may be used to examine coverage during testing as well as characterizing the tessellation algorithm's performance. You should call ResetCounts() once, at the beginning of a stream of tetrahedra. It must be called before AdaptivelySample3Facet() to prevent uninitialized memory reads.

  These functions have no effect (and return 0) when PARAVIEW_DEBUG_TESSELLATOR has not been defined. By default, PARAVIEW_DEBUG_TESSELLATOR is not defined, and your code will be fast and efficient. Really!

- `vtkIdType = obj.GetSubcaseCount (int casenum, int sub)`

33.212 vtkStreamLine

33.212.1 Usage

vtkStreamLine is a filter that generates a streamline for an arbitrary dataset. A streamline is a line that is everywhere tangent to the vector field. Scalar values also are calculated along the streamline and can be used to color the line. Streamlines are calculated by integrating from a starting point through the vector field. Integration can be performed forward in time (see where the line goes), backward in time (see where the line came from), or in both directions. It also is possible to compute vorticity along the streamline. Vorticity is the projection (i.e., dot product) of the flow rotation on the velocity vector, i.e., the rotation of flow around the streamline.

vtkStreamLine defines the instance variable StepLength. This parameter controls the time increment used to generate individual points along the streamline(s). Smaller values result in more line primitives but smoother streamlines. The StepLength instance variable is defined in terms of time (i.e., the distance that the particle travels in the specified time period). Thus, the line segments will be smaller in areas of low velocity and larger in regions of high velocity. (NOTE: This is different than the IntegrationStepLength defined by the superclass vtkStreamer. IntegrationStepLength is used to control integration step size and is expressed as a fraction of the cell length.) The StepLength instance variable is important because subclasses of vtkStreamLine (e.g., vtkDashedStreamLine) depend on this value to build their representation.

To create an instance of class vtkStreamLine, simply invoke its constructor as follows

```
obj = vtkStreamLine
```

33.212.2 Methods

The class vtkStreamLine has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamLine class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamLine = obj.NewInstance ()`
- `vtkStreamLine = obj.SafeDownCast (vtkObject o)`
- `obj.SetStepLength (double )` - Specify the length of a line segment. The length is expressed in terms of elapsed time. Smaller values result in smoother appearing streamlines, but greater numbers of line primitives.
- `double = obj.GetStepLengthMinValue ()` - Specify the length of a line segment. The length is expressed in terms of elapsed time. Smaller values result in smoother appearing streamlines, but greater numbers of line primitives.
- `double = obj.GetStepLengthMaxValue ()` - Specify the length of a line segment. The length is expressed in terms of elapsed time. Smaller values result in smoother appearing streamlines, but greater numbers of line primitives.
- `double = obj.GetStepLength ()` - Specify the length of a line segment. The length is expressed in terms of elapsed time. Smaller values result in smoother appearing streamlines, but greater numbers of line primitives.

33.213 vtkStreamPoints

33.213.1 Usage

vtkStreamPoints is a filter that generates points along a streamer. The points are separated by a constant time increment. The resulting visual effect (especially when coupled with vtkGlyph3D) is an indication of particle speed.

To create an instance of class vtkStreamPoints, simply invoke its constructor as follows

```
obj = vtkStreamPoints
```

33.213.2 Methods

The class vtkStreamPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamPoints = obj.NewInstance ()`
- `vtkStreamPoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetTimeIncrement (double )` - Specify the separation of points in terms of absolute time.
- `double = obj.GetTimeIncrementMinValue ()` - Specify the separation of points in terms of absolute time.
- `double = obj.GetTimeIncrementMaxValue ()` - Specify the separation of points in terms of absolute time.
- `double = obj.GetTimeIncrement ()` - Specify the separation of points in terms of absolute time.

33.214 vtkStreamTracer

33.214.1 Usage

vtkStreamTracer is a filter that integrates a vector field to generate streamlines. The integration is performed using a specified integrator, by default Runge-Kutta2.

vtkStreamTracer produces polylines as the output, with each cell (i.e., polyline) representing a streamline. The attribute values associated with each streamline are stored in the cell data, whereas those associated with streamline-points are stored in the point data.

vtkStreamTracer supports forward (the default), backward, and combined (i.e., BOTH) integration. The length of a streamline is governed by specifying a maximum value either in physical arc length or in (local) cell length. Otherwise, the integration terminates upon exiting the flow field domain, or if the particle speed is reduced to a value less than a specified terminal speed, or when a maximum number of steps is completed. The specific reason for the termination is stored in a cell array named ReasonForTermination.

Note that normalized vectors are adopted in streamline integration, which achieves high numerical accuracy/smoothness of flow lines that is particularly guranteed for Runge-Kutta45 with adaptive step size and error control). In support of this feature, the underlying step size is ALWAYS in arc length unit (LENGTH_UNIT) while the 'real' time interval (virtual for steady flows) that a particle actually takes to trave in a single step is obtained by dividing the arc length by the LOCAL speed. The overall elapsed time (i.e., the life span) of the particle is the sum of those individual step-wise time intervals.

The quality of streamline integration can be controlled by setting the initial integration step (InitialIntegrationStep), particularly for Runge-Kutta2 and Runge-Kutta4 (with a fixed step size), and in the case of

Runge-Kutta45 (with an adaptive step size and error control) the minimum integration step, the maximum integration step, and the maximum error. These steps are in either LENGTH_UNIT or CELL_LENGTH_UNIT while the error is in physical arc length. For the former two integrators, there is a trade-off between integration speed and streamline quality.

The integration time, vorticity, rotation and angular velocity are stored in point data arrays named "IntegrationTime", "Vorticity", "Rotation" and "AngularVelocity", respectively (vorticity, rotation and angular velocity are computed only when ComputeVorticity is on). All point data attributes in the source dataset are interpolated on the new streamline points.

vtkStreamTracer supports integration through any type of dataset. Thus if the dataset contains 2D cells like polygons or triangles, the integration is constrained to lie on the surface defined by 2D cells.

The starting point, or the so-called 'seed', of a streamline may be set in two different ways. Starting from global x-y-z "position" allows you to start a single trace at a specified x-y-z coordinate. If you specify a source object, traces will be generated from each point in the source that is inside the dataset.

To create an instance of class vtkStreamTracer, simply invoke its constructor as follows

```
obj = vtkStreamTracer
```

33.214.2 Methods

The class vtkStreamTracer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamTracer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamTracer = obj.NewInstance ()`
- `vtkStreamTracer = obj.SafeDownCast (vtkObject o)`
- `obj.SetStartPosition (double , double , double )` - Specify the starting point (seed) of a streamline in the global coordinate system. Search must be performed to find the initial cell from which to start integration.
- `obj.SetStartPosition (double a[3])` - Specify the starting point (seed) of a streamline in the global coordinate system. Search must be performed to find the initial cell from which to start integration.
- `double = obj. GetStartPosition ()` - Specify the starting point (seed) of a streamline in the global coordinate system. Search must be performed to find the initial cell from which to start integration.
- `obj.SetSource (vtkDataSet source)` - Specify the source object used to generate starting points (seeds). Old style. Do not use.
- `vtkDataSet = obj.GetSource ()` - Specify the source object used to generate starting points (seeds). Old style. Do not use.
- `obj.SetSourceConnection (vtkAlgorithmOutput algOutput)` - Specify the source object used to generate starting points (seeds). New style.
- `obj.SetIntegrator (vtkInitialValueProblemSolver )` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `vtkInitialValueProblemSolver = obj.GetIntegrator ()` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `obj.SetIntegratorType (int type)` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `int = obj.GetIntegratorType ()` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `obj.SetIntegratorTypeToRungeKutta2 ()` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `obj.SetIntegratorTypeToRungeKutta4 ()` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `obj.SetIntegratorTypeToRungeKutta45 ()` - Set/get the integrator type to be used for streamline generation. The object passed is not actually used but is cloned with NewInstance in the process of integration (prototype pattern). The default is Runge-Kutta2. The integrator can also be changed using SetIntegratorType. The recognized solvers are: RUNGE_KUTTA2 = 0 RUNGE_KUTTA4 = 1 RUNGE_KUTTA45 = 2

- `obj.SetInterpolatorTypeToDataSetPointLocator ()` - Set the velocity field interpolator type to the one involving a dataset point locator.

- `obj.SetInterpolatorTypeToCellLocator ()` - Set the velocity field interpolator type to the one involving a cell locator.

- `obj.SetMaximumPropagation (double max)` - Specify the maximum length of a streamline expressed in LENGTH_UNIT.

- `double = obj.GetMaximumPropagation ()` - Specify a uniform integration step unit for MinimumIntegrationStep, InitialIntegrationStep, and MaximumIntegrationStep. NOTE: The valid unit is now limited to only LENGTH_UNIT (1) and CELL_LENGTH_UNIT (2), EXCLUDING the previously-supported TIME_UNIT.

- `obj.SetIntegrationStepUnit (int unit)` - Specify a uniform integration step unit for MinimumIntegrationStep, InitialIntegrationStep, and MaximumIntegrationStep. NOTE: The valid unit is now limited to only LENGTH_UNIT (1) and CELL_LENGTH_UNIT (2), EXCLUDING the previously-supported TIME_UNIT.

- `int = obj.GetIntegrationStepUnit ()` - Specify the Initial step size used for line integration, expressed in: LENGTH_UNIT = 1 CELL_LENGTH_UNIT = 2 (either the starting size for an adaptive integrator, e.g., RK45, or the constant / fixed size for non-adaptive ones, i.e., RK2 and RK4)

- `obj.SetInitialIntegrationStep (double step)` - Specify the Initial step size used for line integration, expressed in: LENGTH_UNIT = 1 CELL_LENGTH_UNIT = 2 (either the starting size for an adaptive integrator, e.g., RK45, or the constant / fixed size for non-adaptive ones, i.e., RK2 and RK4)
- `double = obj.GetInitialIntegrationStep ()` - Specify the Minimum step size used for line integration, expressed in: LENGTH_UNIT = 1 CELL_LENGTH_UNIT = 2 (Only valid for an adaptive integrator, e.g., RK45)
- `obj.SetMinimumIntegrationStep (double step)` - Specify the Minimum step size used for line integration, expressed in: LENGTH_UNIT = 1 CELL_LENGTH_UNIT = 2 (Only valid for an adaptive integrator, e.g., RK45)
- `double = obj.GetMinimumIntegrationStep ()` - Specify the Maximum step size used for line integration, expressed in: LENGTH_UNIT = 1 CELL_LENGTH_UNIT = 2 (Only valid for an adaptive integrator, e.g., RK45)
- `obj.SetMaximumIntegrationStep (double step)` - Specify the Maximum step size used for line integration, expressed in: LENGTH_UNIT = 1 CELL_LENGTH_UNIT = 2 (Only valid for an adaptive integrator, e.g., RK45)
- `double = obj.GetMaximumIntegrationStep ()`
- `obj.SetMaximumError (double )`
- `double = obj.GetMaximumError ()`
- `obj.SetMaximumNumberOfSteps (vtkIdType )`
- `vtkIdType = obj.GetMaximumNumberOfSteps ()`
- `obj.SetTerminalSpeed (double )`
- `double = obj.GetTerminalSpeed ()`
- `obj.SetIntegrationDirection (int )` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `int = obj.GetIntegrationDirectionMinValue ()` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `int = obj.GetIntegrationDirectionMaxValue ()` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `int = obj.GetIntegrationDirection ()` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `obj.SetIntegrationDirectionToForward ()` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `obj.SetIntegrationDirectionToBackward ()` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `obj.SetIntegrationDirectionToBoth ()` - Specify whether the streamline is integrated in the upstream or downstream direction.
- `obj.SetComputeVorticity (bool )`
- `bool = obj.GetComputeVorticity ()`
- `obj.SetRotationScale (double )`
- `double = obj.GetRotationScale ()`

- `obj.SetInterpolatorPrototype (vtkAbstractInterpolatedVelocityField ivf)` - The object used to interpolate the velocity field during integration is of the same class as this prototype.
- `obj.SetInterpolatorType (int interpType)` - Set the type of the velocity field interpolator to determine whether vtkInterpolatedVelocityField (INTERPOLATOR_WITH_DATASET_POINT_LOCATOR) or vtkCellLocatorInterpolatedVelocityField (INTERPOLATOR_WITH_CELL_LOCATOR) is employed for locating cells during streamline integration. The latter (adopting vtkAbstractCellLocator subclasses such as vtkCellLocator and vtkModifiedBSPTree) is more robust then the former (through vtkDataSet / vtkPointSet::FindCell() coupled with vtkPointLocator).

33.215 vtkStripper

33.215.1 Usage

To create an instance of class vtkStripper, simply invoke its constructor as follows

```
obj = vtkStripper
```

33.215.2 Methods

The class vtkStripper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStripper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStripper = obj.NewInstance ()`
- `vtkStripper = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaximumLength (int )` - Specify the maximum number of triangles in a triangle strip, and/or the maximum number of lines in a poly-line.
- `int = obj.GetMaximumLengthMinValue ()` - Specify the maximum number of triangles in a triangle strip, and/or the maximum number of lines in a poly-line.
- `int = obj.GetMaximumLengthMaxValue ()` - Specify the maximum number of triangles in a triangle strip, and/or the maximum number of lines in a poly-line.
- `int = obj.GetMaximumLength ()` - Specify the maximum number of triangles in a triangle strip, and/or the maximum number of lines in a poly-line.
- `obj.PassCellDataAsFieldDataOn ()` - Enable/Disable passing of the CellData in the input to the output as FieldData. Note the field data is tranformed.
- `obj.PassCellDataAsFieldDataOff ()` - Enable/Disable passing of the CellData in the input to the output as FieldData. Note the field data is tranformed.
- `obj.SetPassCellDataAsFieldData (int )` - Enable/Disable passing of the CellData in the input to the output as FieldData. Note the field data is tranformed.
- `int = obj.GetPassCellDataAsFieldData ()` - Enable/Disable passing of the CellData in the input to the output as FieldData. Note the field data is tranformed.
- `obj.SetPassThroughCellIds (int )` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for picking. The default is off to conserve memory.

- `int = obj.GetPassThroughCellIds ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for picking. The default is off to conserve memory.
- `obj.PassThroughCellIdsOn ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for picking. The default is off to conserve memory.
- `obj.PassThroughCellIdsOff ()` - If on, the output polygonal dataset will have a celldata array that holds the cell index of the original 3D cell that produced each output cell. This is useful for picking. The default is off to conserve memory.
- `obj.SetPassThroughPointIds (int )` - If on, the output polygonal dataset will have a pointdata array that holds the point index of the original vertex that produced each output vertex. This is useful for picking. The default is off to conserve memory.
- `int = obj.GetPassThroughPointIds ()` - If on, the output polygonal dataset will have a pointdata array that holds the point index of the original vertex that produced each output vertex. This is useful for picking. The default is off to conserve memory.
- `obj.PassThroughPointIdsOn ()` - If on, the output polygonal dataset will have a pointdata array that holds the point index of the original vertex that produced each output vertex. This is useful for picking. The default is off to conserve memory.
- `obj.PassThroughPointIdsOff ()` - If on, the output polygonal dataset will have a pointdata array that holds the point index of the original vertex that produced each output vertex. This is useful for picking. The default is off to conserve memory.

33.216 vtkStructuredGridClip

33.216.1 Usage

vtkStructuredGridClip will make an image smaller. The output must have an image extent which is the subset of the input. The filter has two modes of operation: 1: By default, the data is not copied in this filter. Only the whole extent is modified. 2: If ClipDataOn is set, then you will get no more that the clipped extent.

To create an instance of class vtkStructuredGridClip, simply invoke its constructor as follows

```
obj = vtkStructuredGridClip
```

33.216.2 Methods

The class vtkStructuredGridClip has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridClip class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridClip = obj.NewInstance ()`
- `vtkStructuredGridClip = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputWholeExtent (int extent[6], vtkInformation outInfo)` - The whole extent of the output has to be set explicitly.

- `obj.SetOutputWholeExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - The whole extent of the output has to be set explicitly.
- `obj.GetOutputWholeExtent (int extent[6])` - The whole extent of the output has to be set explicitly.
- `obj.ResetOutputWholeExtent ()`
- `obj.SetClipData (int )` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `int = obj.GetClipData ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.ClipDataOn ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.ClipDataOff ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.SetOutputWholeExtent (int piece, int numPieces)` - Hack set output by piece

33.217 vtkStructuredGridGeometryFilter

33.217.1 Usage

vtkStructuredGridGeometryFilter is a filter that extracts geometry from a structured grid. By specifying appropriate i-j-k indices, it is possible to extract a point, a curve, a surface, or a "volume". Depending upon the type of data, the curve and surface may be curved or planar. (The volume is actually a (n x m x o) region of points.)

The extent specification is zero-offset. That is, the first k-plane in a 50x50x50 structured grid is given by (0,49, 0,49, 0,0).

The output of this filter is affected by the structured grid blanking. If blanking is on, and a blanking array defined, then those cells attached to blanked points are not output. (Blanking is a property of the input vtkStructuredGrid.)

To create an instance of class vtkStructuredGridGeometryFilter, simply invoke its constructor as follows

```
obj = vtkStructuredGridGeometryFilter
```

33.217.2 Methods

The class vtkStructuredGridGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridGeometryFilter = obj.NewInstance ()`
- `vtkStructuredGridGeometryFilter = obj.SafeDownCast (vtkObject o)`

- `int = obj. GetExtent ()` - Get the extent in topological coordinate range (imin,imax, jmin,jmax, kmin,kmax).
- `obj.SetExtent (int iMin, int iMax, int jMin, int jMax, int kMin, int kMax)` - Specify (imin,imax, jmin,jmax, kmin,kmax) indices.
- `obj.SetExtent (int extent[6])` - Specify (imin,imax, jmin,jmax, kmin,kmax) indices in array form.

33.218 vtkStructuredGridOutlineFilter

33.218.1 Usage

vtkStructuredGridOutlineFilter is a filter that generates a wireframe outline of a structured grid (vtkStructuredGrid). Structured data is topologically a cube, so the outline will have 12 "edges".

To create an instance of class vtkStructuredGridOutlineFilter, simply invoke its constructor as follows

```
obj = vtkStructuredGridOutlineFilter
```

33.218.2 Methods

The class vtkStructuredGridOutlineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridOutlineFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridOutlineFilter = obj.NewInstance ()`
- `vtkStructuredGridOutlineFilter = obj.SafeDownCast (vtkObject o)`

33.219 vtkStructuredPointsGeometryFilter

33.219.1 Usage

vtkStructuredPointsGeometryFilter has been renamed to vtkImageDataGeometryFilter

To create an instance of class vtkStructuredPointsGeometryFilter, simply invoke its constructor as follows

```
obj = vtkStructuredPointsGeometryFilter
```

33.219.2 Methods

The class vtkStructuredPointsGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsGeometryFilter = obj.NewInstance ()`
- `vtkStructuredPointsGeometryFilter = obj.SafeDownCast (vtkObject o)`

33.220 vtkSubdivideTetra

33.220.1 Usage

This filter subdivides tetrahedra in an unstructured grid into twelve tetrahedra.

To create an instance of class vtkSubdivideTetra, simply invoke its constructor as follows

```
obj = vtkSubdivideTetra
```

33.220.2 Methods

The class vtkSubdivideTetra has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSubdivideTetra class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSubdivideTetra = obj.NewInstance ()`
- `vtkSubdivideTetra = obj.SafeDownCast (vtkObject o)`

33.221 vtkSubPixelPositionEdgels

33.221.1 Usage

vtkSubPixelPositionEdgels is a filter that takes a series of linked edgels (digital curves) and gradient maps as input. It then adjusts the edgel locations based on the gradient data. Specifically, the algorithm first determines the neighboring gradient magnitudes of an edgel using simple interpolation of its neighbors. It then fits the following three data points: negative gradient direction gradient magnitude, edgel gradient magnitude and positive gradient direction gradient magnitude to a quadratic function. It then solves this quadratic to find the maximum gradient location along the gradient orientation. It then modifies the edgels location along the gradient orientation to the calculated maximum location. This algorithm does not adjust an edgel in the direction orthogonal to its gradient vector.

To create an instance of class vtkSubPixelPositionEdgels, simply invoke its constructor as follows

```
obj = vtkSubPixelPositionEdgels
```

33.221.2 Methods

The class vtkSubPixelPositionEdgels has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSubPixelPositionEdgels class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSubPixelPositionEdgels = obj.NewInstance ()`
- `vtkSubPixelPositionEdgels = obj.SafeDownCast (vtkObject o)`
- `obj.SetGradMaps (vtkStructuredPoints gm)` - Set/Get the gradient data for doing the position adjustments.

- `vtkStructuredPoints = obj.GetGradMaps ()` - Set/Get the gradient data for doing the position adjustments.
- `obj.SetTargetFlag (int )` - These methods can make the positioning look for a target scalar value instead of looking for a maximum.
- `int = obj.GetTargetFlag ()` - These methods can make the positioning look for a target scalar value instead of looking for a maximum.
- `obj.TargetFlagOn ()` - These methods can make the positioning look for a target scalar value instead of looking for a maximum.
- `obj.TargetFlagOff ()` - These methods can make the positioning look for a target scalar value instead of looking for a maximum.
- `obj.SetTargetValue (double )` - These methods can make the positioning look for a target scalar value instead of looking for a maximum.
- `double = obj.GetTargetValue ()` - These methods can make the positioning look for a target scalar value instead of looking for a maximum.

33.222 vtkSuperquadricSource

33.222.1 Usage

vtkSuperquadricSource creates a superquadric (represented by polygons) of specified size centered at the origin. The resolution (polygonal discretization) in both the latitude (phi) and longitude (theta) directions can be specified. Roundness parameters (PhiRoundness and ThetaRoundness) control the shape of the superquadric. The Toroidal boolean controls whether a toroidal superquadric is produced. If so, the Thickness parameter controls the thickness of the toroid: 0 is the thinnest allowable toroid, and 1 has a minimum sized hole. The Scale parameters allow the superquadric to be scaled in x, y, and z (normal vectors are correctly generated in any case). The Size parameter controls size of the superquadric.

This code is based on "Rigid physically based superquadrics", A. H. Barr, in "Graphics Gems III", David Kirk, ed., Academic Press, 1992.

To create an instance of class vtkSuperquadricSource, simply invoke its constructor as follows

```
obj = vtkSuperquadricSource
```

33.222.2 Methods

The class vtkSuperquadricSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSuperquadricSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSuperquadricSource = obj.NewInstance ()`
- `vtkSuperquadricSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetCenter (double , double , double )` - Set the center of the superquadric. Default is 0,0,0.
- `obj.SetCenter (double  a[3])` - Set the center of the superquadric. Default is 0,0,0.
- `double = obj. GetCenter ()` - Set the center of the superquadric. Default is 0,0,0.

- `obj.SetScale (double , double , double )` - Set the scale factors of the superquadric. Default is 1,1,1.
- `obj.SetScale (double a[3])` - Set the scale factors of the superquadric. Default is 1,1,1.
- `double = obj. GetScale ()` - Set the scale factors of the superquadric. Default is 1,1,1.
- `int = obj.GetThetaResolution ()` - Set the number of points in the longitude direction. Initial value is 16.
- `obj.SetThetaResolution (int i)` - Set the number of points in the longitude direction. Initial value is 16.
- `int = obj.GetPhiResolution ()` - Set the number of points in the latitude direction. Initial value is 16.
- `obj.SetPhiResolution (int i)` - Set the number of points in the latitude direction. Initial value is 16.
- `double = obj.GetThickness ()` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid. Initial value is 0.3333.
- `obj.SetThickness (double )` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid. Initial value is 0.3333.
- `double = obj.GetThicknessMinValue ()` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid. Initial value is 0.3333.
- `double = obj.GetThicknessMaxValue ()` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid. Initial value is 0.3333.
- `double = obj.GetPhiRoundness ()` - Set/Get Superquadric north/south roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders. Initial value is 1.0.
- `obj.SetPhiRoundness (double e)` - Set/Get Superquadric north/south roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders. Initial value is 1.0.
- `double = obj.GetThetaRoundness ()` - Set/Get Superquadric east/west roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders. Initial value is 1.0.
- `obj.SetThetaRoundness (double e)` - Set/Get Superquadric east/west roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders. Initial value is 1.0.
- `obj.SetSize (double )` - Set/Get Superquadric isotropic size. Initial value is 0.5;
- `double = obj.GetSize ()` - Set/Get Superquadric isotropic size. Initial value is 0.5;
- `obj.ToroidalOn ()` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0). Initial value is 0.
- `obj.ToroidalOff ()` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0). Initial value is 0.
- `int = obj.GetToroidal ()` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0). Initial value is 0.
- `obj.SetToroidal (int )` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0). Initial value is 0.

33.223 vtkSynchronizedTemplates2D

33.223.1 Usage

vtkSynchronizedTemplates2D is a 2D implementation of the synchronized template algorithm. Note that vtkContourFilter will automatically use this class when appropriate.

To create an instance of class vtkSynchronizedTemplates2D, simply invoke its constructor as follows

```
obj = vtkSynchronizedTemplates2D
```

33.223.2 Methods

The class vtkSynchronizedTemplates2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSynchronizedTemplates2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSynchronizedTemplates2D = obj.NewInstance ()`
- `vtkSynchronizedTemplates2D = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Because we delegate to vtkContourValues
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Option to set the point scalars of the output. The scalars will be the iso value of course. By default this flag is on.
- `obj.SetComputeScalars (int )` - Option to set the point scalars of the output. The scalars will be the iso value of course. By default this flag is on.
- `int = obj.GetComputeScalars ()` - Option to set the point scalars of the output. The scalars will be the iso value of course. By default this flag is on.
- `obj.ComputeScalarsOn ()` - Option to set the point scalars of the output. The scalars will be the iso value of course. By default this flag is on.
- `obj.ComputeScalarsOff ()` - Option to set the point scalars of the output. The scalars will be the iso value of course. By default this flag is on.
- `obj.SetArrayComponent (int )` - Set/get which component of the scalar array to contour on; defaults to 0.
- `int = obj.GetArrayComponent ()` - Set/get which component of the scalar array to contour on; defaults to 0.

33.224 vtkSynchronizedTemplates3D

33.224.1 Usage

vtkSynchronizedTemplates3D is a 3D implementation of the synchronized template algorithm. Note that vtkContourFilter will automatically use this class when appropriate.

To create an instance of class vtkSynchronizedTemplates3D, simply invoke its constructor as follows

```
obj = vtkSynchronizedTemplates3D
```

33.224.2 Methods

The class vtkSynchronizedTemplates3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSynchronizedTemplates3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSynchronizedTemplates3D = obj.NewInstance ()`
- `vtkSynchronizedTemplates3D = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Because we delegate to vtkContourValues
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. Normal computation is fairly expensive in both time and storage. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeGradients (int )` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `int = obj.GetComputeGradients ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.ComputeGradientsOn ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.

- `obj.ComputeGradientsOff ()` - Set/Get the computation of gradients. Gradient computation is fairly expensive in both time and storage. Note that if ComputeNormals is on, gradients will have to be calculated, but will not be stored in the output dataset. If the output data will be processed by filters that modify topology or geometry, it may be wise to turn Normals and Gradients off.
- `obj.SetComputeScalars (int )` - Set/Get the computation of scalars.
- `int = obj.GetComputeScalars ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOn ()` - Set/Get the computation of scalars.
- `obj.ComputeScalarsOff ()` - Set/Get the computation of scalars.
- `obj.SetValue (int i, double value)` - Get the ith contour value.
- `double = obj.GetValue (int i)` - Get a pointer to an array of contour values. There will be GetNumberOfContours() values in the list.
- `obj.GetValues (double contourValues)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `obj.SetNumberOfContours (int number)` - Get the number of contours in the list of contour values.
- `int = obj.GetNumberOfContours ()` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Needed by templated functions.
- `int = obj.GetExecuteExtent ()` - Needed by templated functions.
- `obj.ThreadedExecute (vtkImageData data, vtkInformation inInfo, vtkInformation outInfo, int exExt, v` - Needed by templated functions.
- `obj.SetInputMemoryLimit (long limit)` - Determines the chunk size fro streaming. This filter will act like a collector: ask for many input pieces, but generate one output. Limit is in KBytes
- `long = obj.GetInputMemoryLimit ()` - Determines the chunk size fro streaming. This filter will act like a collector: ask for many input pieces, but generate one output. Limit is in KBytes
- `obj.SetArrayComponent (int )` - Set/get which component of the scalar array to contour on; defaults to 0.
- `int = obj.GetArrayComponent ()` - Set/get which component of the scalar array to contour on; defaults to 0.

33.225 vtkSynchronizedTemplatesCutter3D

33.225.1 Usage

vtkSynchronizedTemplatesCutter3D is an implementation of the synchronized template algorithm. Note that vtkCutFilter will automatically use this class when appropriate.

To create an instance of class vtkSynchronizedTemplatesCutter3D, simply invoke its constructor as follows

```
obj = vtkSynchronizedTemplatesCutter3D
```

33.225.2 Methods

The class vtkSynchronizedTemplatesCutter3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSynchronizedTemplatesCutter3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSynchronizedTemplatesCutter3D = obj.NewInstance ()`
- `vtkSynchronizedTemplatesCutter3D = obj.SafeDownCast (vtkObject o)`
- `obj.ThreadedExecute (vtkImageData data, vtkInformation outInfo, int exExt, int )` - Needed by templated functions.
- `obj.SetCutFunction (vtkImplicitFunction )`
- `vtkImplicitFunction = obj.GetCutFunction ()`

33.226 vtkTableBasedClipDataSet

33.226.1 Usage

vtkTableBasedClipDataSet is a filter that clips any type of dataset using either any subclass of vtkImplicitFunction or an input scalar point data array. Clipping means that it actually "cuts" through the cells of the dataset, returning everything outside the specified implicit function (or greater than the scalar value) including "pieces" of a cell (Note to compare this with vtkExtractGeometry, which pulls out entire, uncut cells). The output of this filter is a vtkUnstructuredGrid data.

To use this filter, you need to decide whether an implicit function or an input scalar point data array is used for clipping. For the former case, 1) define an implicit function 2) provide it to this filter via SetClipFunction() If a clipping function is not specified, or GenerateClipScalars is off(the default), the input scalar point data array is then employed for clipping.

You can also specify a scalar (iso-)value, which is used to decide what is inside and outside the implicit function. You can also reverse the sense of what inside/outside is by setting IVAR InsideOut. The clipping algorithm proceeds by computing an implicit function value or using the input scalar point data value for each point in the dataset. This is compared against the scalar (iso-)value to determine the inside/outside status.

Although this filter sometimes (but rarely) may resort to the sibling class vtkClipDataSet for handling some special grids (such as cylinders or cones with capping faces in the form of a vtkPolyData), it itself is able to deal with most grids. It is worth mentioning that vtkTableBasedClipDataSet is capable of addressing the artifacts that may occur with vtkClipDataSet due to the possibly inconsistent triagulation modes between neighboring cells. In addition, the former is much faster than the latter. Furthermore, the former produces less cells (with ratio usually being 5 6) than by the latter in the output. In other words, this filter retains the original cells (i.e., without triangulation / tetrahedralization) wherever possible. All these advantages are gained by adopting the unique clipping and triangulation tables proposed by VisIt.

To create an instance of class vtkTableBasedClipDataSet, simply invoke its constructor as follows

```
obj = vtkTableBasedClipDataSet
```

33.226.2 Methods

The class vtkTableBasedClipDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableBasedClipDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableBasedClipDataSet = obj.NewInstance ()`
- `vtkTableBasedClipDataSet = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Get the MTime for which the point locator and clip function are consdiered.
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. With this flag off, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is greater than IVAR Value. With this flag on, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is less than or equal to IVAR Value. This flag is off by default.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. With this flag off, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is greater than IVAR Value. With this flag on, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is less than or equal to IVAR Value. This flag is off by default.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. With this flag off, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is greater than IVAR Value. With this flag on, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is less than or equal to IVAR Value. This flag is off by default.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. With this flag off, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is greater than IVAR Value. With this flag on, a vertex is considered inside (the implicit function or the isosurface) if the (function or scalar) value is less than or equal to IVAR Value. This flag is off by default.
- `obj.SetValue (double )` - Set/Get the clipping value of the implicit function (if an implicit function is applied) or scalar data array (if a scalar data array is used), with 0.0 as the default value. This value is ignored if flag UseValueAsOffset is true AND a clip function is defined.
- `double = obj.GetValue ()` - Set/Get the clipping value of the implicit function (if an implicit function is applied) or scalar data array (if a scalar data array is used), with 0.0 as the default value. This value is ignored if flag UseValueAsOffset is true AND a clip function is defined.
- `obj.SetUseValueAsOffset (bool )` - Set/Get flag UseValueAsOffset, with true as the default value. With this flag on, IVAR Value is used as an offset parameter to the implicit function. Value is used only when clipping using a scalar array.
- `bool = obj.GetUseValueAsOffset ()` - Set/Get flag UseValueAsOffset, with true as the default value. With this flag on, IVAR Value is used as an offset parameter to the implicit function. Value is used only when clipping using a scalar array.
- `obj.UseValueAsOffsetOn ()` - Set/Get flag UseValueAsOffset, with true as the default value. With this flag on, IVAR Value is used as an offset parameter to the implicit function. Value is used only when clipping using a scalar array.
- `obj.UseValueAsOffsetOff ()` - Set/Get flag UseValueAsOffset, with true as the default value. With this flag on, IVAR Value is used as an offset parameter to the implicit function. Value is used only when clipping using a scalar array.
- `obj.SetClipFunction (vtkImplicitFunction )`
- `vtkImplicitFunction = obj.GetClipFunction ()`

- `obj.SetGenerateClipScalars (int )` - Set/Get flag GenerateClipScalars, with 0 as the default value. With this flag on, the scalar point data values obtained by evaluating the implicit function will be exported to the output. Note that this flag requries that an implicit function be provided.
- `int = obj.GetGenerateClipScalars ()` - Set/Get flag GenerateClipScalars, with 0 as the default value. With this flag on, the scalar point data values obtained by evaluating the implicit function will be exported to the output. Note that this flag requries that an implicit function be provided.
- `obj.GenerateClipScalarsOn ()` - Set/Get flag GenerateClipScalars, with 0 as the default value. With this flag on, the scalar point data values obtained by evaluating the implicit function will be exported to the output. Note that this flag requries that an implicit function be provided.
- `obj.GenerateClipScalarsOff ()` - Set/Get flag GenerateClipScalars, with 0 as the default value. With this flag on, the scalar point data values obtained by evaluating the implicit function will be exported to the output. Note that this flag requries that an implicit function be provided.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set/Get a point locator locator for merging duplicate points. By default, an instance of vtkMergePoints is used. Note that this IVAR is provided in this class only because this filter may resort to its sibling class vtkClipDataSet when processing some special grids (such as cylinders or cones with capping faces in the form of a vtkPolyData) while the latter requires a point locator. This filter itself does not need a locator.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set/Get a point locator locator for merging duplicate points. By default, an instance of vtkMergePoints is used. Note that this IVAR is provided in this class only because this filter may resort to its sibling class vtkClipDataSet when processing some special grids (such as cylinders or cones with capping faces in the form of a vtkPolyData) while the latter requires a point locator. This filter itself does not need a locator.
- `obj.SetMergeTolerance (double )` - Set/Get the tolerance used for merging duplicate points near the clipping intersection cells. This tolerance may prevent the generation of degenerate primitives. Note that only 3D cells actually use this IVAR.
- `double = obj.GetMergeToleranceMinValue ()` - Set/Get the tolerance used for merging duplicate points near the clipping intersection cells. This tolerance may prevent the generation of degenerate primitives. Note that only 3D cells actually use this IVAR.
- `double = obj.GetMergeToleranceMaxValue ()` - Set/Get the tolerance used for merging duplicate points near the clipping intersection cells. This tolerance may prevent the generation of degenerate primitives. Note that only 3D cells actually use this IVAR.
- `double = obj.GetMergeTolerance ()` - Set/Get the tolerance used for merging duplicate points near the clipping intersection cells. This tolerance may prevent the generation of degenerate primitives. Note that only 3D cells actually use this IVAR.
- `obj.CreateDefaultLocator ()` - Create a default point locator when none is specified. The point locator is used to merge coincident points.
- `obj.SetGenerateClippedOutput (int )` - Set/Get whether a second output is generated. The second output contains the polygonal data that is clipped away by the iso-surface.
- `int = obj.GetGenerateClippedOutput ()` - Set/Get whether a second output is generated. The second output contains the polygonal data that is clipped away by the iso-surface.
- `obj.GenerateClippedOutputOn ()` - Set/Get whether a second output is generated. The second output contains the polygonal data that is clipped away by the iso-surface.
- `obj.GenerateClippedOutputOff ()` - Set/Get whether a second output is generated. The second output contains the polygonal data that is clipped away by the iso-surface.
- `vtkUnstructuredGrid = obj.GetClippedOutput ()` - Return the clipped output.

33.227 vtkTableToPolyData

33.227.1 Usage

vtkTableToPolyData is a filter used to convert a vtkTable to a vtkPolyData consisting of vertices.

To create an instance of class vtkTableToPolyData, simply invoke its constructor as follows

```
obj = vtkTableToPolyData
```

33.227.2 Methods

The class vtkTableToPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableToPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableToPolyData = obj.NewInstance ()`
- `vtkTableToPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetXColumn (string )` - Set the name of the column to use as the X coordinate for the points.
- `string = obj.GetXColumn ()` - Set the name of the column to use as the X coordinate for the points.
- `obj.SetXColumnIndex (int )` - Set the index of the column to use as the X coordinate for the points.
- `int = obj.GetXColumnIndexMinValue ()` - Set the index of the column to use as the X coordinate for the points.
- `int = obj.GetXColumnIndexMaxValue ()` - Set the index of the column to use as the X coordinate for the points.
- `int = obj.GetXColumnIndex ()` - Set the index of the column to use as the X coordinate for the points.
- `obj.SetXComponent (int )` - Specify the component for the column specified using SetXColumn() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `int = obj.GetXComponentMinValue ()` - Specify the component for the column specified using SetXColumn() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `int = obj.GetXComponentMaxValue ()` - Specify the component for the column specified using SetXColumn() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `int = obj.GetXComponent ()` - Specify the component for the column specified using SetXColumn() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `obj.SetYColumn (string )` - Set the name of the column to use as the Y coordinate for the points. Default is 0.
- `string = obj.GetYColumn ()` - Set the name of the column to use as the Y coordinate for the points. Default is 0.
- `obj.SetYColumnIndex (int )` - Set the index of the column to use as the Y coordinate for the points.
- `int = obj.GetYColumnIndexMinValue ()` - Set the index of the column to use as the Y coordinate for the points.

- `int = obj.GetYColumnIndexMaxValue ()` - Set the index of the column to use as the Y coordinate for the points.
- `int = obj.GetYColumnIndex ()` - Set the index of the column to use as the Y coordinate for the points.
- `obj.SetYComponent (int )` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `int = obj.GetYComponentMinValue ()` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `int = obj.GetYComponentMaxValue ()` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `int = obj.GetYComponent ()` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `obj.SetZColumn (string )` - Set the name of the column to use as the Z coordinate for the points. Default is 0.
- `string = obj.GetZColumn ()` - Set the name of the column to use as the Z coordinate for the points. Default is 0.
- `obj.SetZColumnIndex (int )` - Set the index of the column to use as the Z coordinate for the points.
- `int = obj.GetZColumnIndexMinValue ()` - Set the index of the column to use as the Z coordinate for the points.
- `int = obj.GetZColumnIndexMaxValue ()` - Set the index of the column to use as the Z coordinate for the points.
- `int = obj.GetZColumnIndex ()` - Set the index of the column to use as the Z coordinate for the points.
- `obj.SetZComponent (int )` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `int = obj.GetZComponentMinValue ()` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `int = obj.GetZComponentMaxValue ()` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `int = obj.GetZComponent ()` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `obj.SetCreate2DPoints (bool )` - Specify whether the points of the polydata are 3D or 2D. If this is set to true then the Z Column will be ignored and the z value of each point on the polydata will be set to 0. By default this will be off.
- `bool = obj.GetCreate2DPoints ()` - Specify whether the points of the polydata are 3D or 2D. If this is set to true then the Z Column will be ignored and the z value of each point on the polydata will be set to 0. By default this will be off.
- `obj.Create2DPointsOn ()` - Specify whether the points of the polydata are 3D or 2D. If this is set to true then the Z Column will be ignored and the z value of each point on the polydata will be set to 0. By default this will be off.
- `obj.Create2DPointsOff ()` - Specify whether the points of the polydata are 3D or 2D. If this is set to true then the Z Column will be ignored and the z value of each point on the polydata will be set to 0. By default this will be off.

33.228 vtkTableToStructuredGrid

33.228.1 Usage

vtkTableToStructuredGrid is a filter that converts an input vtkTable to a vtkStructuredGrid. It provides API to select columns to use as points in the output structured grid. The specified dimensions of the output (specified using SetWholeExtent()) must match the number of rows in the input table.

To create an instance of class vtkTableToStructuredGrid, simply invoke its constructor as follows

```
obj = vtkTableToStructuredGrid
```

33.228.2 Methods

The class vtkTableToStructuredGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableToStructuredGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableToStructuredGrid = obj.NewInstance ()`
- `vtkTableToStructuredGrid = obj.SafeDownCast (vtkObject o)`
- `obj.SetWholeExtent (int , int , int , int , int , int )` - Get/Set the whole extents for the image to produce. The size of the image must match the number of rows in the input table.
- `obj.SetWholeExtent (int a[6])` - Get/Set the whole extents for the image to produce. The size of the image must match the number of rows in the input table.
- `int = obj. GetWholeExtent ()` - Get/Set the whole extents for the image to produce. The size of the image must match the number of rows in the input table.
- `obj.SetXColumn (string )` - Set the name of the column to use as the X coordinate for the points.
- `string = obj.GetXColumn ()` - Set the name of the column to use as the X coordinate for the points.
- `obj.SetXComponent (int )` - Specify the component for the column specified using SetXColumn() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `int = obj.GetXComponentMinValue ()` - Specify the component for the column specified using SetX-Column() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `int = obj.GetXComponentMaxValue ()` - Specify the component for the column specified using SetX-Column() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `int = obj.GetXComponent ()` - Specify the component for the column specified using SetXColumn() to use as the xcoordinate in case the column is a multi-component array. Default is 0.
- `obj.SetYColumn (string )` - Set the name of the column to use as the Y coordinate for the points. Default is 0.
- `string = obj.GetYColumn ()` - Set the name of the column to use as the Y coordinate for the points. Default is 0.
- `obj.SetYComponent (int )` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.

- `int = obj.GetYComponentMinValue ()` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `int = obj.GetYComponentMaxValue ()` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `int = obj.GetYComponent ()` - Specify the component for the column specified using SetYColumn() to use as the Ycoordinate in case the column is a multi-component array.
- `obj.SetZColumn (string )` - Set the name of the column to use as the Z coordinate for the points. Default is 0.
- `string = obj.GetZColumn ()` - Set the name of the column to use as the Z coordinate for the points. Default is 0.
- `obj.SetZComponent (int )` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `int = obj.GetZComponentMinValue ()` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `int = obj.GetZComponentMaxValue ()` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.
- `int = obj.GetZComponent ()` - Specify the component for the column specified using SetZColumn() to use as the Zcoordinate in case the column is a multi-component array.

33.229 vtkTemporalPathLineFilter

33.229.1 Usage

vtkTemporalPathLineFilter takes any dataset as input, it extracts the point locations of all cells over time to build up a polyline trail. The point number (index) is used as the 'key' if the points are randomly changing their respective order in the points list, then you should specify a scalar that represents the unique ID. This is intended to handle the output of a filter such as the TemporalStreamTracer.

To create an instance of class vtkTemporalPathLineFilter, simply invoke its constructor as follows

```
obj = vtkTemporalPathLineFilter
```

33.229.2 Methods

The class vtkTemporalPathLineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalPathLineFilter class.

- `string = obj.GetClassName ()` - Standard Type-Macro
- `int = obj.IsA (string name)` - Standard Type-Macro
- `vtkTemporalPathLineFilter = obj.NewInstance ()` - Standard Type-Macro
- `vtkTemporalPathLineFilter = obj.SafeDownCast (vtkObject o)` - Standard Type-Macro
- `obj.SetMaskPoints (int )` - Set the number of particles to track as a ratio of the input example: setting MaskPoints to 10 will track every 10th point
- `int = obj.GetMaskPoints ()` - Set the number of particles to track as a ratio of the input example: setting MaskPoints to 10 will track every 10th point

- `obj.SetMaxTrackLength (int )` - If the Particles being traced animate for a long time, the trails or traces will become long and stringy. Setting the MaxTraceTimeLength will limit how much of the trace is displayed. Tracks longer then the Max will disappear and the trace will apppear like a snake of fixed length which progresses as the particle moves

- `int = obj.GetMaxTrackLength ()` - If the Particles being traced animate for a long time, the trails or traces will become long and stringy. Setting the MaxTraceTimeLength will limit how much of the trace is displayed. Tracks longer then the Max will disappear and the trace will apppear like a snake of fixed length which progresses as the particle moves

- `obj.SetIdChannelArray (string )` - Specify the name of a scalar array which will be used to fetch the index of each point. This is necessary only if the particles change position (Id order) on each time step. The Id can be used to identify particles at each step and hence track them properly. If this array is NULL, the global point ids are used. If an Id array cannot otherwise be found, the point index is used as the ID.

- `string = obj.GetIdChannelArray ()` - Specify the name of a scalar array which will be used to fetch the index of each point. This is necessary only if the particles change position (Id order) on each time step. The Id can be used to identify particles at each step and hence track them properly. If this array is NULL, the global point ids are used. If an Id array cannot otherwise be found, the point index is used as the ID.

- `obj.SetScalarArray (string )`

- `string = obj.GetScalarArray ()`

- `obj.SetMaxStepDistance (double , double , double )` - If a particle disappears from one end of a simulation and reappears on the other side, the track left will be unrepresentative. Set a MaxStepDistancex,y,z which acts as a threshold above which if a step occurs larger than the value (for the dimension), the track will be dropped and restarted after the step. (ie the part before the wrap around will be dropped and the newer part kept).

- `obj.SetMaxStepDistance (double  a[3])` - If a particle disappears from one end of a simulation and reappears on the other side, the track left will be unrepresentative. Set a MaxStepDistancex,y,z which acts as a threshold above which if a step occurs larger than the value (for the dimension), the track will be dropped and restarted after the step. (ie the part before the wrap around will be dropped and the newer part kept).

- `double = obj. GetMaxStepDistance ()` - If a particle disappears from one end of a simulation and reappears on the other side, the track left will be unrepresentative. Set a MaxStepDistancex,y,z which acts as a threshold above which if a step occurs larger than the value (for the dimension), the track will be dropped and restarted after the step. (ie the part before the wrap around will be dropped and the newer part kept).

- `obj.SetKeepDeadTrails (int )` - When a particle 'disappears', the trail belonging to it is removed from the list. When this flag is enabled, dead trails will persist until the next time the list is cleared. Use carefully as it may cause excessive memory consumption if left on by mistake.

- `int = obj.GetKeepDeadTrails ()` - When a particle 'disappears', the trail belonging to it is removed from the list. When this flag is enabled, dead trails will persist until the next time the list is cleared. Use carefully as it may cause excessive memory consumption if left on by mistake.

- `obj.Flush ()` - Flush will wipe any existing data so that traces can be restarted from whatever time step is next supplied.

- `obj.SetSelectionConnection (vtkAlgorithmOutput algOutput)` - Set a second input which is a selection. Particles with the same Id in the selection as the primary input will be chosen for pathlines Note that you must have the same IdChannelArray in the selection as the input

- `obj.SetSelection (vtkDataSet input)` - Set a second input which is a selection. Particles with the same Id in the selection as the primary input will be chosen for pathlines Note that you must have the same IdChannelArray in the selection as the input

33.230 vtkTemporalStatistics

33.230.1 Usage

Given an input that changes over time, vtkTemporalStatistics looks at the data for each time step and computes some statistical information of how a point or cell variable changes over time. For example, vtkTemporalStatistics can compute the average value of "pressure" over time of each point.

Note that this filter will require the upstream filter to be run on every time step that it reports that it can compute. This may be a time consuming operation.

vtkTemporalStatistics ignores the temporal spacing. Each timestep will be weighted the same regardless of how long of an interval it is to the next timestep. Thus, the average statistic may be quite different from an integration of the variable if the time spacing varies.

.SECTION Thanks This class was originally written by Kenneth Moreland (kmorel@sandia.gov) from Sandia National Laboratories.

To create an instance of class vtkTemporalStatistics, simply invoke its constructor as follows

```
obj = vtkTemporalStatistics
```

33.230.2 Methods

The class vtkTemporalStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalStatistics = obj.NewInstance ()`
- `vtkTemporalStatistics = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetComputeAverage ()` - Turn on/off the computation of the average values over time. On by default. The resulting array names have "_average" appended to them.
- `obj.SetComputeAverage (int )` - Turn on/off the computation of the average values over time. On by default. The resulting array names have "_average" appended to them.
- `obj.ComputeAverageOn ()` - Turn on/off the computation of the average values over time. On by default. The resulting array names have "_average" appended to them.
- `obj.ComputeAverageOff ()` - Turn on/off the computation of the average values over time. On by default. The resulting array names have "_average" appended to them.
- `int = obj.GetComputeMinimum ()` - Turn on/off the computation of the minimum values over time. On by default. The resulting array names have "_minimum" appended to them.
- `obj.SetComputeMinimum (int )` - Turn on/off the computation of the minimum values over time. On by default. The resulting array names have "_minimum" appended to them.
- `obj.ComputeMinimumOn ()` - Turn on/off the computation of the minimum values over time. On by default. The resulting array names have "_minimum" appended to them.

- `obj.ComputeMinimumOff ()` - Turn on/off the computation of the minimum values over time. On by default. The resulting array names have "_minimum" appended to them.
- `int = obj.GetComputeMaximum ()` - Turn on/off the computation of the maximum values over time. On by default. The resulting array names have "_maximum" appended to them.
- `obj.SetComputeMaximum (int )` - Turn on/off the computation of the maximum values over time. On by default. The resulting array names have "_maximum" appended to them.
- `obj.ComputeMaximumOn ()` - Turn on/off the computation of the maximum values over time. On by default. The resulting array names have "_maximum" appended to them.
- `obj.ComputeMaximumOff ()` - Turn on/off the computation of the maximum values over time. On by default. The resulting array names have "_maximum" appended to them.
- `int = obj.GetComputeStandardDeviation ()`
- `obj.SetComputeStandardDeviation (int )`
- `obj.ComputeStandardDeviationOn ()`
- `obj.ComputeStandardDeviationOff ()`

33.231 vtkTensorGlyph

33.231.1 Usage

vtkTensorGlyph is a filter that copies a geometric representation (specified as polygonal data) to every input point. The geometric representation, or glyph, can be scaled and/or rotated according to the tensor at the input point. Scaling and rotation is controlled by the eigenvalues/eigenvectors of the tensor as follows. For each tensor, the eigenvalues (and associated eigenvectors) are sorted to determine the major, medium, and minor eigenvalues/eigenvectors.

If the boolean variable ThreeGlyphs is not set the major eigenvalue scales the glyph in the x-direction, the medium in the y-direction, and the minor in the z-direction. Then, the glyph is rotated so that the glyph's local x-axis lies along the major eigenvector, y-axis along the medium eigenvector, and z-axis along the minor.

If the boolean variable ThreeGlyphs is set three glyphs are produced, each of them oriented along an eigenvector and scaled according to the corresponding eigenvector.

If the boolean variable Symmetric is set each glyph is mirrored (2 or 6 glyphs will be produced)

The x-axis of the source glyph will correspond to the eigenvector on output. Point (0,0,0) in the source will be placed in the data point. Variable Length will normally correspond to the distance from the origin to the tip of the source glyph along the x-axis, but can be changed to produce other results when Symmetric is on, e.g. glyphs that do not touch or that overlap.

Please note that when Symmetric is false it will generally be better to place the source glyph from (-0.5,0,0) to (0.5,0,0), i.e. centred at the origin. When symmetric is true the placement from (0,0,0) to (1,0,0) will generally be more convenient.

A scale factor is provided to control the amount of scaling. Also, you can turn off scaling completely if desired. The boolean variable ClampScaling controls the maximum scaling (in conjunction with MaxScaleFactor.) This is useful in certain applications where singularities or large order of magnitude differences exist in the eigenvalues.

If the boolean variable ColorGlyphs is set to true the glyphs are colored. The glyphs can be colored using the input scalars (SetColorModeToScalars), which is the default, or colored using the eigenvalues (SetColorModeToEigenvalues).

Another instance variable, ExtractEigenvalues, has been provided to control extraction of eigenvalues/eigenvectors. If this boolean is false, then eigenvalues/eigenvectors are not extracted, and the columns of the tensor are taken as the eigenvectors (the norm of column, always positive, is the eigenvalue). This allows

additional capability over the vtkGlyph3D object. That is, the glyph can be oriented in three directions instead of one.

To create an instance of class vtkTensorGlyph, simply invoke its constructor as follows

```
obj = vtkTensorGlyph
```

33.231.2 Methods

The class vtkTensorGlyph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTensorGlyph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTensorGlyph = obj.NewInstance ()`
- `vtkTensorGlyph = obj.SafeDownCast (vtkObject o)`
- `obj.SetSource (vtkPolyData source)` - Specify the geometry to copy to each point. Old style. See SetSourceConnection.
- `vtkPolyData = obj.GetSource ()` - Specify the geometry to copy to each point. Old style. See SetSourceConnection.
- `obj.SetSourceConnection (int id, vtkAlgorithmOutput algOutput)` - Specify a source object at a specified table location. New style. Source connection is stored in port 1. This method is equivalent to SetInputConnection(1, id, outputPort).
- `obj.SetSourceConnection (vtkAlgorithmOutput algOutput)` - Turn on/off scaling of glyph with eigenvalues.
- `obj.SetScaling (int )` - Turn on/off scaling of glyph with eigenvalues.
- `int = obj.GetScaling ()` - Turn on/off scaling of glyph with eigenvalues.
- `obj.ScalingOn ()` - Turn on/off scaling of glyph with eigenvalues.
- `obj.ScalingOff ()` - Turn on/off scaling of glyph with eigenvalues.
- `obj.SetScaleFactor (double )` - Specify scale factor to scale object by. (Scale factor always affects output even if scaling is off.)
- `double = obj.GetScaleFactor ()` - Specify scale factor to scale object by. (Scale factor always affects output even if scaling is off.)
- `obj.SetThreeGlyphs (int )` - Turn on/off drawing three glyphs
- `int = obj.GetThreeGlyphs ()` - Turn on/off drawing three glyphs
- `obj.ThreeGlyphsOn ()` - Turn on/off drawing three glyphs
- `obj.ThreeGlyphsOff ()` - Turn on/off drawing three glyphs
- `obj.SetSymmetric (int )` - Turn on/off drawing a mirror of each glyph
- `int = obj.GetSymmetric ()` - Turn on/off drawing a mirror of each glyph
- `obj.SymmetricOn ()` - Turn on/off drawing a mirror of each glyph

- `obj.SymmetricOff ()` - Turn on/off drawing a mirror of each glyph
- `obj.SetLength (double )` - Set/Get the distance, along x, from the origin to the end of the source glyph. It is used to draw the symmetric glyphs.
- `double = obj.GetLength ()` - Set/Get the distance, along x, from the origin to the end of the source glyph. It is used to draw the symmetric glyphs.
- `obj.SetExtractEigenvalues (int )` - Turn on/off extraction of eigenvalues from tensor.
- `obj.ExtractEigenvaluesOn ()` - Turn on/off extraction of eigenvalues from tensor.
- `obj.ExtractEigenvaluesOff ()` - Turn on/off extraction of eigenvalues from tensor.
- `int = obj.GetExtractEigenvalues ()` - Turn on/off extraction of eigenvalues from tensor.
- `obj.SetColorGlyphs (int )` - Turn on/off coloring of glyph with input scalar data or eigenvalues. If false, or input scalar data not present, then the scalars from the source object are passed through the filter.
- `int = obj.GetColorGlyphs ()` - Turn on/off coloring of glyph with input scalar data or eigenvalues. If false, or input scalar data not present, then the scalars from the source object are passed through the filter.
- `obj.ColorGlyphsOn ()` - Turn on/off coloring of glyph with input scalar data or eigenvalues. If false, or input scalar data not present, then the scalars from the source object are passed through the filter.
- `obj.ColorGlyphsOff ()` - Turn on/off coloring of glyph with input scalar data or eigenvalues. If false, or input scalar data not present, then the scalars from the source object are passed through the filter.
- `obj.SetColorMode (int )` - Set the color mode to be used for the glyphs. This can be set to use the input scalars (default) or to use the eigenvalues at the point. If ThreeGlyphs is set and the eigenvalues are chosen for coloring then each glyph is colored by the corresponding eigenvalue and if not set the color corresponding to the largest eigenvalue is chosen. The recognized values are: COLOR_BY_SCALARS = 0 (default) COLOR_BY_EIGENVALUES = 1
- `int = obj.GetColorModeMinValue ()` - Set the color mode to be used for the glyphs. This can be set to use the input scalars (default) or to use the eigenvalues at the point. If ThreeGlyphs is set and the eigenvalues are chosen for coloring then each glyph is colored by the corresponding eigenvalue and if not set the color corresponding to the largest eigenvalue is chosen. The recognized values are: COLOR_BY_SCALARS = 0 (default) COLOR_BY_EIGENVALUES = 1
- `int = obj.GetColorModeMaxValue ()` - Set the color mode to be used for the glyphs. This can be set to use the input scalars (default) or to use the eigenvalues at the point. If ThreeGlyphs is set and the eigenvalues are chosen for coloring then each glyph is colored by the corresponding eigenvalue and if not set the color corresponding to the largest eigenvalue is chosen. The recognized values are: COLOR_BY_SCALARS = 0 (default) COLOR_BY_EIGENVALUES = 1
- `int = obj.GetColorMode ()` - Set the color mode to be used for the glyphs. This can be set to use the input scalars (default) or to use the eigenvalues at the point. If ThreeGlyphs is set and the eigenvalues are chosen for coloring then each glyph is colored by the corresponding eigenvalue and if not set the color corresponding to the largest eigenvalue is chosen. The recognized values are: COLOR_BY_SCALARS = 0 (default) COLOR_BY_EIGENVALUES = 1
- `obj.SetColorModeToScalars ()` - Set the color mode to be used for the glyphs. This can be set to use the input scalars (default) or to use the eigenvalues at the point. If ThreeGlyphs is set and the eigenvalues are chosen for coloring then each glyph is colored by the corresponding eigenvalue and if not set the color corresponding to the largest eigenvalue is chosen. The recognized values are: COLOR_BY_SCALARS = 0 (default) COLOR_BY_EIGENVALUES = 1

- `obj.SetColorModeToEigenvalues ()` - Set the color mode to be used for the glyphs. This can be set to use the input scalars (default) or to use the eigenvalues at the point. If ThreeGlyphs is set and the eigenvalues are chosen for coloring then each glyph is colored by the corresponding eigenvalue and if not set the color corresponding to the largest eigenvalue is chosen. The recognized values are: COLOR_BY_SCALARS = 0 (default) COLOR_BY_EIGENVALUES = 1

- `obj.SetClampScaling (int )` - Turn on/off scalar clamping. If scalar clamping is on, the ivar MaxScaleFactor is used to control the maximum scale factor. (This is useful to prevent uncontrolled scaling near singularities.)

- `int = obj.GetClampScaling ()` - Turn on/off scalar clamping. If scalar clamping is on, the ivar MaxScaleFactor is used to control the maximum scale factor. (This is useful to prevent uncontrolled scaling near singularities.)

- `obj.ClampScalingOn ()` - Turn on/off scalar clamping. If scalar clamping is on, the ivar MaxScaleFactor is used to control the maximum scale factor. (This is useful to prevent uncontrolled scaling near singularities.)

- `obj.ClampScalingOff ()` - Turn on/off scalar clamping. If scalar clamping is on, the ivar MaxScaleFactor is used to control the maximum scale factor. (This is useful to prevent uncontrolled scaling near singularities.)

- `obj.SetMaxScaleFactor (double )` - Set/Get the maximum allowable scale factor. This value is compared to the combination of the scale factor times the eigenvalue. If less, the scale factor is reset to the MaxScaleFactor. The boolean ClampScaling has to be "on" for this to work.

- `double = obj.GetMaxScaleFactor ()` - Set/Get the maximum allowable scale factor. This value is compared to the combination of the scale factor times the eigenvalue. If less, the scale factor is reset to the MaxScaleFactor. The boolean ClampScaling has to be "on" for this to work.

33.232 vtkTessellatedBoxSource

33.232.1 Usage

vtkTessellatedBoxSource creates a axis-aligned box defined by its bounds and a level of subdivision. Connectivity is strong: points of the vertices and inside the edges are shared between faces. In other words, faces are connected. Each face looks like a grid of quads, each quad is composed of 2 triangles. Given a level of subdivision 'l', each edge has 'l'+2 points, 'l' of them are internal edge points, the 2 other ones are the vertices. Each face has a total of ('l'+2)*('l'+2) points, 4 of them are vertices, 4*'l' are internal edge points, it remains 'l'$\hat{}$2 internal face points.

This source only generate geometry, no DataArrays like normals or texture coordinates.

To create an instance of class vtkTessellatedBoxSource, simply invoke its constructor as follows

```
obj = vtkTessellatedBoxSource
```

33.232.2 Methods

The class vtkTessellatedBoxSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTessellatedBoxSource class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkTessellatedBoxSource = obj.NewInstance ()`

- `vtkTessellatedBoxSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetBounds (double , double , double , double , double , double )` - Set the bounds of the box. See GetBounds() for a detail description.
- `obj.SetBounds (double a[6])` - Set the bounds of the box. See GetBounds() for a detail description.
- `double = obj. GetBounds ()` - Bounds of the box in world coordinates. This a 6-uple of xmin,xmax,ymin, ymax,zmin and zmax. Initial value is (-0.5,0.5,-0.5,0.5,-0.5,0.5), bounds of a cube of length 1 centered at (0,0,0). Bounds are defined such that xmin¡=xmax, ymin¡=ymax and zmin¡zmax.
- `obj.SetLevel (int )` - Set the level of subdivision of the faces.
- `int = obj.GetLevel ()` - Level of subdivision of the faces. Initial value is 0.
- `obj.SetDuplicateSharedPoints (int )` - Flag to tell the source to duplicate points shared between faces (vertices of the box and internal edge points). Initial value is false. Implementation note: duplicating points is an easier method to implement than a minimal number of points.
- `int = obj.GetDuplicateSharedPoints ()` - Flag to tell the source to duplicate points shared between faces (vertices of the box and internal edge points). Initial value is false. Implementation note: duplicating points is an easier method to implement than a minimal number of points.
- `obj.DuplicateSharedPointsOn ()` - Flag to tell the source to duplicate points shared between faces (vertices of the box and internal edge points). Initial value is false. Implementation note: duplicating points is an easier method to implement than a minimal number of points.
- `obj.DuplicateSharedPointsOff ()` - Flag to tell the source to duplicate points shared between faces (vertices of the box and internal edge points). Initial value is false. Implementation note: duplicating points is an easier method to implement than a minimal number of points.
- `obj.SetQuads (int )` - Flag to tell the source to generate either a quad or two triangle for a set of four points. Initial value is false (generate triangles).
- `int = obj.GetQuads ()` - Flag to tell the source to generate either a quad or two triangle for a set of four points. Initial value is false (generate triangles).
- `obj.QuadsOn ()` - Flag to tell the source to generate either a quad or two triangle for a set of four points. Initial value is false (generate triangles).
- `obj.QuadsOff ()` - Flag to tell the source to generate either a quad or two triangle for a set of four points. Initial value is false (generate triangles).

33.233 vtkTessellatorFilter

33.233.1 Usage

This class approximates nonlinear FEM elements with linear simplices.

¡b¿Warning¡/b¿: This class is temporary and will go away at some point after ParaView 1.4.0.

This filter rifles through all the cells in an input vtkDataSet. It tesselates each cell and uses the vtkStreamingTessellator and vtkDataSetEdgeSubdivisionCriterion classes to generate simplices that approximate the nonlinear mesh using some approximation metric (encoded in the particular vtkDataSetEdgeSubdivisionCriterion::EvaluateEdge implementation). The simplices are placed into the filter's output vtkDataSet object by the callback routines AddATetrahedron, AddATriangle, and AddALine, which are registered with the triangulator.

The output mesh will have geometry and any fields specified as attributes in the input mesh's point data. The attribute's copy flags are honored, except for normals.

.SECTION Internals

The filter's main member function is RequestData(). This function first calls SetupOutput() which allocates arrays and some temporary variables for the primitive callbacks (OutputTriangle and OutputLine which are called by AddATriangle and AddALine, respectively). Each cell is given an initial tesselation, which results in one or more calls to OutputTetrahedron, OutputTriangle or OutputLine to add elements to the OutputMesh. Finally, Teardown() is called to free the filter's working space.

To create an instance of class vtkTessellatorFilter, simply invoke its constructor as follows

```
obj = vtkTessellatorFilter
```

33.233.2 Methods

The class vtkTessellatorFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTessellatorFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTessellatorFilter = obj.NewInstance ()`
- `vtkTessellatorFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetTessellator (vtkStreamingTessellator )`
- `vtkStreamingTessellator = obj.GetTessellator ()`
- `obj.SetSubdivider (vtkDataSetEdgeSubdivisionCriterion )`
- `vtkDataSetEdgeSubdivisionCriterion = obj.GetSubdivider ()`
- `long = obj.GetMTime ()`
- `obj.SetOutputDimension (int )` - Set the dimension of the output tessellation. Cells in dimensions higher than the given value will have their boundaries of dimension OutputDimension tessellated. For example, if OutputDimension is 2, a hexahedron's quadrilateral faces would be tessellated rather than its interior.
- `int = obj.GetOutputDimensionMinValue ()` - Set the dimension of the output tessellation. Cells in dimensions higher than the given value will have their boundaries of dimension OutputDimension tessellated. For example, if OutputDimension is 2, a hexahedron's quadrilateral faces would be tessellated rather than its interior.
- `int = obj.GetOutputDimensionMaxValue ()` - Set the dimension of the output tessellation. Cells in dimensions higher than the given value will have their boundaries of dimension OutputDimension tessellated. For example, if OutputDimension is 2, a hexahedron's quadrilateral faces would be tessellated rather than its interior.
- `int = obj.GetOutputDimension ()` - Set the dimension of the output tessellation. Cells in dimensions higher than the given value will have their boundaries of dimension OutputDimension tessellated. For example, if OutputDimension is 2, a hexahedron's quadrilateral faces would be tessellated rather than its interior.
- `obj.SetMaximumNumberOfSubdivisions (int num\_subdiv\_in)` - These are convenience routines for setting properties maintained by the tessellator and subdivider. They are implemented here for ParaView's sake.
- `int = obj.GetMaximumNumberOfSubdivisions ()` - These are convenience routines for setting properties maintained by the tessellator and subdivider. They are implemented here for ParaView's sake.

- `obj.SetChordError (double ce)` - These are convenience routines for setting properties maintained by the tessellator and subdivider. They are implemented here for ParaView's sake.
- `double = obj.GetChordError ()` - These are convenience routines for setting properties maintained by the tessellator and subdivider. They are implemented here for ParaView's sake.
- `obj.ResetFieldCriteria ()` - These methods are for the ParaView client.
- `obj.SetFieldCriterion (int field, double chord)` - These methods are for the ParaView client.
- `int = obj.GetMergePoints ()` - The adaptive tessellation will output vertices that are not shared among cells, even where they should be. This can be corrected to some extents with a vtkMergeFilter. By default, the filter is off and vertices will not be shared.
- `obj.SetMergePoints (int )` - The adaptive tessellation will output vertices that are not shared among cells, even where they should be. This can be corrected to some extents with a vtkMergeFilter. By default, the filter is off and vertices will not be shared.
- `obj.MergePointsOn ()` - The adaptive tessellation will output vertices that are not shared among cells, even where they should be. This can be corrected to some extents with a vtkMergeFilter. By default, the filter is off and vertices will not be shared.
- `obj.MergePointsOff ()` - The adaptive tessellation will output vertices that are not shared among cells, even where they should be. This can be corrected to some extents with a vtkMergeFilter. By default, the filter is off and vertices will not be shared.

33.234 vtkTextSource

33.234.1 Usage

vtkTextSource converts a text string into polygons. This way you can insert text into your renderings. It uses the 9x15 font from X Windows. You can specify if you want the background to be drawn or not. The characters are formed by scan converting the raster font into quadrilaterals. Colors are assigned to the letters using scalar data. To set the color of the characters with the source's actor property, set BackingOff on the text source and ScalarVisibilityOff on the associated vtkPolyDataMapper. Then, the color can be set using the associated actor's property.

vtkVectorText generates higher quality polygonal representations of characters.

To create an instance of class vtkTextSource, simply invoke its constructor as follows

```
obj = vtkTextSource
```

33.234.2 Methods

The class vtkTextSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextSource = obj.NewInstance ()`
- `vtkTextSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetText (string )` - Set/Get the text to be drawn.
- `string = obj.GetText ()` - Set/Get the text to be drawn.

- `obj.SetBacking (int )` - Controls whether or not a background is drawn with the text.
- `int = obj.GetBacking ()` - Controls whether or not a background is drawn with the text.
- `obj.BackingOn ()` - Controls whether or not a background is drawn with the text.
- `obj.BackingOff ()` - Controls whether or not a background is drawn with the text.
- `obj.SetForegroundColor (double , double , double )` - Set/Get the foreground color. Default is white (1,1,1). ALpha is always 1.
- `obj.SetForegroundColor (double a[3])` - Set/Get the foreground color. Default is white (1,1,1). ALpha is always 1.
- `double = obj. GetForegroundColor ()` - Set/Get the foreground color. Default is white (1,1,1). ALpha is always 1.
- `obj.SetBackgroundColor (double , double , double )` - Set/Get the background color. Default is black (0,0,0). Alpha is always 1.
- `obj.SetBackgroundColor (double a[3])` - Set/Get the background color. Default is black (0,0,0). Alpha is always 1.
- `double = obj. GetBackgroundColor ()` - Set/Get the background color. Default is black (0,0,0). Alpha is always 1.

33.235 vtkTexturedSphereSource

33.235.1 Usage

vtkTexturedSphereSource creates a polygonal sphere of specified radius centered at the origin. The resolution (polygonal discretization) in both the latitude (phi) and longitude (theta) directions can be specified. It also is possible to create partial sphere by specifying maximum phi and theta angles.

To create an instance of class vtkTexturedSphereSource, simply invoke its constructor as follows

```
obj = vtkTexturedSphereSource
```

33.235.2 Methods

The class vtkTexturedSphereSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTexturedSphereSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTexturedSphereSource = obj.NewInstance ()`
- `vtkTexturedSphereSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetRadius (double )` - Set radius of sphere.
- `double = obj.GetRadiusMinValue ()` - Set radius of sphere.
- `double = obj.GetRadiusMaxValue ()` - Set radius of sphere.
- `double = obj.GetRadius ()` - Set radius of sphere.
- `obj.SetThetaResolution (int )` - Set the number of points in the longitude direction.

- `int = obj.GetThetaResolutionMinValue ()` - Set the number of points in the longitude direction.
- `int = obj.GetThetaResolutionMaxValue ()` - Set the number of points in the longitude direction.
- `int = obj.GetThetaResolution ()` - Set the number of points in the longitude direction.
- `obj.SetPhiResolution (int )` - Set the number of points in the latitude direction.
- `int = obj.GetPhiResolutionMinValue ()` - Set the number of points in the latitude direction.
- `int = obj.GetPhiResolutionMaxValue ()` - Set the number of points in the latitude direction.
- `int = obj.GetPhiResolution ()` - Set the number of points in the latitude direction.
- `obj.SetTheta (double )` - Set the maximum longitude angle.
- `double = obj.GetThetaMinValue ()` - Set the maximum longitude angle.
- `double = obj.GetThetaMaxValue ()` - Set the maximum longitude angle.
- `double = obj.GetTheta ()` - Set the maximum longitude angle.
- `obj.SetPhi (double )` - Set the maximum latitude angle (0 is at north pole).
- `double = obj.GetPhiMinValue ()` - Set the maximum latitude angle (0 is at north pole).
- `double = obj.GetPhiMaxValue ()` - Set the maximum latitude angle (0 is at north pole).
- `double = obj.GetPhi ()` - Set the maximum latitude angle (0 is at north pole).

33.236 vtkTextureMapToCylinder

33.236.1 Usage

vtkTextureMapToCylinder is a filter that generates 2D texture coordinates by mapping input dataset points onto a cylinder. The cylinder can either be user specified or generated automatically. (The cylinder is generated automatically by computing the axis of the cylinder.) Note that the generated texture coordinates for the s-coordinate ranges from (0-1) (corresponding to angle of 0-¿360 around axis), while the mapping of the t-coordinate is controlled by the projection of points along the axis.

To specify a cylinder manually, you must provide two points that define the axis of the cylinder. The length of the axis will affect the t-coordinates.

A special ivar controls how the s-coordinate is generated. If PreventSeam is set to true, the s-texture varies from 0-¿1 and then 1-¿0 (corresponding to angles of 0-¿180 and 180-¿360).

To create an instance of class vtkTextureMapToCylinder, simply invoke its constructor as follows

```
obj = vtkTextureMapToCylinder
```

33.236.2 Methods

The class vtkTextureMapToCylinder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextureMapToCylinder class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextureMapToCylinder = obj.NewInstance ()`
- `vtkTextureMapToCylinder = obj.SafeDownCast (vtkObject o)`

- `obj.SetPoint1 (double , double , double )` - Specify the first point defining the cylinder axis,
- `obj.SetPoint1 (double  a[3])` - Specify the first point defining the cylinder axis,
- `double = obj. GetPoint1 ()` - Specify the first point defining the cylinder axis,
- `obj.SetPoint2 (double , double , double )` - Specify the second point defining the cylinder axis,
- `obj.SetPoint2 (double  a[3])` - Specify the second point defining the cylinder axis,
- `double = obj. GetPoint2 ()` - Specify the second point defining the cylinder axis,
- `obj.SetAutomaticCylinderGeneration (int )` - Turn on/off automatic cylinder generation. This means it automatically finds the cylinder center and axis.
- `int = obj.GetAutomaticCylinderGeneration ()` - Turn on/off automatic cylinder generation. This means it automatically finds the cylinder center and axis.
- `obj.AutomaticCylinderGenerationOn ()` - Turn on/off automatic cylinder generation. This means it automatically finds the cylinder center and axis.
- `obj.AutomaticCylinderGenerationOff ()` - Turn on/off automatic cylinder generation. This means it automatically finds the cylinder center and axis.
- `obj.SetPreventSeam (int )` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the angle variation from 0-¿180 and 180-¿0. Otherwise, the s-coordinate ranges from 0-¿1 from 0-¿360 degrees.
- `int = obj.GetPreventSeam ()` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the angle variation from 0-¿180 and 180-¿0. Otherwise, the s-coordinate ranges from 0-¿1 from 0-¿360 degrees.
- `obj.PreventSeamOn ()` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the angle variation from 0-¿180 and 180-¿0. Otherwise, the s-coordinate ranges from 0-¿1 from 0-¿360 degrees.
- `obj.PreventSeamOff ()` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the angle variation from 0-¿180 and 180-¿0. Otherwise, the s-coordinate ranges from 0-¿1 from 0-¿360 degrees.

33.237 vtkTextureMapToPlane

33.237.1 Usage

vtkTextureMapToPlane is a filter that generates 2D texture coordinates by mapping input dataset points onto a plane. The plane can either be user specified or generated automatically. (A least squares method is used to generate the plane automatically.)

There are two ways you can specify the plane. The first is to provide a plane normal. In this case the points are projected to a plane, and the points are then mapped into the user specified s-t coordinate range. For more control, you can specify a plane with three points: an origin and two points defining the two axes of the plane. (This is compatible with the vtkPlaneSource.) Using the second method, the SRange and TRange vectors are ignored, since the presumption is that the user does not want to scale the texture coordinates; and you can adjust the origin and axes points to achieve the texture coordinate scaling you need. Note also that using the three point method the axes do not have to be orthogonal.

To create an instance of class vtkTextureMapToPlane, simply invoke its constructor as follows

```
obj = vtkTextureMapToPlane
```

33.237.2 Methods

The class vtkTextureMapToPlane has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextureMapToPlane class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextureMapToPlane = obj.NewInstance ()`
- `vtkTextureMapToPlane = obj.SafeDownCast (vtkObject o)`
- `obj.SetOrigin (double , double , double )` - Specify a point defining the origin of the plane. Used in conjunction with the Point1 and Point2 ivars to specify a map plane.
- `obj.SetOrigin (double a[3])` - Specify a point defining the origin of the plane. Used in conjunction with the Point1 and Point2 ivars to specify a map plane.
- `double = obj. GetOrigin ()` - Specify a point defining the origin of the plane. Used in conjunction with the Point1 and Point2 ivars to specify a map plane.
- `obj.SetPoint1 (double , double , double )` - Specify a point defining the first axis of the plane.
- `obj.SetPoint1 (double a[3])` - Specify a point defining the first axis of the plane.
- `double = obj. GetPoint1 ()` - Specify a point defining the first axis of the plane.
- `obj.SetPoint2 (double , double , double )` - Specify a point defining the second axis of the plane.
- `obj.SetPoint2 (double a[3])` - Specify a point defining the second axis of the plane.
- `double = obj. GetPoint2 ()` - Specify a point defining the second axis of the plane.
- `obj.SetNormal (double , double , double )` - Specify plane normal. An alternative way to specify a map plane. Using this method, the object will scale the resulting texture coordinate between the SRange and TRange specified.
- `obj.SetNormal (double a[3])` - Specify plane normal. An alternative way to specify a map plane. Using this method, the object will scale the resulting texture coordinate between the SRange and TRange specified.
- `double = obj. GetNormal ()` - Specify plane normal. An alternative way to specify a map plane. Using this method, the object will scale the resulting texture coordinate between the SRange and TRange specified.
- `obj.SetSRange (double , double )` - Specify s-coordinate range for texture s-t coordinate pair.
- `obj.SetSRange (double a[2])` - Specify s-coordinate range for texture s-t coordinate pair.
- `double = obj. GetSRange ()` - Specify s-coordinate range for texture s-t coordinate pair.
- `obj.SetTRange (double , double )` - Specify t-coordinate range for texture s-t coordinate pair.
- `obj.SetTRange (double a[2])` - Specify t-coordinate range for texture s-t coordinate pair.
- `double = obj. GetTRange ()` - Specify t-coordinate range for texture s-t coordinate pair.
- `obj.SetAutomaticPlaneGeneration (int )` - Turn on/off automatic plane generation.
- `int = obj.GetAutomaticPlaneGeneration ()` - Turn on/off automatic plane generation.
- `obj.AutomaticPlaneGenerationOn ()` - Turn on/off automatic plane generation.
- `obj.AutomaticPlaneGenerationOff ()` - Turn on/off automatic plane generation.

33.238 vtkTextureMapToSphere

33.238.1 Usage

vtkTextureMapToSphere is a filter that generates 2D texture coordinates by mapping input dataset points onto a sphere. The sphere can either be user specified or generated automatically. (The sphere is generated automatically by computing the center (i.e., averaged coordinates) of the sphere.) Note that the generated texture coordinates range between (0,1). The s-coordinate lies in the angular direction around the z-axis, measured counter-clockwise from the x-axis. The t-coordinate lies in the angular direction measured down from the north pole towards the south pole.

A special ivar controls how the s-coordinate is generated. If PreventSeam is set to true, the s-texture varies from 0-¿1 and then 1-¿0 (corresponding to angles of 0-¿180 and 180-¿360).

To create an instance of class vtkTextureMapToSphere, simply invoke its constructor as follows

```
obj = vtkTextureMapToSphere
```

33.238.2 Methods

The class vtkTextureMapToSphere has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextureMapToSphere class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextureMapToSphere = obj.NewInstance ()`
- `vtkTextureMapToSphere = obj.SafeDownCast (vtkObject o)`
- `obj.SetCenter (double , double , double )` - Specify a point defining the center of the sphere.
- `obj.SetCenter (double  a[3])` - Specify a point defining the center of the sphere.
- `double = obj. GetCenter ()` - Specify a point defining the center of the sphere.
- `obj.SetAutomaticSphereGeneration (int )` - Turn on/off automatic sphere generation. This means it automatically finds the sphere center.
- `int = obj.GetAutomaticSphereGeneration ()` - Turn on/off automatic sphere generation. This means it automatically finds the sphere center.
- `obj.AutomaticSphereGenerationOn ()` - Turn on/off automatic sphere generation. This means it automatically finds the sphere center.
- `obj.AutomaticSphereGenerationOff ()` - Turn on/off automatic sphere generation. This means it automatically finds the sphere center.
- `obj.SetPreventSeam (int )` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the theta angle variation between 0-¿180 and 180-¿0 degrees. Otherwise, the s-coordinate ranges from 0-¿1 between 0-¿360 degrees.
- `int = obj.GetPreventSeam ()` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the theta angle variation between 0-¿180 and 180-¿0 degrees. Otherwise, the s-coordinate ranges from 0-¿1 between 0-¿360 degrees.
- `obj.PreventSeamOn ()` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the theta angle variation between 0-¿180 and 180-¿0 degrees. Otherwise, the s-coordinate ranges from 0-¿1 between 0-¿360 degrees.

- `obj.PreventSeamOff ()` - Control how the texture coordinates are generated. If PreventSeam is set, the s-coordinate ranges from 0-¿1 and 1-¿0 corresponding to the theta angle variation between 0-¿180 and 180-¿0 degrees. Otherwise, the s-coordinate ranges from 0-¿1 between 0-¿360 degrees.

33.239 vtkThreshold

33.239.1 Usage

vtkThreshold is a filter that extracts cells from any dataset type that satisfy a threshold criterion. A cell satisfies the criterion if the scalar value of (every or any) point satisfies the criterion. The criterion can take three forms: 1) greater than a particular value; 2) less than a particular value; or 3) between two values. The output of this filter is an unstructured grid.

Note that scalar values are available from the point and cell attribute data. By default, point data is used to obtain scalars, but you can control this behavior. See the AttributeMode ivar below.

By default only the first scalar value is used in the decision. Use the ComponentMode and SelectedComponent ivars to control this behavior.

To create an instance of class vtkThreshold, simply invoke its constructor as follows

```
obj = vtkThreshold
```

33.239.2 Methods

The class vtkThreshold has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThreshold class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThreshold = obj.NewInstance ()`
- `vtkThreshold = obj.SafeDownCast (vtkObject o)`
- `obj.ThresholdByLower (double lower)` - Criterion is cells whose scalars are less or equal to lower threshold.
- `obj.ThresholdByUpper (double upper)` - Criterion is cells whose scalars are greater or equal to upper threshold.
- `obj.ThresholdBetween (double lower, double upper)` - Criterion is cells whose scalars are between lower and upper thresholds (inclusive of the end values).
- `double = obj.GetUpperThreshold ()` - Get the Upper and Lower thresholds.
- `double = obj.GetLowerThreshold ()` - Get the Upper and Lower thresholds.
- `obj.SetAttributeMode (int )` - Control how the filter works with scalar point data and cell attribute data. By default (AttributeModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).
- `int = obj.GetAttributeMode ()` - Control how the filter works with scalar point data and cell attribute data. By default (AttributeModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

- `obj.SetAttributeModeToDefault ()` - Control how the filter works with scalar point data and cell attribute data. By default (AttributeModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

- `obj.SetAttributeModeToUsePointData ()` - Control how the filter works with scalar point data and cell attribute data. By default (AttributeModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

- `obj.SetAttributeModeToUseCellData ()` - Control how the filter works with scalar point data and cell attribute data. By default (AttributeModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

- `string = obj.GetAttributeModeAsString ()` - Control how the filter works with scalar point data and cell attribute data. By default (AttributeModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

- `obj.SetComponentMode (int )` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `int = obj.GetComponentModeMinValue ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `int = obj.GetComponentModeMaxValue ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `int = obj.GetComponentMode ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `obj.SetComponentModeToUseSelected ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `obj.SetComponentModeToUseAll ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `obj.SetComponentModeToUseAny ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `string = obj.GetComponentModeAsString ()` - Control how the decision of in / out is made with multi-component data. The choices are to use the selected component (specified in the SelectedComponent ivar), or to look at all components. When looking at all components, the evaluation can pass

if all the components satisfy the rule (UseAll) or if any satisfy is (UseAny). The default value is UseSelected.

- `obj.SetSelectedComponent (int )` - When the component mode is UseSelected, this ivar indicated the selected component. The default value is 0.
- `int = obj.GetSelectedComponentMinValue ()` - When the component mode is UseSelected, this ivar indicated the selected component. The default value is 0.
- `int = obj.GetSelectedComponentMaxValue ()` - When the component mode is UseSelected, this ivar indicated the selected component. The default value is 0.
- `int = obj.GetSelectedComponent ()` - When the component mode is UseSelected, this ivar indicated the selected component. The default value is 0.
- `obj.SetAllScalars (int )` - If using scalars from point data, all scalars for all points in a cell must satisfy the threshold criterion if AllScalars is set. Otherwise, just a single scalar value satisfying the threshold criterion enables will extract the cell.
- `int = obj.GetAllScalars ()` - If using scalars from point data, all scalars for all points in a cell must satisfy the threshold criterion if AllScalars is set. Otherwise, just a single scalar value satisfying the threshold criterion enables will extract the cell.
- `obj.AllScalarsOn ()` - If using scalars from point data, all scalars for all points in a cell must satisfy the threshold criterion if AllScalars is set. Otherwise, just a single scalar value satisfying the threshold criterion enables will extract the cell.
- `obj.AllScalarsOff ()` - If using scalars from point data, all scalars for all points in a cell must satisfy the threshold criterion if AllScalars is set. Otherwise, just a single scalar value satisfying the threshold criterion enables will extract the cell.
- `obj.SetPointsDataTypeToDouble ()` - Set the data type of the output points (See the data types defined in vtkType.h). The default data type is float.
- `obj.SetPointsDataTypeToFloat ()` - Set the data type of the output points (See the data types defined in vtkType.h). The default data type is float.
- `obj.SetPointsDataType (int )` - Set the data type of the output points (See the data types defined in vtkType.h). The default data type is float.
- `int = obj.GetPointsDataType ()` - Set the data type of the output points (See the data types defined in vtkType.h). The default data type is float.

33.240 vtkThresholdPoints

33.240.1 Usage

vtkThresholdPoints is a filter that extracts points from a dataset that satisfy a threshold criterion. The criterion can take three forms: 1) greater than a particular value; 2) less than a particular value; or 3) between a particular value. The output of the filter is polygonal data.

To create an instance of class vtkThresholdPoints, simply invoke its constructor as follows

```
obj = vtkThresholdPoints
```

33.240.2 Methods

The class vtkThresholdPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThresholdPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThresholdPoints = obj.NewInstance ()`
- `vtkThresholdPoints = obj.SafeDownCast (vtkObject o)`
- `obj.ThresholdByLower (double lower)` - Criterion is cells whose scalars are less or equal to lower threshold.
- `obj.ThresholdByUpper (double upper)` - Criterion is cells whose scalars are greater or equal to upper threshold.
- `obj.ThresholdBetween (double lower, double upper)` - Criterion is cells whose scalars are between lower and upper thresholds (inclusive of the end values).
- `obj.SetUpperThreshold (double )` - Set/Get the upper threshold.
- `double = obj.GetUpperThreshold ()` - Set/Get the upper threshold.
- `obj.SetLowerThreshold (double )` - Set/Get the lower threshold.
- `double = obj.GetLowerThreshold ()` - Set/Get the lower threshold.

33.241 vtkThresholdTextureCoords

33.241.1 Usage

vtkThresholdTextureCoords is a filter that generates texture coordinates for any input dataset type given a threshold criterion. The criterion can take three forms: 1) greater than a particular value (ThresholdByUpper()); 2) less than a particular value (ThresholdByLower(); or 3) between two values (ThresholdBetween(). If the threshold criterion is satisfied, the "in" texture coordinate will be set (this can be specified by the user). If the threshold criterion is not satisfied the "out" is set.

To create an instance of class vtkThresholdTextureCoords, simply invoke its constructor as follows

```
obj = vtkThresholdTextureCoords
```

33.241.2 Methods

The class vtkThresholdTextureCoords has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThresholdTextureCoords class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThresholdTextureCoords = obj.NewInstance ()`
- `vtkThresholdTextureCoords = obj.SafeDownCast (vtkObject o)`

- `obj.ThresholdByLower (double lower)` - Criterion is cells whose scalars are less than lower threshold.
- `obj.ThresholdByUpper (double upper)` - Criterion is cells whose scalars are less than upper threshold.
- `obj.ThresholdBetween (double lower, double upper)` - Criterion is cells whose scalars are between lower and upper thresholds.
- `double = obj.GetUpperThreshold ()` - Return the upper and lower thresholds.
- `double = obj.GetLowerThreshold ()` - Return the upper and lower thresholds.
- `obj.SetTextureDimension (int )` - Set the desired dimension of the texture map.
- `int = obj.GetTextureDimensionMinValue ()` - Set the desired dimension of the texture map.
- `int = obj.GetTextureDimensionMaxValue ()` - Set the desired dimension of the texture map.
- `int = obj.GetTextureDimension ()` - Set the desired dimension of the texture map.
- `obj.SetInTextureCoord (double , double , double )` - Set the texture coordinate value for point satisfying threshold criterion.
- `obj.SetInTextureCoord (double a[3])` - Set the texture coordinate value for point satisfying threshold criterion.
- `double = obj. GetInTextureCoord ()` - Set the texture coordinate value for point satisfying threshold criterion.
- `obj.SetOutTextureCoord (double , double , double )` - Set the texture coordinate value for point NOT satisfying threshold criterion.
- `obj.SetOutTextureCoord (double a[3])` - Set the texture coordinate value for point NOT satisfying threshold criterion.
- `double = obj. GetOutTextureCoord ()` - Set the texture coordinate value for point NOT satisfying threshold criterion.

33.242 vtkTimeSourceExample

33.242.1 Usage

Creates a small easily understood time varying data set for testing. The output is a vtkUntructuredGrid in which the point and cell values vary over time in a sin wave. The analytic ivar controls whether the output corresponds to a step function over time or is continuous. The X and Y Amplitude ivars make the output move in the X and Y directions over time. The Growing ivar makes the number of cells in the output grow and then shrink over time.

To create an instance of class vtkTimeSourceExample, simply invoke its constructor as follows

```
obj = vtkTimeSourceExample
```

33.242.2 Methods

The class vtkTimeSourceExample has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTimeSourceExample class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTimeSourceExample = obj.NewInstance ()`
- `vtkTimeSourceExample = obj.SafeDownCast (vtkObject o)`
- `obj.SetAnalytic (int )`
- `int = obj.GetAnalyticMinValue ()`
- `int = obj.GetAnalyticMaxValue ()`
- `int = obj.GetAnalytic ()`
- `obj.AnalyticOn ()`
- `obj.AnalyticOff ()`
- `obj.SetXAmplitude (double )`
- `double = obj.GetXAmplitude ()`
- `obj.SetYAmplitude (double )`
- `double = obj.GetYAmplitude ()`
- `obj.SetGrowing (int )`
- `int = obj.GetGrowingMinValue ()`
- `int = obj.GetGrowingMaxValue ()`
- `int = obj.GetGrowing ()`
- `obj.GrowingOn ()`
- `obj.GrowingOff ()`

33.243 vtkTransformCoordinateSystems

33.243.1 Usage

This filter transforms points from one coordinate system to another. The user must specify the coordinate systems in which the input and output are specified. The user must also specify the VTK viewport (i.e., renderer) in which the transformation occurs.

To create an instance of class vtkTransformCoordinateSystems, simply invoke its constructor as follows

```
obj = vtkTransformCoordinateSystems
```

33.243.2 Methods

The class vtkTransformCoordinateSystems has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformCoordinateSystems class.

- `string = obj.GetClassName ()` - Standard methods for type information and printing.
- `int = obj.IsA (string name)` - Standard methods for type information and printing.
- `vtkTransformCoordinateSystems = obj.NewInstance ()` - Standard methods for type information and printing.
- `vtkTransformCoordinateSystems = obj.SafeDownCast (vtkObject o)` - Standard methods for type information and printing.
- `obj.SetInputCoordinateSystem (int )` - Set/get the coordinate system in which the input is specified. The current options are World, Viewport, and Display. By default the input coordinate system is World.
- `int = obj.GetInputCoordinateSystem ()` - Set/get the coordinate system in which the input is specified. The current options are World, Viewport, and Display. By default the input coordinate system is World.
- `obj.SetInputCoordinateSystemToDisplay ()` - Set/get the coordinate system in which the input is specified. The current options are World, Viewport, and Display. By default the input coordinate system is World.
- `obj.SetInputCoordinateSystemToViewport ()` - Set/get the coordinate system in which the input is specified. The current options are World, Viewport, and Display. By default the input coordinate system is World.
- `obj.SetInputCoordinateSystemToWorld ()` - Set/get the coordinate system to which to transform the output. The current options are World, Viewport, and Display. By default the output coordinate system is Display.
- `obj.SetOutputCoordinateSystem (int )` - Set/get the coordinate system to which to transform the output. The current options are World, Viewport, and Display. By default the output coordinate system is Display.
- `int = obj.GetOutputCoordinateSystem ()` - Set/get the coordinate system to which to transform the output. The current options are World, Viewport, and Display. By default the output coordinate system is Display.
- `obj.SetOutputCoordinateSystemToDisplay ()` - Set/get the coordinate system to which to transform the output. The current options are World, Viewport, and Display. By default the output coordinate system is Display.
- `obj.SetOutputCoordinateSystemToViewport ()` - Set/get the coordinate system to which to transform the output. The current options are World, Viewport, and Display. By default the output coordinate system is Display.
- `obj.SetOutputCoordinateSystemToWorld ()` - Return the MTime also considering the instance of vtkCoordinate.
- `long = obj.GetMTime ()` - Return the MTime also considering the instance of vtkCoordinate.

- `obj.SetViewport (vtkViewport viewport)` - In order for successful coordinate transformation to occur, an instance of vtkViewport (e.g., a VTK renderer) must be specified. NOTE: this is a raw pointer, not a weak pointer not a reference counted object to avoid reference cycle loop between rendering classes and filter classes.
- `vtkViewport = obj.GetViewport ()` - In order for successful coordinate transformation to occur, an instance of vtkViewport (e.g., a VTK renderer) must be specified. NOTE: this is a raw pointer, not a weak pointer not a reference counted object to avoid reference cycle loop between rendering classes and filter classes.

33.244 vtkTransformFilter

33.244.1 Usage

vtkTransformFilter is a filter to transform point coordinates, and associated point normals and vectors. Other point data is passed through the filter.

An alternative method of transformation is to use vtkActor's methods to scale, rotate, and translate objects. The difference between the two methods is that vtkActor's transformation simply effects where objects are rendered (via the graphics pipeline), whereas vtkTransformFilter actually modifies point coordinates in the visualization pipeline. This is necessary for some objects (e.g., vtkProbeFilter) that require point coordinates as input.

To create an instance of class vtkTransformFilter, simply invoke its constructor as follows

```
obj = vtkTransformFilter
```

33.244.2 Methods

The class vtkTransformFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransformFilter = obj.NewInstance ()`
- `vtkTransformFilter = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime also considering the transform.
- `obj.SetTransform (vtkAbstractTransform )` - Specify the transform object used to transform points.
- `vtkAbstractTransform = obj.GetTransform ()` - Specify the transform object used to transform points.

33.245 vtkTransformPolyDataFilter

33.245.1 Usage

vtkTransformPolyDataFilter is a filter to transform point coordinates and associated point and cell normals and vectors. Other point and cell data is passed through the filter unchanged. This filter is specialized for polygonal data. See vtkTransformFilter for more general data.

An alternative method of transformation is to use vtkActor's methods to scale, rotate, and translate objects. The difference between the two methods is that vtkActor's transformation simply effects where objects are rendered (via the graphics pipeline), whereas vtkTransformPolyDataFilter actually modifies

point coordinates in the visualization pipeline. This is necessary for some objects (e.g., vtkProbeFilter) that require point coordinates as input.

To create an instance of class vtkTransformPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkTransformPolyDataFilter
```

33.245.2 Methods

The class vtkTransformPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransformPolyDataFilter = obj.NewInstance ()`
- `vtkTransformPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime also considering the transform.
- `obj.SetTransform (vtkAbstractTransform )` - Specify the transform object used to transform points.
- `vtkAbstractTransform = obj.GetTransform ()` - Specify the transform object used to transform points.

33.246 vtkTransformTextureCoords

33.246.1 Usage

vtkTransformTextureCoords is a filter that operates on texture coordinates. It ingests any type of dataset, and outputs a dataset of the same type. The filter lets you scale, translate, and rotate texture coordinates. For example, by using the the Scale ivar, you can shift texture coordinates that range from (0-¿1) to range from (0-¿10) (useful for repeated patterns).

The filter operates on texture coordinates of dimension 1-¿3. The texture coordinates are referred to as r-s-t. If the texture map is two dimensional, the t-coordinate (and operations on the t-coordinate) are ignored.

To create an instance of class vtkTransformTextureCoords, simply invoke its constructor as follows

```
obj = vtkTransformTextureCoords
```

33.246.2 Methods

The class vtkTransformTextureCoords has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformTextureCoords class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransformTextureCoords = obj.NewInstance ()`
- `vtkTransformTextureCoords = obj.SafeDownCast (vtkObject o)`

- `obj.SetPosition (double , double , double )` - Set/Get the position of the texture map. Setting the position translates the texture map by the amount specified.
- `obj.SetPosition (double a[3])` - Set/Get the position of the texture map. Setting the position translates the texture map by the amount specified.
- `double = obj. GetPosition ()` - Set/Get the position of the texture map. Setting the position translates the texture map by the amount specified.
- `obj.AddPosition (double deltaR, double deltaS, double deltaT)` - Incrementally change the position of the texture map (i.e., does a translate or shift of the texture coordinates).
- `obj.AddPosition (double deltaPosition[3])` - Incrementally change the position of the texture map (i.e., does a translate or shift of the texture coordinates).
- `obj.SetScale (double , double , double )` - Set/Get the scale of the texture map. Scaling in performed independently on the r, s and t axes.
- `obj.SetScale (double a[3])` - Set/Get the scale of the texture map. Scaling in performed independently on the r, s and t axes.
- `double = obj. GetScale ()` - Set/Get the scale of the texture map. Scaling in performed independently on the r, s and t axes.
- `obj.SetOrigin (double , double , double )` - Set/Get the origin of the texture map. This is the point about which the texture map is flipped (e.g., rotated). Since a typical texture map ranges from (0,1) in the r-s-t coordinates, the default origin is set at (0.5,0.5,0.5).
- `obj.SetOrigin (double a[3])` - Set/Get the origin of the texture map. This is the point about which the texture map is flipped (e.g., rotated). Since a typical texture map ranges from (0,1) in the r-s-t coordinates, the default origin is set at (0.5,0.5,0.5).
- `double = obj. GetOrigin ()` - Set/Get the origin of the texture map. This is the point about which the texture map is flipped (e.g., rotated). Since a typical texture map ranges from (0,1) in the r-s-t coordinates, the default origin is set at (0.5,0.5,0.5).
- `obj.SetFlipR (int )` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `int = obj.GetFlipR ()` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `obj.FlipROn ()` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `obj.FlipROff ()` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `obj.SetFlipS (int )` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `int = obj.GetFlipS ()` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `obj.FlipSOn ()` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.
- `obj.FlipSOff ()` - Boolean indicates whether the texture map should be flipped around the s-axis. Note that the flips occur around the texture origin.

- `obj.SetFlipT (int )` - Boolean indicates whether the texture map should be flipped around the t-axis. Note that the flips occur around the texture origin.

- `int = obj.GetFlipT ()` - Boolean indicates whether the texture map should be flipped around the t-axis. Note that the flips occur around the texture origin.

- `obj.FlipTOn ()` - Boolean indicates whether the texture map should be flipped around the t-axis. Note that the flips occur around the texture origin.

- `obj.FlipTOff ()` - Boolean indicates whether the texture map should be flipped around the t-axis. Note that the flips occur around the texture origin.

33.247 vtkTriangleFilter

33.247.1 Usage

vtkTriangleFilter generates triangles from input polygons and triangle strips. The filter also will pass through vertices and lines, if requested.

To create an instance of class vtkTriangleFilter, simply invoke its constructor as follows

```
obj = vtkTriangleFilter
```

33.247.2 Methods

The class vtkTriangleFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTriangleFilter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkTriangleFilter = obj.NewInstance ()`

- `vtkTriangleFilter = obj.SafeDownCast (vtkObject o)`

- `obj.PassVertsOn ()` - Turn on/off passing vertices through filter.

- `obj.PassVertsOff ()` - Turn on/off passing vertices through filter.

- `obj.SetPassVerts (int )` - Turn on/off passing vertices through filter.

- `int = obj.GetPassVerts ()` - Turn on/off passing vertices through filter.

- `obj.PassLinesOn ()` - Turn on/off passing lines through filter.

- `obj.PassLinesOff ()` - Turn on/off passing lines through filter.

- `obj.SetPassLines (int )` - Turn on/off passing lines through filter.

- `int = obj.GetPassLines ()` - Turn on/off passing lines through filter.

33.248 vtkTriangularTCoords

33.248.1 Usage

vtkTriangularTCoords is a filter that generates texture coordinates for triangles. Texture coordinates for each triangle are: (0,0), (1,0) and (.5,sqrt(3)/2). This filter assumes that the triangle texture map is symmetric about the center of the triangle. Thus the order Of the texture coordinates is not important. The procedural texture in vtkTriangularTexture is designed with this symmetry. For more information see the paper "Opacity-modulating Triangular Textures for Irregular Surfaces," by Penny Rheingans, IEEE Visualization '96, pp. 219-225.

To create an instance of class vtkTriangularTCoords, simply invoke its constructor as follows

```
obj = vtkTriangularTCoords
```

33.248.2 Methods

The class vtkTriangularTCoords has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTriangularTCoords class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTriangularTCoords = obj.NewInstance ()`
- `vtkTriangularTCoords = obj.SafeDownCast (vtkObject o)`

33.249 vtkTubeFilter

33.249.1 Usage

vtkTubeFilter is a filter that generates a tube around each input line. The tubes are made up of triangle strips and rotate around the tube with the rotation of the line normals. (If no normals are present, they are computed automatically.) The radius of the tube can be set to vary with scalar or vector value. If the radius varies with scalar value the radius is linearly adjusted. If the radius varies with vector value, a mass flux preserving variation is used. The number of sides for the tube also can be specified. You can also specify which of the sides are visible. This is useful for generating interesting striping effects. Other options include the ability to cap the tube and generate texture coordinates. Texture coordinates can be used with an associated texture map to create interesting effects such as marking the tube with stripes corresponding to length or time.

This filter is typically used to create thick or dramatic lines. Another common use is to combine this filter with vtkStreamLine to generate streamtubes.

To create an instance of class vtkTubeFilter, simply invoke its constructor as follows

```
obj = vtkTubeFilter
```

33.249.2 Methods

The class vtkTubeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTubeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkTubeFilter = obj.NewInstance ()`
- `vtkTubeFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetRadius (double )` - Set the minimum tube radius (minimum because the tube radius may vary).
- `double = obj.GetRadiusMinValue ()` - Set the minimum tube radius (minimum because the tube radius may vary).
- `double = obj.GetRadiusMaxValue ()` - Set the minimum tube radius (minimum because the tube radius may vary).
- `double = obj.GetRadius ()` - Set the minimum tube radius (minimum because the tube radius may vary).
- `obj.SetVaryRadius (int )` - Turn on/off the variation of tube radius with scalar value.
- `int = obj.GetVaryRadiusMinValue ()` - Turn on/off the variation of tube radius with scalar value.
- `int = obj.GetVaryRadiusMaxValue ()` - Turn on/off the variation of tube radius with scalar value.
- `int = obj.GetVaryRadius ()` - Turn on/off the variation of tube radius with scalar value.
- `obj.SetVaryRadiusToVaryRadiusOff ()` - Turn on/off the variation of tube radius with scalar value.
- `obj.SetVaryRadiusToVaryRadiusByScalar ()` - Turn on/off the variation of tube radius with scalar value.
- `obj.SetVaryRadiusToVaryRadiusByVector ()` - Turn on/off the variation of tube radius with scalar value.
- `obj.SetVaryRadiusToVaryRadiusByAbsoluteScalar ()` - Turn on/off the variation of tube radius with scalar value.
- `string = obj.GetVaryRadiusAsString ()` - Turn on/off the variation of tube radius with scalar value.
- `obj.SetNumberOfSides (int )` - Set the number of sides for the tube. At a minimum, number of sides is 3.
- `int = obj.GetNumberOfSidesMinValue ()` - Set the number of sides for the tube. At a minimum, number of sides is 3.
- `int = obj.GetNumberOfSidesMaxValue ()` - Set the number of sides for the tube. At a minimum, number of sides is 3.
- `int = obj.GetNumberOfSides ()` - Set the number of sides for the tube. At a minimum, number of sides is 3.
- `obj.SetRadiusFactor (double )` - Set the maximum tube radius in terms of a multiple of the minimum radius.
- `double = obj.GetRadiusFactor ()` - Set the maximum tube radius in terms of a multiple of the minimum radius.
- `obj.SetDefaultNormal (double , double , double )` - Set the default normal to use if no normals are supplied, and the DefaultNormalOn is set.
- `obj.SetDefaultNormal (double  a[3])` - Set the default normal to use if no normals are supplied, and the DefaultNormalOn is set.

- `double = obj. GetDefaultNormal ()` - Set the default normal to use if no normals are supplied, and the DefaultNormalOn is set.
- `obj.SetUseDefaultNormal (int )` - Set a boolean to control whether to use default normals. DefaultNormalOn is set.
- `int = obj.GetUseDefaultNormal ()` - Set a boolean to control whether to use default normals. DefaultNormalOn is set.
- `obj.UseDefaultNormalOn ()` - Set a boolean to control whether to use default normals. DefaultNormalOn is set.
- `obj.UseDefaultNormalOff ()` - Set a boolean to control whether to use default normals. DefaultNormalOn is set.
- `obj.SetSidesShareVertices (int )` - Set a boolean to control whether tube sides should share vertices. This creates independent strips, with constant normals so the tube is always faceted in appearance.
- `int = obj.GetSidesShareVertices ()` - Set a boolean to control whether tube sides should share vertices. This creates independent strips, with constant normals so the tube is always faceted in appearance.
- `obj.SidesShareVerticesOn ()` - Set a boolean to control whether tube sides should share vertices. This creates independent strips, with constant normals so the tube is always faceted in appearance.
- `obj.SidesShareVerticesOff ()` - Set a boolean to control whether tube sides should share vertices. This creates independent strips, with constant normals so the tube is always faceted in appearance.
- `obj.SetCapping (int )` - Turn on/off whether to cap the ends with polygons.
- `int = obj.GetCapping ()` - Turn on/off whether to cap the ends with polygons.
- `obj.CappingOn ()` - Turn on/off whether to cap the ends with polygons.
- `obj.CappingOff ()` - Turn on/off whether to cap the ends with polygons.
- `obj.SetOnRatio (int )` - Control the striping of the tubes. If OnRatio is greater than 1, then every nth tube side is turned on, beginning with the Offset side.
- `int = obj.GetOnRatioMinValue ()` - Control the striping of the tubes. If OnRatio is greater than 1, then every nth tube side is turned on, beginning with the Offset side.
- `int = obj.GetOnRatioMaxValue ()` - Control the striping of the tubes. If OnRatio is greater than 1, then every nth tube side is turned on, beginning with the Offset side.
- `int = obj.GetOnRatio ()` - Control the striping of the tubes. If OnRatio is greater than 1, then every nth tube side is turned on, beginning with the Offset side.
- `obj.SetOffset (int )` - Control the striping of the tubes. The offset sets the first tube side that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `int = obj.GetOffsetMinValue ()` - Control the striping of the tubes. The offset sets the first tube side that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `int = obj.GetOffsetMaxValue ()` - Control the striping of the tubes. The offset sets the first tube side that is visible. Offset is generally used with OnRatio to create nifty striping effects.
- `int = obj.GetOffset ()` - Control the striping of the tubes. The offset sets the first tube side that is visible. Offset is generally used with OnRatio to create nifty striping effects.

- `obj.SetGenerateTCoords (int )` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `int = obj.GetGenerateTCoordsMinValue ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `int = obj.GetGenerateTCoordsMaxValue ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `int = obj.GetGenerateTCoords ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `obj.SetGenerateTCoordsToOff ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `obj.SetGenerateTCoordsToNormalizedLength ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `obj.SetGenerateTCoordsToUseLength ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `obj.SetGenerateTCoordsToUseScalars ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `string = obj.GetGenerateTCoordsAsString ()` - Control whether and how texture coordinates are produced. This is useful for striping the tube with length textures, etc. If you use scalars to create the texture, the scalars are assumed to be monotonically increasing (or decreasing).
- `obj.SetTextureLength (double )` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.
- `double = obj.GetTextureLengthMinValue ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.
- `double = obj.GetTextureLengthMaxValue ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.
- `double = obj.GetTextureLength ()` - Control the conversion of units during the texture coordinates calculation. The TextureLength indicates what length (whether calculated from scalars or length) is mapped to the [0,1) texture space.

33.250 vtkUncertaintyTubeFilter

33.250.1 Usage

vtkUncertaintyTubeFilter is a filter that generates ellipsoidal (in cross section) tubes that follows a polyline. The input is a vtkPolyData with polylines that have associated vector point data. The vector data represents the uncertainty of the polyline in the x-y-z directions.

To create an instance of class vtkUncertaintyTubeFilter, simply invoke its constructor as follows

```
obj = vtkUncertaintyTubeFilter
```

33.250.2 Methods

The class vtkUncertaintyTubeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUncertaintyTubeFilter class.

- `string = obj.GetClassName ()` - Standard methods for printing and obtaining type information for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for printing and obtaining type information for instances of this class.
- `vtkUncertaintyTubeFilter = obj.NewInstance ()` - Standard methods for printing and obtaining type information for instances of this class.
- `vtkUncertaintyTubeFilter = obj.SafeDownCast (vtkObject o)` - Standard methods for printing and obtaining type information for instances of this class.
- `obj.SetNumberOfSides (int )` - Set / get the number of sides for the tube. At a minimum, the number of sides is 3.
- `int = obj.GetNumberOfSidesMinValue ()` - Set / get the number of sides for the tube. At a minimum, the number of sides is 3.
- `int = obj.GetNumberOfSidesMaxValue ()` - Set / get the number of sides for the tube. At a minimum, the number of sides is 3.
- `int = obj.GetNumberOfSides ()` - Set / get the number of sides for the tube. At a minimum, the number of sides is 3.

33.251 vtkUnstructuredGridGeometryFilter

33.251.1 Usage

vtkUnstructuredGridGeometryFilter is a filter that extracts geometry (and associated data) from an unstructured grid. It differs from vtkGeometryFilter by not tessellating higher order faces: 2D faces of quadratic 3D cells will be quadratic. A quadratic edge is extracted as a quadratic edge. For that purpose, the output of this filter is an unstructured grid, not a polydata. Also, the face of a voxel is a pixel, not a quad. Geometry is obtained as follows: all 0D, 1D, and 2D cells are extracted. All 2D faces that are used by only one 3D cell (i.e., boundary faces) are extracted. It also is possible to specify conditions on point ids, cell ids, and on bounding box (referred to as "Extent") to control the extraction process.

To create an instance of class vtkUnstructuredGridGeometryFilter, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridGeometryFilter
```

33.251.2 Methods

The class vtkUnstructuredGridGeometryFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridGeometryFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridGeometryFilter = obj.NewInstance ()`
- `vtkUnstructuredGridGeometryFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointClipping (int )` - Turn on/off selection of geometry by point id.
- `int = obj.GetPointClipping ()` - Turn on/off selection of geometry by point id.
- `obj.PointClippingOn ()` - Turn on/off selection of geometry by point id.
- `obj.PointClippingOff ()` - Turn on/off selection of geometry by point id.
- `obj.SetCellClipping (int )` - Turn on/off selection of geometry by cell id.
- `int = obj.GetCellClipping ()` - Turn on/off selection of geometry by cell id.
- `obj.CellClippingOn ()` - Turn on/off selection of geometry by cell id.
- `obj.CellClippingOff ()` - Turn on/off selection of geometry by cell id.
- `obj.SetExtentClipping (int )` - Turn on/off selection of geometry via bounding box.
- `int = obj.GetExtentClipping ()` - Turn on/off selection of geometry via bounding box.
- `obj.ExtentClippingOn ()` - Turn on/off selection of geometry via bounding box.
- `obj.ExtentClippingOff ()` - Turn on/off selection of geometry via bounding box.
- `obj.SetPointMinimum (vtkIdType )` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimumMinValue ()` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimumMaxValue ()` - Specify the minimum point id for point id selection.
- `vtkIdType = obj.GetPointMinimum ()` - Specify the minimum point id for point id selection.
- `obj.SetPointMaximum (vtkIdType )` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximumMinValue ()` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximumMaxValue ()` - Specify the maximum point id for point id selection.
- `vtkIdType = obj.GetPointMaximum ()` - Specify the maximum point id for point id selection.
- `obj.SetCellMinimum (vtkIdType )` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimumMinValue ()` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimumMaxValue ()` - Specify the minimum cell id for point id selection.
- `vtkIdType = obj.GetCellMinimum ()` - Specify the minimum cell id for point id selection.
- `obj.SetCellMaximum (vtkIdType )` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximumMinValue ()` - Specify the maximum cell id for point id selection.
- `vtkIdType = obj.GetCellMaximumMaxValue ()` - Specify the maximum cell id for point id selection.

- `vtkIdType = obj.GetCellMaximum ()` - Specify the maximum cell id for point id selection.
- `obj.SetExtent (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)` - Specify a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `obj.SetExtent (double extent[6])` - Set / get a (xmin,xmax, ymin,ymax, zmin,zmax) bounding box to clip data.
- `obj.SetMerging (int )` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `int = obj.GetMerging ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOn ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.MergingOff ()` - Turn on/off merging of coincident points. Note that is merging is on, points with different point attributes (e.g., normals) are merged, which may cause rendering artifacts.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.
- `long = obj.GetMTime ()` - Return the MTime also considering the locator.

33.252 vtkVectorDot

33.252.1 Usage

vtkVectorDot is a filter to generate scalar values from a dataset. The scalar value at a point is created by computing the dot product between the normal and vector at that point. Combined with the appropriate color map, this can show nodal lines/mode shapes of vibration, or a displacement plot.

To create an instance of class vtkVectorDot, simply invoke its constructor as follows

```
obj = vtkVectorDot
```

33.252.2 Methods

The class vtkVectorDot has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVectorDot class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVectorDot = obj.NewInstance ()`
- `vtkVectorDot = obj.SafeDownCast (vtkObject o)`
- `obj.SetScalarRange (double , double )` - Specify range to map scalars into.
- `obj.SetScalarRange (double  a[2])` - Specify range to map scalars into.
- `double = obj. GetScalarRange ()` - Get the range that scalars map into.

33.253 vtkVectorNorm

33.253.1 Usage

vtkVectorNorm is a filter that generates scalar values by computing Euclidean norm of vector triplets. Scalars can be normalized 0¡=s¡=1 if desired.

Note that this filter operates on point or cell attribute data, or both. By default, the filter operates on both point and cell data if vector point and cell data, respectively, are available from the input. Alternatively, you can choose to generate scalar norm values for just cell or point data.

To create an instance of class vtkVectorNorm, simply invoke its constructor as follows

```
obj = vtkVectorNorm
```

33.253.2 Methods

The class vtkVectorNorm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVectorNorm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVectorNorm = obj.NewInstance ()`
- `vtkVectorNorm = obj.SafeDownCast (vtkObject o)`
- `obj.SetNormalize (int )` - Specify whether to normalize scalar values.
- `int = obj.GetNormalize ()` - Specify whether to normalize scalar values.
- `obj.NormalizeOn ()` - Specify whether to normalize scalar values.
- `obj.NormalizeOff ()` - Specify whether to normalize scalar values.
- `obj.SetAttributeMode (int )` - Control how the filter works to generate scalar data from the input vector data. By default, (AttributeModeToDefault) the filter will generate the scalar norm for point and cell data (if vector data present in the input). Alternatively, you can explicitly set the filter to generate point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).
- `int = obj.GetAttributeMode ()` - Control how the filter works to generate scalar data from the input vector data. By default, (AttributeModeToDefault) the filter will generate the scalar norm for point and cell data (if vector data present in the input). Alternatively, you can explicitly set the filter to generate point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).
- `obj.SetAttributeModeToDefault ()` - Control how the filter works to generate scalar data from the input vector data. By default, (AttributeModeToDefault) the filter will generate the scalar norm for point and cell data (if vector data present in the input). Alternatively, you can explicitly set the filter to generate point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).
- `obj.SetAttributeModeToUsePointData ()` - Control how the filter works to generate scalar data from the input vector data. By default, (AttributeModeToDefault) the filter will generate the scalar norm for point and cell data (if vector data present in the input). Alternatively, you can explicitly set the filter to generate point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).
- `obj.SetAttributeModeToUseCellData ()` - Control how the filter works to generate scalar data from the input vector data. By default, (AttributeModeToDefault) the filter will generate the scalar norm for point and cell data (if vector data present in the input). Alternatively, you can explicitly set the filter to generate point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

- `string = obj.GetAttributeModeAsString ()` - Control how the filter works to generate scalar data from the input vector data. By default, (AttributeModeToDefault) the filter will generate the scalar norm for point and cell data (if vector data present in the input). Alternatively, you can explicitly set the filter to generate point data (AttributeModeToUsePointData) or cell data (AttributeModeToUseCellData).

33.254 vtkVertexGlyphFilter

33.254.1 Usage

This filter throws away all of the cells in the input and replaces them with a vertex on each point. The intended use of this filter is roughly equivalent to the vtkGlyph3D filter, except this filter is specifically for data that has many vertices, making the rendered result faster and less cluttered than the glyph filter. This filter may take a graph or point set as input.

To create an instance of class vtkVertexGlyphFilter, simply invoke its constructor as follows

```
obj = vtkVertexGlyphFilter
```

33.254.2 Methods

The class vtkVertexGlyphFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVertexGlyphFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVertexGlyphFilter = obj.NewInstance ()`
- `vtkVertexGlyphFilter = obj.SafeDownCast (vtkObject o)`

33.255 vtkVoxelContoursToSurfaceFilter

33.255.1 Usage

vtkVoxelContoursToSurfaceFilter is a filter that takes contours and produces surfaces. There are some restrictions for the contours:

- The contours are input as vtkPolyData, with the contours being polys in the vtkPolyData. - The contours lie on XY planes - each contour has a constant Z - The contours are ordered in the polys of the vtkPolyData such that all contours on the first (lowest) XY plane are first, then continuing in order of increasing Z value. - The X, Y and Z coordinates are all integer values. - The desired sampling of the contour data is 1x1x1 - Aspect can be used to control the aspect ratio in the output polygonal dataset.

This filter takes the contours and produces a structured points dataset of signed floating point number indicating distance from a contour. A contouring filter is then applied to generate 3D surfaces from a stack of 2D contour distance slices. This is done in a streaming fashion so as not to use to much memory.

To create an instance of class vtkVoxelContoursToSurfaceFilter, simply invoke its constructor as follows

```
obj = vtkVoxelContoursToSurfaceFilter
```

33.255.2 Methods

The class vtkVoxelContoursToSurfaceFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVoxelContoursToSurfaceFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVoxelContoursToSurfaceFilter = obj.NewInstance ()`
- `vtkVoxelContoursToSurfaceFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetMemoryLimitInBytes (int )` - Set / Get the memory limit in bytes for this filter. This is the limit of the size of the structured points data set that is created for intermediate processing. The data will be streamed through this volume in as many pieces as necessary.
- `int = obj.GetMemoryLimitInBytes ()` - Set / Get the memory limit in bytes for this filter. This is the limit of the size of the structured points data set that is created for intermediate processing. The data will be streamed through this volume in as many pieces as necessary.
- `obj.SetSpacing (double , double , double )`
- `obj.SetSpacing (double  a[3])`
- `double = obj. GetSpacing ()`

33.256 vtkWarpLens

33.256.1 Usage

vtkWarpLens is a filter that modifies point coordinates by moving in accord with a lens distortion model.

To create an instance of class vtkWarpLens, simply invoke its constructor as follows

```
obj = vtkWarpLens
```

33.256.2 Methods

The class vtkWarpLens has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWarpLens class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWarpLens = obj.NewInstance ()`
- `vtkWarpLens = obj.SafeDownCast (vtkObject o)`
- `obj.SetKappa (double kappa)` - Specify second order symmetric radial lens distortion parameter. This is obsoleted by newer instance variables.
- `double = obj.GetKappa ()` - Specify second order symmetric radial lens distortion parameter. This is obsoleted by newer instance variables.
- `obj.SetCenter (double centerX, double centerY)` - Specify the center of radial distortion in pixels. This is obsoleted by newer instance variables.

- `double = obj.GetCenter ()` - Specify the center of radial distortion in pixels. This is obsoleted by newer instance variables.
- `obj.SetPrincipalPoint (double , double )` - Specify the calibrated principal point of the camera/lens
- `obj.SetPrincipalPoint (double a[2])` - Specify the calibrated principal point of the camera/lens
- `double = obj. GetPrincipalPoint ()` - Specify the calibrated principal point of the camera/lens
- `obj.SetK1 (double )` - Specify the symmetric radial distortion parameters for the lens
- `double = obj.GetK1 ()` - Specify the symmetric radial distortion parameters for the lens
- `obj.SetK2 (double )` - Specify the symmetric radial distortion parameters for the lens
- `double = obj.GetK2 ()` - Specify the symmetric radial distortion parameters for the lens
- `obj.SetP1 (double )` - Specify the decentering distortion parameters for the lens
- `double = obj.GetP1 ()` - Specify the decentering distortion parameters for the lens
- `obj.SetP2 (double )` - Specify the decentering distortion parameters for the lens
- `double = obj.GetP2 ()` - Specify the decentering distortion parameters for the lens
- `obj.SetFormatWidth (double )` - Specify the imager format width / height in mm
- `double = obj.GetFormatWidth ()` - Specify the imager format width / height in mm
- `obj.SetFormatHeight (double )` - Specify the imager format width / height in mm
- `double = obj.GetFormatHeight ()` - Specify the imager format width / height in mm
- `obj.SetImageWidth (int )` - Specify the image width / height in pixels
- `int = obj.GetImageWidth ()` - Specify the image width / height in pixels
- `obj.SetImageHeight (int )` - Specify the image width / height in pixels
- `int = obj.GetImageHeight ()` - Specify the image width / height in pixels

33.257 vtkWarpScalar

33.257.1 Usage

vtkWarpScalar is a filter that modifies point coordinates by moving points along point normals by the scalar amount times the scale factor. Useful for creating carpet or x-y-z plots.

If normals are not present in data, the Normal instance variable will be used as the direction along which to warp the geometry. If normals are present but you would like to use the Normal instance variable, set the UseNormal boolean to true.

If XYPlane boolean is set true, then the z-value is considered to be a scalar value (still scaled by scale factor), and the displacement is along the z-axis. If scalars are also present, these are copied through and can be used to color the surface.

Note that the filter passes both its point data and cell data to its output, except for normals, since these are distorted by the warping.

To create an instance of class vtkWarpScalar, simply invoke its constructor as follows

```
obj = vtkWarpScalar
```

33.257.2 Methods

The class vtkWarpScalar has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWarpScalar class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWarpScalar = obj.NewInstance ()`
- `vtkWarpScalar = obj.SafeDownCast (vtkObject o)`
- `obj.SetScaleFactor (double )` - Specify value to scale displacement.
- `double = obj.GetScaleFactor ()` - Specify value to scale displacement.
- `obj.SetUseNormal (int )` - Turn on/off use of user specified normal. If on, data normals will be ignored and instance variable Normal will be used instead.
- `int = obj.GetUseNormal ()` - Turn on/off use of user specified normal. If on, data normals will be ignored and instance variable Normal will be used instead.
- `obj.UseNormalOn ()` - Turn on/off use of user specified normal. If on, data normals will be ignored and instance variable Normal will be used instead.
- `obj.UseNormalOff ()` - Turn on/off use of user specified normal. If on, data normals will be ignored and instance variable Normal will be used instead.
- `obj.SetNormal (double , double , double )` - Normal (i.e., direction) along which to warp geometry. Only used if UseNormal boolean set to true or no normals available in data.
- `obj.SetNormal (double  a[3])` - Normal (i.e., direction) along which to warp geometry. Only used if UseNormal boolean set to true or no normals available in data.
- `double = obj. GetNormal ()` - Normal (i.e., direction) along which to warp geometry. Only used if UseNormal boolean set to true or no normals available in data.
- `obj.SetXYPlane (int )` - Turn on/off flag specifying that input data is x-y plane. If x-y plane, then the z value is used to warp the surface in the z-axis direction (times the scale factor) and scalars are used to color the surface.
- `int = obj.GetXYPlane ()` - Turn on/off flag specifying that input data is x-y plane. If x-y plane, then the z value is used to warp the surface in the z-axis direction (times the scale factor) and scalars are used to color the surface.
- `obj.XYPlaneOn ()` - Turn on/off flag specifying that input data is x-y plane. If x-y plane, then the z value is used to warp the surface in the z-axis direction (times the scale factor) and scalars are used to color the surface.
- `obj.XYPlaneOff ()` - Turn on/off flag specifying that input data is x-y plane. If x-y plane, then the z value is used to warp the surface in the z-axis direction (times the scale factor) and scalars are used to color the surface.

33.258 vtkWarpTo

33.258.1 Usage

vtkWarpTo is a filter that modifies point coordinates by moving the points towards a user specified position.

To create an instance of class vtkWarpTo, simply invoke its constructor as follows

```
obj = vtkWarpTo
```

33.258.2 Methods

The class vtkWarpTo has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWarpTo class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWarpTo = obj.NewInstance ()`
- `vtkWarpTo = obj.SafeDownCast (vtkObject o)`
- `obj.SetScaleFactor (double )` - Set/Get the value to scale displacement.
- `double = obj.GetScaleFactor ()` - Set/Get the value to scale displacement.
- `double = obj. GetPosition ()` - Set/Get the position to warp towards.
- `obj.SetPosition (double , double , double )` - Set/Get the position to warp towards.
- `obj.SetPosition (double  a[3])` - Set/Get the position to warp towards.
- `obj.SetAbsolute (int )` - Set/Get the Absolute ivar. Turning Absolute on causes scale factor of the new position to be one unit away from Position.
- `int = obj.GetAbsolute ()` - Set/Get the Absolute ivar. Turning Absolute on causes scale factor of the new position to be one unit away from Position.
- `obj.AbsoluteOn ()` - Set/Get the Absolute ivar. Turning Absolute on causes scale factor of the new position to be one unit away from Position.
- `obj.AbsoluteOff ()` - Set/Get the Absolute ivar. Turning Absolute on causes scale factor of the new position to be one unit away from Position.

33.259 vtkWarpVector

33.259.1 Usage

vtkWarpVector is a filter that modifies point coordinates by moving points along vector times the scale factor. Useful for showing flow profiles or mechanical deformation.

The filter passes both its point data and cell data to its output.

To create an instance of class vtkWarpVector, simply invoke its constructor as follows

```
obj = vtkWarpVector
```

33.259.2 Methods

The class vtkWarpVector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWarpVector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWarpVector = obj.NewInstance ()`
- `vtkWarpVector = obj.SafeDownCast (vtkObject o)`
- `obj.SetScaleFactor (double )` - Specify value to scale displacement.
- `double = obj.GetScaleFactor ()` - Specify value to scale displacement.

33.260 vtkWindowedSincPolyDataFilter

33.260.1 Usage

vtkWindowedSincPolyDataFiler adjust point coordinate using a windowed sinc function interpolation kernel. The effect is to "relax" the mesh, making the cells better shaped and the vertices more evenly distributed. Note that this filter operates the lines, polygons, and triangle strips composing an instance of vtkPolyData. Vertex or poly-vertex cells are never modified.

The algorithm proceeds as follows. For each vertex v, a topological and geometric analysis is performed to determine which vertices are connected to v, and which cells are connected to v. Then, a connectivity array is constructed for each vertex. (The connectivity array is a list of lists of vertices that directly attach to each vertex.) Next, an iteration phase begins over all vertices. For each vertex v, the coordinates of v are modified using a windowed sinc function interpolation kernel. Taubin describes this methodology is the IBM tech report RC-20404 (#90237, dated 3/12/96) "Optimal Surface Smoothing as Filter Design" G. Taubin, T. Zhang and G. Golub. (Zhang and Golub are at Stanford University).

This report discusses using standard signal processing low-pass filters (in particular windowed sinc functions) to smooth polyhedra. The transfer functions of the low-pass filters are approximated by Chebyshev polynomials. This facilitates applying the filters in an iterative diffusion process (as opposed to a kernel convolution). The more smoothing iterations applied, the higher the degree of polynomial approximating the low-pass filter transfer function. Each smoothing iteration, therefore, applies the next higher term of the Chebyshev filter approximation to the polyhedron. This decoupling of the filter into an iteratively applied polynomial is possible since the Chebyshev polynomials are orthogonal, i.e. increasing the order of the approximation to the filter transfer function does not alter the previously calculated coefficients for the low order terms.

Note: Care must be taken to avoid smoothing with too few iterations. A Chebyshev approximation with too few terms is an poor approximation. The first few smoothing iterations represent a severe scaling and translation of the data. Subsequent iterations cause the smoothed polyhedron to converge to the true location and scale of the object. We have attempted to protect against this by automatically adjusting the filter, effectively widening the pass band. This adjustment is only possible if the number of iterations is greater than 1. Note that this sacrifices some degree of smoothing for model integrity. For those interested, the filter is adjusted by searching for a value sigma such that the actual pass band is k_pb + sigma and such that the filter transfer function evaluates to unity at k_pb, i.e. f(k_pb) = 1

To improve the numerical stability of the solution and minimize the scaling the translation effects, the algorithm can translate and scale the position coordinates to within the unit cube [-1, 1], perform the smoothing, and translate and scale the position coordinates back to the original coordinate frame. This mode is controlled with the NormalizeCoordinatesOn() / NormalizeCoordinatesOff() methods. For legacy reasons, the default is NormalizeCoordinatesOff.

This implementation is currently limited to using an interpolation kernel based on Hamming windows. Other windows (such as Hann, Blackman, Kaiser, Lanczos, Gaussian, and exponential windows) could be used instead.

There are some special instance variables used to control the execution of this filter. (These ivars basically control what vertices can be smoothed, and the creation of the connectivity array.) The BoundarySmoothing ivar enables/disables the smoothing operation on vertices that are on the "boundary" of the mesh. A boundary vertex is one that is surrounded by a semi-cycle of polygons (or used by a single line).

Another important ivar is FeatureEdgeSmoothing. If this ivar is enabled, then interior vertices are classified as either "simple", "interior edge", or "fixed", and smoothed differently. (Interior vertices are manifold vertices surrounded by a cycle of polygons; or used by two line cells.) The classification is based on the number of feature edges attached to v. A feature edge occurs when the angle between the two surface normals of a polygon sharing an edge is greater than the FeatureAngle ivar. Then, vertices used by no feature edges are classified "simple", vertices used by exactly two feature edges are classified "interior edge", and all others are "fixed" vertices.

Once the classification is known, the vertices are smoothed differently. Corner (i.e., fixed) vertices are not smoothed at all. Simple vertices are smoothed as before . Interior edge vertices are smoothed only along their two connected edges, and only if the angle between the edges is less than the EdgeAngle ivar.

The total smoothing can be controlled by using two ivars. The NumberOfIterations determines the maximum number of smoothing passes. The NumberOfIterations corresponds to the degree of the polynomial that is used to approximate the windowed sinc function. Ten or twenty iterations is all the is usually necessary. Contrast this with vtkSmoothPolyDataFilter which usually requires 100 to 200 smoothing iterations. vtkSmoothPolyDataFilter is also not an approximation to an ideal low-pass filter, which can cause the geometry to shrink as the amount of smoothing increases.

The second ivar is the specification of the PassBand for the windowed sinc filter. By design, the PassBand is specified as a doubleing point number between 0 and 2. Lower PassBand values produce more smoothing. A good default value for the PassBand is 0.1 (for those interested, the PassBand (and frequencies) for PolyData are based on the valence of the vertices, this limits all the frequency modes in a polyhedral mesh to between 0 and 2.)

There are two instance variables that control the generation of error data. If the ivar GenerateErrorScalars is on, then a scalar value indicating the distance of each vertex from its original position is computed. If the ivar GenerateErrorVectors is on, then a vector representing change in position is computed.

To create an instance of class vtkWindowedSincPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkWindowedSincPolyDataFilter
```

33.260.2 Methods

The class vtkWindowedSincPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWindowedSincPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWindowedSincPolyDataFilter = obj.NewInstance ()`
- `vtkWindowedSincPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfIterations (int )` - Specify the number of iterations (or degree of the polynomial approximating the windowed sinc function).
- `int = obj.GetNumberOfIterationsMinValue ()` - Specify the number of iterations (or degree of the polynomial approximating the windowed sinc function).
- `int = obj.GetNumberOfIterationsMaxValue ()` - Specify the number of iterations (or degree of the polynomial approximating the windowed sinc function).

- `int = obj.GetNumberOfIterations ()` - Specify the number of iterations (or degree of the polynomial approximating the windowed sinc function).
- `obj.SetPassBand (double )` - Set the passband value for the windowed sinc filter
- `double = obj.GetPassBandMinValue ()` - Set the passband value for the windowed sinc filter
- `double = obj.GetPassBandMaxValue ()` - Set the passband value for the windowed sinc filter
- `double = obj.GetPassBand ()` - Set the passband value for the windowed sinc filter
- `obj.SetNormalizeCoordinates (int )` - Turn on/off coordinate normalization. The positions can be translated and scaled such that they fit within a [-1, 1] prior to the smoothing computation. The default is off. The numerical stability of the solution can be improved by turning normalization on. If normalization is on, the coordinates will be rescaled to the original coordinate system after smoothing has completed.
- `int = obj.GetNormalizeCoordinates ()` - Turn on/off coordinate normalization. The positions can be translated and scaled such that they fit within a [-1, 1] prior to the smoothing computation. The default is off. The numerical stability of the solution can be improved by turning normalization on. If normalization is on, the coordinates will be rescaled to the original coordinate system after smoothing has completed.
- `obj.NormalizeCoordinatesOn ()` - Turn on/off coordinate normalization. The positions can be translated and scaled such that they fit within a [-1, 1] prior to the smoothing computation. The default is off. The numerical stability of the solution can be improved by turning normalization on. If normalization is on, the coordinates will be rescaled to the original coordinate system after smoothing has completed.
- `obj.NormalizeCoordinatesOff ()` - Turn on/off coordinate normalization. The positions can be translated and scaled such that they fit within a [-1, 1] prior to the smoothing computation. The default is off. The numerical stability of the solution can be improved by turning normalization on. If normalization is on, the coordinates will be rescaled to the original coordinate system after smoothing has completed.
- `obj.SetFeatureEdgeSmoothing (int )` - Turn on/off smoothing along sharp interior edges.
- `int = obj.GetFeatureEdgeSmoothing ()` - Turn on/off smoothing along sharp interior edges.
- `obj.FeatureEdgeSmoothingOn ()` - Turn on/off smoothing along sharp interior edges.
- `obj.FeatureEdgeSmoothingOff ()` - Turn on/off smoothing along sharp interior edges.
- `obj.SetFeatureAngle (double )` - Specify the feature angle for sharp edge identification.
- `double = obj.GetFeatureAngleMinValue ()` - Specify the feature angle for sharp edge identification.
- `double = obj.GetFeatureAngleMaxValue ()` - Specify the feature angle for sharp edge identification.
- `double = obj.GetFeatureAngle ()` - Specify the feature angle for sharp edge identification.
- `obj.SetEdgeAngle (double )` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `double = obj.GetEdgeAngleMinValue ()` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `double = obj.GetEdgeAngleMaxValue ()` - Specify the edge angle to control smoothing along edges (either interior or boundary).
- `double = obj.GetEdgeAngle ()` - Specify the edge angle to control smoothing along edges (either interior or boundary).

- `obj.SetBoundarySmoothing (int )` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `int = obj.GetBoundarySmoothing ()` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `obj.BoundarySmoothingOn ()` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `obj.BoundarySmoothingOff ()` - Turn on/off the smoothing of vertices on the boundary of the mesh.
- `obj.SetNonManifoldSmoothing (int )` - Smooth non-manifold vertices.
- `int = obj.GetNonManifoldSmoothing ()` - Smooth non-manifold vertices.
- `obj.NonManifoldSmoothingOn ()` - Smooth non-manifold vertices.
- `obj.NonManifoldSmoothingOff ()` - Smooth non-manifold vertices.
- `obj.SetGenerateErrorScalars (int )` - Turn on/off the generation of scalar distance values.
- `int = obj.GetGenerateErrorScalars ()` - Turn on/off the generation of scalar distance values.
- `obj.GenerateErrorScalarsOn ()` - Turn on/off the generation of scalar distance values.
- `obj.GenerateErrorScalarsOff ()` - Turn on/off the generation of scalar distance values.
- `obj.SetGenerateErrorVectors (int )` - Turn on/off the generation of error vectors.
- `int = obj.GetGenerateErrorVectors ()` - Turn on/off the generation of error vectors.
- `obj.GenerateErrorVectorsOn ()` - Turn on/off the generation of error vectors.
- `obj.GenerateErrorVectorsOff ()` - Turn on/off the generation of error vectors.

33.261 vtkYoungsMaterialInterface

33.261.1 Usage

Reconstructs material interfaces from a mesh containing mixed cells (where several materials are mixed) this implementation is based on the youngs algorithm, generalized to arbitrary cell types and works on both 2D and 3D meshes. the main advantage of the youngs algorithm is it guarantees the material volume correctness. for 2D meshes, the AxisSymetric flag allows to switch between a pure 2D (plannar) algorithm and an axis symetric 2D algorithm handling volumes of revolution.

.SECTION Thanks This file is part of the generalized Youngs material interface reconstruction algorithm contributed by ¡br¿ CEA/DIF - Commissariat a l'Energie Atomique, Centre DAM Ile-De-France ¡br¿ BP12, F-91297 Arpajon, France. ¡br¿ Implementation by Thierry Carrard (thierry.carrard@cea.fr)

To create an instance of class vtkYoungsMaterialInterface, simply invoke its constructor as follows

```
obj = vtkYoungsMaterialInterface
```

33.261.2 Methods

The class vtkYoungsMaterialInterface has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkYoungsMaterialInterface class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkYoungsMaterialInterface = obj.NewInstance ()`
- `vtkYoungsMaterialInterface = obj.SafeDownCast (vtkObject o)`
- `obj.SetInverseNormal (int )` - Set/Get wether the normal vector has to be flipped.
- `int = obj.GetInverseNormal ()` - Set/Get wether the normal vector has to be flipped.
- `obj.InverseNormalOn ()` - Set/Get wether the normal vector has to be flipped.
- `obj.InverseNormalOff ()` - Set/Get wether the normal vector has to be flipped.
- `obj.SetReverseMaterialOrder (int )` - If this flag is on, material order in reversed. Otherwise, materials are sorted in ascending order depending on the given ordering array.
- `int = obj.GetReverseMaterialOrder ()` - If this flag is on, material order in reversed. Otherwise, materials are sorted in ascending order depending on the given ordering array.
- `obj.ReverseMaterialOrderOn ()` - If this flag is on, material order in reversed. Otherwise, materials are sorted in ascending order depending on the given ordering array.
- `obj.ReverseMaterialOrderOff ()` - If this flag is on, material order in reversed. Otherwise, materials are sorted in ascending order depending on the given ordering array.
- `obj.SetOnionPeel (int )` - Set/Get OnionPeel flag. if this flag is on, the normal vector of the first material (which depends on material ordering) is used for all materials.
- `int = obj.GetOnionPeel ()` - Set/Get OnionPeel flag. if this flag is on, the normal vector of the first material (which depends on material ordering) is used for all materials.
- `obj.OnionPeelOn ()` - Set/Get OnionPeel flag. if this flag is on, the normal vector of the first material (which depends on material ordering) is used for all materials.
- `obj.OnionPeelOff ()` - Set/Get OnionPeel flag. if this flag is on, the normal vector of the first material (which depends on material ordering) is used for all materials.
- `obj.SetAxisSymetric (int )` - Turns on/off AxisSymetric computation of 2D interfaces. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `int = obj.GetAxisSymetric ()` - Turns on/off AxisSymetric computation of 2D interfaces. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `obj.AxisSymetricOn ()` - Turns on/off AxisSymetric computation of 2D interfaces. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `obj.AxisSymetricOff ()` - Turns on/off AxisSymetric computation of 2D interfaces. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `obj.SetUseFractionAsDistance (int )` - when UseFractionAsDistance is true, the volume fraction is interpreted as the distance of the cutting plane from the origin. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `int = obj.GetUseFractionAsDistance ()` - when UseFractionAsDistance is true, the volume fraction is interpreted as the distance of the cutting plane from the origin. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `obj.UseFractionAsDistanceOn ()` - when UseFractionAsDistance is true, the volume fraction is interpreted as the distance of the cutting plane from the origin. in axis symetric mode, 2D meshes are understood as volumes of revolution.

- `obj.UseFractionAsDistanceOff ()` - when UseFractionAsDistance is true, the volume fraction is interpreted as the distance of the cutting plane from the origin. in axis symetric mode, 2D meshes are understood as volumes of revolution.
- `obj.SetFillMaterial (int )` - When FillMaterial is set to 1, the volume containing material is output and not only the interface surface.
- `int = obj.GetFillMaterial ()` - When FillMaterial is set to 1, the volume containing material is output and not only the interface surface.
- `obj.FillMaterialOn ()` - When FillMaterial is set to 1, the volume containing material is output and not only the interface surface.
- `obj.FillMaterialOff ()` - When FillMaterial is set to 1, the volume containing material is output and not only the interface surface.
- `obj.SetTwoMaterialsOptimization (int )` - Triggers some additional optimizations for cells containing only two materials. This option might produce different result than expected if the sum of volume fractions is not 1.
- `int = obj.GetTwoMaterialsOptimization ()` - Triggers some additional optimizations for cells containing only two materials. This option might produce different result than expected if the sum of volume fractions is not 1.
- `obj.TwoMaterialsOptimizationOn ()` - Triggers some additional optimizations for cells containing only two materials. This option might produce different result than expected if the sum of volume fractions is not 1.
- `obj.TwoMaterialsOptimizationOff ()` - Triggers some additional optimizations for cells containing only two materials. This option might produce different result than expected if the sum of volume fractions is not 1.
- `obj.SetVolumeFractionRange (double , double )` - Set/Get minimum and maximum volume fraction value. if a material fills a volume above the minimum value, the material is considered to be void. if a material fills a volume fraction beyond the maximum value it is considered as filling the whole volume.
- `obj.SetVolumeFractionRange (double a[2])` - Set/Get minimum and maximum volume fraction value. if a material fills a volume above the minimum value, the material is considered to be void. if a material fills a volume fraction beyond the maximum value it is considered as filling the whole volume.
- `double = obj. GetVolumeFractionRange ()` - Set/Get minimum and maximum volume fraction value. if a material fills a volume above the minimum value, the material is considered to be void. if a material fills a volume fraction beyond the maximum value it is considered as filling the whole volume.
- `obj.SetNumberOfMaterials (int n)` - Sets/Gets the number of materials.
- `int = obj.GetNumberOfMaterials ()` - Sets/Gets the number of materials.
- `obj.SetMaterialArrays (int i, string volumeFraction, string interfaceNormal, string materialOrderir` - Set ith Material arrays to be used as volume fraction, interface normal and material ordering. Each parameter name a cell array.
- `obj.SetMaterialVolumeFractionArray (int i, string volume)` - Set ith Material arrays to be used as volume fraction, interface normal and material ordering. Each parameter name a cell array.
- `obj.SetMaterialNormalArray (int i, string normal)` - Set ith Material arrays to be used as volume fraction, interface normal and material ordering. Each parameter name a cell array.

- `obj.SetMaterialOrderingArray (int i, string ordering)` - Set ith Material arrays to be used as volume fraction, interface normal and material ordering. Each parameter name a cell array.
- `obj.RemoveAllMaterials ()` - Removes all meterials previously added.

Chapter 34

Visualization Toolkit Hybrid Classes

34.1 vtk3DSImporter

34.1.1 Usage

vtk3DSImporter imports 3D Studio files into vtk.

To create an instance of class vtk3DSImporter, simply invoke its constructor as follows

```
obj = vtk3DSImporter
```

34.1.2 Methods

The class vtk3DSImporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtk3DSImporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtk3DSImporter = obj.NewInstance ()`
- `vtk3DSImporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the name of the file to read.
- `string = obj.GetFileName ()` - Specify the name of the file to read.
- `obj.SetComputeNormals (int )` - Set/Get the computation of normals. If on, imported geometry will be run through vtkPolyDataNormals.
- `int = obj.GetComputeNormals ()` - Set/Get the computation of normals. If on, imported geometry will be run through vtkPolyDataNormals.
- `obj.ComputeNormalsOn ()` - Set/Get the computation of normals. If on, imported geometry will be run through vtkPolyDataNormals.
- `obj.ComputeNormalsOff ()` - Set/Get the computation of normals. If on, imported geometry will be run through vtkPolyDataNormals.

34.2 vtkAnnotatedCubeActor

34.2.1 Usage

vtkAnnotatedCubeActor is a hybrid 3D actor used to represent an anatomical orientation marker in a scene. The class consists of a 3D unit cube centered on the origin with each face labelled in correspondance to a particular coordinate direction. For example, with Cartesian directions, the user defined text labels could be: +X, -X, +Y, -Y, +Z, -Z, while for anatomical directions: A, P, L, R, S, I. Text is automatically centered on each cube face and is not restriceted to single characters. In addition to or in replace of a solid text label representation, the outline edges of the labels can be displayed. The individual properties of the cube, face labels and text outlines can be manipulated as can their visibility.

To create an instance of class vtkAnnotatedCubeActor, simply invoke its constructor as follows

```
obj = vtkAnnotatedCubeActor
```

34.2.2 Methods

The class vtkAnnotatedCubeActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnnotatedCubeActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnnotatedCubeActor = obj.NewInstance ()`
- `vtkAnnotatedCubeActor = obj.SafeDownCast (vtkObject o)`
- `obj.GetActors (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an axes actor. Overloads the virtual vtkProp method.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.GetBounds (double bounds[6])` - Get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). (The method GetBounds(double bounds[6]) is available from the superclass.)
- `double = obj.GetBounds ()` - Get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). (The method GetBounds(double bounds[6]) is available from the superclass.)
- `long = obj.GetMTime ()` - Get the actors mtime plus consider its properties and texture if set.
- `obj.SetFaceTextScale (double )` - Set/Get the scale factor for the face text
- `double = obj.GetFaceTextScale ()` - Set/Get the scale factor for the face text

- `vtkProperty = obj.GetXPlusFaceProperty ()` - Get the individual face text properties.
- `vtkProperty = obj.GetXMinusFaceProperty ()` - Get the individual face text properties.
- `vtkProperty = obj.GetYPlusFaceProperty ()` - Get the individual face text properties.
- `vtkProperty = obj.GetYMinusFaceProperty ()` - Get the individual face text properties.
- `vtkProperty = obj.GetZPlusFaceProperty ()` - Get the individual face text properties.
- `vtkProperty = obj.GetZMinusFaceProperty ()` - Get the individual face text properties.
- `vtkProperty = obj.GetCubeProperty ()` - Get the cube properties.
- `vtkProperty = obj.GetTextEdgesProperty ()` - Get the text edges properties.
- `obj.SetXPlusFaceText (string )` - Set/get the face text.
- `string = obj.GetXPlusFaceText ()` - Set/get the face text.
- `obj.SetXMinusFaceText (string )` - Set/get the face text.
- `string = obj.GetXMinusFaceText ()` - Set/get the face text.
- `obj.SetYPlusFaceText (string )` - Set/get the face text.
- `string = obj.GetYPlusFaceText ()` - Set/get the face text.
- `obj.SetYMinusFaceText (string )` - Set/get the face text.
- `string = obj.GetYMinusFaceText ()` - Set/get the face text.
- `obj.SetZPlusFaceText (string )` - Set/get the face text.
- `string = obj.GetZPlusFaceText ()` - Set/get the face text.
- `obj.SetZMinusFaceText (string )` - Set/get the face text.
- `string = obj.GetZMinusFaceText ()` - Set/get the face text.
- `obj.SetTextEdgesVisibility (int )` - Enable/disable drawing the vector text edges.
- `int = obj.GetTextEdgesVisibility ()` - Enable/disable drawing the vector text edges.
- `obj.SetCubeVisibility (int )` - Enable/disable drawing the cube.
- `int = obj.GetCubeVisibility ()` - Enable/disable drawing the cube.
- `obj.SetFaceTextVisibility (int )` - Enable/disable drawing the vector text.
- `int = obj.GetFaceTextVisibility ()` - Enable/disable drawing the vector text.
- `obj.SetXFaceTextRotation (double )` - Augment individual face text orientations.
- `double = obj.GetXFaceTextRotation ()` - Augment individual face text orientations.
- `obj.SetYFaceTextRotation (double )` - Augment individual face text orientations.
- `double = obj.GetYFaceTextRotation ()` - Augment individual face text orientations.
- `obj.SetZFaceTextRotation (double )` - Augment individual face text orientations.
- `double = obj.GetZFaceTextRotation ()` - Augment individual face text orientations.
- `vtkAssembly = obj.GetAssembly ()`

34.3 vtkArcPlotter

34.3.1 Usage

vtkArcPlotter performs plotting of attribute data along polylines defined with an input vtkPolyData data object. Any type of attribute data can be plotted including scalars, vectors, tensors, normals, texture coordinates, and field data. Either one or multiple data components can be plotted.

To use this class you must specify an input data set that contains one or more polylines, and some attribute data including which component of the attribute data. (By default, this class processes the first component of scalar data.) You will also need to set an offset radius (the distance of the polyline to the median line of the plot), a width for the plot (the distance that the minimum and maximum plot values are mapped into), an possibly an offset (used to offset attribute data with multiple components).

Normally the filter automatically computes normals for generating the offset arc plot. However, you can specify a default normal and use that instead.

To create an instance of class vtkArcPlotter, simply invoke its constructor as follows

```
obj = vtkArcPlotter
```

34.3.2 Methods

The class vtkArcPlotter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArcPlotter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArcPlotter = obj.NewInstance ()`
- `vtkArcPlotter = obj.SafeDownCast (vtkObject o)`
- `obj.SetCamera (vtkCamera )` - Specify a camera used to orient the plot along the arc. If no camera is specified, then the orientation of the plot is arbitrary.
- `vtkCamera = obj.GetCamera ()` - Specify a camera used to orient the plot along the arc. If no camera is specified, then the orientation of the plot is arbitrary.
- `obj.SetPlotMode (int )` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `int = obj.GetPlotMode ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `obj.SetPlotModeToPlotScalars ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `obj.SetPlotModeToPlotVectors ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `obj.SetPlotModeToPlotNormals ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.

- `obj.SetPlotModeToPlotTCoords ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `obj.SetPlotModeToPlotTensors ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `obj.SetPlotModeToPlotFieldData ()` - Specify which data to plot: scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetPlotComponent to control which component to plot.
- `obj.SetPlotComponent (int )` - Set/Get the component number to plot if the data has more than one component. If the value of the plot component is == (-1), then all the components will be plotted.
- `int = obj.GetPlotComponent ()` - Set/Get the component number to plot if the data has more than one component. If the value of the plot component is == (-1), then all the components will be plotted.
- `obj.SetRadius (double )` - Set the radius of the "median" value of the first plotted component.
- `double = obj.GetRadiusMinValue ()` - Set the radius of the "median" value of the first plotted component.
- `double = obj.GetRadiusMaxValue ()` - Set the radius of the "median" value of the first plotted component.
- `double = obj.GetRadius ()` - Set the radius of the "median" value of the first plotted component.
- `obj.SetHeight (double )` - Set the height of the plot. (The radius combined with the height define the location of the plot relative to the generating polyline.)
- `double = obj.GetHeightMinValue ()` - Set the height of the plot. (The radius combined with the height define the location of the plot relative to the generating polyline.)
- `double = obj.GetHeightMaxValue ()` - Set the height of the plot. (The radius combined with the height define the location of the plot relative to the generating polyline.)
- `double = obj.GetHeight ()` - Set the height of the plot. (The radius combined with the height define the location of the plot relative to the generating polyline.)
- `obj.SetOffset (double )` - Specify an offset that translates each subsequent plot (if there is more than one component plotted) from the defining arc (i.e., polyline).
- `double = obj.GetOffsetMinValue ()` - Specify an offset that translates each subsequent plot (if there is more than one component plotted) from the defining arc (i.e., polyline).
- `double = obj.GetOffsetMaxValue ()` - Specify an offset that translates each subsequent plot (if there is more than one component plotted) from the defining arc (i.e., polyline).
- `double = obj.GetOffset ()` - Specify an offset that translates each subsequent plot (if there is more than one component plotted) from the defining arc (i.e., polyline).
- `obj.SetUseDefaultNormal (int )` - Set a boolean to control whether to use default normals. By default, normals are automatically computed from the generating polyline and camera.
- `int = obj.GetUseDefaultNormal ()` - Set a boolean to control whether to use default normals. By default, normals are automatically computed from the generating polyline and camera.
- `obj.UseDefaultNormalOn ()` - Set a boolean to control whether to use default normals. By default, normals are automatically computed from the generating polyline and camera.

- `obj.UseDefaultNormalOff ()` - Set a boolean to control whether to use default normals. By default, normals are automatically computed from the generating polyline and camera.
- `obj.SetDefaultNormal (float , float , float )` - Set the default normal to use if you do not wish automatic normal calculation. The arc plot will be generated using this normal.
- `obj.SetDefaultNormal (float a[3])` - Set the default normal to use if you do not wish automatic normal calculation. The arc plot will be generated using this normal.
- `float = obj. GetDefaultNormal ()` - Set the default normal to use if you do not wish automatic normal calculation. The arc plot will be generated using this normal.
- `obj.SetFieldDataArray (int )` - Set/Get the field data array to plot. This instance variable is only applicable if field data is plotted.
- `int = obj.GetFieldDataArrayMinValue ()` - Set/Get the field data array to plot. This instance variable is only applicable if field data is plotted.
- `int = obj.GetFieldDataArrayMaxValue ()` - Set/Get the field data array to plot. This instance variable is only applicable if field data is plotted.
- `int = obj.GetFieldDataArray ()` - Set/Get the field data array to plot. This instance variable is only applicable if field data is plotted.
- `long = obj.GetMTime ()` - New GetMTime because of camera dependency.

34.4 vtkAxesActor

34.4.1 Usage

vtkAxesActor is a hybrid 2D/3D actor used to represent 3D axes in a scene. The user can define the geometry to use for the shaft or the tip, and the user can set the text for the three axes. The text will appear to follow the camera since it is implemented by means of vtkCaptionActor2D. All of the functionality of the underlying vtkCaptionActor2D objects are accessable so that, for instance, the font attributes of the axes text can be manipulated through vtkTextProperty. Since this class inherits from vtkProp3D, one can apply a user transform to the underlying geometry and the positioning of the labels. For example, a rotation transform could be used to generate a left-handed axes representation.

To create an instance of class vtkAxesActor, simply invoke its constructor as follows

```
obj = vtkAxesActor
```

34.4.2 Methods

The class vtkAxesActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAxesActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAxesActor = obj.NewInstance ()`
- `vtkAxesActor = obj.SafeDownCast (vtkObject o)`
- `obj.GetActors (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.

- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an axes actor. Overloads the virtual vtkProp method.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.GetBounds (double bounds[6])` - Get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). (The method GetBounds(double bounds[6]) is available from the superclass.)
- `double = obj.GetBounds ()` - Get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). (The method GetBounds(double bounds[6]) is available from the superclass.)
- `long = obj.GetMTime ()` - Get the actors mtime plus consider its properties and texture if set.
- `long = obj.GetRedrawMTime ()` - Return the mtime of anything that would cause the rendered image to appear differently. Usually this involves checking the mtime of the prop plus anything else it depends on such as properties, textures etc.
- `obj.SetTotalLength (double v[3])` - Set the total length of the axes in 3 dimensions.
- `obj.SetTotalLength (double x, double y, double z)` - Set the total length of the axes in 3 dimensions.
- `double = obj. GetTotalLength ()` - Set the total length of the axes in 3 dimensions.
- `obj.SetNormalizedShaftLength (double v[3])` - Set the normalized (0-1) length of the shaft.
- `obj.SetNormalizedShaftLength (double x, double y, double z)` - Set the normalized (0-1) length of the shaft.
- `double = obj. GetNormalizedShaftLength ()` - Set the normalized (0-1) length of the shaft.
- `obj.SetNormalizedTipLength (double v[3])` - Set the normalized (0-1) length of the tip. Normally, this would be 1 - the normalized length of the shaft.
- `obj.SetNormalizedTipLength (double x, double y, double z)` - Set the normalized (0-1) length of the tip. Normally, this would be 1 - the normalized length of the shaft.
- `double = obj. GetNormalizedTipLength ()` - Set the normalized (0-1) length of the tip. Normally, this would be 1 - the normalized length of the shaft.
- `obj.SetNormalizedLabelPosition (double v[3])` - Set the normalized (0-1) position of the label along the length of the shaft. A value ¿ 1 is permissible.
- `obj.SetNormalizedLabelPosition (double x, double y, double z)` - Set the normalized (0-1) position of the label along the length of the shaft. A value ¿ 1 is permissible.
- `double = obj. GetNormalizedLabelPosition ()` - Set the normalized (0-1) position of the label along the length of the shaft. A value ¿ 1 is permissible.

- `obj.SetConeResolution (int )` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetConeResolutionMinValue ()` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetConeResolutionMaxValue ()` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetConeResolution ()` - Set/get the resolution of the pieces of the axes actor.
- `obj.SetSphereResolution (int )` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetSphereResolutionMinValue ()` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetSphereResolutionMaxValue ()` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetSphereResolution ()` - Set/get the resolution of the pieces of the axes actor.
- `obj.SetCylinderResolution (int )` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetCylinderResolutionMinValue ()` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetCylinderResolutionMaxValue ()` - Set/get the resolution of the pieces of the axes actor.
- `int = obj.GetCylinderResolution ()` - Set/get the resolution of the pieces of the axes actor.
- `obj.SetConeRadius (double )` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetConeRadiusMinValue ()` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetConeRadiusMaxValue ()` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetConeRadius ()` - Set/get the radius of the pieces of the axes actor.
- `obj.SetSphereRadius (double )` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetSphereRadiusMinValue ()` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetSphereRadiusMaxValue ()` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetSphereRadius ()` - Set/get the radius of the pieces of the axes actor.
- `obj.SetCylinderRadius (double )` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetCylinderRadiusMinValue ()` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetCylinderRadiusMaxValue ()` - Set/get the radius of the pieces of the axes actor.
- `double = obj.GetCylinderRadius ()` - Set/get the radius of the pieces of the axes actor.
- `obj.SetShaftType (int type)` - Set the type of the shaft to a cylinder, line, or user defined geometry.
- `obj.SetShaftTypeToCylinder ()` - Set the type of the shaft to a cylinder, line, or user defined geometry.
- `obj.SetShaftTypeToLine ()` - Set the type of the shaft to a cylinder, line, or user defined geometry.
- `obj.SetShaftTypeToUserDefined ()` - Set the type of the shaft to a cylinder, line, or user defined geometry.
- `int = obj.GetShaftType ()` - Set the type of the shaft to a cylinder, line, or user defined geometry.
- `obj.SetTipType (int type)` - Set the type of the tip to a cone, sphere, or user defined geometry.
- `obj.SetTipTypeToCone ()` - Set the type of the tip to a cone, sphere, or user defined geometry.

- `obj.SetTipTypeToSphere ()` - Set the type of the tip to a cone, sphere, or user defined geometry.
- `obj.SetTipTypeToUserDefined ()` - Set the type of the tip to a cone, sphere, or user defined geometry.
- `int = obj.GetTipType ()` - Set the type of the tip to a cone, sphere, or user defined geometry.
- `obj.SetUserDefinedTip (vtkPolyData )` - Set the user defined tip polydata.
- `vtkPolyData = obj.GetUserDefinedTip ()` - Set the user defined tip polydata.
- `obj.SetUserDefinedShaft (vtkPolyData )` - Set the user defined shaft polydata.
- `vtkPolyData = obj.GetUserDefinedShaft ()` - Set the user defined shaft polydata.
- `vtkProperty = obj.GetXAxisTipProperty ()` - Get the tip properties.
- `vtkProperty = obj.GetYAxisTipProperty ()` - Get the tip properties.
- `vtkProperty = obj.GetZAxisTipProperty ()` - Get the tip properties.
- `vtkProperty = obj.GetXAxisShaftProperty ()` - Get the shaft properties.
- `vtkProperty = obj.GetYAxisShaftProperty ()` - Get the shaft properties.
- `vtkProperty = obj.GetZAxisShaftProperty ()` - Get the shaft properties.
- `vtkCaptionActor2D = obj.GetXAxisCaptionActor2D ()` - Retrieve handles to the X, Y and Z axis (so that you can set their text properties for example)
- `vtkCaptionActor2D = obj.GetYAxisCaptionActor2D ()` - Retrieve handles to the X, Y and Z axis (so that you can set their text properties for example)
- `vtkCaptionActor2D = obj.GetZAxisCaptionActor2D ()` - Set/get the label text.
- `obj.SetXAxisLabelText (string )` - Set/get the label text.
- `string = obj.GetXAxisLabelText ()` - Set/get the label text.
- `obj.SetYAxisLabelText (string )` - Set/get the label text.
- `string = obj.GetYAxisLabelText ()` - Set/get the label text.
- `obj.SetZAxisLabelText (string )` - Set/get the label text.
- `string = obj.GetZAxisLabelText ()` - Set/get the label text.
- `obj.SetAxisLabels (int )` - Enable/disable drawing the axis labels.
- `int = obj.GetAxisLabels ()` - Enable/disable drawing the axis labels.
- `obj.AxisLabelsOn ()` - Enable/disable drawing the axis labels.
- `obj.AxisLabelsOff ()` - Enable/disable drawing the axis labels.

34.5 vtkAxisActor

34.5.1 Usage

vtkAxisActor creates an axis with tick marks, labels, and/or a title, depending on the particular instance variable settings. It is assumed that the axes is part of a bounding box and is orthoganal to one of the coordinate axes. To use this class, you typically specify two points defining the start and end points of the line (xyz definition using vtkCoordinate class), the axis type (X, Y or Z), the axis location in relation to the bounding box, the bounding box, the number of labels, and the data range (min,max). You can also control what parts of the axis are visible including the line, the tick marks, the labels, and the title. It is also possible to control gridlines, and specifiy on which 'side' the tickmarks are drawn (again with respect to the underlying assumed bounding box). You can also specify the label format (a printf style format).

This class decides how to locate the labels, and how to create reasonable tick marks and labels.

Labels follow the camera so as to be legible from any viewpoint.

The instance variables Point1 and Point2 are instances of vtkCoordinate. All calculations and references are in World Coordinates.

.SECTION Notes This class was adapted from a 2D version created by Hank Childs called vtkHankAxisActor2D.

To create an instance of class vtkAxisActor, simply invoke its constructor as follows

```
obj = vtkAxisActor
```

34.5.2 Methods

The class vtkAxisActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAxisActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAxisActor = obj.NewInstance ()`
- `vtkAxisActor = obj.SafeDownCast (vtkObject o)`
- `vtkCoordinate = obj.GetPoint1Coordinate ()` - Specify the position of the first point defining the axis.
- `obj.SetPoint1 (double x[3])` - Specify the position of the first point defining the axis.
- `obj.SetPoint1 (double x, double y, double z)` - Specify the position of the first point defining the axis.
- `vtkCoordinate = obj.GetPoint2Coordinate ()` - Specify the position of the second point defining the axis.
- `obj.SetPoint2 (double x[3])` - Specify the position of the second point defining the axis.
- `obj.SetPoint2 (double x, double y, double z)` - Specify the position of the second point defining the axis.
- `obj.SetRange (double , double )` - Specify the (min,max) axis range. This will be used in the generation of labels, if labels are visible.
- `obj.SetRange (double  a[2])` - Specify the (min,max) axis range. This will be used in the generation of labels, if labels are visible.

- `double = obj. GetRange ()` - Specify the (min,max) axis range. This will be used in the generation of labels, if labels are visible.
- `obj.SetBounds (double bounds[6])` - Set or get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `double = obj.GetBounds (void )` - Set or get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `obj.GetBounds (double bounds[6])` - Set or get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the labels on the axis.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the labels on the axis.
- `obj.SetMinorTicksVisible (int )` - Set/Get the flag that controls whether the minor ticks are visible.
- `int = obj.GetMinorTicksVisible ()` - Set/Get the flag that controls whether the minor ticks are visible.
- `obj.MinorTicksVisibleOn ()` - Set/Get the flag that controls whether the minor ticks are visible.
- `obj.MinorTicksVisibleOff ()` - Set/Get the flag that controls whether the minor ticks are visible.
- `obj.SetTitle (string t)` - Set/Get the title of the axis actor,
- `string = obj.GetTitle ()` - Set/Get the title of the axis actor,
- `obj.SetMajorTickSize (double )` - Set/Get the size of the major tick marks
- `double = obj.GetMajorTickSize ()` - Set/Get the size of the major tick marks
- `obj.SetMinorTickSize (double )` - Set/Get the size of the major tick marks
- `double = obj.GetMinorTickSize ()` - Set/Get the size of the major tick marks
- `obj.SetTickLocation (int )` - Set/Get the location of the ticks.
- `int = obj.GetTickLocationMinValue ()` - Set/Get the location of the ticks.
- `int = obj.GetTickLocationMaxValue ()` - Set/Get the location of the ticks.
- `int = obj.GetTickLocation ()` - Set/Get the location of the ticks.
- `obj.SetTickLocationToInside (void )`
- `obj.SetTickLocationToOutside (void )`
- `obj.SetTickLocationToBoth (void )`
- `obj.SetAxisVisibility (int )` - Set/Get visibility of the axis line.
- `int = obj.GetAxisVisibility ()` - Set/Get visibility of the axis line.
- `obj.AxisVisibilityOn ()` - Set/Get visibility of the axis line.
- `obj.AxisVisibilityOff ()` - Set/Get visibility of the axis line.
- `obj.SetTickVisibility (int )` - Set/Get visibility of the axis tick marks.
- `int = obj.GetTickVisibility ()` - Set/Get visibility of the axis tick marks.
- `obj.TickVisibilityOn ()` - Set/Get visibility of the axis tick marks.
- `obj.TickVisibilityOff ()` - Set/Get visibility of the axis tick marks.

- `obj.SetLabelVisibility (int )` - Set/Get visibility of the axis labels.
- `int = obj.GetLabelVisibility ()` - Set/Get visibility of the axis labels.
- `obj.LabelVisibilityOn ()` - Set/Get visibility of the axis labels.
- `obj.LabelVisibilityOff ()` - Set/Get visibility of the axis labels.
- `obj.SetTitleVisibility (int )` - Set/Get visibility of the axis title.
- `int = obj.GetTitleVisibility ()` - Set/Get visibility of the axis title.
- `obj.TitleVisibilityOn ()` - Set/Get visibility of the axis title.
- `obj.TitleVisibilityOff ()` - Set/Get visibility of the axis title.
- `obj.SetDrawGridlines (int )` - Set/Get whether gridlines should be drawn.
- `int = obj.GetDrawGridlines ()` - Set/Get whether gridlines should be drawn.
- `obj.DrawGridlinesOn ()` - Set/Get whether gridlines should be drawn.
- `obj.DrawGridlinesOff ()` - Set/Get whether gridlines should be drawn.
- `obj.SetGridlineXLength (double )` - Set/Get the length to use when drawing gridlines.
- `double = obj.GetGridlineXLength ()` - Set/Get the length to use when drawing gridlines.
- `obj.SetGridlineYLength (double )` - Set/Get the length to use when drawing gridlines.
- `double = obj.GetGridlineYLength ()` - Set/Get the length to use when drawing gridlines.
- `obj.SetGridlineZLength (double )` - Set/Get the length to use when drawing gridlines.
- `double = obj.GetGridlineZLength ()` - Set/Get the length to use when drawing gridlines.
- `obj.SetAxisType (int )` - Set/Get the type of this axis.
- `int = obj.GetAxisTypeMinValue ()` - Set/Get the type of this axis.
- `int = obj.GetAxisTypeMaxValue ()` - Set/Get the type of this axis.
- `int = obj.GetAxisType ()` - Set/Get the type of this axis.
- `obj.SetAxisTypeToX (void )` - Set/Get the type of this axis.
- `obj.SetAxisTypeToY (void )` - Set/Get the type of this axis.
- `obj.SetAxisTypeToZ (void )` - Set/Get the type of this axis.
- `obj.SetAxisPosition (int )` - Set/Get the position of this axis (in relation to an an assumed bounding box). For an x-type axis, MINMIN corresponds to the x-edge in the bounding box where Y values are minimum and Z values are minimum. For a y-type axis, MAXMIN corresponds to the y-edge where X values are maximum and Z values are minimum.
- `int = obj.GetAxisPositionMinValue ()` - Set/Get the position of this axis (in relation to an an assumed bounding box). For an x-type axis, MINMIN corresponds to the x-edge in the bounding box where Y values are minimum and Z values are minimum. For a y-type axis, MAXMIN corresponds to the y-edge where X values are maximum and Z values are minimum.
- `int = obj.GetAxisPositionMaxValue ()` - Set/Get the position of this axis (in relation to an an assumed bounding box). For an x-type axis, MINMIN corresponds to the x-edge in the bounding box where Y values are minimum and Z values are minimum. For a y-type axis, MAXMIN corresponds to the y-edge where X values are maximum and Z values are minimum.

- `int = obj.GetAxisPosition ()` - Set/Get the position of this axis (in relation to an an assumed bounding box). For an x-type axis, MINMIN corresponds to the x-edge in the bounding box where Y values are minimum and Z values are minimum. For a y-type axis, MAXMIN corresponds to the y-edge where X values are maximum and Z values are minimum.
- `obj.SetAxisPositionToMinMin (void )`
- `obj.SetAxisPositionToMinMax (void )`
- `obj.SetAxisPositionToMaxMax (void )`
- `obj.SetAxisPositionToMaxMin (void )`
- `obj.SetCamera (vtkCamera )` - Set/Get the camera for this axis. The camera is used by the labels to 'follow' the camera and be legible from any viewpoint.
- `vtkCamera = obj.GetCamera ()` - Set/Get the camera for this axis. The camera is used by the labels to 'follow' the camera and be legible from any viewpoint.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Draw the axis.
- `int = obj.RenderTranslucentGeometry (vtkViewport )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an axis actor. Overloads the virtual vtkProp method.
- `obj.SetLabelScale (double )`
- `obj.SetTitleScale (double )`
- `obj.SetMinorStart (double )` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `double = obj.GetMinorStart ()` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `obj.SetMajorStart (double )` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `double = obj.GetMajorStart ()` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `obj.SetDeltaMinor (double )` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `double = obj.GetDeltaMinor ()` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `obj.SetDeltaMajor (double )` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `double = obj.GetDeltaMajor ()` - Set/Get the starting position for minor and major tick points, and the delta values that determine their spacing.
- `obj.BuildAxis (vtkViewport viewport, bool )`

34.6 vtkBarChartActor

34.6.1 Usage

vtkBarChartActor generates a bar chart from an array of numbers defined in field data (a vtkDataObject). To use this class, you must specify an input data object. You'll probably also want to specify the position of the plot be setting the Position and Position2 instance variables, which define a rectangle in which the plot lies. There are also many other instance variables that control the look of the plot includes its title and legend.

Set the text property/attributes of the title and the labels through the vtkTextProperty objects associated with these components.

To create an instance of class vtkBarChartActor, simply invoke its constructor as follows

```
obj = vtkBarChartActor
```

34.6.2 Methods

The class vtkBarChartActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBarChartActor class.

- `string = obj.GetClassName ()` - Standard methods for type information and printing.
- `int = obj.IsA (string name)` - Standard methods for type information and printing.
- `vtkBarChartActor = obj.NewInstance ()` - Standard methods for type information and printing.
- `vtkBarChartActor = obj.SafeDownCast (vtkObject o)` - Standard methods for type information and printing.
- `obj.SetInput (vtkDataObject )` - Set the input to the bar chart actor.
- `vtkDataObject = obj.GetInput ()` - Get the input data object to this actor.
- `obj.SetTitleVisibility (int )` - Enable/Disable the display of a plot title.
- `int = obj.GetTitleVisibility ()` - Enable/Disable the display of a plot title.
- `obj.TitleVisibilityOn ()` - Enable/Disable the display of a plot title.
- `obj.TitleVisibilityOff ()` - Enable/Disable the display of a plot title.
- `obj.SetTitle (string )` - Set/Get the title of the bar chart.
- `string = obj.GetTitle ()` - Set/Get the title of the bar chart.
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property. The property controls the appearance of the plot title.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property. The property controls the appearance of the plot title.
- `obj.SetLabelVisibility (int )` - Enable/Disable the display of bar labels.
- `int = obj.GetLabelVisibility ()` - Enable/Disable the display of bar labels.
- `obj.LabelVisibilityOn ()` - Enable/Disable the display of bar labels.
- `obj.LabelVisibilityOff ()` - Enable/Disable the display of bar labels.

- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property. This controls the appearance of all bar bar labels.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the labels text property. This controls the appearance of all bar bar labels.
- `obj.SetBarColor (int i, double r, double g, double b)` - Specify colors for each bar. If not specified, they are automatically generated.
- `obj.SetBarColor (int i, double color[3])` - Specify colors for each bar. If not specified, they are automatically generated.
- `obj.SetBarLabel (int i, string )` - Specify the names of each bar. If not specified, then an integer number is automatically generated.
- `string = obj.GetBarLabel (int i)` - Specify the names of each bar. If not specified, then an integer number is automatically generated.
- `obj.SetYTitle (string )` - Specify the title of the y-axis.
- `string = obj.GetYTitle ()` - Specify the title of the y-axis.
- `obj.SetLegendVisibility (int )` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `int = obj.GetLegendVisibility ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendVisibilityOn ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendVisibilityOff ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `vtkLegendBoxActor = obj.GetLegendActor ()` - Retrieve handles to the legend box. This is useful if you would like to manually control the legend appearance.
- `int = obj.RenderOverlay (vtkViewport )` - Draw the bar plot.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Draw the bar plot.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

34.7 vtkCaptionActor2D

34.7.1 Usage

vtkCaptionActor2D is a hybrid 2D/3D actor that is used to associate text with a point (the AttachmentPoint) in the scene. The caption can be drawn with a rectangular border and a leader connecting the caption to the attachment point. Optionally, the leader can be glyphed at its endpoint to create arrow heads or other indicators.

To use the caption actor, you normally specify the Position and Position2 coordinates (these are inherited from the vtkActor2D superclass). (Note that Position2 can be set using vtkActor2D's SetWidth() and SetHeight() methods.) Position and Position2 define the size of the caption, and a third point, the AttachmentPoint, defines a point that the caption is associated with. You must also define the caption text, whether you want a border around the caption, and whether you want a leader from the caption to the attachment point. The font attributes of the text can be set through the vtkTextProperty associated to this actor. You also indicate whether you want the leader to be 2D or 3D. (2D leaders are always drawn over the underlying geometry. 3D leaders may be occluded by the geometry.) The leader may also be terminated by an optional glyph (e.g., arrow).

The trickiest part about using this class is setting Position, Position2, and AttachmentPoint correctly. These instance variables are vtkCoordinates, and can be set up in various ways. In default usage, the AttachmentPoint is defined in the world coordinate system, Position is the lower-left corner of the caption and relative to AttachmentPoint (defined in display coordaintes, i.e., pixels), and Position2 is relative to Position and is the upper-right corner (also in display coordinates). However, the user has full control over the coordinates, and can do things like place the caption in a fixed position in the renderer, with the leader moving with the AttachmentPoint.

To create an instance of class vtkCaptionActor2D, simply invoke its constructor as follows

```
obj = vtkCaptionActor2D
```

34.7.2 Methods

The class vtkCaptionActor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCaptionActor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCaptionActor2D = obj.NewInstance ()`
- `vtkCaptionActor2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetCaption (string )` - Define the text to be placed in the caption. The text can be multiple lines (separated by ”
n”).
- `string = obj.GetCaption ()` - Define the text to be placed in the caption. The text can be multiple lines (separated by ”
n”).
- `vtkCoordinate = obj.GetAttachmentPointCoordinate ()` - Set/Get the attachment point for the caption. By default, the attachment point is defined in world coordinates, but this can be changed using vtkCoordinate methods.
- `obj.SetAttachmentPoint (double, double, double)` - Set/Get the attachment point for the caption. By default, the attachment point is defined in world coordinates, but this can be changed using vtkCoordinate methods.
- `obj.SetAttachmentPoint (double a[3])` - Set/Get the attachment point for the caption. By default, the attachment point is defined in world coordinates, but this can be changed using vtkCoordinate methods.
- `double = obj.GetAttachmentPoint ()` - Set/Get the attachment point for the caption. By default, the attachment point is defined in world coordinates, but this can be changed using vtkCoordinate methods.

- `obj.SetBorder (int )` - Enable/disable the placement of a border around the text.
- `int = obj.GetBorder ()` - Enable/disable the placement of a border around the text.
- `obj.BorderOn ()` - Enable/disable the placement of a border around the text.
- `obj.BorderOff ()` - Enable/disable the placement of a border around the text.
- `obj.SetLeader (int )` - Enable/disable drawing a "line" from the caption to the attachment point.
- `int = obj.GetLeader ()` - Enable/disable drawing a "line" from the caption to the attachment point.
- `obj.LeaderOn ()` - Enable/disable drawing a "line" from the caption to the attachment point.
- `obj.LeaderOff ()` - Enable/disable drawing a "line" from the caption to the attachment point.
- `obj.SetThreeDimensionalLeader (int )` - Indicate whether the leader is 2D (no hidden line) or 3D (z-buffered).
- `int = obj.GetThreeDimensionalLeader ()` - Indicate whether the leader is 2D (no hidden line) or 3D (z-buffered).
- `obj.ThreeDimensionalLeaderOn ()` - Indicate whether the leader is 2D (no hidden line) or 3D (z-buffered).
- `obj.ThreeDimensionalLeaderOff ()` - Indicate whether the leader is 2D (no hidden line) or 3D (z-buffered).
- `obj.SetLeaderGlyph (vtkPolyData )` - Specify a glyph to be used as the leader "head". This could be something like an arrow or sphere. If not specified, no glyph is drawn. Note that the glyph is assumed to be aligned along the x-axis and is rotated about the origin.
- `vtkPolyData = obj.GetLeaderGlyph ()` - Specify a glyph to be used as the leader "head". This could be something like an arrow or sphere. If not specified, no glyph is drawn. Note that the glyph is assumed to be aligned along the x-axis and is rotated about the origin.
- `obj.SetLeaderGlyphSize (double )` - Specify the relative size of the leader head. This is expressed as a fraction of the size (diagonal length) of the renderer. The leader head is automatically scaled so that window resize, zooming or other camera motion results in proportional changes in size to the leader glyph.
- `double = obj.GetLeaderGlyphSizeMinValue ()` - Specify the relative size of the leader head. This is expressed as a fraction of the size (diagonal length) of the renderer. The leader head is automatically scaled so that window resize, zooming or other camera motion results in proportional changes in size to the leader glyph.
- `double = obj.GetLeaderGlyphSizeMaxValue ()` - Specify the relative size of the leader head. This is expressed as a fraction of the size (diagonal length) of the renderer. The leader head is automatically scaled so that window resize, zooming or other camera motion results in proportional changes in size to the leader glyph.
- `double = obj.GetLeaderGlyphSize ()` - Specify the relative size of the leader head. This is expressed as a fraction of the size (diagonal length) of the renderer. The leader head is automatically scaled so that window resize, zooming or other camera motion results in proportional changes in size to the leader glyph.
- `obj.SetMaximumLeaderGlyphSize (int )` - Specify the maximum size of the leader head (if any) in pixels. This is used in conjunction with LeaderGlyphSize to cap the maximum size of the LeaderGlyph.

- `int = obj.GetMaximumLeaderGlyphSizeMinValue ()` - Specify the maximum size of the leader head (if any) in pixels. This is used in conjunction with LeaderGlyphSize to cap the maximum size of the LeaderGlyph.

- `int = obj.GetMaximumLeaderGlyphSizeMaxValue ()` - Specify the maximum size of the leader head (if any) in pixels. This is used in conjunction with LeaderGlyphSize to cap the maximum size of the LeaderGlyph.

- `int = obj.GetMaximumLeaderGlyphSize ()` - Specify the maximum size of the leader head (if any) in pixels. This is used in conjunction with LeaderGlyphSize to cap the maximum size of the LeaderGlyph.

- `obj.SetPadding (int )` - Set/Get the padding between the caption and the border. The value is specified in pixels.

- `int = obj.GetPaddingMinValue ()` - Set/Get the padding between the caption and the border. The value is specified in pixels.

- `int = obj.GetPaddingMaxValue ()` - Set/Get the padding between the caption and the border. The value is specified in pixels.

- `int = obj.GetPadding ()` - Set/Get the padding between the caption and the border. The value is specified in pixels.

- `vtkTextActor = obj.GetTextActor ()` - Get the text actor used by the caption. This is useful if you want to control justification and other characteristics of the text actor.

- `obj.SetCaptionTextProperty (vtkTextProperty p)` - Set/Get the text property.

- `vtkTextProperty = obj.GetCaptionTextProperty ()` - Set/Get the text property.

- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this scaled text actor. Overloads the virtual vtkProp method.

- `obj.SetAttachEdgeOnly (int )` - Enable/disable whether to attach the arrow only to the edge, NOT the vertices of the caption border.

- `int = obj.GetAttachEdgeOnly ()` - Enable/disable whether to attach the arrow only to the edge, NOT the vertices of the caption border.

- `obj.AttachEdgeOnlyOn ()` - Enable/disable whether to attach the arrow only to the edge, NOT the vertices of the caption border.

- `obj.AttachEdgeOnlyOff ()` - Enable/disable whether to attach the arrow only to the edge, NOT the vertices of the caption border.

34.8 vtkCornerAnnotation

34.8.1 Usage

This is an annotation object that manages four text actors / mappers to provide annotation in the four corners of a viewport

To create an instance of class vtkCornerAnnotation, simply invoke its constructor as follows

```
obj = vtkCornerAnnotation
```

34.8.2 Methods

The class vtkCornerAnnotation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCornerAnnotation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCornerAnnotation = obj.NewInstance ()`
- `vtkCornerAnnotation = obj.SafeDownCast (vtkObject o)`
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Draw the scalar bar and annotation text to the screen.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Draw the scalar bar and annotation text to the screen.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Draw the scalar bar and annotation text to the screen.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.SetMaximumLineHeight (double )` - Set/Get the maximum height of a line of text as a percentage of the vertical area allocated to this scaled text actor. Defaults to 1.0
- `double = obj.GetMaximumLineHeight ()` - Set/Get the maximum height of a line of text as a percentage of the vertical area allocated to this scaled text actor. Defaults to 1.0
- `obj.SetMinimumFontSize (int )` - Set/Get the minimum/maximum size font that will be shown. If the font drops below the minimum size it will not be rendered.
- `int = obj.GetMinimumFontSize ()` - Set/Get the minimum/maximum size font that will be shown. If the font drops below the minimum size it will not be rendered.
- `obj.SetMaximumFontSize (int )` - Set/Get the minimum/maximum size font that will be shown. If the font drops below the minimum size it will not be rendered.
- `int = obj.GetMaximumFontSize ()` - Set/Get the minimum/maximum size font that will be shown. If the font drops below the minimum size it will not be rendered.
- `obj.SetLinearFontScaleFactor (double )` - Set/Get font scaling factors The font size, f, is calculated as the largest possible value such that the annotations for the given viewport do not overlap. This font size is scaled non-linearly with the viewport size, to maintain an acceptable readable size at larger viewport sizes, without being too big. f' = linearScale * pow(f,nonlinearScale)
- `double = obj.GetLinearFontScaleFactor ()` - Set/Get font scaling factors The font size, f, is calculated as the largest possible value such that the annotations for the given viewport do not overlap. This font size is scaled non-linearly with the viewport size, to maintain an acceptable readable size at larger viewport sizes, without being too big. f' = linearScale * pow(f,nonlinearScale)
- `obj.SetNonlinearFontScaleFactor (double )` - Set/Get font scaling factors The font size, f, is calculated as the largest possible value such that the annotations for the given viewport do not overlap. This font size is scaled non-linearly with the viewport size, to maintain an acceptable readable size at larger viewport sizes, without being too big. f' = linearScale * pow(f,nonlinearScale)

- `double = obj.GetNonlinearFontScaleFactor ()` - Set/Get font scaling factors The font size, f, is calculated as the largest possible value such that the annotations for the given viewport do not overlap. This font size is scaled non-linearly with the viewport size, to maintain an acceptable readable size at larger viewport sizes, without being too big. f' = linearScale * pow(f,nonlinearScale)
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.SetText (int i, string text)` - Set/Get the text to be displayed for each corner
- `string = obj.GetText (int i)` - Set/Get the text to be displayed for each corner
- `obj.ClearAllTexts ()` - Set/Get the text to be displayed for each corner
- `obj.CopyAllTextsFrom (vtkCornerAnnotation ca)` - Set/Get the text to be displayed for each corner
- `obj.SetImageActor (vtkImageActor )` - Set an image actor to look at for slice information
- `vtkImageActor = obj.GetImageActor ()` - Set an image actor to look at for slice information
- `obj.SetWindowLevel (vtkImageMapToWindowLevelColors )` - Set an instance of vtkImageMapToWindowLevelColors to use for looking at window level changes
- `vtkImageMapToWindowLevelColors = obj.GetWindowLevel ()` - Set an instance of vtkImageMapToWindowLevelColors to use for looking at window level changes
- `obj.SetLevelShift (double )` - Set the value to shift the level by.
- `double = obj.GetLevelShift ()` - Set the value to shift the level by.
- `obj.SetLevelScale (double )` - Set the value to scale the level by.
- `double = obj.GetLevelScale ()` - Set the value to scale the level by.
- `obj.SetTextProperty (vtkTextProperty p)` - Set/Get the text property of all corners.
- `vtkTextProperty = obj.GetTextProperty ()` - Set/Get the text property of all corners.
- `obj.ShowSliceAndImageOn ()` - Even if there is an image actor, should 'slice' and 'image' be displayed?
- `obj.ShowSliceAndImageOff ()` - Even if there is an image actor, should 'slice' and 'image' be displayed?
- `obj.SetShowSliceAndImage (int )` - Even if there is an image actor, should 'slice' and 'image' be displayed?
- `int = obj.GetShowSliceAndImage ()` - Even if there is an image actor, should 'slice' and 'image' be displayed?

34.9 vtkCubeAxesActor

34.9.1 Usage

vtkCubeAxesActor is a composite actor that draws axes of the bounding box of an input dataset. The axes include labels and titles for the x-y-z axes. The algorithm selects which axes to draw based on the user-defined 'fly' mode. (STATIC is default). 'STATIC' constructs axes from all edges of the bounding box. 'CLOSEST_TRIAD' consists of the three axes x-y-z forming a triad that lies closest to the specified camera. 'FURTHEST_TRIAD' consists of the three axes x-y-z forming a triad that lies furthest from the

specified camera. 'OUTER_EDGES' is constructed from edges that are on the "exterior" of the bounding box, exterior as determined from examining outer edges of the bounding box in projection (display) space.

To use this object you must define a bounding box and the camera used to render the vtkCubeAxesActor. You can optionally turn on/off labels, ticks, gridlines, and set tick location, number of labels, and text to use for axis-titles. A 'corner offset' can also be set. This allows the axes to be set partially away from the actual bounding box to perhaps prevent overlap of labels between the various axes.

The Bounds instance variable (an array of six doubles) is used to determine the bounding box.

To create an instance of class vtkCubeAxesActor, simply invoke its constructor as follows

```
obj = vtkCubeAxesActor
```

34.9.2 Methods

The class vtkCubeAxesActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCubeAxesActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCubeAxesActor = obj.NewInstance ()`
- `vtkCubeAxesActor = obj.SafeDownCast (vtkObject o)`
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Draw the axes as per the vtkProp superclass' API.
- `int = obj.RenderTranslucentGeometry (vtkViewport )` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetBounds (double , double , double , double , double , double )` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetBounds (double a[6])` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `double = obj.GetBounds ()` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.GetBounds (double bounds[6])` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetCamera (vtkCamera )` - Set/Get the camera to perform scaling and translation of the vtkCubeAxesActor.
- `vtkCamera = obj.GetCamera ()` - Set/Get the camera to perform scaling and translation of the vtkCubeAxesActor.
- `obj.SetFlyMode (int )` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.

- `int = obj.GetFlyModeMinValue ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `int = obj.GetFlyModeMaxValue ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `int = obj.GetFlyMode ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `obj.SetFlyModeToOuterEdges ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `obj.SetFlyModeToClosestTriad ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `obj.SetFlyModeToFurthestTriad ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `obj.SetFlyModeToStaticTriad ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `obj.SetFlyModeToStaticEdges ()` - Specify a mode to control how the axes are drawn: either static, closest triad, furthest triad or outer edges in relation to the camera position.
- `obj.SetXTitle (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `string = obj.GetXTitle ()` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `obj.SetXUnits (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `string = obj.GetXUnits ()` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `obj.SetYTitle (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `string = obj.GetYTitle ()` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `obj.SetYUnits (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `string = obj.GetYUnits ()` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `obj.SetZTitle (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `string = obj.GetZTitle ()` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `obj.SetZUnits (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `string = obj.GetZUnits ()` - Set/Get the labels for the x, y, and z axes. By default, use "X-Axis", "Y-Axis" and "Z-Axis".
- `obj.SetXLabelFormat (string )` - Set/Get the format with which to print the labels on each of the x-y-z axes.

- `string = obj.GetXLabelFormat ()` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `obj.SetYLabelFormat (string )` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `string = obj.GetYLabelFormat ()` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `obj.SetZLabelFormat (string )` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `string = obj.GetZLabelFormat ()` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `obj.SetInertia (int )` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `int = obj.GetInertiaMinValue ()` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `int = obj.GetInertiaMaxValue ()` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `int = obj.GetInertia ()` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `obj.SetCornerOffset (double )` - Specify an offset value to "pull back" the axes from the corner at which they are joined to avoid overlap of axes labels. The "CornerOffset" is the fraction of the axis length to pull back.
- `double = obj.GetCornerOffset ()` - Specify an offset value to "pull back" the axes from the corner at which they are joined to avoid overlap of axes labels. The "CornerOffset" is the fraction of the axis length to pull back.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.SetXAxisVisibility (int )` - Turn on and off the visibility of each axis.
- `int = obj.GetXAxisVisibility ()` - Turn on and off the visibility of each axis.
- `obj.XAxisVisibilityOn ()` - Turn on and off the visibility of each axis.
- `obj.XAxisVisibilityOff ()` - Turn on and off the visibility of each axis.
- `obj.SetYAxisVisibility (int )` - Turn on and off the visibility of each axis.
- `int = obj.GetYAxisVisibility ()` - Turn on and off the visibility of each axis.
- `obj.YAxisVisibilityOn ()` - Turn on and off the visibility of each axis.
- `obj.YAxisVisibilityOff ()` - Turn on and off the visibility of each axis.
- `obj.SetZAxisVisibility (int )` - Turn on and off the visibility of each axis.
- `int = obj.GetZAxisVisibility ()` - Turn on and off the visibility of each axis.
- `obj.ZAxisVisibilityOn ()` - Turn on and off the visibility of each axis.
- `obj.ZAxisVisibilityOff ()` - Turn on and off the visibility of each axis.

- `obj.SetXAxisLabelVisibility (int )` - Turn on and off the visibility of labels for each axis.
- `int = obj.GetXAxisLabelVisibility ()` - Turn on and off the visibility of labels for each axis.
- `obj.XAxisLabelVisibilityOn ()` - Turn on and off the visibility of labels for each axis.
- `obj.XAxisLabelVisibilityOff ()` - Turn on and off the visibility of labels for each axis.
- `obj.SetYAxisLabelVisibility (int )`
- `int = obj.GetYAxisLabelVisibility ()`
- `obj.YAxisLabelVisibilityOn ()`
- `obj.YAxisLabelVisibilityOff ()`
- `obj.SetZAxisLabelVisibility (int )`
- `int = obj.GetZAxisLabelVisibility ()`
- `obj.ZAxisLabelVisibilityOn ()`
- `obj.ZAxisLabelVisibilityOff ()`
- `obj.SetXAxisTickVisibility (int )` - Turn on and off the visibility of ticks for each axis.
- `int = obj.GetXAxisTickVisibility ()` - Turn on and off the visibility of ticks for each axis.
- `obj.XAxisTickVisibilityOn ()` - Turn on and off the visibility of ticks for each axis.
- `obj.XAxisTickVisibilityOff ()` - Turn on and off the visibility of ticks for each axis.
- `obj.SetYAxisTickVisibility (int )`
- `int = obj.GetYAxisTickVisibility ()`
- `obj.YAxisTickVisibilityOn ()`
- `obj.YAxisTickVisibilityOff ()`
- `obj.SetZAxisTickVisibility (int )`
- `int = obj.GetZAxisTickVisibility ()`
- `obj.ZAxisTickVisibilityOn ()`
- `obj.ZAxisTickVisibilityOff ()`
- `obj.SetXAxisMinorTickVisibility (int )` - Turn on and off the visibility of minor ticks for each axis.
- `int = obj.GetXAxisMinorTickVisibility ()` - Turn on and off the visibility of minor ticks for each axis.
- `obj.XAxisMinorTickVisibilityOn ()` - Turn on and off the visibility of minor ticks for each axis.
- `obj.XAxisMinorTickVisibilityOff ()` - Turn on and off the visibility of minor ticks for each axis.
- `obj.SetYAxisMinorTickVisibility (int )`
- `int = obj.GetYAxisMinorTickVisibility ()`
- `obj.YAxisMinorTickVisibilityOn ()`
- `obj.YAxisMinorTickVisibilityOff ()`

- `obj.SetZAxisMinorTickVisibility (int )`
- `int = obj.GetZAxisMinorTickVisibility ()`
- `obj.ZAxisMinorTickVisibilityOn ()`
- `obj.ZAxisMinorTickVisibilityOff ()`
- `obj.SetDrawXGridlines (int )`
- `int = obj.GetDrawXGridlines ()`
- `obj.DrawXGridlinesOn ()`
- `obj.DrawXGridlinesOff ()`
- `obj.SetDrawYGridlines (int )`
- `int = obj.GetDrawYGridlines ()`
- `obj.DrawYGridlinesOn ()`
- `obj.DrawYGridlinesOff ()`
- `obj.SetDrawZGridlines (int )`
- `int = obj.GetDrawZGridlines ()`
- `obj.DrawZGridlinesOn ()`
- `obj.DrawZGridlinesOff ()`
- `obj.SetTickLocation (int )` - Set/Get the location of ticks marks.
- `int = obj.GetTickLocationMinValue ()` - Set/Get the location of ticks marks.
- `int = obj.GetTickLocationMaxValue ()` - Set/Get the location of ticks marks.
- `int = obj.GetTickLocation ()` - Set/Get the location of ticks marks.
- `obj.SetTickLocationToInside (void )`
- `obj.SetTickLocationToOutside (void )`
- `obj.SetTickLocationToBoth (void )`
- `obj.SetLabelScaling (bool , int , int , int )`
- `obj.ShallowCopy (vtkCubeAxesActor actor)` - Shallow copy of a KatCubeAxesActor.

34.10 vtkCubeAxesActor2D

34.10.1 Usage

vtkCubeAxesActor2D is a composite actor that draws three axes of the bounding box of an input dataset. The axes include labels and titles for the x-y-z axes. The algorithm selects the axes that are on the "exterior" of the bounding box, exterior as determined from examining outer edges of the bounding box in projection (display) space. Alternatively, the edges closest to the viewer (i.e., camera position) can be drawn.

To use this object you must define a bounding box and the camera used to render the vtkCubeAxesActor2D. The camera is used to control the scaling and position of the vtkCubeAxesActor2D so that it fits in the viewport and always remains visible.)

The font property of the axes titles and labels can be modified through the AxisTitleTextProperty and AxisLabelTextProperty attributes. You may also use the GetXAxisActor2D, GetYAxisActor2D or GetZAxisActor2D methods to access each individual axis actor to modify their font properties.

The bounding box to use is defined in one of three ways. First, if the Input ivar is defined, then the input dataset's bounds is used. If the Input is not defined, and the Prop (superclass of all actors) is defined, then the Prop's bounds is used. If neither the Input or Prop is defined, then the Bounds instance variable (an array of six doubles) is used.

To create an instance of class vtkCubeAxesActor2D, simply invoke its constructor as follows

```
obj = vtkCubeAxesActor2D
```

34.10.2 Methods

The class vtkCubeAxesActor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCubeAxesActor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCubeAxesActor2D = obj.NewInstance ()`
- `vtkCubeAxesActor2D = obj.SafeDownCast (vtkObject o)`
- `int = obj.RenderOverlay (vtkViewport )` - Draw the axes as per the vtkProp superclass' API.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Draw the axes as per the vtkProp superclass' API.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.SetInput (vtkDataSet )` - Use the bounding box of this input dataset to draw the cube axes. If this is not specified, then the class will attempt to determine the bounds from the defined Prop or Bounds.
- `vtkDataSet = obj.GetInput ()` - Use the bounding box of this input dataset to draw the cube axes. If this is not specified, then the class will attempt to determine the bounds from the defined Prop or Bounds.
- `obj.SetViewProp (vtkProp prop)` - Use the bounding box of this prop to draw the cube axes. The ViewProp is used to determine the bounds only if the Input is not defined.
- `vtkProp = obj.GetViewProp ()` - Use the bounding box of this prop to draw the cube axes. The ViewProp is used to determine the bounds only if the Input is not defined.
- `obj.SetBounds (double , double , double , double , double , double )` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetBounds (double a[6])` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.

- `double = obj.GetBounds ()` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.GetBounds (double bounds[6])` - Explicitly specify the region in space around which to draw the bounds. The bounds is used only when no Input or Prop is specified. The bounds are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetRanges (double , double , double , double , double , double )` - Explicitly specify the range of values used on the bounds. The ranges are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetRanges (double a[6])` - Explicitly specify the range of values used on the bounds. The ranges are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `double = obj.GetRanges ()` - Explicitly specify the range of values used on the bounds. The ranges are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.GetRanges (double ranges[6])` - Explicitly specify the range of values used on the bounds. The ranges are specified according to (xmin,xmax, ymin,ymax, zmin,zmax), making sure that the min's are less than the max's.
- `obj.SetXOrigin (double )` - Explicitly specify an origin for the axes. These usually intersect at one of the corners of the bounding box, however users have the option to override this if necessary
- `obj.SetYOrigin (double )` - Explicitly specify an origin for the axes. These usually intersect at one of the corners of the bounding box, however users have the option to override this if necessary
- `obj.SetZOrigin (double )` - Explicitly specify an origin for the axes. These usually intersect at one of the corners of the bounding box, however users have the option to override this if necessary
- `obj.SetUseRanges (int )` - Set/Get a flag that controls whether the axes use the data ranges or the ranges set by SetRanges. By default the axes use the data ranges.
- `int = obj.GetUseRanges ()` - Set/Get a flag that controls whether the axes use the data ranges or the ranges set by SetRanges. By default the axes use the data ranges.
- `obj.UseRangesOn ()` - Set/Get a flag that controls whether the axes use the data ranges or the ranges set by SetRanges. By default the axes use the data ranges.
- `obj.UseRangesOff ()` - Set/Get a flag that controls whether the axes use the data ranges or the ranges set by SetRanges. By default the axes use the data ranges.
- `obj.SetCamera (vtkCamera )` - Set/Get the camera to perform scaling and translation of the vtkCubeAxesActor2D.
- `vtkCamera = obj.GetCamera ()` - Set/Get the camera to perform scaling and translation of the vtkCubeAxesActor2D.
- `obj.SetFlyMode (int )` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.
- `int = obj.GetFlyModeMinValue ()` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.
- `int = obj.GetFlyModeMaxValue ()` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.

- `int = obj.GetFlyMode ()` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.
- `obj.SetFlyModeToOuterEdges ()` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.
- `obj.SetFlyModeToClosestTriad ()` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.
- `obj.SetFlyModeToNone ()` - Specify a mode to control how the axes are drawn: either outer edges or closest triad to the camera position, or you may also disable flying of the axes.
- `obj.SetScaling (int )` - Set/Get a flag that controls whether the axes are scaled to fit in the viewport. If off, the axes size remains constant (i.e., stay the size of the bounding box). By default scaling is on so the axes are scaled to fit inside the viewport.
- `int = obj.GetScaling ()` - Set/Get a flag that controls whether the axes are scaled to fit in the viewport. If off, the axes size remains constant (i.e., stay the size of the bounding box). By default scaling is on so the axes are scaled to fit inside the viewport.
- `obj.ScalingOn ()` - Set/Get a flag that controls whether the axes are scaled to fit in the viewport. If off, the axes size remains constant (i.e., stay the size of the bounding box). By default scaling is on so the axes are scaled to fit inside the viewport.
- `obj.ScalingOff ()` - Set/Get a flag that controls whether the axes are scaled to fit in the viewport. If off, the axes size remains constant (i.e., stay the size of the bounding box). By default scaling is on so the axes are scaled to fit inside the viewport.
- `obj.SetNumberOfLabels (int )` - Set/Get the number of annotation labels to show along the x, y, and z axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `int = obj.GetNumberOfLabelsMinValue ()` - Set/Get the number of annotation labels to show along the x, y, and z axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `int = obj.GetNumberOfLabelsMaxValue ()` - Set/Get the number of annotation labels to show along the x, y, and z axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `int = obj.GetNumberOfLabels ()` - Set/Get the number of annotation labels to show along the x, y, and z axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `obj.SetXLabel (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X", "Y" and "Z".
- `string = obj.GetXLabel ()` - Set/Get the labels for the x, y, and z axes. By default, use "X", "Y" and "Z".
- `obj.SetYLabel (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X", "Y" and "Z".
- `string = obj.GetYLabel ()` - Set/Get the labels for the x, y, and z axes. By default, use "X", "Y" and "Z".
- `obj.SetZLabel (string )` - Set/Get the labels for the x, y, and z axes. By default, use "X", "Y" and "Z".

- `string = obj.GetZLabel ()` - Set/Get the labels for the x, y, and z axes. By default, use "X", "Y" and "Z".
- `vtkAxisActor2D = obj.GetXAxisActor2D ()` - Retrieve handles to the X, Y and Z axis (so that you can set their text properties for example)
- `vtkAxisActor2D = obj.GetYAxisActor2D ()` - Retrieve handles to the X, Y and Z axis (so that you can set their text properties for example)
- `vtkAxisActor2D = obj.GetZAxisActor2D ()` - Set/Get the title text property of all axes. Note that each axis can be controlled individually through the GetX/Y/ZAxisActor2D() methods.
- `obj.SetAxisTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property of all axes. Note that each axis can be controlled individually through the GetX/Y/ZAxisActor2D() methods.
- `vtkTextProperty = obj.GetAxisTitleTextProperty ()` - Set/Get the title text property of all axes. Note that each axis can be controlled individually through the GetX/Y/ZAxisActor2D() methods.
- `obj.SetAxisLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property of all axes. Note that each axis can be controlled individually through the GetX/Y/ZAxisActor2D() methods.
- `vtkTextProperty = obj.GetAxisLabelTextProperty ()` - Set/Get the labels text property of all axes. Note that each axis can be controlled individually through the GetX/Y/ZAxisActor2D() methods.
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the labels on each of the x-y-z axes.
- `obj.SetFontFactor (double )` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes.
- `double = obj.GetFontFactorMinValue ()` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes.
- `double = obj.GetFontFactorMaxValue ()` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes.
- `double = obj.GetFontFactor ()` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes.
- `obj.SetInertia (int )` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `int = obj.GetInertiaMinValue ()` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `int = obj.GetInertiaMaxValue ()` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `int = obj.GetInertia ()` - Set/Get the inertial factor that controls how often (i.e, how many renders) the axes can switch position (jump from one axes to another).
- `obj.SetShowActualBounds (int )` - Set/Get the variable that controls whether the actual bounds of the dataset are always shown. Setting this variable to 1 means that clipping is disabled and that the actual value of the bounds is displayed even with corner offsets Setting this variable to 0 means these axis will clip themselves and show variable bounds (legacy mode)

- `int = obj.GetShowActualBoundsMinValue ()` - Set/Get the variable that controls whether the actual bounds of the dataset are always shown. Setting this variable to 1 means that clipping is disabled and that the actual value of the bounds is displayed even with corner offsets Setting this variable to 0 means these axis will clip themselves and show variable bounds (legacy mode)

- `int = obj.GetShowActualBoundsMaxValue ()` - Set/Get the variable that controls whether the actual bounds of the dataset are always shown. Setting this variable to 1 means that clipping is disabled and that the actual value of the bounds is displayed even with corner offsets Setting this variable to 0 means these axis will clip themselves and show variable bounds (legacy mode)

- `int = obj.GetShowActualBounds ()` - Set/Get the variable that controls whether the actual bounds of the dataset are always shown. Setting this variable to 1 means that clipping is disabled and that the actual value of the bounds is displayed even with corner offsets Setting this variable to 0 means these axis will clip themselves and show variable bounds (legacy mode)

- `obj.SetCornerOffset (double )` - Specify an offset value to "pull back" the axes from the corner at which they are joined to avoid overlap of axes labels. The "CornerOffset" is the fraction of the axis length to pull back.

- `double = obj.GetCornerOffset ()` - Specify an offset value to "pull back" the axes from the corner at which they are joined to avoid overlap of axes labels. The "CornerOffset" is the fraction of the axis length to pull back.

- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

- `obj.SetXAxisVisibility (int )` - Turn on and off the visibility of each axis.

- `int = obj.GetXAxisVisibility ()` - Turn on and off the visibility of each axis.

- `obj.XAxisVisibilityOn ()` - Turn on and off the visibility of each axis.

- `obj.XAxisVisibilityOff ()` - Turn on and off the visibility of each axis.

- `obj.SetYAxisVisibility (int )` - Turn on and off the visibility of each axis.

- `int = obj.GetYAxisVisibility ()` - Turn on and off the visibility of each axis.

- `obj.YAxisVisibilityOn ()` - Turn on and off the visibility of each axis.

- `obj.YAxisVisibilityOff ()` - Turn on and off the visibility of each axis.

- `obj.SetZAxisVisibility (int )` - Turn on and off the visibility of each axis.

- `int = obj.GetZAxisVisibility ()` - Turn on and off the visibility of each axis.

- `obj.ZAxisVisibilityOn ()` - Turn on and off the visibility of each axis.

- `obj.ZAxisVisibilityOff ()` - Turn on and off the visibility of each axis.

- `obj.ShallowCopy (vtkCubeAxesActor2D actor)` - Shallow copy of a CubeAxesActor2D.

- `obj.SetProp (vtkProp prop)` - @deprecated Replaced by vtkCubeAxesActor2D::SetViewProp() as of VTK 5.0.

- `vtkProp = obj.GetProp ()` - @deprecated Replaced by vtkCubeAxesActor2D::GetViewProp() as of VTK 5.0.

34.11 vtkDepthSortPolyData

34.11.1 Usage

vtkDepthSortPolyData rearranges the order of cells so that certain rendering operations (e.g., transparency or Painter's algorithms) generate correct results. To use this filter you must specify the direction vector along which to sort the cells. You can do this by specifying a camera and/or prop to define a view direction; or explicitly set a view direction.

To create an instance of class vtkDepthSortPolyData, simply invoke its constructor as follows

```
obj = vtkDepthSortPolyData
```

34.11.2 Methods

The class vtkDepthSortPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDepthSortPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDepthSortPolyData = obj.NewInstance ()`
- `vtkDepthSortPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetDirection (int )` - Specify the sort method for the polygonal primitives. By default, the poly data is sorted from back to front.
- `int = obj.GetDirection ()` - Specify the sort method for the polygonal primitives. By default, the poly data is sorted from back to front.
- `obj.SetDirectionToFrontToBack ()` - Specify the sort method for the polygonal primitives. By default, the poly data is sorted from back to front.
- `obj.SetDirectionToBackToFront ()` - Specify the sort method for the polygonal primitives. By default, the poly data is sorted from back to front.
- `obj.SetDirectionToSpecifiedVector ()` - Specify the point to use when sorting. The fastest is to just take the first cell point. Other options are to take the bounding box center or the parametric center of the cell. By default, the first cell point is used.
- `obj.SetDepthSortMode (int )` - Specify the point to use when sorting. The fastest is to just take the first cell point. Other options are to take the bounding box center or the parametric center of the cell. By default, the first cell point is used.
- `int = obj.GetDepthSortMode ()` - Specify the point to use when sorting. The fastest is to just take the first cell point. Other options are to take the bounding box center or the parametric center of the cell. By default, the first cell point is used.
- `obj.SetDepthSortModeToFirstPoint ()` - Specify the point to use when sorting. The fastest is to just take the first cell point. Other options are to take the bounding box center or the parametric center of the cell. By default, the first cell point is used.
- `obj.SetDepthSortModeToBoundsCenter ()` - Specify the point to use when sorting. The fastest is to just take the first cell point. Other options are to take the bounding box center or the parametric center of the cell. By default, the first cell point is used.

- `obj.SetDepthSortModeToParametricCenter ()` - Specify a camera that is used to define a view direction along which the cells are sorted. This ivar only has effect if the direction is set to front-to-back or back-to-front, and a camera is specified.
- `obj.SetCamera (vtkCamera )` - Specify a camera that is used to define a view direction along which the cells are sorted. This ivar only has effect if the direction is set to front-to-back or back-to-front, and a camera is specified.
- `vtkCamera = obj.GetCamera ()` - Specify a camera that is used to define a view direction along which the cells are sorted. This ivar only has effect if the direction is set to front-to-back or back-to-front, and a camera is specified.
- `obj.SetProp3D (vtkProp3D )` - Specify a transformation matrix (via the vtkProp3D::GetMatrix() method) that is used to include the effects of transformation. This ivar only has effect if the direction is set to front-to-back or back-to-front, and a camera is specified. Specifying the vtkProp3D is optional.
- `vtkProp3D = obj.GetProp3D ()` - Specify a transformation matrix (via the vtkProp3D::GetMatrix() method) that is used to include the effects of transformation. This ivar only has effect if the direction is set to front-to-back or back-to-front, and a camera is specified. Specifying the vtkProp3D is optional.
- `obj.SetVector (double , double , double )` - Set/Get the sort direction. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The sort occurs in the direction of the vector.
- `obj.SetVector (double a[3])` - Set/Get the sort direction. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The sort occurs in the direction of the vector.
- `double = obj. GetVector ()` - Set/Get the sort direction. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The sort occurs in the direction of the vector.
- `obj.SetOrigin (double , double , double )` - Set/Get the sort origin. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The sort occurs in the direction of the vector, with this point specifying the origin.
- `obj.SetOrigin (double a[3])` - Set/Get the sort origin. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The sort occurs in the direction of the vector, with this point specifying the origin.
- `double = obj. GetOrigin ()` - Set/Get the sort origin. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The sort occurs in the direction of the vector, with this point specifying the origin.
- `obj.SetSortScalars (int )` - Set/Get a flag that controls the generation of scalar values corresponding to the sort order. If enabled, the output of this filter will include scalar values that range from 0 to (ncells-1), where 0 is closest to the sort direction.
- `int = obj.GetSortScalars ()` - Set/Get a flag that controls the generation of scalar values corresponding to the sort order. If enabled, the output of this filter will include scalar values that range from 0 to (ncells-1), where 0 is closest to the sort direction.
- `obj.SortScalarsOn ()` - Set/Get a flag that controls the generation of scalar values corresponding to the sort order. If enabled, the output of this filter will include scalar values that range from 0 to (ncells-1), where 0 is closest to the sort direction.
- `obj.SortScalarsOff ()` - Set/Get a flag that controls the generation of scalar values corresponding to the sort order. If enabled, the output of this filter will include scalar values that range from 0 to (ncells-1), where 0 is closest to the sort direction.
- `long = obj.GetMTime ()` - Return MTime also considering the dependent objects: the camera and/or the prop3D.

34.12 vtkDSPFilterDefinition

34.12.1 Usage

vtkDSPFilterDefinition is used by vtkExodusReader, vtkExodusIIReader and vtkPExodusReader to do temporal smoothing of data

To create an instance of class vtkDSPFilterDefinition, simply invoke its constructor as follows

```
obj = vtkDSPFilterDefinition
```

34.12.2 Methods

The class vtkDSPFilterDefinition has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDSPFilterDefinition class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDSPFilterDefinition = obj.NewInstance ()`
- `vtkDSPFilterDefinition = obj.SafeDownCast (vtkObject o)`
- `obj.Copy (vtkDSPFilterDefinition other)`
- `obj.Clear ()`
- `bool = obj.IsThisInputVariableInstanceNeeded (int a\_timestep, int a\_outputTimestep)`
- `obj.PushBackNumeratorWeight (double a\_value)`
- `obj.PushBackDenominatorWeight (double a\_value)`
- `obj.PushBackForwardNumeratorWeight (double a\_value)`
- `obj.SetInputVariableName (string a\_value)`
- `obj.SetOutputVariableName (string a\_value)`
- `string = obj.GetInputVariableName ()`
- `string = obj.GetOutputVariableName ()`
- `int = obj.GetNumNumeratorWeights ()`
- `int = obj.GetNumDenominatorWeights ()`
- `int = obj.GetNumForwardNumeratorWeights ()`
- `double = obj.GetNumeratorWeight (int a\_which)`
- `double = obj.GetDenominatorWeight (int a\_which)`
- `double = obj.GetForwardNumeratorWeight (int a\_which)`

34.13 vtkDSPFilterGroup

34.13.1 Usage

vtkDSPFilterGroup is used by vtkExodusReader, vtkExodusIIReader and vtkPExodusReader to do temporal smoothing of data

To create an instance of class vtkDSPFilterGroup, simply invoke its constructor as follows

```
obj = vtkDSPFilterGroup
```

34.13.2 Methods

The class vtkDSPFilterGroup has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDSPFilterGroup class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDSPFilterGroup = obj.NewInstance ()`
- `vtkDSPFilterGroup = obj.SafeDownCast (vtkObject o)`
- `obj.AddFilter (vtkDSPFilterDefinition filter)`
- `obj.RemoveFilter (string a\_outputVariableName)`
- `bool = obj.IsThisInputVariableInstanceNeeded (string a\_name, int a\_timestep, int a\_outputTimeste`
- `bool = obj.IsThisInputVariableInstanceCached (string a\_name, int a\_timestep)`
- `obj.AddInputVariableInstance (string a\_name, int a\_timestep, vtkFloatArray a\_data)`
- `vtkFloatArray = obj.GetCachedInput (int a\_whichFilter, int a\_whichTimestep)`
- `vtkFloatArray = obj.GetCachedOutput (int a\_whichFilter, int a\_whichTimestep)`
- `string = obj.GetInputVariableName (int a\_whichFilter)`
- `int = obj.GetNumFilters ()`
- `obj.Copy (vtkDSPFilterGroup other)`
- `vtkDSPFilterDefinition = obj.GetFilter (int a\_whichFilter)`

34.14 vtkEarthSource

34.14.1 Usage

vtkEarthSource creates a spherical rendering of the geographical shapes of the major continents of the earth. The OnRatio determines how much of the data is actually used. The radius defines the radius of the sphere at which the continents are placed. Obtains data from an imbedded array of coordinates.

To create an instance of class vtkEarthSource, simply invoke its constructor as follows

```
obj = vtkEarthSource
```

34.14.2 Methods

The class vtkEarthSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEarthSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEarthSource = obj.NewInstance ()`
- `vtkEarthSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetRadius (double )` - Set radius of earth.
- `double = obj.GetRadiusMinValue ()` - Set radius of earth.
- `double = obj.GetRadiusMaxValue ()` - Set radius of earth.
- `double = obj.GetRadius ()` - Set radius of earth.
- `obj.SetOnRatio (int )` - Turn on every nth entity. This controls how much detail the model will have. The maximum ratio is sixteen. (The smaller OnRatio, the more detail there is.)
- `int = obj.GetOnRatioMinValue ()` - Turn on every nth entity. This controls how much detail the model will have. The maximum ratio is sixteen. (The smaller OnRatio, the more detail there is.)
- `int = obj.GetOnRatioMaxValue ()` - Turn on every nth entity. This controls how much detail the model will have. The maximum ratio is sixteen. (The smaller OnRatio, the more detail there is.)
- `int = obj.GetOnRatio ()` - Turn on every nth entity. This controls how much detail the model will have. The maximum ratio is sixteen. (The smaller OnRatio, the more detail there is.)
- `obj.SetOutline (int )` - Turn on/off drawing continents as filled polygons or as wireframe outlines. Warning: some graphics systems will have trouble with the very large, concave filled polygons. Recommend you use OutlienOn (i.e., disable filled polygons) for now.
- `int = obj.GetOutline ()` - Turn on/off drawing continents as filled polygons or as wireframe outlines. Warning: some graphics systems will have trouble with the very large, concave filled polygons. Recommend you use OutlienOn (i.e., disable filled polygons) for now.
- `obj.OutlineOn ()` - Turn on/off drawing continents as filled polygons or as wireframe outlines. Warning: some graphics systems will have trouble with the very large, concave filled polygons. Recommend you use OutlienOn (i.e., disable filled polygons) for now.
- `obj.OutlineOff ()` - Turn on/off drawing continents as filled polygons or as wireframe outlines. Warning: some graphics systems will have trouble with the very large, concave filled polygons. Recommend you use OutlienOn (i.e., disable filled polygons) for now.

34.15 vtkExodusIIReader

34.15.1 Usage

vtkExodusIIReader is a unstructured grid source object that reads ExodusII files. Most of the meta data associated with the file is loaded when UpdateInformation is called. This includes information like Title, number of blocks, number and names of arrays. This data can be retrieved from methods in this reader. Separate arrays that are meant to be a single vector, are combined internally for convenience. To be combined, the array names have to be identical except for a trailing X,Y and Z (or x,y,z). By default cell and point

arrays are not loaded. However, the user can flag arrays to load with the methods "SetPointArrayStatus" and "SetCellArrayStatus". The reader DOES NOT respond to piece requests

To create an instance of class vtkExodusIIReader, simply invoke its constructor as follows

```
obj = vtkExodusIIReader
```

34.15.2 Methods

The class vtkExodusIIReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExodusIIReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExodusIIReader = obj.NewInstance ()`
- `vtkExodusIIReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)` - Determine if the file can be readed with this reader.
- `long = obj.GetMTime ()` - Return the object's MTime. This is overridden to include the timestamp of its internal class.
- `long = obj.GetMetadataMTime ()` - Return the MTime of the internal data structure. This is really only intended for use by vtkPExodusIIReader in order to determine if the filename is newer than the metadata.
- `obj.SetFileName (string fname)` - Specify file name of the Exodus file.
- `string = obj.GetFileName ()` - Specify file name of the Exodus file.
- `obj.SetXMLFileName (string fname)` - Specify file name of the xml file.
- `string = obj.GetXMLFileName ()` - Specify file name of the xml file.
- `obj.SetTimeStep (int )` - Which TimeStep to read.
- `int = obj.GetTimeStep ()` - Which TimeStep to read.
- `obj.SetModeShape (int val)` - Returns the available range of valid integer time steps.
- `int = obj. GetTimeStepRange ()` - Returns the available range of valid integer time steps.
- `obj.SetTimeStepRange (int , int )` - Returns the available range of valid integer time steps.
- `obj.SetTimeStepRange (int  a[2])` - Returns the available range of valid integer time steps.
- `obj.SetGenerateObjectIdCellArray (int g)` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName(). For cells representing elements from an Exodus element block, this is set to the element block ID. For cells representing edges from an Exodus edge block, this is the edge block ID. Similarly, ths is the face block ID for cells representing faces from an Exodus face block. The same holds for cells representing entries of node, edge, face, side, and element sets.

- `int = obj.GetGenerateObjectIdCellArray ()` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName(). For cells representing elements from an Exodus element block, this is set to the element block ID. For cells representing edges from an Exodus edge block, this is the edge block ID. Similarly, ths is the face block ID for cells representing faces from an Exodus face block. The same holds for cells representing entries of node, edge, face, side, and element sets.
- `obj.GenerateObjectIdCellArrayOn ()` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName(). For cells representing elements from an Exodus element block, this is set to the element block ID. For cells representing edges from an Exodus edge block, this is the edge block ID. Similarly, ths is the face block ID for cells representing faces from an Exodus face block. The same holds for cells representing entries of node, edge, face, side, and element sets.
- `obj.GenerateObjectIdCellArrayOff ()` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName(). For cells representing elements from an Exodus element block, this is set to the element block ID. For cells representing edges from an Exodus edge block, this is the edge block ID. Similarly, ths is the face block ID for cells representing faces from an Exodus face block. The same holds for cells representing entries of node, edge, face, side, and element sets.
- `obj.SetGenerateGlobalElementIdArray (int g)`
- `int = obj.GetGenerateGlobalElementIdArray ()`
- `obj.GenerateGlobalElementIdArrayOn ()`
- `obj.GenerateGlobalElementIdArrayOff ()`
- `obj.SetGenerateGlobalNodeIdArray (int g)`
- `int = obj.GetGenerateGlobalNodeIdArray ()`
- `obj.GenerateGlobalNodeIdArrayOn ()`
- `obj.GenerateGlobalNodeIdArrayOff ()`
- `obj.SetGenerateImplicitElementIdArray (int g)`
- `int = obj.GetGenerateImplicitElementIdArray ()`
- `obj.GenerateImplicitElementIdArrayOn ()`
- `obj.GenerateImplicitElementIdArrayOff ()`
- `obj.SetGenerateImplicitNodeIdArray (int g)`
- `int = obj.GetGenerateImplicitNodeIdArray ()`
- `obj.GenerateImplicitNodeIdArrayOn ()`
- `obj.GenerateImplicitNodeIdArrayOff ()`
- `obj.SetGenerateFileIdArray (int f)`
- `int = obj.GetGenerateFileIdArray ()`
- `obj.GenerateFileIdArrayOn ()`
- `obj.GenerateFileIdArrayOff ()`

- `obj.SetFileId (int f)`
- `int = obj.GetFileId ()`
- `obj.SetApplyDisplacements (int d)` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `int = obj.GetApplyDisplacements ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.ApplyDisplacementsOn ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.ApplyDisplacementsOff ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.SetDisplacementMagnitude (float s)` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `float = obj.GetDisplacementMagnitude ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.SetHasModeShapes (int ms)` - Set/Get whether the Exodus sequence number corresponds to time steps or mode shapes. By default, HasModeShapes is false unless two time values in the Exodus file are identical, in which case it is true.
- `int = obj.GetHasModeShapes ()` - Set/Get whether the Exodus sequence number corresponds to time steps or mode shapes. By default, HasModeShapes is false unless two time values in the Exodus file are identical, in which case it is true.
- `obj.HasModeShapesOn ()` - Set/Get whether the Exodus sequence number corresponds to time steps or mode shapes. By default, HasModeShapes is false unless two time values in the Exodus file are identical, in which case it is true.
- `obj.HasModeShapesOff ()` - Set/Get whether the Exodus sequence number corresponds to time steps or mode shapes. By default, HasModeShapes is false unless two time values in the Exodus file are identical, in which case it is true.
- `obj.SetModeShapeTime (double phase)` - Set/Get the time used to animate mode shapes. This is a number between 0 and 1 that is used to scale the DisplacementMagnitude in a sinusoidal pattern. Specifically, the displacement vector for each vertex is scaled by DisplacementMagnitude$cos(2i$ModeShapeTime) before it is added to the vertex coordinates.
- `double = obj.GetModeShapeTime ()` - Set/Get the time used to animate mode shapes. This is a number between 0 and 1 that is used to scale the DisplacementMagnitude in a sinusoidal pattern. Specifically, the displacement vector for each vertex is scaled by DisplacementMagnitude$cos(2i$ModeShapeTime) before it is added to the vertex coordinates.
- `obj.SetAnimateModeShapes (int flag)` - If this flag is on (the default) and HasModeShapes is also on, then this reader will report a continuous time range [0,1] and animate the displacements in a periodic sinusoid. If this flag is off and HasModeShapes is on, this reader ignores time. This flag has no effect if HasModeShapes is off.

- `int = obj.GetAnimateModeShapes ()` - If this flag is on (the default) and HasModeShapes is also on, then this reader will report a continuous time range [0,1] and animate the displacements in a periodic sinusoid. If this flag is off and HasModeShapes is on, this reader ignores time. This flag has no effect if HasModeShapes is off.
- `obj.AnimateModeShapesOn ()` - If this flag is on (the default) and HasModeShapes is also on, then this reader will report a continuous time range [0,1] and animate the displacements in a periodic sinusoid. If this flag is off and HasModeShapes is on, this reader ignores time. This flag has no effect if HasModeShapes is off.
- `obj.AnimateModeShapesOff ()` - If this flag is on (the default) and HasModeShapes is also on, then this reader will report a continuous time range [0,1] and animate the displacements in a periodic sinusoid. If this flag is off and HasModeShapes is on, this reader ignores time. This flag has no effect if HasModeShapes is off.
- `obj.SetEdgeFieldDecorations (int d)` - FIXME
- `int = obj.GetEdgeFieldDecorations ()` - FIXME
- `obj.EdgeFieldDecorationsNone ()` - FIXME
- `obj.EdgeFieldDecorationsGlyphs ()` - FIXME
- `obj.EdgeFieldDecorationsCornerAveraged ()` - FIXME
- `obj.SetFaceFieldDecorations (int d)` - FIXME
- `int = obj.GetFaceFieldDecorations ()` - FIXME
- `obj.FaceFieldDecorationsNone ()` - FIXME
- `obj.FaceFieldDecorationsGlyphs ()` - FIXME
- `obj.FaceFieldDecorationsCornerAveraged ()` - Access to meta data generated by UpdateInformation.
- `string = obj.GetTitle ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetDimensionality ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetNumberOfTimeSteps ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetNumberOfNodesInFile ()`
- `int = obj.GetNumberOfEdgesInFile ()`
- `int = obj.GetNumberOfFacesInFile ()`
- `int = obj.GetNumberOfElementsInFile ()`
- `int = obj.GetObjectTypeFromName (string name)`
- `string = obj.GetObjectTypeName (int )`
- `int = obj.GetNumberOfNodes ()`

- `obj.SetFaceSetArrayStatus (string name, int flag)`
- `int = obj.GetNumberOfElementSetArrays ()`
- `string = obj.GetElementSetArrayName (int index)`
- `int = obj.GetElementSetArrayStatus (string name)`
- `obj.SetElementSetArrayStatus (string name, int flag)`
- `int = obj.GetNumberOfNodeSetResultArrays ()`
- `string = obj.GetNodeSetResultArrayName (int index)`
- `int = obj.GetNodeSetResultArrayStatus (string name)`
- `obj.SetNodeSetResultArrayStatus (string name, int flag)`
- `int = obj.GetNumberOfSideSetResultArrays ()`
- `string = obj.GetSideSetResultArrayName (int index)`
- `int = obj.GetSideSetResultArrayStatus (string name)`
- `obj.SetSideSetResultArrayStatus (string name, int flag)`
- `int = obj.GetNumberOfEdgeSetResultArrays ()`
- `string = obj.GetEdgeSetResultArrayName (int index)`
- `int = obj.GetEdgeSetResultArrayStatus (string name)`
- `obj.SetEdgeSetResultArrayStatus (string name, int flag)`
- `int = obj.GetNumberOfFaceSetResultArrays ()`
- `string = obj.GetFaceSetResultArrayName (int index)`
- `int = obj.GetFaceSetResultArrayStatus (string name)`
- `obj.SetFaceSetResultArrayStatus (string name, int flag)`
- `int = obj.GetNumberOfElementSetResultArrays ()`
- `string = obj.GetElementSetResultArrayName (int index)`
- `int = obj.GetElementSetResultArrayStatus (string name)`
- `obj.SetElementSetResultArrayStatus (string name, int flag)` - Set the fast-path keys. All three must be set for the fast-path option to work. Possible argument values: "POINT","CELL","EDGE","FACE"
- `obj.SetFastPathObjectType (string type)` - Set the fast-path keys. All three must be set for the fast-path option to work. Possible argument values: "POINT","CELL","EDGE","FACE"
- `obj.SetFastPathIdType (string type)` - Possible argument values: "INDEX","GLOBAL" "GLOBAL" means the id refers to a global id "INDEX" means the id refers to an index into the VTK array
- `obj.SetFastPathObjectId (vtkIdType id)` - Possible argument values: "INDEX","GLOBAL" "GLOBAL" means the id refers to a global id "INDEX" means the id refers to an index into the VTK array
- `obj.Reset ()` - Reset the user-specified parameters and flush internal arrays so that the reader state is just as it was after the reader was instantiated.

  It doesn't make sense to let users reset only the internal state; both the settings and the state are changed by this call.

- `obj.ResetSettings ()` - Reset the user-specified parameters to their default values. The only settings not affected are the filename and/or pattern because these have no default.

  Resetting the settings but not the state allows users to keep the active cache but return to initial array selections, etc.

- `obj.ResetCache ()` - Clears out the cache entries.

- `obj.UpdateTimeInformation ()` - Re-reads time information from the exodus file and updates TimeStepRange accordingly.

- `obj.Dump ()`

- `vtkGraph = obj.GetSIL ()` - SIL describes organization of/relationships between classifications eg. blocks/materials/hierarchies.

- `int = obj.GetSILUpdateStamp ()` - Every time the SIL is updated a this will return a different value.

- `bool = obj.GetProducedFastPathOutput ()` - HACK: Used by vtkPExodusIIReader to tell is the reader produced a valid fast path output.

34.16 vtkExodusModel

34.16.1 Usage

A vtkUnstructuredGrid output by vtkExodusReader or vtkPExodusReader is missing a great deal of initialization and static model data that is in an Exodus II file. (Global variables, properties, node sets, side sets, and so on.) This data can be stored in a vtkModelMetadata object, which can be initialized using this vtkExodusModel class.

This class can be initialized with a file handle for an open Exodus file, and the vtkUnstructuredGrid derived from that file. The methods used would be SetGlobalInformation, SetLocalInformation, AddUGridElementVariable and AddUGridNodeVariable. The vtkExodusReader does this.

It can also be initialized (using UnpackExodusModel) from a vtkUnstructuredGrid that has had metadata packed into it's field arrays with PackExodusModel. The vtkExodusIIWriter does this.

If you plan to write out the Exodus file (with vtkExodusIIWriter), you should direct the Exodus reader to create a vtkExodusModel object. This will be used by the Exodus writer to create a correct Exodus II file on output. In addition, the vtkDistributedDataFilter is cognizant of the ExodusModel object and will unpack, extract, merge, and pack these objects associated with the grids it is partitioning.

.SECTION See also vtkExodusReader vtkPExodusReader vtkExodusIIWriter vtkModelMetadata vtkDistributedDataFilter

To create an instance of class vtkExodusModel, simply invoke its constructor as follows

```
obj = vtkExodusModel
```

34.16.2 Methods

The class vtkExodusModel has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExodusModel class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkExodusModel = obj.NewInstance ()`

- `vtkExodusModel = obj.SafeDownCast (vtkObject o)`

- `int = obj.SetGlobalInformation (int fid, int compute\_word\_size)`
- `int = obj.AddUGridElementVariable (string ugridVarName, string origName, int numComponents)`
- `int = obj.RemoveUGridElementVariable (string ugridVarName)`
- `int = obj.AddUGridNodeVariable (string ugridVarName, string origName, int numComponents)`
- `int = obj.RemoveUGridNodeVariable (string ugridVarName)`
- `int = obj.SetLocalInformation (vtkUnstructuredGrid ugrid, int fid, int timeStep, int newGeometry, i`
- `vtkModelMetadata = obj.GetModelMetadata ()`
- `obj.SetModelMetadata (vtkModelMetadata emData)`
- `int = obj.UnpackExodusModel (vtkUnstructuredGrid grid, int deleteIt)`
- `int = obj.MergeExodusModel (vtkExodusModel em)`
- `vtkExodusModel = obj.ExtractExodusModel (vtkIdTypeArray globalCellIdList, vtkUnstructuredGrid grid)`
- `obj.PackExodusModel (vtkUnstructuredGrid grid)`
- `obj.Reset ()`

34.17 vtkExodusReader

34.17.1 Usage

vtkExodusReader is a unstructured grid source object that reads ExodusII files. Most of the meta data associated with the file is loaded when UpdateInformation is called. This includes information like Title, number of blocks, number and names of arrays. This data can be retrieved from methods in this reader. Separate arrays that are meant to be a single vector, are combined internally for convenience. To be combined, the array names have to be identical except for a trailing X,Y and Z (or x,y,z). By default cell and point arrays are not loaded. However, the user can flag arrays to load with the methods "SetPointArrayStatus" and "SetCellArrayStatus". The reader DOES NOT respond to piece requests

To create an instance of class vtkExodusReader, simply invoke its constructor as follows

```
obj = vtkExodusReader
```

34.17.2 Methods

The class vtkExodusReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExodusReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExodusReader = obj.NewInstance ()`
- `vtkExodusReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)` - Determine if the file can be readed with this reader.
- `obj.SetFileName (string )` - Specify file name of the Exodus file.
- `string = obj.GetFileName ()` - Specify file name of the Exodus file.

- `obj.SetXMLFileName (string )` - Specify file name of the xml file.
- `string = obj.GetXMLFileName ()` - Specify file name of the xml file.
- `obj.SetTimeStep (int )` - Which TimeStep to read.
- `int = obj.GetTimeStep ()` - Which TimeStep to read.
- `obj.SetGenerateBlockIdCellArray (int )` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName()
- `int = obj.GetGenerateBlockIdCellArray ()` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName()
- `obj.GenerateBlockIdCellArrayOn ()` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName()
- `obj.GenerateBlockIdCellArrayOff ()` - Extra cell data array that can be generated. By default, this array is ON. The value of the array is the integer id found in the exodus file. The name of the array is returned by GetBlockIdArrayName()
- `string = obj.GetBlockIdArrayName ()` - Extra cell data array that can be generated. By default, this array is off. The value of the array is the integer global id of the cell. The name of the array is returned by GetGlobalElementIdArrayName()
- `obj.SetGenerateGlobalElementIdArray (int )` - Extra cell data array that can be generated. By default, this array is off. The value of the array is the integer global id of the cell. The name of the array is returned by GetGlobalElementIdArrayName()
- `int = obj.GetGenerateGlobalElementIdArray ()` - Extra cell data array that can be generated. By default, this array is off. The value of the array is the integer global id of the cell. The name of the array is returned by GetGlobalElementIdArrayName()
- `obj.GenerateGlobalElementIdArrayOn ()` - Extra cell data array that can be generated. By default, this array is off. The value of the array is the integer global id of the cell. The name of the array is returned by GetGlobalElementIdArrayName()
- `obj.GenerateGlobalElementIdArrayOff ()` - Extra cell data array that can be generated. By default, this array is off. The value of the array is the integer global id of the cell. The name of the array is returned by GetGlobalElementIdArrayName()
- `obj.SetGenerateGlobalNodeIdArray (int )` - Extra point data array that can be generated. By default, this array is ON. The value of the array is the integer id of the node. The id is relative to the entire data set. The name of the array is returned by GlobalNodeIdArrayName().
- `int = obj.GetGenerateGlobalNodeIdArray ()` - Extra point data array that can be generated. By default, this array is ON. The value of the array is the integer id of the node. The id is relative to the entire data set. The name of the array is returned by GlobalNodeIdArrayName().
- `obj.GenerateGlobalNodeIdArrayOn ()` - Extra point data array that can be generated. By default, this array is ON. The value of the array is the integer id of the node. The id is relative to the entire data set. The name of the array is returned by GlobalNodeIdArrayName().
- `obj.GenerateGlobalNodeIdArrayOff ()` - Extra point data array that can be generated. By default, this array is ON. The value of the array is the integer id of the node. The id is relative to the entire data set. The name of the array is returned by GlobalNodeIdArrayName().

- `obj.SetApplyDisplacements (int )` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `int = obj.GetApplyDisplacements ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.ApplyDisplacementsOn ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.ApplyDisplacementsOff ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `obj.SetDisplacementMagnitude (float )` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `float = obj.GetDisplacementMagnitude ()` - Geometric locations can include displacements. By default, this is ON. The nodal positions are 'displaced' by the standard exodus displacment vector. If displacements are turned 'off', the user can explicitly add them by applying a warp filter.
- `string = obj.GetTitle ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetDimensionality ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetNumberOfTimeSteps ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetNumberOfElements ()` - Access to meta data generated by UpdateInformation.
- `int = obj.GetNumberOfNodeSets ()` - Access to meta data generated by UpdateInformation.

- obj.SetArrayStatus (string type, string name, int flag)
- int = obj.GetArrayStatus (string type, string name)
- int = obj.GetTimeSeriesData (int ID, string vName, string vType, vtkFloatArray result)
- int = obj.GetNumberOfVariableArrays ()
- string = obj.GetVariableArrayName (int a_which)
- obj.EnableDSPFiltering ()
- obj.AddFilter (vtkDSPFilterDefinition a_filter)
- obj.StartAddingFilter ()
- obj.AddFilterInputVar (string name)
- obj.AddFilterOutputVar (string name)
- obj.AddFilterNumeratorWeight (double weight)
- obj.AddFilterForwardNumeratorWeight (double weight)
- obj.AddFilterDenominatorWeight (double weight)
- obj.FinishAddingFilter ()
- obj.RemoveFilter (string a_outputVariableName)
- obj.GetDSPOutputArrays (int exoid, vtkUnstructuredGrid output)

34.18 vtkFacetReader

34.18.1 Usage

vtkFacetReader creates a poly data dataset. It reads ASCII files stored in Facet format

The facet format looks like this: FACET FILE ... nparts Part 1 name 0 npoints 0 0 p1x p1y p1z p2x p2y p2z ... 1 Part 1 name ncells npointspercell p1c1 p2c1 p3c1 ... pnc1 materialnum partnum p1c2 p2c2 p3c2 ... pnc2 materialnum partnum ...

To create an instance of class vtkFacetReader, simply invoke its constructor as follows

```
obj = vtkFacetReader
```

34.18.2 Methods

The class vtkFacetReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFacetReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFacetReader = obj.NewInstance ()`
- `vtkFacetReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of Facet datafile to read
- `string = obj.GetFileName ()` - Specify file name of Facet datafile to read

34.19 vtkGreedyTerrainDecimation

34.19.1 Usage

vtkGreedyTerrainDecimation approximates a height field with a triangle mesh (triangulated irregular network - TIN) using a greedy insertion algorithm similar to that described by Garland and Heckbert in their paper "Fast Polygonal Approximations of Terrain and Height Fields" (Technical Report CMU-CS-95-181). The input to the filter is a height field (represented by a image whose scalar values are height) and the output of the filter is polygonal data consisting of triangles. The number of triangles in the output is reduced in number as compared to a naive tessellation of the input height field. This filter copies point data from the input to the output for those points present in the output.

An brief description of the algorithm is as follows. The algorithm uses a top-down decimation approach that initially represents the height field with two triangles (whose vertices are at the four corners of the image). These two triangles form a Delaunay triangulation. In an iterative fashion, the point in the image with the greatest error (as compared to the original height field) is injected into the triangulation. (Note that the single point with the greatest error per triangle is identified and placed into a priority queue. As the triangulation is modified, the errors from the deleted triangles are removed from the queue, error values from the new triangles are added.) The point whose error is at the top of the queue is added to the triangulaion modifying it using the standard incremental Delaunay point insertion (see vtkDelaunay2D) algorithm. Points are repeatedly inserted until the appropriate (user-specified) error criterion is met.

To use this filter, set the input and specify the error measure to be used. The error measure options are 1) the absolute number of triangles to be produced; 2) a fractional reduction of the mesh (numTris/maxTris) where maxTris is the largest possible number of triangles 2*(dims[0]-1)*(dims[1]-1); 3) an absolute measure on error (maximum difference in height field to reduced TIN); and 4) relative error (the absolute error is normalized by the diagonal of the bounding box of the height field).

To create an instance of class vtkGreedyTerrainDecimation, simply invoke its constructor as follows

```
obj = vtkGreedyTerrainDecimation
```

34.19.2 Methods

The class vtkGreedyTerrainDecimation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGreedyTerrainDecimation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkGreedyTerrainDecimation = obj.NewInstance ()`
- `vtkGreedyTerrainDecimation = obj.SafeDownCast (vtkObject o)`
- `obj.SetErrorMeasure (int )` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `int = obj.GetErrorMeasureMinValue ()` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `int = obj.GetErrorMeasureMaxValue ()` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `int = obj.GetErrorMeasure ()` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `obj.SetErrorMeasureToNumberOfTriangles ()` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `obj.SetErrorMeasureToSpecifiedReduction ()` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `obj.SetErrorMeasureToAbsoluteError ()` - Specify how to terminate the algorithm: either as an absolute number of triangles, a relative number of triangles (normalized by the full resolution mesh), an absolute error (in the height field), or relative error (normalized by the length of the diagonal of the image).
- `obj.SetErrorMeasureToRelativeError ()` - Specify the number of triangles to produce on output. (It is a good idea to make sure this is less than a tessellated mesh at full resolution.) You need to set this value only when the error measure is set to NumberOfTriangles.
- `obj.SetNumberOfTriangles (vtkIdType )` - Specify the number of triangles to produce on output. (It is a good idea to make sure this is less than a tessellated mesh at full resolution.) You need to set this value only when the error measure is set to NumberOfTriangles.
- `vtkIdType = obj.GetNumberOfTrianglesMinValue ()` - Specify the number of triangles to produce on output. (It is a good idea to make sure this is less than a tessellated mesh at full resolution.) You need to set this value only when the error measure is set to NumberOfTriangles.
- `vtkIdType = obj.GetNumberOfTrianglesMaxValue ()` - Specify the number of triangles to produce on output. (It is a good idea to make sure this is less than a tessellated mesh at full resolution.) You need to set this value only when the error measure is set to NumberOfTriangles.
- `vtkIdType = obj.GetNumberOfTriangles ()` - Specify the number of triangles to produce on output. (It is a good idea to make sure this is less than a tessellated mesh at full resolution.) You need to set this value only when the error measure is set to NumberOfTriangles.
- `obj.SetReduction (double )` - Specify the reduction of the mesh (represented as a fraction). Note that a value of 0.10 means a 10only when the error measure is set to SpecifiedReduction.

- `double = obj.GetReductionMinValue ()` - Specify the reduction of the mesh (represented as a fraction). Note that a value of 0.10 means a 10only when the error measure is set to SpecifiedReduction.
- `double = obj.GetReductionMaxValue ()` - Specify the reduction of the mesh (represented as a fraction). Note that a value of 0.10 means a 10only when the error measure is set to SpecifiedReduction.
- `double = obj.GetReduction ()` - Specify the reduction of the mesh (represented as a fraction). Note that a value of 0.10 means a 10only when the error measure is set to SpecifiedReduction.
- `obj.SetAbsoluteError (double )` - Specify the absolute error of the mesh; that is, the error in height between the decimated mesh and the original height field. You need to set this value only when the error measure is set to AbsoluteError.
- `double = obj.GetAbsoluteErrorMinValue ()` - Specify the absolute error of the mesh; that is, the error in height between the decimated mesh and the original height field. You need to set this value only when the error measure is set to AbsoluteError.
- `double = obj.GetAbsoluteErrorMaxValue ()` - Specify the absolute error of the mesh; that is, the error in height between the decimated mesh and the original height field. You need to set this value only when the error measure is set to AbsoluteError.
- `double = obj.GetAbsoluteError ()` - Specify the absolute error of the mesh; that is, the error in height between the decimated mesh and the original height field. You need to set this value only when the error measure is set to AbsoluteError.
- `obj.SetRelativeError (double )` - Specify the relative error of the mesh; that is, the error in height between the decimated mesh and the original height field normalized by the diagonal of the image. You need to set this value only when the error measure is set to RelativeError.
- `double = obj.GetRelativeErrorMinValue ()` - Specify the relative error of the mesh; that is, the error in height between the decimated mesh and the original height field normalized by the diagonal of the image. You need to set this value only when the error measure is set to RelativeError.
- `double = obj.GetRelativeErrorMaxValue ()` - Specify the relative error of the mesh; that is, the error in height between the decimated mesh and the original height field normalized by the diagonal of the image. You need to set this value only when the error measure is set to RelativeError.
- `double = obj.GetRelativeError ()` - Specify the relative error of the mesh; that is, the error in height between the decimated mesh and the original height field normalized by the diagonal of the image. You need to set this value only when the error measure is set to RelativeError.
- `obj.SetBoundaryVertexDeletion (int )` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.
- `int = obj.GetBoundaryVertexDeletion ()` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.
- `obj.BoundaryVertexDeletionOn ()` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.
- `obj.BoundaryVertexDeletionOff ()` - Turn on/off the deletion of vertices on the boundary of a mesh. This may limit the maximum reduction that may be achieved.
- `obj.SetComputeNormals (int )` - Compute normals based on the input image. Off by default.
- `int = obj.GetComputeNormals ()` - Compute normals based on the input image. Off by default.
- `obj.ComputeNormalsOn ()` - Compute normals based on the input image. Off by default.
- `obj.ComputeNormalsOff ()` - Compute normals based on the input image. Off by default.

34.20 vtkGridTransform

34.20.1 Usage

vtkGridTransform describes a nonlinear warp transformation as a set of displacement vectors sampled along a uniform 3D grid.

To create an instance of class vtkGridTransform, simply invoke its constructor as follows

```
obj = vtkGridTransform
```

34.20.2 Methods

The class vtkGridTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGridTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGridTransform = obj.NewInstance ()`
- `vtkGridTransform = obj.SafeDownCast (vtkObject o)`
- `obj.SetDisplacementGrid (vtkImageData )` - Set/Get the grid transform (the grid transform must have three components for displacement in x, y, and z respectively). The vtkGridTransform class will never modify the data.
- `vtkImageData = obj.GetDisplacementGrid ()` - Set/Get the grid transform (the grid transform must have three components for displacement in x, y, and z respectively). The vtkGridTransform class will never modify the data.
- `obj.SetDisplacementScale (double )` - Set scale factor to be applied to the displacements. This is used primarily for grids which contain integer data types. Default: 1
- `double = obj.GetDisplacementScale ()` - Set scale factor to be applied to the displacements. This is used primarily for grids which contain integer data types. Default: 1
- `obj.SetDisplacementShift (double )` - Set a shift to be applied to the displacements. The shift is applied after the scale, i.e. x = scale*y + shift. Default: 0
- `double = obj.GetDisplacementShift ()` - Set a shift to be applied to the displacements. The shift is applied after the scale, i.e. x = scale*y + shift. Default: 0
- `obj.SetInterpolationMode (int mode)` - Set interpolation mode for sampling the grid. Higher-order interpolation allows you to use a sparser grid. Default: Linear.
- `int = obj.GetInterpolationMode ()` - Set interpolation mode for sampling the grid. Higher-order interpolation allows you to use a sparser grid. Default: Linear.
- `obj.SetInterpolationModeToNearestNeighbor ()` - Set interpolation mode for sampling the grid. Higher-order interpolation allows you to use a sparser grid. Default: Linear.
- `obj.SetInterpolationModeToLinear ()` - Set interpolation mode for sampling the grid. Higher-order interpolation allows you to use a sparser grid. Default: Linear.
- `obj.SetInterpolationModeToCubic ()` - Set interpolation mode for sampling the grid. Higher-order interpolation allows you to use a sparser grid. Default: Linear.

- `string = obj.GetInterpolationModeAsString ()` - Set interpolation mode for sampling the grid. Higher-order interpolation allows you to use a sparser grid. Default: Linear.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.
- `long = obj.GetMTime ()` - Get the MTime.

34.21 vtkImageDataLIC2D

34.21.1 Usage

GPU implementation of a Line Integral Convolution, a technique for imaging vector fields.

The input on port 0 is an vtkImageData with extents of a 2D image. It needs a vector field on point data. Port 1 is a special port for customized noise input. It is an optional port. If not present, noise is generated by the filter. Even if none-power-of-two texture are supported, giving a power-of-two image may result in faster execution on the GPU. If noise input is not specified, then the filter using vtkImageNoiseSource to generate a 128x128 noise texture. This filter only works on point vectors. One can use a vtkCellDataToPointData filter to convert cell vectors to point vectors.

.SECTION Required OpenGL Extensins GL_ARB_texture_non_power_of_two GL_VERSION_2_0 GL_ARB_texture_float GL_ARB_draw_buffers GL_EXT_framebuffer_object GL_ARB_pixel_buffer_object

To create an instance of class vtkImageDataLIC2D, simply invoke its constructor as follows

```
obj = vtkImageDataLIC2D
```

34.21.2 Methods

The class vtkImageDataLIC2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDataLIC2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDataLIC2D = obj.NewInstance ()`
- `vtkImageDataLIC2D = obj.SafeDownCast (vtkObject o)`
- `int = obj.SetContext (vtkRenderWindow context)` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions. Return 0 upon failure and 1 upon success.
- `vtkRenderWindow = obj.GetContext ()` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions. Return 0 upon failure and 1 upon success.
- `obj.SetSteps (int )` - Number of steps. Initial value is 20. class invariant: Steps¿0. In term of visual quality, the greater the better.
- `int = obj.GetSteps ()` - Number of steps. Initial value is 20. class invariant: Steps¿0. In term of visual quality, the greater the better.
- `obj.SetStepSize (double )` - Step size. Specify the step size as a unit of the cell length of the input vector field. Cell lenghth is the length of the diagonal of a cell. Initial value is 1.0. class invariant: StepSize¿0.0. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is double but GPU only supports float. This value will be converted to float in the execution of the algorithm.

- `double = obj.GetStepSizeMinValue ()` - Step size. Specify the step size as a unit of the cell length of the input vector field. Cell lenghth is the length of the diagonal of a cell. Initial value is 1.0. class invariant: StepSize¿0.0. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is double but GPU only supports float. This value will be converted to float in the execution of the algorithm.
- `double = obj.GetStepSizeMaxValue ()` - Step size. Specify the step size as a unit of the cell length of the input vector field. Cell lenghth is the length of the diagonal of a cell. Initial value is 1.0. class invariant: StepSize¿0.0. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is double but GPU only supports float. This value will be converted to float in the execution of the algorithm.
- `double = obj.GetStepSize ()` - Step size. Specify the step size as a unit of the cell length of the input vector field. Cell lenghth is the length of the diagonal of a cell. Initial value is 1.0. class invariant: StepSize¿0.0. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is double but GPU only supports float. This value will be converted to float in the execution of the algorithm.
- `obj.SetMagnification (int )` - The the magnification factor. Default is 1
- `int = obj.GetMagnificationMinValue ()` - The the magnification factor. Default is 1
- `int = obj.GetMagnificationMaxValue ()` - The the magnification factor. Default is 1
- `int = obj.GetMagnification ()` - The the magnification factor. Default is 1
- `int = obj.GetOpenGLExtensionsSupported ()` - Check if the required OpenGL extensions / GPU are supported.
- `int = obj.GetFBOSuccess ()` - Check if LIC runs properly.
- `int = obj.GetLICSuccess ()`
- `obj.TranslateInputExtent (int inExt, int inWholeExtent, int outExt)`

34.22 vtkImageDataLIC2DExtentTranslator

34.22.1 Usage

To create an instance of class vtkImageDataLIC2DExtentTranslator, simply invoke its constructor as follows

```
obj = vtkImageDataLIC2DExtentTranslator
```

34.22.2 Methods

The class vtkImageDataLIC2DExtentTranslator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDataLIC2DExtentTranslator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDataLIC2DExtentTranslator = obj.NewInstance ()`
- `vtkImageDataLIC2DExtentTranslator = obj.SafeDownCast (vtkObject o)`
- `obj.SetAlgorithm (vtkImageDataLIC2D )` - Set the vtkImageDataLIC2D algorithm for which this extent translator is being used.

- `vtkImageDataLIC2D = obj.GetAlgorithm ()` - Set the vtkImageDataLIC2D algorithm for which this extent translator is being used.
- `obj.SetInputExtentTranslator (vtkExtentTranslator )`
- `vtkExtentTranslator = obj.GetInputExtentTranslator ()`
- `obj.SetInputWholeExtent (int , int , int , int , int , int )`
- `obj.SetInputWholeExtent (int  a[6])`
- `int = obj. GetInputWholeExtent ()`
- `int = obj.PieceToExtentThreadSafe (int piece, int numPieces, int ghostLevel, int wholeExtent, int r`

34.23 vtkImageToPolyDataFilter

34.23.1 Usage

vtkImageToPolyDataFilter converts raster data (i.e., an image) into polygonal data (i.e., quads or n-sided polygons), with each polygon assigned a constant color. This is useful for writers that generate vector formats (i.e., CGM or PostScript). To use this filter, you specify how to quantize the color (or whether to use an image with a lookup table), and what style the output should be. The output is always polygons, but the choice is n x m quads (where n and m define the input image dimensions) "Pixelize" option; arbitrary polygons "Polygonalize" option; or variable number of quads of constant color generated along scan lines "RunLength" option.

The algorithm quantizes color in order to create coherent regions that the polygons can represent with good compression. By default, the input image is quantized to 256 colors using a 3-3-2 bits for red-green-blue. However, you can also supply a single component image and a lookup table, with the single component assumed to be an index into the table. (Note: a quantized image can be generated with the filter vtkImageQuantizeRGBToIndex.) The number of colors on output is equal to the number of colors in the input lookup table (or 256 if the built in linear ramp is used).

The output of the filter is polygons with a single color per polygon cell. If the output style is set to "Polygonalize", the polygons may have an large number of points (bounded by something like 2*(n+m)); and the polygon may not be convex which may cause rendering problems on some systems (use vtkTriangleFilter). Otherwise, each polygon will have four vertices. The output also contains scalar data defining RGB color in unsigned char form.

To create an instance of class vtkImageToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkImageToPolyDataFilter
```

34.23.2 Methods

The class vtkImageToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageToPolyDataFilter = obj.NewInstance ()`
- `vtkImageToPolyDataFilter = obj.SafeDownCast (vtkObject o)`

- `obj.SetOutputStyle (int )` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `int = obj.GetOutputStyleMinValue ()` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `int = obj.GetOutputStyleMaxValue ()` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `int = obj.GetOutputStyle ()` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `obj.SetOutputStyleToPixelize ()` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `obj.SetOutputStyleToPolygonalize ()` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `obj.SetOutputStyleToRunLength ()` - Specify how to create the output. Pixelize means converting the image to quad polygons with a constant color per quad. Polygonalize means merging colors together into polygonal regions, and then smoothing the regions (if smoothing is turned on). RunLength means creating quad polygons that may encompass several pixels on a scan line. The default behavior is Polygonalize.

- `obj.SetColorMode (int )` - Specify how to quantize color.

- `int = obj.GetColorModeMinValue ()` - Specify how to quantize color.

- `int = obj.GetColorModeMaxValue ()` - Specify how to quantize color.

- `int = obj.GetColorMode ()` - Specify how to quantize color.

- `obj.SetColorModeToLUT ()` - Specify how to quantize color.

- `obj.SetColorModeToLinear256 ()` - Specify how to quantize color.

- `obj.SetLookupTable (vtkScalarsToColors )` - Set/Get the vtkLookupTable to use. The lookup table is used when the color mode is set to LUT and a single component scalar is input.

- `vtkScalarsToColors = obj.GetLookupTable ()` - Set/Get the vtkLookupTable to use. The lookup table is used when the color mode is set to LUT and a single component scalar is input.

- `obj.SetSmoothing (int )` - If the output style is set to polygonalize, then you can control whether to smooth boundaries.
- `int = obj.GetSmoothing ()` - If the output style is set to polygonalize, then you can control whether to smooth boundaries.
- `obj.SmoothingOn ()` - If the output style is set to polygonalize, then you can control whether to smooth boundaries.
- `obj.SmoothingOff ()` - If the output style is set to polygonalize, then you can control whether to smooth boundaries.
- `obj.SetNumberOfSmoothingIterations (int )` - Specify the number of smoothing iterations to smooth polygons. (Only in effect if output style is Polygonalize and smoothing is on.)
- `int = obj.GetNumberOfSmoothingIterationsMinValue ()` - Specify the number of smoothing iterations to smooth polygons. (Only in effect if output style is Polygonalize and smoothing is on.)
- `int = obj.GetNumberOfSmoothingIterationsMaxValue ()` - Specify the number of smoothing iterations to smooth polygons. (Only in effect if output style is Polygonalize and smoothing is on.)
- `int = obj.GetNumberOfSmoothingIterations ()` - Specify the number of smoothing iterations to smooth polygons. (Only in effect if output style is Polygonalize and smoothing is on.)
- `obj.SetDecimation (int )` - Turn on/off whether the final polygons should be decimated. whether to smooth boundaries.
- `int = obj.GetDecimation ()` - Turn on/off whether the final polygons should be decimated. whether to smooth boundaries.
- `obj.DecimationOn ()` - Turn on/off whether the final polygons should be decimated. whether to smooth boundaries.
- `obj.DecimationOff ()` - Turn on/off whether the final polygons should be decimated. whether to smooth boundaries.
- `obj.SetDecimationError (double )` - Specify the error to use for decimation (if decimation is on). The error is an absolute number–the image spacing and dimensions are used to create points so the error should be consistent with the image size.
- `double = obj.GetDecimationErrorMinValue ()` - Specify the error to use for decimation (if decimation is on). The error is an absolute number–the image spacing and dimensions are used to create points so the error should be consistent with the image size.
- `double = obj.GetDecimationErrorMaxValue ()` - Specify the error to use for decimation (if decimation is on). The error is an absolute number–the image spacing and dimensions are used to create points so the error should be consistent with the image size.
- `double = obj.GetDecimationError ()` - Specify the error to use for decimation (if decimation is on). The error is an absolute number–the image spacing and dimensions are used to create points so the error should be consistent with the image size.
- `obj.SetError (int )` - Specify the error value between two colors where the colors are considered the same. Only use this if the color mode uses the default 256 table.
- `int = obj.GetErrorMinValue ()` - Specify the error value between two colors where the colors are considered the same. Only use this if the color mode uses the default 256 table.
- `int = obj.GetErrorMaxValue ()` - Specify the error value between two colors where the colors are considered the same. Only use this if the color mode uses the default 256 table.

- `int = obj.GetError ()` - Specify the error value between two colors where the colors are considered the same. Only use this if the color mode uses the default 256 table.

- `obj.SetSubImageSize (int )` - Specify the size (n by n pixels) of the largest region to polygonalize. When the OutputStyle is set to VTK_STYLE_POLYGONALIZE, large amounts of memory are used. In order to process large images, the image is broken into pieces that are at most Size pixels in width and height.

- `int = obj.GetSubImageSizeMinValue ()` - Specify the size (n by n pixels) of the largest region to polygonalize. When the OutputStyle is set to VTK_STYLE_POLYGONALIZE, large amounts of memory are used. In order to process large images, the image is broken into pieces that are at most Size pixels in width and height.

- `int = obj.GetSubImageSizeMaxValue ()` - Specify the size (n by n pixels) of the largest region to polygonalize. When the OutputStyle is set to VTK_STYLE_POLYGONALIZE, large amounts of memory are used. In order to process large images, the image is broken into pieces that are at most Size pixels in width and height.

- `int = obj.GetSubImageSize ()` - Specify the size (n by n pixels) of the largest region to polygonalize. When the OutputStyle is set to VTK_STYLE_POLYGONALIZE, large amounts of memory are used. In order to process large images, the image is broken into pieces that are at most Size pixels in width and height.

34.24 vtkImplicitModeller

34.24.1 Usage

vtkImplicitModeller is a filter that computes the distance from the input geometry to the points of an output structured point set. This distance function can then be "contoured" to generate new, offset surfaces from the original geometry. An important feature of this object is "capping". If capping is turned on, after the implicit model is created, the values on the boundary of the structured points dataset are set to the cap value. This is used to force closure of the resulting contoured surface. Note, however, that large cap values can generate weird surface normals in those cells adjacent to the boundary of the dataset. Using smaller cap value will reduce this effect. ¡P¿ Another important ivar is MaximumDistance. This controls how far into the volume the distance function is computed from the input geometry. Small values give significant increases in performance. However, there can strange sampling effects at the extreme range of the MaximumDistance. ¡P¿ In order to properly execute and sample the input data, a rectangular region in space must be defined (this is the ivar ModelBounds). If not explicitly defined, the model bounds will be computed. Note that to avoid boundary effects, it is possible to adjust the model bounds (i.e., using the AdjustBounds and AdjustDistance ivars) to strictly contain the sampled data. ¡P¿ This filter has one other unusual capability: it is possible to append data in a sequence of operations to generate a single output. This is useful when you have multiple datasets and want to create a conglomeration of all the data. However, the user must be careful to either specify the ModelBounds or specify the first item such that its bounds completely contain all other items. This is because the rectangular region of the output can not be changed after the 1st Append. ¡P¿ The ProcessMode ivar controls the method used within the Append function (where the actual work is done regardless if the Append function is explicitly called) to compute the implicit model. If set to work in voxel mode, each voxel is visited once. If set to cell mode, each cell is visited once. Tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode. Also, if explicitly using the Append feature many times, the cell mode will probably be better because each voxel will be visited each Append. Append the data before input if possible when using the voxel mode. Do not switch between voxel and cell mode between execution of StartAppend and EndAppend. ¡P¿ Further performance improvement is now possible using the PerVoxel process mode on multi-processor machines (the mode is now multithreaded). Each thread processes a different "slab" of the output. Also, if the input is vtkPolyData, it is appropriately clipped for each thread; that is, each thread

only considers the input which could affect its slab of the output. ¡P¿ This filter can now produce output of any type supported by vtkImageData. However to support this change, additional sqrts must be executed during the Append step. Previously, the output was initialized to the squared CapValue in StartAppend, the output was updated with squared distance values during the Append, and then the sqrt of the distances was computed in EndAppend. To support different scalar types in the output (largely to reduce memory requirements as an vtkImageShiftScale and/or vtkImageCast could have achieved the same result), we can't "afford" to save squared value in the output, because then we could only represent up to the sqrt of the scalar max for an integer type in the output; 1 (instead of 255) for an unsigned char; 11 for a char (instead of 127). Thus this change may result in a minor performance degradation. Non-float output types can be scaled to the CapValue by turning ScaleToMaximumDistance On.

To create an instance of class vtkImplicitModeller, simply invoke its constructor as follows

```
obj = vtkImplicitModeller
```

34.24.2 Methods

The class vtkImplicitModeller has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitModeller class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitModeller = obj.NewInstance ()`
- `vtkImplicitModeller = obj.SafeDownCast (vtkObject o)`
- `double = obj.ComputeModelBounds (vtkDataSet inputNULL)` - Compute ModelBounds from input geometry. If input is not specified, the input of the filter will be used.
- `int = obj. GetSampleDimensions ()` - Set/Get the i-j-k dimensions on which to sample distance function.
- `obj.SetSampleDimensions (int i, int j, int k)` - Set/Get the i-j-k dimensions on which to sample distance function.
- `obj.SetSampleDimensions (int dim[3])` - Set/Get the i-j-k dimensions on which to sample distance function.
- `obj.SetMaximumDistance (double )` - Set / get the distance away from surface of input geometry to sample. Smaller values make large increases in performance.
- `double = obj.GetMaximumDistanceMinValue ()` - Set / get the distance away from surface of input geometry to sample. Smaller values make large increases in performance.
- `double = obj.GetMaximumDistanceMaxValue ()` - Set / get the distance away from surface of input geometry to sample. Smaller values make large increases in performance.
- `double = obj.GetMaximumDistance ()` - Set / get the distance away from surface of input geometry to sample. Smaller values make large increases in performance.
- `obj.SetModelBounds (double , double , double , double , double , double )` - Set / get the region in space in which to perform the sampling. If not specified, it will be computed automatically.
- `obj.SetModelBounds (double a[6])` - Set / get the region in space in which to perform the sampling. If not specified, it will be computed automatically.

- `double = obj. GetModelBounds ()` - Set / get the region in space in which to perform the sampling. If not specified, it will be computed automatically.
- `obj.SetAdjustBounds (int )` - Control how the model bounds are computed. If the ivar AdjustBounds is set, then the bounds specified (or computed automatically) is modified by the fraction given by AdjustDistance. This means that the model bounds is expanded in each of the x-y-z directions.
- `int = obj.GetAdjustBounds ()` - Control how the model bounds are computed. If the ivar AdjustBounds is set, then the bounds specified (or computed automatically) is modified by the fraction given by AdjustDistance. This means that the model bounds is expanded in each of the x-y-z directions.
- `obj.AdjustBoundsOn ()` - Control how the model bounds are computed. If the ivar AdjustBounds is set, then the bounds specified (or computed automatically) is modified by the fraction given by AdjustDistance. This means that the model bounds is expanded in each of the x-y-z directions.
- `obj.AdjustBoundsOff ()` - Control how the model bounds are computed. If the ivar AdjustBounds is set, then the bounds specified (or computed automatically) is modified by the fraction given by AdjustDistance. This means that the model bounds is expanded in each of the x-y-z directions.
- `obj.SetAdjustDistance (double )` - Specify the amount to grow the model bounds (if the ivar AdjustBounds is set). The value is a fraction of the maximum length of the sides of the box specified by the model bounds.
- `double = obj.GetAdjustDistanceMinValue ()` - Specify the amount to grow the model bounds (if the ivar AdjustBounds is set). The value is a fraction of the maximum length of the sides of the box specified by the model bounds.
- `double = obj.GetAdjustDistanceMaxValue ()` - Specify the amount to grow the model bounds (if the ivar AdjustBounds is set). The value is a fraction of the maximum length of the sides of the box specified by the model bounds.
- `double = obj.GetAdjustDistance ()` - Specify the amount to grow the model bounds (if the ivar AdjustBounds is set). The value is a fraction of the maximum length of the sides of the box specified by the model bounds.
- `obj.SetCapping (int )` - The outer boundary of the structured point set can be assigned a particular value. This can be used to close or "cap" all surfaces.
- `int = obj.GetCapping ()` - The outer boundary of the structured point set can be assigned a particular value. This can be used to close or "cap" all surfaces.
- `obj.CappingOn ()` - The outer boundary of the structured point set can be assigned a particular value. This can be used to close or "cap" all surfaces.
- `obj.CappingOff ()` - The outer boundary of the structured point set can be assigned a particular value. This can be used to close or "cap" all surfaces.
- `obj.SetCapValue (double value)` - Specify the capping value to use. The CapValue is also used as an initial distance value at each point in the dataset.
- `double = obj.GetCapValue ()` - Specify the capping value to use. The CapValue is also used as an initial distance value at each point in the dataset.
- `obj.SetScaleToMaximumDistance (int )` - If a non-floating output type is specified, the output distances can be scaled to use the entire positive scalar range of the output type specified (up to the CapValue which is equal to the max for the type unless modified by the user). For example, if ScaleToMaximumDistance is On and the OutputScalarType is UnsignedChar the distances saved in the output would be linearly scaled between 0 (for distances "very close" to the surface) and 255 (at the specifed maximum distance)... assuming the CapValue is not changed from 255.

- `int = obj.GetScaleToMaximumDistance ()` - If a non-floating output type is specified, the output distances can be scaled to use the entire positive scalar range of the output type specified (up to the CapValue which is equal to the max for the type unless modified by the user). For example, if ScaleToMaximumDistance is On and the OutputScalarType is UnsignedChar the distances saved in the output would be linearly scaled between 0 (for distances "very close" to the surface) and 255 (at the specifed maximum distance)... assuming the CapValue is not changed from 255.

- `obj.ScaleToMaximumDistanceOn ()` - If a non-floating output type is specified, the output distances can be scaled to use the entire positive scalar range of the output type specified (up to the CapValue which is equal to the max for the type unless modified by the user). For example, if ScaleToMaximumDistance is On and the OutputScalarType is UnsignedChar the distances saved in the output would be linearly scaled between 0 (for distances "very close" to the surface) and 255 (at the specifed maximum distance)... assuming the CapValue is not changed from 255.

- `obj.ScaleToMaximumDistanceOff ()` - If a non-floating output type is specified, the output distances can be scaled to use the entire positive scalar range of the output type specified (up to the CapValue which is equal to the max for the type unless modified by the user). For example, if ScaleToMaximumDistance is On and the OutputScalarType is UnsignedChar the distances saved in the output would be linearly scaled between 0 (for distances "very close" to the surface) and 255 (at the specifed maximum distance)... assuming the CapValue is not changed from 255.

- `obj.SetProcessMode (int )` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `int = obj.GetProcessModeMinValue ()` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `int = obj.GetProcessModeMaxValue ()` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `int = obj.GetProcessMode ()` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `obj.SetProcessModeToPerVoxel ()` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `obj.SetProcessModeToPerCell ()` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `string = obj.GetProcessModeAsString (void )` - Specify whether to visit each cell once per append or each voxel once per append. Some tests have shown once per voxel to be faster when there are a lot of cells (at least a thousand?); relative performance improvement increases with addition cells. Primitives should not be stripped for best performance of the voxel mode.

- `obj.SetLocatorMaxLevel (int )` - Specify the level of the locator to use when using the per voxel process mode.

- `int = obj.GetLocatorMaxLevel ()` - Specify the level of the locator to use when using the per voxel process mode.
- `obj.SetNumberOfThreads (int )` - Set / Get the number of threads used during Per-Voxel processing mode
- `int = obj.GetNumberOfThreadsMinValue ()` - Set / Get the number of threads used during Per-Voxel processing mode
- `int = obj.GetNumberOfThreadsMaxValue ()` - Set / Get the number of threads used during Per-Voxel processing mode
- `int = obj.GetNumberOfThreads ()` - Set / Get the number of threads used during Per-Voxel processing mode
- `obj.SetOutputScalarType (int type)` - Set the desired output scalar type.
- `int = obj.GetOutputScalarType ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToFloat ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToDouble ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToInt ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToLong ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToShort ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToUnsignedChar ()` - Set the desired output scalar type.
- `obj.SetOutputScalarTypeToChar ()` - Set the desired output scalar type.
- `obj.StartAppend ()` - Initialize the filter for appending data. You must invoke the StartAppend() method before doing successive Appends(). It's also a good idea to manually specify the model bounds; otherwise the input bounds for the data will be used.
- `obj.Append (vtkDataSet input)` - Append a data set to the existing output. To use this function, you'll have to invoke the StartAppend() method before doing successive appends. It's also a good idea to specify the model bounds; otherwise the input model bounds is used. When you've finished appending, use the EndAppend() method.
- `obj.EndAppend ()` - Method completes the append process.

34.25 vtkIterativeClosestPointTransform

34.25.1 Usage

Match two surfaces using the iterative closest point (ICP) algorithm. The core of the algorithm is to match each vertex in one surface with the closest surface point on the other, then apply the transformation that modify one surface to best match the other (in a least square sense). This has to be iterated to get proper convergence of the surfaces. .SECTION Note Use vtkTransformPolyDataFilter to apply the resulting ICP transform to your data. You might also set it to your actor's user transform. .SECTION Note This class makes use of vtkLandmarkTransform internally to compute the best fit. Use the GetLandmarkTransform

member to get a pointer to that transform and set its parameters. You might, for example, constrain the number of degrees of freedom of the solution (i.e. rigid body, similarity, etc.) by checking the vtkLandmarkTransform documentation for its SetMode member.

To create an instance of class vtkIterativeClosestPointTransform, simply invoke its constructor as follows

```
obj = vtkIterativeClosestPointTransform
```

34.25.2 Methods

The class vtkIterativeClosestPointTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIterativeClosestPointTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIterativeClosestPointTransform = obj.NewInstance ()`
- `vtkIterativeClosestPointTransform = obj.SafeDownCast (vtkObject o)`
- `obj.SetSource (vtkDataSet source)` - Specify the source and target data sets.
- `obj.SetTarget (vtkDataSet target)` - Specify the source and target data sets.
- `vtkDataSet = obj.GetSource ()` - Specify the source and target data sets.
- `vtkDataSet = obj.GetTarget ()` - Specify the source and target data sets.
- `obj.SetLocator (vtkCellLocator locator)` - Set/Get a spatial locator for speeding up the search process. An instance of vtkCellLocator is used by default.
- `vtkCellLocator = obj.GetLocator ()` - Set/Get a spatial locator for speeding up the search process. An instance of vtkCellLocator is used by default.
- `obj.SetMaximumNumberOfIterations (int )` - Set/Get the maximum number of iterations. Default is 50.
- `int = obj.GetMaximumNumberOfIterations ()` - Set/Get the maximum number of iterations. Default is 50.
- `int = obj.GetNumberOfIterations ()` - Get the number of iterations since the last update
- `obj.SetCheckMeanDistance (int )` - Force the algorithm to check the mean distance between two iterations. Default is Off.
- `int = obj.GetCheckMeanDistance ()` - Force the algorithm to check the mean distance between two iterations. Default is Off.
- `obj.CheckMeanDistanceOn ()` - Force the algorithm to check the mean distance between two iterations. Default is Off.
- `obj.CheckMeanDistanceOff ()` - Force the algorithm to check the mean distance between two iterations. Default is Off.
- `obj.SetMeanDistanceMode (int )` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS

- `int = obj.GetMeanDistanceModeMinValue ()` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS
- `int = obj.GetMeanDistanceModeMaxValue ()` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS
- `int = obj.GetMeanDistanceMode ()` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS
- `obj.SetMeanDistanceModeToRMS ()` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS
- `obj.SetMeanDistanceModeToAbsoluteValue ()` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS
- `string = obj.GetMeanDistanceModeAsString ()` - Specify the mean distance mode. This mode expresses how the mean distance is computed. The RMS mode is the square root of the average of the sum of squares of the closest point distances. The Absolute Value mode is the mean of the sum of absolute values of the closest point distances. The default is VTK_ICP_MODE_RMS
- `obj.SetMaximumMeanDistance (double )` - Set/Get the maximum mean distance between two iteration. If the mean distance is lower than this, the convergence stops. The default is 0.01.
- `double = obj.GetMaximumMeanDistance ()` - Set/Get the maximum mean distance between two iteration. If the mean distance is lower than this, the convergence stops. The default is 0.01.
- `double = obj.GetMeanDistance ()` - Get the mean distance between the last two iterations.
- `obj.SetMaximumNumberOfLandmarks (int )` - Set/Get the maximum number of landmarks sampled in your dataset. If your dataset is dense, then you will typically not need all the points to compute the ICP transform. The default is 200.
- `int = obj.GetMaximumNumberOfLandmarks ()` - Set/Get the maximum number of landmarks sampled in your dataset. If your dataset is dense, then you will typically not need all the points to compute the ICP transform. The default is 200.
- `obj.SetStartByMatchingCentroids (int )` - Starts the process by translating source centroid to target centroid. The default is Off.
- `int = obj.GetStartByMatchingCentroids ()` - Starts the process by translating source centroid to target centroid. The default is Off.
- `obj.StartByMatchingCentroidsOn ()` - Starts the process by translating source centroid to target centroid. The default is Off.
- `obj.StartByMatchingCentroidsOff ()` - Starts the process by translating source centroid to target centroid. The default is Off.
- `vtkLandmarkTransform = obj.GetLandmarkTransform ()` - Get the internal landmark transform. Use it to constrain the number of degrees of freedom of the solution (i.e. rigid body, similarity, etc.).

- `obj.Inverse ()` - Invert the transformation. This is done by switching the source and target.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

34.26 vtkLandmarkTransform

34.26.1 Usage

A vtkLandmarkTransform is defined by two sets of landmarks, the transform computed gives the best fit mapping one onto the other, in a least squares sense. The indices are taken to correspond, so point 1 in the first set will get mapped close to point 1 in the second set, etc. Call SetSourceLandmarks and SetTargetLandmarks to specify the two sets of landmarks, ensure they have the same number of points.

To create an instance of class vtkLandmarkTransform, simply invoke its constructor as follows

```
obj = vtkLandmarkTransform
```

34.26.2 Methods

The class vtkLandmarkTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLandmarkTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLandmarkTransform = obj.NewInstance ()`
- `vtkLandmarkTransform = obj.SafeDownCast (vtkObject o)`
- `obj.SetSourceLandmarks (vtkPoints points)` - Specify the source and target landmark sets. The two sets must have the same number of points. If you add or change points in these objects, you must call Modified() on them or the transformation might not update.
- `obj.SetTargetLandmarks (vtkPoints points)` - Specify the source and target landmark sets. The two sets must have the same number of points. If you add or change points in these objects, you must call Modified() on them or the transformation might not update.
- `vtkPoints = obj.GetSourceLandmarks ()` - Specify the source and target landmark sets. The two sets must have the same number of points. If you add or change points in these objects, you must call Modified() on them or the transformation might not update.
- `vtkPoints = obj.GetTargetLandmarks ()` - Specify the source and target landmark sets. The two sets must have the same number of points. If you add or change points in these objects, you must call Modified() on them or the transformation might not update.
- `obj.SetMode (int )` - Set the number of degrees of freedom to constrain the solution to. Rigidbody (VTK_LANDMARK_RIGIDBODY): rotation and translation only. Similarity (VTK_LANDMARK_SIMILARITY): rotation, translation and isotropic scaling. Affine (VTK_LANDMARK_AFFINE): collinearity is preserved. Ratios of distances along a line are preserved. The default is similarity.
- `obj.SetModeToRigidBody ()` - Set the number of degrees of freedom to constrain the solution to. Rigidbody (VTK_LANDMARK_RIGIDBODY): rotation and translation only. Similarity (VTK_LANDMARK_SIMILA rotation, translation and isotropic scaling. Affine (VTK_LANDMARK_AFFINE): collinearity is preserved. Ratios of distances along a line are preserved. The default is similarity.

- `obj.SetModeToSimilarity ()` - Set the number of degrees of freedom to constrain the solution to. Rigidbody (VTK_LANDMARK_RIGIDBODY): rotation and translation only. Similarity (VTK_LANDMARK_SIMILA rotation, translation and isotropic scaling. Affine (VTK_LANDMARK_AFFINE): collinearity is preserved. Ratios of distances along a line are preserved. The default is similarity.

- `obj.SetModeToAffine ()` - Set the number of degrees of freedom to constrain the solution to. Rigidbody (VTK_LANDMARK_RIGIDBODY): rotation and translation only. Similarity (VTK_LANDMARK_SIMILARITY rotation, translation and isotropic scaling. Affine (VTK_LANDMARK_AFFINE): collinearity is preserved. Ratios of distances along a line are preserved. The default is similarity.

- `int = obj.GetMode ()` - Get the current transformation mode.

- `string = obj.GetModeAsString ()` - Get the current transformation mode.

- `obj.Inverse ()` - Invert the transformation. This is done by switching the source and target landmarks.

- `long = obj.GetMTime ()` - Get the MTime.

- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

34.27 vtkLegendBoxActor

34.27.1 Usage

vtkLegendBoxActor is used to associate a symbol with a text string. The user specifies a vtkPolyData to use as the symbol, and a string associated with the symbol. The actor can then be placed in the scene in the same way that any other vtkActor2D can be used.

To use this class, you must define the position of the legend box by using the superclasses' vtkActor2D::Position coordinate and Position2 coordinate. Then define the set of symbols and text strings that make up the menu box. The font attributes of the entries can be set through the vtkTextProperty associated to this actor. The class will scale the symbols and text to fit in the legend box defined by (Position,Position2). Optional features like turning on a border line and setting the spacing between the border and the symbols/text can also be set.

To create an instance of class vtkLegendBoxActor, simply invoke its constructor as follows

```
obj = vtkLegendBoxActor
```

34.27.2 Methods

The class vtkLegendBoxActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLegendBoxActor class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkLegendBoxActor = obj.NewInstance ()`

- `vtkLegendBoxActor = obj.SafeDownCast (vtkObject o)`

- `obj.SetNumberOfEntries (int num)` - Specify the number of entries in the legend box.

- `int = obj.GetNumberOfEntries ()` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `obj.SetEntry (int i, vtkPolyData symbol, string string, double color[3])` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `obj.SetEntrySymbol (int i, vtkPolyData symbol)` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `obj.SetEntryString (int i, string string)` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `obj.SetEntryColor (int i, double color[3])` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `obj.SetEntryColor (int i, double r, double g, double b)` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `vtkPolyData = obj.GetEntrySymbol (int i)` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `string = obj.GetEntryString (int i)` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)

- `double = obj.GetEntryColor (int i)` - Add an entry to the legend box. You must supply a vtkPolyData to be used as a symbol (it can be NULL) and a text string (which also can be NULL). The vtkPolyData is assumed to be defined in the x-y plane, and the text is assumed to be a single line in height. Note that when this method is invoked previous entries are deleted. Also supply a text string and optionally a color. (If a color is not specified, then the entry color is the same as this actor's color.) (Note: use the set methods when you use SetNumberOfEntries().)
- `obj.SetEntryTextProperty (vtkTextProperty p)` - Set/Get the text property.
- `vtkTextProperty = obj.GetEntryTextProperty ()` - Set/Get the text property.
- `obj.SetBorder (int )` - Set/Get the flag that controls whether a border will be drawn around the legend box.
- `int = obj.GetBorder ()` - Set/Get the flag that controls whether a border will be drawn around the legend box.
- `obj.BorderOn ()` - Set/Get the flag that controls whether a border will be drawn around the legend box.
- `obj.BorderOff ()` - Set/Get the flag that controls whether a border will be drawn around the legend box.
- `obj.SetLockBorder (int )` - Set/Get the flag that controls whether the border and legend placement is locked into the rectangle defined by (Position,Position2). If off, then the legend box will adjust its size so that the border fits nicely around the text and symbols. (The ivar is off by default.) Note: the legend box is guaranteed to lie within the original border definition.
- `int = obj.GetLockBorder ()` - Set/Get the flag that controls whether the border and legend placement is locked into the rectangle defined by (Position,Position2). If off, then the legend box will adjust its size so that the border fits nicely around the text and symbols. (The ivar is off by default.) Note: the legend box is guaranteed to lie within the original border definition.
- `obj.LockBorderOn ()` - Set/Get the flag that controls whether the border and legend placement is locked into the rectangle defined by (Position,Position2). If off, then the legend box will adjust its size so that the border fits nicely around the text and symbols. (The ivar is off by default.) Note: the legend box is guaranteed to lie within the original border definition.
- `obj.LockBorderOff ()` - Set/Get the flag that controls whether the border and legend placement is locked into the rectangle defined by (Position,Position2). If off, then the legend box will adjust its size so that the border fits nicely around the text and symbols. (The ivar is off by default.) Note: the legend box is guaranteed to lie within the original border definition.
- `obj.SetBox (int )` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `int = obj.GetBox ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `obj.BoxOn ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `obj.BoxOff ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `vtkProperty2D = obj.GetBoxProperty ()` - Get the box vtkProperty2D.
- `obj.SetPadding (int )` - Set/Get the padding between the legend entries and the border. The value is specified in pixels.

- `int = obj.GetPaddingMinValue ()` - Set/Get the padding between the legend entries and the border. The value is specified in pixels.
- `int = obj.GetPaddingMaxValue ()` - Set/Get the padding between the legend entries and the border. The value is specified in pixels.
- `int = obj.GetPadding ()` - Set/Get the padding between the legend entries and the border. The value is specified in pixels.
- `obj.SetScalarVisibility (int )` - Turn on/off flag to control whether the symbol's scalar data is used to color the symbol. If off, the color of the vtkLegendBoxActor is used.
- `int = obj.GetScalarVisibility ()` - Turn on/off flag to control whether the symbol's scalar data is used to color the symbol. If off, the color of the vtkLegendBoxActor is used.
- `obj.ScalarVisibilityOn ()` - Turn on/off flag to control whether the symbol's scalar data is used to color the symbol. If off, the color of the vtkLegendBoxActor is used.
- `obj.ScalarVisibilityOff ()` - Turn on/off flag to control whether the symbol's scalar data is used to color the symbol. If off, the color of the vtkLegendBoxActor is used.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this scaled text actor. Overloads the virtual vtkProp method.

34.28 vtkLegendScaleActor

34.28.1 Usage

This class is used to annotate the render window. Its basic goal is to provide an indication of the scale of the scene. Four axes surrounding the render window indicate (in a variety of ways) the scale of what the camera is viewing. An option also exists for displaying a scale legend.

The axes can be programmed either to display distance scales or x-y coordinate values. By default, the scales display a distance. However, if you know that the view is down the z-axis, the scales can be programmed to display x-y coordinate values.

To create an instance of class vtkLegendScaleActor, simply invoke its constructor as follows

```
obj = vtkLegendScaleActor
```

34.28.2 Methods

The class vtkLegendScaleActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLegendScaleActor class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkLegendScaleActor = obj.NewInstance ()` - Standard methods for the class.
- `vtkLegendScaleActor = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `obj.SetLabelMode (int )` - Specify the mode for labeling the scale axes. By default, the axes are labeled with the distance between points (centered at a distance of 0.0). Alternatively if you know that the view is down the z-axis; the axes can be labeled with x-y coordinate values.
- `int = obj.GetLabelModeMinValue ()` - Specify the mode for labeling the scale axes. By default, the axes are labeled with the distance between points (centered at a distance of 0.0). Alternatively if you know that the view is down the z-axis; the axes can be labeled with x-y coordinate values.

- `int = obj.GetLabelModeMaxValue ()` - Specify the mode for labeling the scale axes. By default, the axes are labeled with the distance between points (centered at a distance of 0.0). Alternatively if you know that the view is down the z-axis; the axes can be labeled with x-y coordinate values.
- `int = obj.GetLabelMode ()` - Specify the mode for labeling the scale axes. By default, the axes are labeled with the distance between points (centered at a distance of 0.0). Alternatively if you know that the view is down the z-axis; the axes can be labeled with x-y coordinate values.
- `obj.SetLabelModeToDistance ()` - Specify the mode for labeling the scale axes. By default, the axes are labeled with the distance between points (centered at a distance of 0.0). Alternatively if you know that the view is down the z-axis; the axes can be labeled with x-y coordinate values.
- `obj.SetLabelModeToXYCoordinates ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.SetRightAxisVisibility (int )` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `int = obj.GetRightAxisVisibility ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.RightAxisVisibilityOn ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.RightAxisVisibilityOff ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.SetTopAxisVisibility (int )` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `int = obj.GetTopAxisVisibility ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.TopAxisVisibilityOn ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.TopAxisVisibilityOff ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.SetLeftAxisVisibility (int )` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `int = obj.GetLeftAxisVisibility ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.LeftAxisVisibilityOn ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.LeftAxisVisibilityOff ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.SetBottomAxisVisibility (int )` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `int = obj.GetBottomAxisVisibility ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.BottomAxisVisibilityOn ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.

- `obj.BottomAxisVisibilityOff ()` - Set/Get the flags that control which of the four axes to display (top, bottom, left and right). By default, all the axes are displayed.
- `obj.SetLegendVisibility (int )` - Indicate whether the legend scale should be displayed or not. The default is On.
- `int = obj.GetLegendVisibility ()` - Indicate whether the legend scale should be displayed or not. The default is On.
- `obj.LegendVisibilityOn ()` - Indicate whether the legend scale should be displayed or not. The default is On.
- `obj.LegendVisibilityOff ()` - Indicate whether the legend scale should be displayed or not. The default is On.
- `obj.AllAxesOn ()` - Convenience method that turns all the axes either on or off.
- `obj.AllAxesOff ()` - Convenience method that turns all the axes either on or off.
- `obj.AllAnnotationsOn ()` - Convenience method that turns all the axes and the legend scale.
- `obj.AllAnnotationsOff ()` - Convenience method that turns all the axes and the legend scale.
- `obj.SetRightBorderOffset (int )` - Set/Get the offset of the right axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.
- `int = obj.GetRightBorderOffsetMinValue ()` - Set/Get the offset of the right axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.
- `int = obj.GetRightBorderOffsetMaxValue ()` - Set/Get the offset of the right axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.
- `int = obj.GetRightBorderOffset ()` - Set/Get the offset of the right axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.
- `obj.SetTopBorderOffset (int )` - Set/Get the offset of the top axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.
- `int = obj.GetTopBorderOffsetMinValue ()` - Set/Get the offset of the top axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.
- `int = obj.GetTopBorderOffsetMaxValue ()` - Set/Get the offset of the top axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.
- `int = obj.GetTopBorderOffset ()` - Set/Get the offset of the top axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.
- `obj.SetLeftBorderOffset (int )` - Set/Get the offset of the left axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.

- `int = obj.GetLeftBorderOffsetMinValue ()` - Set/Get the offset of the left axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.

- `int = obj.GetLeftBorderOffsetMaxValue ()` - Set/Get the offset of the left axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.

- `int = obj.GetLeftBorderOffset ()` - Set/Get the offset of the left axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 50.

- `obj.SetBottomBorderOffset (int )` - Set/Get the offset of the bottom axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.

- `int = obj.GetBottomBorderOffsetMinValue ()` - Set/Get the offset of the bottom axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.

- `int = obj.GetBottomBorderOffsetMaxValue ()` - Set/Get the offset of the bottom axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.

- `int = obj.GetBottomBorderOffset ()` - Set/Get the offset of the bottom axis from the border. This number is expressed in pixels, and represents the approximate distance of the axes from the sides of the renderer. The default is 30.

- `obj.SetCornerOffsetFactor (double )` - Get/Set the corner offset. This is the offset factor used to offset the axes at the corners. Default value is 2.0.

- `double = obj.GetCornerOffsetFactorMinValue ()` - Get/Set the corner offset. This is the offset factor used to offset the axes at the corners. Default value is 2.0.

- `double = obj.GetCornerOffsetFactorMaxValue ()` - Get/Set the corner offset. This is the offset factor used to offset the axes at the corners. Default value is 2.0.

- `double = obj.GetCornerOffsetFactor ()` - Get/Set the corner offset. This is the offset factor used to offset the axes at the corners. Default value is 2.0.

- `vtkTextProperty = obj.GetLegendTitleProperty ()` - Set/Get the labels text properties for the legend title and labels.

- `vtkTextProperty = obj.GetLegendLabelProperty ()` - Set/Get the labels text properties for the legend title and labels.

- `vtkAxisActor2D = obj.GetRightAxis ()` - These are methods to retrieve the vtkAxisActors used to represent the four axes that form this representation. Users may retrieve and then modify these axes to control their appearance.

- `vtkAxisActor2D = obj.GetTopAxis ()` - These are methods to retrieve the vtkAxisActors used to represent the four axes that form this representation. Users may retrieve and then modify these axes to control their appearance.

- `vtkAxisActor2D = obj.GetLeftAxis ()` - These are methods to retrieve the vtkAxisActors used to represent the four axes that form this representation. Users may retrieve and then modify these axes to control their appearance.

- `vtkAxisActor2D = obj.GetBottomAxis ()` - These are methods to retrieve the vtkAxisActors used to represent the four axes that form this representation. Users may retrieve and then modify these axes to control their appearance.
- `obj.BuildRepresentation (vtkViewport viewport)`
- `obj.GetActors2D (vtkPropCollection )`
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `int = obj.RenderOverlay (vtkViewport )`
- `int = obj.RenderOpaqueGeometry (vtkViewport )`

34.29 vtkLSDynaReader

34.29.1 Usage

This filter reads LS-Dyna databases.

The Set/GetFileName() routines are actually wrappers around the Set/GetDatabaseDirectory() members; the actual filename you choose is irrelevant – only the directory name is used. This is done in order to accommodate ParaView.

Note that this reader produces 7 output meshes. These meshes are required as several attributes are defined on subsets of the mesh. Below is a list of meshes in the order they are output and an explanation of which attributes are unique to each mesh: - solid (3D) elements: number of integration points are different than 2D - thick shell elements: number of integration points are different than planar 2D - shell (2D) elements: number of integration points are different than 3D - rigid surfaces: can't have deflection, only velocity, accel, etc. - road surfaces: have only a "segment ID" (serves as material ID) and a velocity. - beam elements: have Frenet (TNB) frame and cross-section attributes (shape and size) - spherical particle hydrodynamics (SPH) elements: have a radius of influence, internal energy, etc. Because each mesh has its own cell attributes, the vtkLSDynaReader has a rather large API. Instead of a single set of routines to query and set cell array names and status, one exists for each possible output mesh. Also, GetNumberOfCells() will return the sum of all the cells in all 7 meshes. If you want the number of cells in a specific mesh, there are separate routines for each mesh type.

.SECTION "Developer Notes"

To create an instance of class vtkLSDynaReader, simply invoke its constructor as follows

```
obj = vtkLSDynaReader
```

34.29.2 Methods

The class vtkLSDynaReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLSDynaReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLSDynaReader = obj.NewInstance ()`
- `vtkLSDynaReader = obj.SafeDownCast (vtkObject o)`
- `obj.DebugDump ()` - A routine to call Dump() from within a lame debugger that won't properly pass a C++ iostream object like cout.
- `int = obj.CanReadFile (string fname)` - Determine if the file can be readed with this reader.

- `obj.SetDatabaseDirectory (string )` - Get/Set the directory containing the LS-Dyna database and determine whether it is valid.
- `string = obj.GetDatabaseDirectory ()` - Get/Set the directory containing the LS-Dyna database and determine whether it is valid.
- `int = obj.IsDatabaseValid ()` - Get/Set the directory containing the LS-Dyna database and determine whether it is valid.
- `obj.SetFileName (string )` - Get/Set the filename. The Set/GetFileName() routines are actually wrappers around the Set/GetDatabaseDirectory() members; the actual filename you choose is irrelevant – only the directory name is used. This is done in order to accommodate ParaView.
- `string = obj.GetFileName ()` - Get/Set the filename. The Set/GetFileName() routines are actually wrappers around the Set/GetDatabaseDirectory() members; the actual filename you choose is irrelevant – only the directory name is used. This is done in order to accommodate ParaView.
- `string = obj.GetTitle ()` - The title of the database is a 40 or 80 character text description stored at the front of a d3plot file. Do not call this function before setting the database directory and calling UpdateInformation().
- `int = obj.GetDimensionality ()` - Retrieve the dimension of points in the database. This should return 2 or 3. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfNodes ()` - Retrieve the number of points in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().

  Note that GetNumberOfCells() returns the sum of GetNumberOfContinuumCells() and GetNumberOfParticleCells().
- `vtkIdType = obj.GetNumberOfContinuumCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().

  Note that GetNumberOfContinuumCells() returns the sum of GetNumberOfSolidCells(), GetNumberOfThickShellCells(), GetNumberOfShellCells(), GetNumberOfRigidBodyCells(), GetNumberOfRoadSurfaceCells(), and GetNumberOfBeamCells().
- `vtkIdType = obj.GetNumberOfSolidCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfThickShellCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfShellCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfRigidBodyCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfRoadSurfaceCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().

- `vtkIdType = obj.GetNumberOfBeamCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfParticleCells ()` - Retrieve the number of cells of a given type in the database. Do not call this function before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetNumberOfTimeSteps ()` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `obj.SetTimeStep (vtkIdType )` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `vtkIdType = obj.GetTimeStep ()` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `double = obj.GetTimeValue (vtkIdType )` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `int = obj. GetTimeStepRange ()` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `obj.SetTimeStepRange (int , int )` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `obj.SetTimeStepRange (int a[2])` - Retrieve information about the time extents of the LS-Dyna database. Do not call these functions before setting the database directory and calling UpdateInformation().
- `int = obj.GetNumberOfPointArrays ()` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `string = obj.GetPointArrayName (int )` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `obj.SetPointArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `obj.SetPointArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `int = obj.GetPointArrayStatus (int arr)` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `int = obj.GetPointArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInPointArray (int arr)` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInPointArray (string arrName)` - These methods allow you to load only selected subsets of the nodal variables defined over the mesh.

- `int = obj.GetNumberOfCellArrays (int cellType)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `string = obj.GetCellArrayName (int cellType, int arr)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `obj.SetCellArrayStatus (int cellType, int arr, int status)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `obj.SetCellArrayStatus (int cellType, string arrName, int status)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `int = obj.GetCellArrayStatus (int cellType, int arr)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `int = obj.GetCellArrayStatus (int cellType, string arrName)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `int = obj.GetNumberOfComponentsInCellArray (int cellType, int arr)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `int = obj.GetNumberOfComponentsInCellArray (int cellType, string arrName)` - Routines that allow the status of a cell variable to be adjusted or queried independent of the output mesh. The cellType parameter should be one of: LS_POINT, LS_BEAM, LS_SHELL, LS_THICK_SHELL, LS_SOLID, LS_RIGID_BODY, or LS_ROAD_SURFACE

- `int = obj.GetNumberOfSolidArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `string = obj.GetSolidArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `obj.SetSolidArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `obj.SetSolidArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `int = obj.GetSolidArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `int = obj.GetSolidArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `int = obj.GetNumberOfComponentsInSolidArray (int a)`

- `int = obj.GetNumberOfComponentsInSolidArray (string arrName)`
- `int = obj.GetNumberOfThickShellArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `string = obj.GetThickShellArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetThickShellArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetThickShellArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetThickShellArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetThickShellArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInThickShellArray (int a)`
- `int = obj.GetNumberOfComponentsInThickShellArray (string arrName)`
- `int = obj.GetNumberOfShellArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `string = obj.GetShellArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetShellArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetShellArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetShellArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetShellArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInShellArray (int a)`
- `int = obj.GetNumberOfComponentsInShellArray (string arrName)`
- `int = obj.GetNumberOfRigidBodyArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `string = obj.GetRigidBodyArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetRigidBodyArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetRigidBodyArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetRigidBodyArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `int = obj.GetRigidBodyArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInRigidBodyArray (int a)`
- `int = obj.GetNumberOfComponentsInRigidBodyArray (string arrName)`
- `int = obj.GetNumberOfRoadSurfaceArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `string = obj.GetRoadSurfaceArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetRoadSurfaceArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetRoadSurfaceArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetRoadSurfaceArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetRoadSurfaceArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInRoadSurfaceArray (int a)`
- `int = obj.GetNumberOfComponentsInRoadSurfaceArray (string arrName)`
- `int = obj.GetNumberOfBeamArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `string = obj.GetBeamArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetBeamArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetBeamArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetBeamArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetBeamArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInBeamArray (int a)`
- `int = obj.GetNumberOfComponentsInBeamArray (string arrName)`
- `int = obj.GetNumberOfParticleArrays ()` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `string = obj.GetParticleArrayName (int )` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetParticleArrayStatus (int arr, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `obj.SetParticleArrayStatus (string arrName, int status)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.

- `int = obj.GetParticleArrayStatus (int arr)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetParticleArrayStatus (string arrName)` - These methods allow you to load only selected subsets of the cell variables defined over the mesh.
- `int = obj.GetNumberOfComponentsInParticleArray (int a)`
- `int = obj.GetNumberOfComponentsInParticleArray (string arrName)`
- `obj.SetDeformedMesh (int )` - Should deflected coordinates be used, or should the mesh remain undeflected? By default, this is true but its value is ignored if the nodal "Deflection" array is not set to be loaded.
- `int = obj.GetDeformedMesh ()` - Should deflected coordinates be used, or should the mesh remain undeflected? By default, this is true but its value is ignored if the nodal "Deflection" array is not set to be loaded.
- `obj.DeformedMeshOn ()` - Should deflected coordinates be used, or should the mesh remain undeflected? By default, this is true but its value is ignored if the nodal "Deflection" array is not set to be loaded.
- `obj.DeformedMeshOff ()` - Should deflected coordinates be used, or should the mesh remain undeflected? By default, this is true but its value is ignored if the nodal "Deflection" array is not set to be loaded.
- `obj.SetRemoveDeletedCells (int )` - Should dead cells be removed from the mesh? Cells are marked dead by setting the corresponding entry in the ¡b¿cell¡/b¿ array "Death" to 0. Cells that are not dead have the corresponding entry in the cell array "Death" set to their material ID. By default, this is true but its value is ignored if the cell "Death" array is not set to be loaded. It is also ignored if the database's element deletion option is set to denote ¡b¿points¡/b¿ (not cells) as deleted; in that case, "Death" will appear to be a point array.
- `int = obj.GetRemoveDeletedCells ()` - Should dead cells be removed from the mesh? Cells are marked dead by setting the corresponding entry in the ¡b¿cell¡/b¿ array "Death" to 0. Cells that are not dead have the corresponding entry in the cell array "Death" set to their material ID. By default, this is true but its value is ignored if the cell "Death" array is not set to be loaded. It is also ignored if the database's element deletion option is set to denote ¡b¿points¡/b¿ (not cells) as deleted; in that case, "Death" will appear to be a point array.
- `obj.RemoveDeletedCellsOn ()` - Should dead cells be removed from the mesh? Cells are marked dead by setting the corresponding entry in the ¡b¿cell¡/b¿ array "Death" to 0. Cells that are not dead have the corresponding entry in the cell array "Death" set to their material ID. By default, this is true but its value is ignored if the cell "Death" array is not set to be loaded. It is also ignored if the database's element deletion option is set to denote ¡b¿points¡/b¿ (not cells) as deleted; in that case, "Death" will appear to be a point array.
- `obj.RemoveDeletedCellsOff ()` - Should dead cells be removed from the mesh? Cells are marked dead by setting the corresponding entry in the ¡b¿cell¡/b¿ array "Death" to 0. Cells that are not dead have the corresponding entry in the cell array "Death" set to their material ID. By default, this is true but its value is ignored if the cell "Death" array is not set to be loaded. It is also ignored if the database's element deletion option is set to denote ¡b¿points¡/b¿ (not cells) as deleted; in that case, "Death" will appear to be a point array.
- `obj.SetSplitByMaterialId (int )` - Split each part into submeshes based on material ID. By default, this is false and all cells of a given type (solid, thick shell, shell, ...) are in a single mesh.
- `int = obj.GetSplitByMaterialId ()` - Split each part into submeshes based on material ID. By default, this is false and all cells of a given type (solid, thick shell, shell, ...) are in a single mesh.

- `obj.SplitByMaterialIdOn ()` - Split each part into submeshes based on material ID. By default, this is false and all cells of a given type (solid, thick shell, shell, ...) are in a single mesh.

- `obj.SplitByMaterialIdOff ()` - Split each part into submeshes based on material ID. By default, this is false and all cells of a given type (solid, thick shell, shell, ...) are in a single mesh.

- `obj.SetInputDeck (string )` - The name of the input deck corresponding to the current database. This is used to determine the part names associated with each material ID. This file may be in two formats: a valid LSDyna input deck or a short XML summary. If the file begins with "¡?xml" then the summary format is used. Otherwise, the keyword format is used and a summary file will be created if write permissions exist in the directory containing the keyword file. The newly created summary will have ".k" or ".key" stripped from the end of the keyword filename and ".lsdyna" appended.

- `string = obj.GetInputDeck ()` - The name of the input deck corresponding to the current database. This is used to determine the part names associated with each material ID. This file may be in two formats: a valid LSDyna input deck or a short XML summary. If the file begins with "¡?xml" then the summary format is used. Otherwise, the keyword format is used and a summary file will be created if write permissions exist in the directory containing the keyword file. The newly created summary will have ".k" or ".key" stripped from the end of the keyword filename and ".lsdyna" appended.

- `int = obj.GetNumberOfPartArrays ()` - These methods allow you to load only selected parts of the input. If InputDeck points to a valid keyword file (or summary), then part names will be taken from that file. Otherwise, when arbitrary material numbering is used, parts will be named "PartXXX (MatlYYY)" where XXX is an increasing sequential number and YYY is the respective material ID. If no input deck is specified and arbitrary arbitrary material numbering is not used, parts will be named "PartXXX" where XXX is a sequential material ID.

- `string = obj.GetPartArrayName (int )` - These methods allow you to load only selected parts of the input. If InputDeck points to a valid keyword file (or summary), then part names will be taken from that file. Otherwise, when arbitrary material numbering is used, parts will be named "PartXXX (MatlYYY)" where XXX is an increasing sequential number and YYY is the respective material ID. If no input deck is specified and arbitrary arbitrary material numbering is not used, parts will be named "PartXXX" where XXX is a sequential material ID.

- `obj.SetPartArrayStatus (int arr, int status)` - These methods allow you to load only selected parts of the input. If InputDeck points to a valid keyword file (or summary), then part names will be taken from that file. Otherwise, when arbitrary material numbering is used, parts will be named "PartXXX (MatlYYY)" where XXX is an increasing sequential number and YYY is the respective material ID. If no input deck is specified and arbitrary arbitrary material numbering is not used, parts will be named "PartXXX" where XXX is a sequential material ID.

- `obj.SetPartArrayStatus (string partName, int status)` - These methods allow you to load only selected parts of the input. If InputDeck points to a valid keyword file (or summary), then part names will be taken from that file. Otherwise, when arbitrary material numbering is used, parts will be named "PartXXX (MatlYYY)" where XXX is an increasing sequential number and YYY is the respective material ID. If no input deck is specified and arbitrary arbitrary material numbering is not used, parts will be named "PartXXX" where XXX is a sequential material ID.

- `int = obj.GetPartArrayStatus (int arr)` - These methods allow you to load only selected parts of the input. If InputDeck points to a valid keyword file (or summary), then part names will be taken from that file. Otherwise, when arbitrary material numbering is used, parts will be named "PartXXX (MatlYYY)" where XXX is an increasing sequential number and YYY is the respective material ID. If no input deck is specified and arbitrary arbitrary material numbering is not used, parts will be named "PartXXX" where XXX is a sequential material ID.

- `int = obj.GetPartArrayStatus (string partName)` - These methods allow you to load only selected parts of the input. If InputDeck points to a valid keyword file (or summary), then part names

will be taken from that file. Otherwise, when arbitrary material numbering is used, parts will be named "PartXXX (MatlYYY)" where XXX is an increasing sequential number and YYY is the respective material ID. If no input deck is specified and arbitrary arbitrary material numbering is not used, parts will be named "PartXXX" where XXX is a sequential material ID.

34.30 vtkPCAAnalysisFilter

34.30.1 Usage

vtkPCAAnalysisFilter is a filter that takes as input a set of aligned pointsets (any object derived from vtkPointSet) and performs a principal component analysis of the coordinates. This can be used to visualise the major or minor modes of variation seen in a set of similar biological objects with corresponding landmarks. vtkPCAAnalysisFilter is designed to work with the output from the vtkProcrustesAnalysisFilter

Call SetNumberOfInputs(n) before calling SetInput(0) ... SetInput(n-1). Retrieve the outputs using GetOutput(0) ... GetOutput(n-1).

vtkPCAAnalysisFilter is an implementation of (for example):

T. Cootes et al. : Active Shape Models - their training and application. Computer Vision and Image Understanding, 61(1):38-59, 1995.

The material can also be found in Tim Cootes' ever-changing online report published at his website: http://www.isbe.man.ac.uk/ bim/

To create an instance of class vtkPCAAnalysisFilter, simply invoke its constructor as follows

```
obj = vtkPCAAnalysisFilter
```

34.30.2 Methods

The class vtkPCAAnalysisFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPCAAnalysisFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPCAAnalysisFilter = obj.NewInstance ()`
- `vtkPCAAnalysisFilter = obj.SafeDownCast (vtkObject o)`
- `vtkFloatArray = obj.GetEvals ()` - Get the vector of eigenvalues sorted in descending order
- `obj.SetNumberOfInputs (int n)` - Specify how many pointsets are going to be given as input.
- `obj.SetInput (int idx, vtkPointSet p)` - Specify the input pointset with index idx. Call SetNumberOfInputs before calling this function.
- `obj.SetInput (int idx, vtkDataObject input)` - Specify the input pointset with index idx. Call SetNumberOfInputs before calling this function.
- `vtkPointSet = obj.GetInput (int idx)` - Retrieve the input with index idx (usually only used for pipeline tracing).
- `obj.GetParameterisedShape (vtkFloatArray b, vtkPointSet shape)` - Fills the shape with:

  mean + b[0] * sqrt(eigenvalue[0]) * eigenvector[0] + b[1] * sqrt(eigenvalue[1]) * eigenvector[1] ... + b[sizeb-1] * sqrt(eigenvalue[bsize-1]) * eigenvector[bsize-1]

  here b are the parameters expressed in standard deviations bsize is the number of parameters in the b vector This function assumes that shape is allready allocated with the right size, it just moves the points.

- `obj.GetShapeParameters (vtkPointSet shape, vtkFloatArray b, int bsize)` - Return the bsize parameters b that best model the given shape (in standard deviations). That is that the given shape will be approximated by:

  shape mean + b[0] * sqrt(eigenvalue[0]) * eigenvector[0] + b[1] * sqrt(eigenvalue[1]) * eigenvector[1] ... + b[bsize-1] * sqrt(eigenvalue[bsize-1]) * eigenvector[bsize-1]

- `int = obj.GetModesRequiredFor (double proportion)` - Retrieve how many modes are necessary to model the given proportion of the variation. proportion should be between 0 and 1

34.31 vtkPExodusIIReader

34.31.1 Usage

vtkPExodusIIReader is a unstructured grid source object that reads ExodusII files. Most of the meta data associated with the file is loaded when UpdateInformation is called. This includes information like Title, number of blocks, number and names of arrays. This data can be retrieved from methods in this reader. Separate arrays that are meant to be a single vector, are combined internally for convenience. To be combined, the array names have to be identical except for a trailing X,Y and Z (or x,y,z). By default all cell and point arrays are loaded. However, the user can flag arrays not to load with the methods "SetPointDataArrayLoadFlag" and "SetCellDataArrayLoadFlag". The reader responds to piece requests by loading only a range of the possible blocks. Unused points are filtered out internally.

To create an instance of class vtkPExodusIIReader, simply invoke its constructor as follows

```
obj = vtkPExodusIIReader
```

34.31.2 Methods

The class vtkPExodusIIReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPExodusIIReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPExodusIIReader = obj.NewInstance ()`
- `vtkPExodusIIReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController c)` - Set/get the communication object used to relay a list of files from the rank 0 process to all others. This is the only interprocess communication required by vtkPExodusIIReader.
- `vtkMultiProcessController = obj.GetController ()` - Set/get the communication object used to relay a list of files from the rank 0 process to all others. This is the only interprocess communication required by vtkPExodusIIReader.
- `obj.SetFilePattern (string )` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.
- `string = obj.GetFilePattern ()` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.

- `obj.SetFilePrefix (string )` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.

- `string = obj.GetFilePrefix ()` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.

- `obj.SetFileRange (int , int )` - Set the range of files that are being loaded. The range for single file should add to 0.

- `obj.SetFileRange (int r)` - Set the range of files that are being loaded. The range for single file should add to 0.

- `int = obj. GetFileRange ()` - Set the range of files that are being loaded. The range for single file should add to 0.

- `obj.SetFileName (string name)`

- `int = obj.GetNumberOfFileNames ()` - Return the number of files to be read.

- `int = obj.GetNumberOfFiles ()` - Return the number of files to be read.

- `vtkIdType = obj.GetTotalNumberOfElements ()`

- `vtkIdType = obj.GetTotalNumberOfNodes ()`

- `obj.UpdateTimeInformation ()` - Calls UpdateTimeInformation() on all serial readers so they'll re-read their time info from the file. The last time step that they all have in common is stored in LastCommonTimeStep, which is used in RequestInformation() to override the output time-specific information keys with the range of times that ALL readers can actually read.

- `obj.Broadcast (vtkMultiProcessController ctrl)` - Sends metadata (that read from the input file, not settings modified through this API) from the rank 0 node to all other processes in a job.

34.32 vtkPExodusReader

34.32.1 Usage

vtkPExodusReader is a unstructured grid source object that reads PExodusReaderII files. Most of the meta data associated with the file is loaded when UpdateInformation is called. This includes information like Title, number of blocks, number and names of arrays. This data can be retrieved from methods in this reader. Separate arrays that are meant to be a single vector, are combined internally for convenience. To be combined, the array names have to be identical except for a trailing X,Y and Z (or x,y,z). By default all cell and point arrays are loaded. However, the user can flag arrays not to load with the methods "SetPointDataArrayLoadFlag" and "SetCellDataArrayLoadFlag". The reader responds to piece requests by loading only a range of the possible blocks. Unused points are filtered out internally.

To create an instance of class vtkPExodusReader, simply invoke its constructor as follows

```
obj = vtkPExodusReader
```

34.32.2 Methods

The class vtkPExodusReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPExodusReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPExodusReader = obj.NewInstance ()`
- `vtkPExodusReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilePattern (string )` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.
- `string = obj.GetFilePattern ()` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.
- `obj.SetFilePrefix (string )` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.
- `string = obj.GetFilePrefix ()` - These methods tell the reader that the data is ditributed across multiple files. This is for distributed execution. It this case, pieces are mapped to files. The pattern should have one format the file number. FileNumberRange is used to generate file numbers. I was thinking of having an arbitrary list of file numbers. This may happen in the future. (That is why there is no GetFileNumberRange method.
- `obj.SetFileRange (int , int )` - Set the range of files that are being loaded. The range for single file should add to 0.
- `obj.SetFileRange (int r)` - Set the range of files that are being loaded. The range for single file should add to 0.
- `int = obj. GetFileRange ()` - Set the range of files that are being loaded. The range for single file should add to 0.
- `obj.SetFileName (string name)`
- `int = obj.GetNumberOfFileNames ()` - Return the number of files to be read.
- `int = obj.GetNumberOfFiles ()` - Return the number of files to be read.
- `obj.SetGenerateFileIdArray (int flag)`
- `int = obj.GetGenerateFileIdArray ()`
- `obj.GenerateFileIdArrayOn ()`
- `obj.GenerateFileIdArrayOff ()`

- `int = obj.GetTotalNumberOfElements ()`
- `int = obj.GetTotalNumberOfNodes ()`
- `int = obj.GetNumberOfVariableArrays ()`
- `string = obj.GetVariableArrayName (int a\_which)`
- `obj.EnableDSPFiltering ()`
- `obj.AddFilter (vtkDSPFilterDefinition a\_filter)`
- `obj.StartAddingFilter ()`
- `obj.AddFilterInputVar (string name)`
- `obj.AddFilterOutputVar (string name)`
- `obj.AddFilterNumeratorWeight (double weight)`
- `obj.AddFilterForwardNumeratorWeight (double weight)`
- `obj.AddFilterDenominatorWeight (double weight)`
- `obj.FinishAddingFilter ()`
- `obj.RemoveFilter (string a\_outputVariableName)`

34.33 vtkPieChartActor

34.33.1 Usage

vtkPieChartActor generates a pie chart from an array of numbers defined in field data (a vtkDataObject). To use this class, you must specify an input data object. You'll probably also want to specify the position of the plot be setting the Position and Position2 instance variables, which define a rectangle in which the plot lies. There are also many other instance variables that control the look of the plot includes its title, and legend.

Set the text property/attributes of the title and the labels through the vtkTextProperty objects associated with these components.

To create an instance of class vtkPieChartActor, simply invoke its constructor as follows

```
obj = vtkPieChartActor
```

34.33.2 Methods

The class vtkPieChartActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPieChartActor class.

- `string = obj.GetClassName ()` - Standard methods for type information and printing.
- `int = obj.IsA (string name)` - Standard methods for type information and printing.
- `vtkPieChartActor = obj.NewInstance ()` - Standard methods for type information and printing.
- `vtkPieChartActor = obj.SafeDownCast (vtkObject o)` - Standard methods for type information and printing.
- `obj.SetInput (vtkDataObject )` - Set the input to the pie chart actor.

- `vtkDataObject = obj.GetInput ()` - Get the input data object to this actor.
- `obj.SetTitleVisibility (int )` - Enable/Disable the display of a plot title.
- `int = obj.GetTitleVisibility ()` - Enable/Disable the display of a plot title.
- `obj.TitleVisibilityOn ()` - Enable/Disable the display of a plot title.
- `obj.TitleVisibilityOff ()` - Enable/Disable the display of a plot title.
- `obj.SetTitle (string )` - Set/Get the title of the pie chart.
- `string = obj.GetTitle ()` - Set/Get the title of the pie chart.
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property. The property controls the appearance of the plot title.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property. The property controls the appearance of the plot title.
- `obj.SetLabelVisibility (int )` - Enable/Disable the display of pie piece labels.
- `int = obj.GetLabelVisibility ()` - Enable/Disable the display of pie piece labels.
- `obj.LabelVisibilityOn ()` - Enable/Disable the display of pie piece labels.
- `obj.LabelVisibilityOff ()` - Enable/Disable the display of pie piece labels.
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property. This controls the appearance of all pie piece labels.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the labels text property. This controls the appearance of all pie piece labels.
- `obj.SetPieceColor (int i, double r, double g, double b)` - Specify colors for each piece of pie. If not specified, they are automatically generated.
- `obj.SetPieceColor (int i, double color[3])` - Specify colors for each piece of pie. If not specified, they are automatically generated.
- `obj.SetPieceLabel (int i, string )` - Specify the names for each piece of pie. not specified, then an integer number is automatically generated.
- `string = obj.GetPieceLabel (int i)` - Specify the names for each piece of pie. not specified, then an integer number is automatically generated.
- `obj.SetLegendVisibility (int )` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `int = obj.GetLegendVisibility ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendVisibilityOn ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendVisibilityOff ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `vtkLegendBoxActor = obj.GetLegendActor ()` - Retrieve handles to the legend box. This is useful if you would like to manually control the legend appearance.
- `int = obj.RenderOverlay (vtkViewport )` - Draw the pie plot.

- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Draw the pie plot.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

34.34 vtkPolyDataSilhouette

34.34.1 Usage

vtkPolyDataSilhouette extracts a subset of a polygonal mesh edges to generate an outline (silhouette) of the corresponding 3D object. In addition, this filter can also extracts sharp edges (aka feature angles). In order to use this filter you must specify the a point of view (origin) or a direction (vector). given this direction or origin, a silhouette is generated wherever the surface's normal is orthogonal to the view direction.

To create an instance of class vtkPolyDataSilhouette, simply invoke its constructor as follows

```
obj = vtkPolyDataSilhouette
```

34.34.2 Methods

The class vtkPolyDataSilhouette has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataSilhouette class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataSilhouette = obj.NewInstance ()`
- `vtkPolyDataSilhouette = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnableFeatureAngle (int )` - Enables or Disables generation of silhouette edges along sharp edges
- `int = obj.GetEnableFeatureAngle ()` - Enables or Disables generation of silhouette edges along sharp edges
- `obj.SetFeatureAngle (double )` - Sets/Gets minimal angle for sharp edges detection. Default is 60
- `double = obj.GetFeatureAngle ()` - Sets/Gets minimal angle for sharp edges detection. Default is 60
- `obj.SetBorderEdges (int )` - Enables or Disables generation of border edges. Note: borders exist only in case of non closed surface
- `int = obj.GetBorderEdges ()` - Enables or Disables generation of border edges. Note: borders exist only in case of non closed surface
- `obj.BorderEdgesOn ()` - Enables or Disables generation of border edges. Note: borders exist only in case of non closed surface

- `obj.BorderEdgesOff ()` - Enables or Disables generation of border edges. Note: borders exist only in case of non closed surface
- `obj.SetPieceInvariant (int )` - Enables or Disables piece invariance. This is usefull when dealing with multi-block data sets. Note: requires one level of ghost cells
- `int = obj.GetPieceInvariant ()` - Enables or Disables piece invariance. This is usefull when dealing with multi-block data sets. Note: requires one level of ghost cells
- `obj.PieceInvariantOn ()` - Enables or Disables piece invariance. This is usefull when dealing with multi-block data sets. Note: requires one level of ghost cells
- `obj.PieceInvariantOff ()` - Enables or Disables piece invariance. This is usefull when dealing with multi-block data sets. Note: requires one level of ghost cells
- `obj.SetDirection (int )` - Specify how view direction is computed. By default, the camera origin (eye) is used.
- `int = obj.GetDirection ()` - Specify how view direction is computed. By default, the camera origin (eye) is used.
- `obj.SetDirectionToSpecifiedVector ()` - Specify how view direction is computed. By default, the camera origin (eye) is used.
- `obj.SetDirectionToSpecifiedOrigin ()` - Specify how view direction is computed. By default, the camera origin (eye) is used.
- `obj.SetDirectionToCameraVector ()` - Specify how view direction is computed. By default, the camera origin (eye) is used.
- `obj.SetDirectionToCameraOrigin ()` - Specify a camera that is used to define the view direction. This ivar only has effect if the direction is set to VTK_DIRECTION_CAMERA_ORIGIN or VTK_DIRECTION_CAMERA_VECTOR, and a camera is specified.
- `obj.SetCamera (vtkCamera )` - Specify a camera that is used to define the view direction. This ivar only has effect if the direction is set to VTK_DIRECTION_CAMERA_ORIGIN or VTK_DIRECTION_CAMERA_VECT and a camera is specified.
- `vtkCamera = obj.GetCamera ()` - Specify a camera that is used to define the view direction. This ivar only has effect if the direction is set to VTK_DIRECTION_CAMERA_ORIGIN or VTK_DIRECTION_CAMERA_VECT and a camera is specified.
- `obj.SetProp3D (vtkProp3D )` - Specify a transformation matrix (via the vtkProp3D::GetMatrix() method) that is used to include the effects of transformation. This ivar only has effect if the direction is set to VTK_DIRECTION_CAMERA_ORIGIN or VTK_DIRECTION_CAMERA_VECTOR, and a camera is specified. Specifying the vtkProp3D is optional.
- `vtkProp3D = obj.GetProp3D ()` - Specify a transformation matrix (via the vtkProp3D::GetMatrix() method) that is used to include the effects of transformation. This ivar only has effect if the direction is set to VTK_DIRECTION_CAMERA_ORIGIN or VTK_DIRECTION_CAMERA_VECTOR, and a camera is specified. Specifying the vtkProp3D is optional.
- `obj.SetVector (double , double , double )` - Set/Get the sort direction. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The edge detection occurs in the direction of the vector.
- `obj.SetVector (double a[3])` - Set/Get the sort direction. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The edge detection occurs in the direction of the vector.

- `double = obj. GetVector ()` - Set/Get the sort direction. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedVector(). The edge detection occurs in the direction of the vector.
- `obj.SetOrigin (double , double , double )` - Set/Get the sort origin. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedOrigin(). The edge detection occurs in the direction of the origin to each edge's center.
- `obj.SetOrigin (double a[3])` - Set/Get the sort origin. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedOrigin(). The edge detection occurs in the direction of the origin to each edge's center.
- `double = obj. GetOrigin ()` - Set/Get the sort origin. This ivar only has effect if the sort direction is set to SetDirectionToSpecifiedOrigin(). The edge detection occurs in the direction of the origin to each edge's center.
- `long = obj.GetMTime ()` - Return MTime also considering the dependent objects: the camera and/or the prop3D.

34.35 vtkPolyDataToImageStencil

34.35.1 Usage

The vtkPolyDataToImageStencil class will convert a surface mesh into an image stencil that can be used to mask an image with vtkImageStencil, or used to calculate statistics within the enclosed region with vtkImageAccumulate.

To create an instance of class vtkPolyDataToImageStencil, simply invoke its constructor as follows

```
obj = vtkPolyDataToImageStencil
```

34.35.2 Methods

The class vtkPolyDataToImageStencil has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataToImageStencil class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataToImageStencil = obj.NewInstance ()`
- `vtkPolyDataToImageStencil = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkPolyData )` - Specify the implicit function to convert into a stencil.
- `vtkPolyData = obj.GetInput ()` - Specify the implicit function to convert into a stencil.
- `obj.SetInformationInput (vtkImageData )` - Set a vtkImageData that has the Spacing, Origin, and WholeExtent that will be used for the stencil. This input should be set to the image that you wish to apply the stencil to. If you use this method, then any values set with the SetOutputSpacing, SetOutputOrigin, and SetOutputWholeExtent methods will be ignored.
- `vtkImageData = obj.GetInformationInput ()` - Set a vtkImageData that has the Spacing, Origin, and WholeExtent that will be used for the stencil. This input should be set to the image that you wish to apply the stencil to. If you use this method, then any values set with the SetOutputSpacing, SetOutputOrigin, and SetOutputWholeExtent methods will be ignored.

- `obj.SetOutputOrigin (double , double , double )` - Set the Origin to be used for the stencil. It should be set to the Origin of the image you intend to apply the stencil to. The default value is (0,0,0).
- `obj.SetOutputOrigin (double a[3])` - Set the Origin to be used for the stencil. It should be set to the Origin of the image you intend to apply the stencil to. The default value is (0,0,0).
- `double = obj. GetOutputOrigin ()` - Set the Origin to be used for the stencil. It should be set to the Origin of the image you intend to apply the stencil to. The default value is (0,0,0).
- `obj.SetOutputSpacing (double , double , double )` - Set the Spacing to be used for the stencil. It should be set to the Spacing of the image you intend to apply the stencil to. The default value is (1,1,1)
- `obj.SetOutputSpacing (double a[3])` - Set the Spacing to be used for the stencil. It should be set to the Spacing of the image you intend to apply the stencil to. The default value is (1,1,1)
- `double = obj. GetOutputSpacing ()` - Set the Spacing to be used for the stencil. It should be set to the Spacing of the image you intend to apply the stencil to. The default value is (1,1,1)
- `obj.SetOutputWholeExtent (int , int , int , int , int , int )` - Set the whole extent for the stencil (anything outside this extent will be considered to be "outside" the stencil). If this is not set, then the stencil will always use the requested UpdateExtent as the stencil extent.
- `obj.SetOutputWholeExtent (int a[6])` - Set the whole extent for the stencil (anything outside this extent will be considered to be "outside" the stencil). If this is not set, then the stencil will always use the requested UpdateExtent as the stencil extent.
- `int = obj. GetOutputWholeExtent ()` - Set the whole extent for the stencil (anything outside this extent will be considered to be "outside" the stencil). If this is not set, then the stencil will always use the requested UpdateExtent as the stencil extent.
- `obj.SetTolerance (double )` - The tolerance to apply in when determining whether a voxel is inside the stencil, given as a fraction of a voxel. Only used in X and Y, not in Z.
- `double = obj.GetToleranceMinValue ()` - The tolerance to apply in when determining whether a voxel is inside the stencil, given as a fraction of a voxel. Only used in X and Y, not in Z.
- `double = obj.GetToleranceMaxValue ()` - The tolerance to apply in when determining whether a voxel is inside the stencil, given as a fraction of a voxel. Only used in X and Y, not in Z.
- `double = obj.GetTolerance ()` - The tolerance to apply in when determining whether a voxel is inside the stencil, given as a fraction of a voxel. Only used in X and Y, not in Z.

34.36 vtkProcrustesAlignmentFilter

34.36.1 Usage

vtkProcrustesAlignmentFilter is a filter that takes a set of pointsets (any object derived from vtkPointSet) and aligns them in a least-squares sense to their mutual mean. The algorithm is iterated until convergence, as the mean must be recomputed after each alignment.

Call SetNumberOfInputs(n) before calling SetInput(0) ... SetInput(n-1).

Retrieve the outputs using GetOutput(0) ... GetOutput(n-1).

The default (in vtkLandmarkTransform) is for a similarity alignment. For a rigid-body alignment (to build a 'size-and-shape' model) use:

GetLandmarkTransform()-¿SetModeToRigidBody().

Affine alignments are not normally used but are left in for completeness:

GetLandmarkTransform()-¿SetModeToAffine().

vtkProcrustesAlignmentFilter is an implementation of:

J.C. Gower (1975) Generalized Procrustes Analysis. Psychometrika, 40:33-51.
To create an instance of class vtkProcrustesAlignmentFilter, simply invoke its constructor as follows

```
obj = vtkProcrustesAlignmentFilter
```

34.36.2 Methods

The class vtkProcrustesAlignmentFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProcrustesAlignmentFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProcrustesAlignmentFilter = obj.NewInstance ()`
- `vtkProcrustesAlignmentFilter = obj.SafeDownCast (vtkObject o)`
- `vtkLandmarkTransform = obj.GetLandmarkTransform ()` - Get the internal landmark transform. Use it to constrain the number of degrees of freedom of the alignment (i.e. rigid body, similarity, etc.). The default is a similarity alignment.
- `vtkPoints = obj.GetMeanPoints ()` - Get the estimated mean point cloud
- `obj.SetNumberOfInputs (int n)` - Specify how many pointsets are going to be given as input.
- `obj.SetInput (int idx, vtkPointSet p)` - Specify the input pointset with index idx. Call SetNumberOfInputs before calling this function.
- `obj.SetInput (int idx, vtkDataObject input)` - Specify the input pointset with index idx. Call SetNumberOfInputs before calling this function.
- `obj.SetStartFromCentroid (bool )` - When on, the initial alignment is to the centroid of the cohort curves. When off, the alignment is to the centroid of the first input. Default is off for backward compatibility.
- `bool = obj.GetStartFromCentroid ()` - When on, the initial alignment is to the centroid of the cohort curves. When off, the alignment is to the centroid of the first input. Default is off for backward compatibility.
- `obj.StartFromCentroidOn ()` - When on, the initial alignment is to the centroid of the cohort curves. When off, the alignment is to the centroid of the first input. Default is off for backward compatibility.
- `obj.StartFromCentroidOff ()` - When on, the initial alignment is to the centroid of the cohort curves. When off, the alignment is to the centroid of the first input. Default is off for backward compatibility.
- `vtkPointSet = obj.GetInput (int idx)` - Retrieve the input point set with index idx (usually only for pipeline tracing).

34.37 vtkProjectedTerrainPath

34.37.1 Usage

vtkProjectedTerrainPath projects an input polyline onto a terrain. (The terrain is defined by a 2D height image and is the second input to the filter.) The polyline projection is controlled via several modes as follows. 1) Simple mode projects the polyline points onto the terrain, taking into account the height offset instance variable. 2) Non-occluded mode insures that no parts of the polyline are occluded by the terrain (e.g. a line

passes through a mountain). This may require recursive subdivision of the polyline. 3) Hug mode insures that the polyine points remain within a constant distance from the surface. This may also require recursive subdivision of the polyline. Note that both non-occluded mode and hug mode also take into account the height offset, so it is possible to create paths that hug terrain a certain distance above it. To use this filter, define two inputs: 1) a polyline, and 2) an image whose scalar values represent a height field. Then specify the mode, and the height offset to use.

An description of the algorithm is as follows. The filter begins by projecting the polyline points to the image (offset by the specified height offset). If the mode is non-occluded or hug, then the maximum error along each line segment is computed and placed into a priority queue. Each line segment is then split at the point of maximum error, and the two new line segments are evaluated for maximum error. This process continues until the line is not occluded by the terrain (non-occluded mode) or satisfies the error on variation from the surface (hug mode). (Note this process is repeated for each polyline in the input. Also, the maximum error is computed in two parts: a maximum positive error and maximum negative error. If the polyline is above the terrain–i.e., the height offset is positive–in non-occluded or hug mode all negative errors are eliminated. If the polyline is below the terrain–i.e., the height offset is negative–in non-occluded or hug mode all positive errors are eliminated.)

To create an instance of class vtkProjectedTerrainPath, simply invoke its constructor as follows

```
obj = vtkProjectedTerrainPath
```

34.37.2 Methods

The class vtkProjectedTerrainPath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProjectedTerrainPath class.

- `string = obj.GetClassName ()` - Standard methids for printing and determining type information.
- `int = obj.IsA (string name)` - Standard methids for printing and determining type information.
- `vtkProjectedTerrainPath = obj.NewInstance ()` - Standard methids for printing and determining type information.
- `vtkProjectedTerrainPath = obj.SafeDownCast (vtkObject o)` - Standard methids for printing and determining type information.
- `obj.SetSource (vtkImageData source)` - Specify the second input (the terrain) onto which the polyline(s) should be projected.
- `vtkImageData = obj.GetSource ()` - Specify the second input (the terrain) onto which the polyline(s) should be projected.
- `obj.SetProjectionMode (int )` - Determine how to control the projection process. Simple projection just projects the original polyline points. Non-occluded projection insures that the polyline does not intersect the terrain surface. Hug projection is similar to non-occulded projection except that produces a path that is nearly parallel to the terrain (within the user specified height tolerance).
- `int = obj.GetProjectionModeMinValue ()` - Determine how to control the projection process. Simple projection just projects the original polyline points. Non-occluded projection insures that the polyline does not intersect the terrain surface. Hug projection is similar to non-occulded projection except that produces a path that is nearly parallel to the terrain (within the user specified height tolerance).
- `int = obj.GetProjectionModeMaxValue ()` - Determine how to control the projection process. Simple projection just projects the original polyline points. Non-occluded projection insures that the polyline does not intersect the terrain surface. Hug projection is similar to non-occulded projection except that produces a path that is nearly parallel to the terrain (within the user specified height tolerance).

- `int = obj.GetProjectionMode ()` - Determine how to control the projection process. Simple projection just projects the original polyline points. Non-occluded projection insures that the polyline does not intersect the terrain surface. Hug projection is similar to non-occulded projection except that produces a path that is nearly parallel to the terrain (within the user specified height tolerance).

- `obj.SetProjectionModeToSimple ()` - Determine how to control the projection process. Simple projection just projects the original polyline points. Non-occluded projection insures that the polyline does not intersect the terrain surface. Hug projection is similar to non-occulded projection except that produces a path that is nearly parallel to the terrain (within the user specified height tolerance).

- `obj.SetProjectionModeToNonOccluded ()` - Determine how to control the projection process. Simple projection just projects the original polyline points. Non-occluded projection insures that the polyline does not intersect the terrain surface. Hug projection is similar to non-occulded projection except that produces a path that is nearly parallel to the terrain (within the user specified height tolerance).

- `obj.SetProjectionModeToHug ()` - This is the height above (or below) the terrain that the projected path should be. Positive values indicate distances above the terrain; negative values indicate distances below the terrain.

- `obj.SetHeightOffset (double )` - This is the height above (or below) the terrain that the projected path should be. Positive values indicate distances above the terrain; negative values indicate distances below the terrain.

- `double = obj.GetHeightOffset ()` - This is the height above (or below) the terrain that the projected path should be. Positive values indicate distances above the terrain; negative values indicate distances below the terrain.

- `obj.SetHeightTolerance (double )` - This is the allowable variation in the altitude of the path with respect to the variation in the terrain. It only comes into play if the hug projection mode is enabled.

- `double = obj.GetHeightToleranceMinValue ()` - This is the allowable variation in the altitude of the path with respect to the variation in the terrain. It only comes into play if the hug projection mode is enabled.

- `double = obj.GetHeightToleranceMaxValue ()` - This is the allowable variation in the altitude of the path with respect to the variation in the terrain. It only comes into play if the hug projection mode is enabled.

- `double = obj.GetHeightTolerance ()` - This is the allowable variation in the altitude of the path with respect to the variation in the terrain. It only comes into play if the hug projection mode is enabled.

- `obj.SetMaximumNumberOfLines (vtkIdType )` - This instance variable can be used to limit the total number of line segments created during subdivision. Note that the number of input line segments will be the minimum number that cab be output.

- `vtkIdType = obj.GetMaximumNumberOfLinesMinValue ()` - This instance variable can be used to limit the total number of line segments created during subdivision. Note that the number of input line segments will be the minimum number that cab be output.

- `vtkIdType = obj.GetMaximumNumberOfLinesMaxValue ()` - This instance variable can be used to limit the total number of line segments created during subdivision. Note that the number of input line segments will be the minimum number that cab be output.

- `vtkIdType = obj.GetMaximumNumberOfLines ()` - This instance variable can be used to limit the total number of line segments created during subdivision. Note that the number of input line segments will be the minimum number that cab be output.

34.38 vtkRenderLargeImage

34.38.1 Usage

vtkRenderLargeImage provides methods needed to read a region from a file.

To create an instance of class vtkRenderLargeImage, simply invoke its constructor as follows

```
obj = vtkRenderLargeImage
```

34.38.2 Methods

The class vtkRenderLargeImage has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderLargeImage class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderLargeImage = obj.NewInstance ()`
- `vtkRenderLargeImage = obj.SafeDownCast (vtkObject o)`
- `obj.SetMagnification (int )` - The magnification of the current render window
- `int = obj.GetMagnification ()` - The magnification of the current render window
- `obj.SetInput (vtkRenderer )` - Indicates what renderer to get the pixel data from.
- `vtkRenderer = obj.GetInput ()` - Returns which renderer is being used as the source for the pixel data.
- `vtkImageData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.

34.39 vtkRIBExporter

34.39.1 Usage

vtkRIBExporter is a concrete subclass of vtkExporter that writes a Renderman .RIB files. The input specifies a vtkRenderWindow. All visible actors and lights will be included in the rib file. The following file naming conventions apply: rib file - FilePrefix.rib image file created by RenderMan - FilePrefix.tif texture files - TexturePrefix_0xADDR_MTIME.tif This object does NOT generate an image file. The user must run either RenderMan or a RenderMan emulator like Blue Moon Ray Tracer (BMRT). vtk properties are convert to Renderman shaders as follows: Normal property, no texture map - plastic.sl Normal property with texture map - txtplastic.sl These two shaders must be compiled by the rendering package being used. vtkRIBExporter also supports custom shaders. The shaders are written using the Renderman Shading Language. See "The Renderman Companion", ISBN 0-201-50868, 1989 for details on writing shaders. vtkRIBProperty specifies the declarations and parameter settings for custom shaders. Tcl Example: generate a rib file for the current rendering. vtkRIBExporter myRIB myRIB SetInput $renWin myRIB SetFIlePrefix mine myRIB Write This will create a file mine.rib. After running this file through a Renderman renderer a file mine.tif will contain the rendered image.

To create an instance of class vtkRIBExporter, simply invoke its constructor as follows

```
obj = vtkRIBExporter
```

34.39.2 Methods

The class vtkRIBExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRIBExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRIBExporter = obj.NewInstance ()`
- `vtkRIBExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetSize (int , int )`
- `obj.SetSize (int  a[2])`
- `int = obj. GetSize ()`
- `obj.SetPixelSamples (int , int )`
- `obj.SetPixelSamples (int  a[2])`
- `int = obj. GetPixelSamples ()`
- `obj.SetFilePrefix (string )` - Specify the prefix of the files to write out. The resulting file names will have .RIB appended to them.
- `string = obj.GetFilePrefix ()` - Specify the prefix of the files to write out. The resulting file names will have .RIB appended to them.
- `obj.SetTexturePrefix (string )` - Specify the prefix of any generated texture files.
- `string = obj.GetTexturePrefix ()` - Specify the prefix of any generated texture files.
- `obj.SetBackground (int )` - Set/Get the background flag. Default is 0 (off). If set, the rib file will contain an image shader that will use the renderer window's background color. Normally, RenderMan does generate backgrounds. Backgrounds are composited into the scene with the tiffcomp program that comes with Pixar's RenderMan Toolkit. In fact, Pixar's Renderman will accept an image shader but only sets the alpha of the background. Images created this way will still have a black background but contain an alpha of 1 at all pixels and CANNOT be subsequently composited with other images using tiffcomp. However, other RenderMan compliant renderers like Blue Moon Ray Tracing (BMRT) do allow image shaders and properly set the background color. If this sounds too confusing, use the following rules: If you are using Pixar's Renderman, leave the Background off. Otherwise, try setting BackGroundOn and see if you get the desired results.
- `int = obj.GetBackground ()` - Set/Get the background flag. Default is 0 (off). If set, the rib file will contain an image shader that will use the renderer window's background color. Normally, RenderMan does generate backgrounds. Backgrounds are composited into the scene with the tiffcomp program that comes with Pixar's RenderMan Toolkit. In fact, Pixar's Renderman will accept an image shader but only sets the alpha of the background. Images created this way will still have a black background but contain an alpha of 1 at all pixels and CANNOT be subsequently composited with other images using tiffcomp. However, other RenderMan compliant renderers like Blue Moon Ray Tracing (BMRT) do allow image shaders and properly set the background color. If this sounds too confusing, use the following rules: If you are using Pixar's Renderman, leave the Background off. Otherwise, try setting BackGroundOn and see if you get the desired results.

- `obj.BackgroundOn ()` - Set/Get the background flag. Default is 0 (off). If set, the rib file will contain an image shader that will use the renderer window's background color. Normally, RenderMan does generate backgrounds. Backgrounds are composited into the scene with the tiffcomp program that comes with Pixar's RenderMan Toolkit. In fact, Pixar's Renderman will accept an image shader but only sets the alpha of the background. Images created this way will still have a black background but contain an alpha of 1 at all pixels and CANNOT be subsequently composited with other images using tiffcomp. However, other RenderMan compliant renderers like Blue Moon Ray Tracing (BMRT) do allow image shaders and properly set the background color. If this sounds too confusing, use the following rules: If you are using Pixar's Renderman, leave the Background off. Otherwise, try setting BackGroundOn and see if you get the desired results.

- `obj.BackgroundOff ()` - Set/Get the background flag. Default is 0 (off). If set, the rib file will contain an image shader that will use the renderer window's background color. Normally, RenderMan does generate backgrounds. Backgrounds are composited into the scene with the tiffcomp program that comes with Pixar's RenderMan Toolkit. In fact, Pixar's Renderman will accept an image shader but only sets the alpha of the background. Images created this way will still have a black background but contain an alpha of 1 at all pixels and CANNOT be subsequently composited with other images using tiffcomp. However, other RenderMan compliant renderers like Blue Moon Ray Tracing (BMRT) do allow image shaders and properly set the background color. If this sounds too confusing, use the following rules: If you are using Pixar's Renderman, leave the Background off. Otherwise, try setting BackGroundOn and see if you get the desired results.

- `obj.SetExportArrays (int )` - Set or get the ExportArrays. If ExportArrays is set, then all point data, field data, and cell data arrays will get exported together with polygons.

- `int = obj.GetExportArraysMinValue ()` - Set or get the ExportArrays. If ExportArrays is set, then all point data, field data, and cell data arrays will get exported together with polygons.

- `int = obj.GetExportArraysMaxValue ()` - Set or get the ExportArrays. If ExportArrays is set, then all point data, field data, and cell data arrays will get exported together with polygons.

- `obj.ExportArraysOn ()` - Set or get the ExportArrays. If ExportArrays is set, then all point data, field data, and cell data arrays will get exported together with polygons.

- `obj.ExportArraysOff ()` - Set or get the ExportArrays. If ExportArrays is set, then all point data, field data, and cell data arrays will get exported together with polygons.

- `int = obj.GetExportArrays ()` - Set or get the ExportArrays. If ExportArrays is set, then all point data, field data, and cell data arrays will get exported together with polygons.

34.40 vtkRIBLight

34.40.1 Usage

vtkRIBLight is a subclass of vtkLight that allows the user to specify light source shaders and shadow casting lights for use with RenderMan.

To create an instance of class vtkRIBLight, simply invoke its constructor as follows

```
obj = vtkRIBLight
```

34.40.2 Methods

The class vtkRIBLight has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRIBLight class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRIBLight = obj.NewInstance ()`
- `vtkRIBLight = obj.SafeDownCast (vtkObject o)`
- `obj.ShadowsOn ()`
- `obj.ShadowsOff ()`
- `obj.SetShadows (int )`
- `int = obj.GetShadows ()`
- `obj.Render (vtkRenderer ren, int index)`

34.41 vtkRIBProperty

34.41.1 Usage

vtkRIBProperty is a subclass of vtkProperty that allows the user to specify named shaders for use with RenderMan. Both a surface shader and displacement shader can be specified. Parameters for the shaders can be declared and set.

To create an instance of class vtkRIBProperty, simply invoke its constructor as follows

```
obj = vtkRIBProperty
```

34.41.2 Methods

The class vtkRIBProperty has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRIBProperty class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRIBProperty = obj.NewInstance ()`
- `vtkRIBProperty = obj.SafeDownCast (vtkObject o)`
- `obj.SetSurfaceShader (string )` - Specify the name of a surface shader.
- `string = obj.GetSurfaceShader ()` - Specify the name of a surface shader.
- `obj.SetDisplacementShader (string )` - Specify the name of a displacement shader.
- `string = obj.GetDisplacementShader ()` - Specify the name of a displacement shader.
- `obj.SetVariable (string variable, string declaration)` - Specify declarations for variables..
- `obj.AddVariable (string variable, string declaration)` - Specify declarations for variables..
- `string = obj.GetDeclarations ()` - Get variable declarations
- `obj.SetParameter (string parameter, string value)` - Specify parameter values for variables.
- `obj.AddParameter (string parameter, string value)` - Specify parameter values for variables.
- `string = obj.GetParameters ()` - Get parameters.

34.42 vtkSpiderPlotActor

34.42.1 Usage

vtkSpiderPlotActor generates a spider plot from an input field (i.e., vtkDataObject). A spider plot represents N-dimensional data by using a set of N axes that originate from the center of a circle, and form the spokes of a wheel (like a spider web). Each N-dimensional point is plotted as a polyline that forms a closed polygon; the vertices of the polygon are plotted against the radial axes.

To use this class, you must specify an input data object. You'll probably also want to specify the position of the plot be setting the Position and Position2 instance variables, which define a rectangle in which the plot lies. Another important parameter is the IndependentVariables ivar, which tells the instance how to interpret the field data (independent variables as the rows or columns of the field). There are also many other instance variables that control the look of the plot includes its title and legend.

Set the text property/attributes of the title and the labels through the vtkTextProperty objects associated with these components.

To create an instance of class vtkSpiderPlotActor, simply invoke its constructor as follows

```
obj = vtkSpiderPlotActor
```

34.42.2 Methods

The class vtkSpiderPlotActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSpiderPlotActor class.

- `string = obj.GetClassName ()` - Standard methods for type information and printing.
- `int = obj.IsA (string name)` - Standard methods for type information and printing.
- `vtkSpiderPlotActor = obj.NewInstance ()` - Standard methods for type information and printing.
- `vtkSpiderPlotActor = obj.SafeDownCast (vtkObject o)` - Standard methods for type information and printing.
- `obj.SetInput (vtkDataObject )` - Set the input to the spider plot actor.
- `vtkDataObject = obj.GetInput ()` - Get the input data object to this actor.
- `obj.SetIndependentVariables (int )` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `int = obj.GetIndependentVariablesMinValue ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `int = obj.GetIndependentVariablesMaxValue ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `int = obj.GetIndependentVariables ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `obj.SetIndependentVariablesToColumns ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.

- `obj.SetIndependentVariablesToRows ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `obj.SetTitleVisibility (int )` - Enable/Disable the display of a plot title.
- `int = obj.GetTitleVisibility ()` - Enable/Disable the display of a plot title.
- `obj.TitleVisibilityOn ()` - Enable/Disable the display of a plot title.
- `obj.TitleVisibilityOff ()` - Enable/Disable the display of a plot title.
- `obj.SetTitle (string )` - Set/Get the title of the spider plot.
- `string = obj.GetTitle ()` - Set/Get the title of the spider plot.
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property.
- `obj.SetLabelVisibility (int )`
- `int = obj.GetLabelVisibility ()`
- `obj.LabelVisibilityOn ()`
- `obj.LabelVisibilityOff ()`
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.SetNumberOfRings (int )` - Specify the number of circumferential rings. If set to zero, then none will be shown; othewise the specified number will be shown.
- `int = obj.GetNumberOfRingsMinValue ()` - Specify the number of circumferential rings. If set to zero, then none will be shown; othewise the specified number will be shown.
- `int = obj.GetNumberOfRingsMaxValue ()` - Specify the number of circumferential rings. If set to zero, then none will be shown; othewise the specified number will be shown.
- `int = obj.GetNumberOfRings ()` - Specify the number of circumferential rings. If set to zero, then none will be shown; othewise the specified number will be shown.
- `obj.SetAxisLabel (int i, string )` - Specify the names of the radial spokes (i.e., the radial axes). If not specified, then an integer number is automatically generated.
- `string = obj.GetAxisLabel (int i)` - Specify the names of the radial spokes (i.e., the radial axes). If not specified, then an integer number is automatically generated.
- `obj.SetAxisRange (int i, double min, double max)` - Specify the range of data on each radial axis. If not specified, then the range is computed automatically.
- `obj.SetAxisRange (int i, double range[2])` - Specify the range of data on each radial axis. If not specified, then the range is computed automatically.
- `obj.GetAxisRange (int i, double range[2])` - Specify the range of data on each radial axis. If not specified, then the range is computed automatically.
- `obj.SetPlotColor (int i, double r, double g, double b)` - Specify colors for each plot. If not specified, they are automatically generated.

- `obj.SetPlotColor (int i, double color[3])` - Specify colors for each plot. If not specified, they are automatically generated.
- `obj.SetLegendVisibility (int )` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `int = obj.GetLegendVisibility ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendVisibilityOn ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendVisibilityOff ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `vtkLegendBoxActor = obj.GetLegendActor ()` - Retrieve handles to the legend box. This is useful if you would like to manually control the legend appearance.
- `int = obj.RenderOverlay (vtkViewport )` - Draw the spider plot.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Draw the spider plot.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

34.43 vtkStructuredExtent

34.43.1 Usage

vtkStructuredExtent is an helper class that helps in arithmetic with structured extents. It defines a bunch of static methods (most of which are inlined) to aid in dealing with extents.

To create an instance of class vtkStructuredExtent, simply invoke its constructor as follows

```
obj = vtkStructuredExtent
```

34.43.2 Methods

The class vtkStructuredExtent has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredExtent class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredExtent = obj.NewInstance ()`
- `vtkStructuredExtent = obj.SafeDownCast (vtkObject o)`

34.44 vtkTemporalDataSetCache

34.44.1 Usage

vtkTemporalDataSetCache cache time step requests of a temporal dataset, when cached data is requested it is returned using a shallow copy. .SECTION Thanks Ken Martin (Kitware) and John Bidiscombe of CSCS - Swiss National Supercomputing Centre for creating and contributing this class. For related material, please refer to : John Biddiscombe, Berk Geveci, Ken Martin, Kenneth Moreland, David Thompson, "Time Dependent Processing in a Parallel Pipeline Architecture", IEEE Visualization 2007.

To create an instance of class vtkTemporalDataSetCache, simply invoke its constructor as follows

```
obj = vtkTemporalDataSetCache
```

34.44.2 Methods

The class vtkTemporalDataSetCache has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalDataSetCache class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalDataSetCache = obj.NewInstance ()`
- `vtkTemporalDataSetCache = obj.SafeDownCast (vtkObject o)`
- `obj.SetCacheSize (int size)` - This is the maximum number of time steps that can be retained in memory. it defaults to 10.
- `int = obj.GetCacheSize ()` - This is the maximum number of time steps that can be retained in memory. it defaults to 10.

34.45 vtkTemporalInterpolator

34.45.1 Usage

vtkTemporalInterpolator interpolates between two time steps to produce new data for an arbitrary T. vtkTemporalInterpolator has three modes of operation. The default mode is to produce a continuous range of time values as output, which enables a filter downstream to request any value of T within the range. The second mode of operation is enabled by setting DiscreteTimeStepInterval to a non zero value. When this mode is activated, the filter will report a finite number of Time steps separated by deltaT between the original range of values. This mode is useful when a dataset of N time steps has one (or more) missing datasets for certain T values and you simply wish to smooth over the missing steps but otherwise use the original data. The third mode of operation is enabled by setting ResampleFactor to a non zero positive integer value. When this mode is activated, the filter will report a finite number of Time steps which contain the original steps, plus N new values between each original step 1/ResampleFactor time units apart. Note that if the input time steps are irregular, then using ResampleFactor will produce an irregular sequence of regular steps between each of the original irregular steps (clear enough, yes?).

@TODO Higher order interpolation schemes will require changes to the API as most calls assume only two timesteps are used.

To create an instance of class vtkTemporalInterpolator, simply invoke its constructor as follows

```
obj = vtkTemporalInterpolator
```

34.45.2 Methods

The class vtkTemporalInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalInterpolator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalInterpolator = obj.NewInstance ()`
- `vtkTemporalInterpolator = obj.SafeDownCast (vtkObject o)`
- `obj.SetDiscreteTimeStepInterval (double )` - If you require a discrete number of outputs steps, to be generated from an input source - for example, you required N steps separated by T, then set DiscreteTimeStepInterval to T and you will get TIME_RANGE/DiscreteTimeStepInterval steps This is a useful option to use if you have a dataset with one missing time step and wish to 'fill-in' the missing data with an interpolated value from the steps either side
- `double = obj.GetDiscreteTimeStepInterval ()` - If you require a discrete number of outputs steps, to be generated from an input source - for example, you required N steps separated by T, then set DiscreteTimeStepInterval to T and you will get TIME_RANGE/DiscreteTimeStepInterval steps This is a useful option to use if you have a dataset with one missing time step and wish to 'fill-in' the missing data with an interpolated value from the steps either side
- `obj.SetResampleFactor (int )` - When ResampleFactor is a non zero positive integer, each pair of input time steps will be interpolated between with the number of steps specified. For example an input of 1,2,3,4,5 and a resample factor of 10, will produce steps 0f 1.0, 1.1, 1.2.....1.9, 2.0 etc NB. Irregular input steps will produce irregular output steps. Resample factor wuill only be used if DiscreteTimeStepInterval is zero otherwise the DiscreteTimeStepInterval takes precedence
- `int = obj.GetResampleFactor ()` - When ResampleFactor is a non zero positive integer, each pair of input time steps will be interpolated between with the number of steps specified. For example an input of 1,2,3,4,5 and a resample factor of 10, will produce steps 0f 1.0, 1.1, 1.2.....1.9, 2.0 etc NB. Irregular input steps will produce irregular output steps. Resample factor wuill only be used if DiscreteTimeStepInterval is zero otherwise the DiscreteTimeStepInterval takes precedence

34.46 vtkTemporalShiftScale

34.46.1 Usage

vtkTemporalShiftScale modify the time range or time steps of the data without changing the data itself. The data is not resampled by this filter, only the information accompanying the data is modified.

To create an instance of class vtkTemporalShiftScale, simply invoke its constructor as follows

```
obj = vtkTemporalShiftScale
```

34.46.2 Methods

The class vtkTemporalShiftScale has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalShiftScale class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkTemporalShiftScale = obj.NewInstance ()`
- `vtkTemporalShiftScale = obj.SafeDownCast (vtkObject o)`
- `obj.SetPreShift (double )` - Apply a translation to the data before scaling. To convert T5,100 to T0,1 use Preshift=-5, Scale=1/95, PostShift=0 To convert T5,105 to T5,10 use Preshift=-5, Scale=5/100, PostShift=5
- `double = obj.GetPreShift ()` - Apply a translation to the data before scaling. To convert T5,100 to T0,1 use Preshift=-5, Scale=1/95, PostShift=0 To convert T5,105 to T5,10 use Preshift=-5, Scale=5/100, PostShift=5
- `obj.SetPostShift (double )` - Apply a translation to the time
- `double = obj.GetPostShift ()` - Apply a translation to the time
- `obj.SetScale (double )` - Apply a scale to the time.
- `double = obj.GetScale ()` - Apply a scale to the time.
- `obj.SetPeriodic (int )` - If Periodic is true, requests for time will be wrapped around so that the source appears to be a periodic time source. If data exists for times 0,N-1, setting periodic to true will cause time 0 to be produced when time N, 2N, 2N etc is requested. This effectively gives the source the ability to generate time data indefinitely in a loop. When combined with Shift/Scale, the time becomes periodic in the shifted and scaled time frame of reference. Note: Since the input time may not start at zero, the wrapping of time from the end of one period to the start of the next, will subtract the initial time - a source with T5..6 repeated periodicaly will have output time 5..6..7..8 etc.
- `int = obj.GetPeriodic ()` - If Periodic is true, requests for time will be wrapped around so that the source appears to be a periodic time source. If data exists for times 0,N-1, setting periodic to true will cause time 0 to be produced when time N, 2N, 2N etc is requested. This effectively gives the source the ability to generate time data indefinitely in a loop. When combined with Shift/Scale, the time becomes periodic in the shifted and scaled time frame of reference. Note: Since the input time may not start at zero, the wrapping of time from the end of one period to the start of the next, will subtract the initial time - a source with T5..6 repeated periodicaly will have output time 5..6..7..8 etc.
- `obj.PeriodicOn ()` - If Periodic is true, requests for time will be wrapped around so that the source appears to be a periodic time source. If data exists for times 0,N-1, setting periodic to true will cause time 0 to be produced when time N, 2N, 2N etc is requested. This effectively gives the source the ability to generate time data indefinitely in a loop. When combined with Shift/Scale, the time becomes periodic in the shifted and scaled time frame of reference. Note: Since the input time may not start at zero, the wrapping of time from the end of one period to the start of the next, will subtract the initial time - a source with T5..6 repeated periodicaly will have output time 5..6..7..8 etc.
- `obj.PeriodicOff ()` - If Periodic is true, requests for time will be wrapped around so that the source appears to be a periodic time source. If data exists for times 0,N-1, setting periodic to true will cause time 0 to be produced when time N, 2N, 2N etc is requested. This effectively gives the source the ability to generate time data indefinitely in a loop. When combined with Shift/Scale, the time becomes periodic in the shifted and scaled time frame of reference. Note: Since the input time may not start at zero, the wrapping of time from the end of one period to the start of the next, will subtract the initial time - a source with T5..6 repeated periodicaly will have output time 5..6..7..8 etc.
- `obj.SetPeriodicEndCorrection (int )` - if Periodic time is enabled, this flag determines if the last time step is the same as the first. If PeriodicEndCorrection is true, then it is assumed that the input data goes from 0-1 (or whatever scaled/shifted actual time) and time 1 is the same as time 0 so that steps will be 0,1,2,3...N,1,2,3...N,1,2,3 where step N is the same as 0 and step 0 is not repeated. When this flag is false the data is assumed to be literal and output is of the form 0,1,2,3...N,0,1,2,3... By default this flag is ON

- `int = obj.GetPeriodicEndCorrection ()` - if Periodic time is enabled, this flag determines if the last time step is the same as the first. If PeriodicEndCorrection is true, then it is assumed that the input data goes from 0-1 (or whatever scaled/shifted actual time) and time 1 is the same as time 0 so that steps will be 0,1,2,3...N,1,2,3...N,1,2,3 where step N is the same as 0 and step 0 is not repeated. When this flag is false the data is assumed to be literal and output is of the form 0,1,2,3...N,0,1,2,3... By default this flag is ON

- `obj.PeriodicEndCorrectionOn ()` - if Periodic time is enabled, this flag determines if the last time step is the same as the first. If PeriodicEndCorrection is true, then it is assumed that the input data goes from 0-1 (or whatever scaled/shifted actual time) and time 1 is the same as time 0 so that steps will be 0,1,2,3...N,1,2,3...N,1,2,3 where step N is the same as 0 and step 0 is not repeated. When this flag is false the data is assumed to be literal and output is of the form 0,1,2,3...N,0,1,2,3... By default this flag is ON

- `obj.PeriodicEndCorrectionOff ()` - if Periodic time is enabled, this flag determines if the last time step is the same as the first. If PeriodicEndCorrection is true, then it is assumed that the input data goes from 0-1 (or whatever scaled/shifted actual time) and time 1 is the same as time 0 so that steps will be 0,1,2,3...N,1,2,3...N,1,2,3 where step N is the same as 0 and step 0 is not repeated. When this flag is false the data is assumed to be literal and output is of the form 0,1,2,3...N,0,1,2,3... By default this flag is ON

- `obj.SetMaximumNumberOfPeriods (double )` - if Periodic time is enabled, this controls how many time periods time is reported for. A filter cannot output an infinite number of time steps and therefore a finite number of periods is generated when reporting time.

- `double = obj.GetMaximumNumberOfPeriods ()` - if Periodic time is enabled, this controls how many time periods time is reported for. A filter cannot output an infinite number of time steps and therefore a finite number of periods is generated when reporting time.

34.47 vtkTemporalSnapToTimeStep

34.47.1 Usage

vtkTemporalSnapToTimeStep modify the time range or time steps of the data without changing the data itself. The data is not resampled by this filter, only the information accompanying the data is modified.

To create an instance of class vtkTemporalSnapToTimeStep, simply invoke its constructor as follows

```
obj = vtkTemporalSnapToTimeStep
```

34.47.2 Methods

The class vtkTemporalSnapToTimeStep has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalSnapToTimeStep class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkTemporalSnapToTimeStep = obj.NewInstance ()`

- `vtkTemporalSnapToTimeStep = obj.SafeDownCast (vtkObject o)`

- `obj.SetSnapMode (int )`

- `int = obj.GetSnapMode ()`

- `obj.SetSnapModeToNearest ()`
- `obj.SetSnapModeToNextBelowOrEqual ()`
- `obj.SetSnapModeToNextAboveOrEqual ()`

34.48 vtkThinPlateSplineTransform

34.48.1 Usage

vtkThinPlateSplineTransform describes a nonlinear warp transform defined by a set of source and target landmarks. Any point on the mesh close to a source landmark will be moved to a place close to the corresponding target landmark. The points in between are interpolated smoothly using Bookstein's Thin Plate Spline algorithm.

To obtain a correct TPS warp, use the R2LogR kernel if your data is 2D, and the R kernel if your data is 3D. Or you can specify your own RBF. (Hence this class is more general than a pure TPS transform.)

To create an instance of class vtkThinPlateSplineTransform, simply invoke its constructor as follows

```
obj = vtkThinPlateSplineTransform
```

34.48.2 Methods

The class vtkThinPlateSplineTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThinPlateSplineTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThinPlateSplineTransform = obj.NewInstance ()`
- `vtkThinPlateSplineTransform = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetSigma ()` - Specify the 'stiffness' of the spline. The default is 1.0.
- `obj.SetSigma (double )` - Specify the 'stiffness' of the spline. The default is 1.0.
- `obj.SetBasis (int basis)` - Specify the radial basis function to use. The default is R2LogR which is appropriate for 2D. Use —R— (SetBasisToR) if your data is 3D. Alternatively specify your own basis function, however this will mean that the transform will no longer be a true thin-plate spline.
- `int = obj.GetBasis ()` - Specify the radial basis function to use. The default is R2LogR which is appropriate for 2D. Use —R— (SetBasisToR) if your data is 3D. Alternatively specify your own basis function, however this will mean that the transform will no longer be a true thin-plate spline.
- `obj.SetBasisToR ()` - Specify the radial basis function to use. The default is R2LogR which is appropriate for 2D. Use —R— (SetBasisToR) if your data is 3D. Alternatively specify your own basis function, however this will mean that the transform will no longer be a true thin-plate spline.
- `obj.SetBasisToR2LogR ()` - Specify the radial basis function to use. The default is R2LogR which is appropriate for 2D. Use —R— (SetBasisToR) if your data is 3D. Alternatively specify your own basis function, however this will mean that the transform will no longer be a true thin-plate spline.
- `string = obj.GetBasisAsString ()` - Specify the radial basis function to use. The default is R2LogR which is appropriate for 2D. Use —R— (SetBasisToR) if your data is 3D. Alternatively specify your own basis function, however this will mean that the transform will no longer be a true thin-plate spline.

- `obj.SetSourceLandmarks (vtkPoints source)` - Set the source landmarks for the warp. If you add or change the vtkPoints object, you must call Modified() on it or the transformation might not update.
- `vtkPoints = obj.GetSourceLandmarks ()` - Set the source landmarks for the warp. If you add or change the vtkPoints object, you must call Modified() on it or the transformation might not update.
- `obj.SetTargetLandmarks (vtkPoints target)` - Set the target landmarks for the warp. If you add or change the vtkPoints object, you must call Modified() on it or the transformation might not update.
- `vtkPoints = obj.GetTargetLandmarks ()` - Set the target landmarks for the warp. If you add or change the vtkPoints object, you must call Modified() on it or the transformation might not update.
- `long = obj.GetMTime ()` - Get the MTime.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

34.49 vtkTransformToGrid

34.49.1 Usage

vtkTransformToGrid takes any transform as input and produces a grid for use by a vtkGridTransform. This can be used, for example, to invert a grid transform, concatenate two grid transforms, or to convert a thin plate spline transform into a grid transform.

To create an instance of class vtkTransformToGrid, simply invoke its constructor as follows

```
obj = vtkTransformToGrid
```

34.49.2 Methods

The class vtkTransformToGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformToGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransformToGrid = obj.NewInstance ()`
- `vtkTransformToGrid = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkAbstractTransform )` - Set/Get the transform which will be converted into a grid.
- `vtkAbstractTransform = obj.GetInput ()` - Set/Get the transform which will be converted into a grid.
- `obj.SetGridExtent (int , int , int , int , int , int )` - Get/Set the extent of the grid.
- `obj.SetGridExtent (int  a[6])` - Get/Set the extent of the grid.
- `int = obj. GetGridExtent ()` - Get/Set the extent of the grid.
- `obj.SetGridOrigin (double , double , double )` - Get/Set the origin of the grid.
- `obj.SetGridOrigin (double  a[3])` - Get/Set the origin of the grid.
- `double = obj. GetGridOrigin ()` - Get/Set the origin of the grid.

- `obj.SetGridSpacing (double , double , double )` - Get/Set the spacing between samples in the grid.
- `obj.SetGridSpacing (double  a[3])` - Get/Set the spacing between samples in the grid.
- `double = obj. GetGridSpacing ()` - Get/Set the spacing between samples in the grid.
- `obj.SetGridScalarType (int )` - Get/Set the scalar type of the grid. The default is double.
- `int = obj.GetGridScalarType ()` - Get/Set the scalar type of the grid. The default is double.
- `obj.SetGridScalarTypeToFloat ()` - Get/Set the scalar type of the grid. The default is double.
- `obj.SetGridScalarTypeToShort ()` - Get/Set the scalar type of the grid. The default is double.
- `obj.SetGridScalarTypeToUnsignedShort ()` - Get/Set the scalar type of the grid. The default is double.
- `obj.SetGridScalarTypeToUnsignedChar ()` - Get/Set the scalar type of the grid. The default is double.
- `obj.SetGridScalarTypeToChar ()` - Get/Set the scalar type of the grid. The default is double.
- `double = obj.GetDisplacementScale ()` - Get the scale and shift to convert integer grid elements into real values: dx = scale*di + shift. If the grid is of double type, then scale = 1 and shift = 0.
- `double = obj.GetDisplacementShift ()` - Get the scale and shift to convert integer grid elements into real values: dx = scale*di + shift. If the grid is of double type, then scale = 1 and shift = 0.
- `vtkImageData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.

34.50 vtkVectorText

34.50.1 Usage

To create an instance of class vtkVectorText, simply invoke its constructor as follows

```
obj = vtkVectorText
```

34.50.2 Methods

The class vtkVectorText has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVectorText class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVectorText = obj.NewInstance ()`
- `vtkVectorText = obj.SafeDownCast (vtkObject o)`
- `obj.SetText (string )` - Set/Get the text to be drawn.
- `string = obj.GetText ()` - Set/Get the text to be drawn.

34.51 vtkVideoSource

34.51.1 Usage

vtkVideoSource is a superclass for video input interfaces for VTK. The goal is to provide an interface which is very similar to the interface of a VCR, where the 'tape' is an internal frame buffer capable of holding a preset number of video frames. Specialized versions of this class record input from various video input sources. This base class records input from a noise source.

To create an instance of class vtkVideoSource, simply invoke its constructor as follows

```
obj = vtkVideoSource
```

34.51.2 Methods

The class vtkVideoSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVideoSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVideoSource = obj.NewInstance ()`
- `vtkVideoSource = obj.SafeDownCast (vtkObject o)`
- `obj.Record ()` - Record incoming video at the specified FrameRate. The recording continues indefinitely until Stop() is called.
- `obj.Play ()` - Play through the 'tape' sequentially at the specified frame rate. If you have just finished Recoding, you should call Rewind() first.
- `obj.Stop ()` - Stop recording or playing.
- `obj.Rewind ()` - Rewind to the frame with the earliest timestamp. Record operations will start on the following frame, therefore if you want to re-record over this frame you must call Seek(-1) before calling Grab() or Record().
- `obj.FastForward ()` - FastForward to the last frame that was recorded (i.e. to the frame that has the most recent timestamp).
- `obj.Seek (int n)` - Seek forwards or backwards by the specified number of frames (positive is forward, negative is backward).
- `obj.Grab ()` - Grab a single video frame.
- `int = obj.GetRecording ()` - Are we in record mode? (record mode and play mode are mutually exclusive).
- `int = obj.GetPlaying ()` - Are we in play mode? (record mode and play mode are mutually exclusive).
- `obj.SetFrameSize (int x, int y, int z)` - Set the full-frame size. This must be an allowed size for the device, the device may either refuse a request for an illegal frame size or automatically choose a new frame size. The default is usually 320x240x1, but can be device specific. The 'depth' should always be 1 (unless you have a device that can handle 3D acquisition).

- `obj.SetFrameSize (int dim[3])` - Set the full-frame size. This must be an allowed size for the device, the device may either refuse a request for an illegal frame size or automatically choose a new frame size. The default is usually 320x240x1, but can be device specific. The 'depth' should always be 1 (unless you have a device that can handle 3D acquisition).

- `int = obj. GetFrameSize ()` - Set the full-frame size. This must be an allowed size for the device, the device may either refuse a request for an illegal frame size or automatically choose a new frame size. The default is usually 320x240x1, but can be device specific. The 'depth' should always be 1 (unless you have a device that can handle 3D acquisition).

- `obj.SetFrameRate (float rate)` - Request a particular frame rate (default 30 frames per second).

- `float = obj.GetFrameRate ()` - Request a particular frame rate (default 30 frames per second).

- `obj.SetOutputFormat (int format)` - Set the output format. This must be appropriate for device, usually only VTK_LUMINANCE, VTK_RGB, and VTK_RGBA are supported.

- `obj.SetOutputFormatToLuminance ()` - Set the output format. This must be appropriate for device, usually only VTK_LUMINANCE, VTK_RGB, and VTK_RGBA are supported.

- `obj.SetOutputFormatToRGB ()` - Set the output format. This must be appropriate for device, usually only VTK_LUMINANCE, VTK_RGB, and VTK_RGBA are supported.

- `obj.SetOutputFormatToRGBA ()` - Set the output format. This must be appropriate for device, usually only VTK_LUMINANCE, VTK_RGB, and VTK_RGBA are supported.

- `int = obj.GetOutputFormat ()` - Set the output format. This must be appropriate for device, usually only VTK_LUMINANCE, VTK_RGB, and VTK_RGBA are supported.

- `obj.SetFrameBufferSize (int FrameBufferSize)` - Set size of the frame buffer, i.e. the number of frames that the 'tape' can store.

- `int = obj.GetFrameBufferSize ()` - Set size of the frame buffer, i.e. the number of frames that the 'tape' can store.

- `obj.SetNumberOfOutputFrames (int )` - Set the number of frames to copy to the output on each execute. The frames will be concatenated along the Z dimension, with the most recent frame first. Default: 1

- `int = obj.GetNumberOfOutputFrames ()` - Set the number of frames to copy to the output on each execute. The frames will be concatenated along the Z dimension, with the most recent frame first. Default: 1

- `obj.AutoAdvanceOn ()` - Set whether to automatically advance the buffer before each grab. Default: on

- `obj.AutoAdvanceOff ()` - Set whether to automatically advance the buffer before each grab. Default: on

- `obj.SetAutoAdvance (int )` - Set whether to automatically advance the buffer before each grab. Default: on

- `int = obj.GetAutoAdvance ()` - Set whether to automatically advance the buffer before each grab. Default: on

- `obj.SetClipRegion (int r[6])` - Set the clip rectangle for the frames. The video will be clipped before it is copied into the framebuffer. Changing the ClipRegion will destroy the current contents of the framebuffer. The default ClipRegion is (0,VTK_INT_MAX,0,VTK_INT_MAX,0,VTK_INT_MAX).

- `obj.SetClipRegion (int x0, int x1, int y0, int y1, int z0, int z1)` - Set the clip rectangle for the frames. The video will be clipped before it is copied into the framebuffer. Changing the ClipRegion will destroy the current contents of the framebuffer. The default ClipRegion is (0,VTK_INT_MAX,0,VTK_INT_MAX,0,VTK_INT_MAX).

- `int = obj. GetClipRegion ()` - Set the clip rectangle for the frames. The video will be clipped before it is copied into the framebuffer. Changing the ClipRegion will destroy the current contents of the framebuffer. The default ClipRegion is (0,VTK_INT_MAX,0,VTK_INT_MAX,0,VTK_INT_MAX).

- `obj.SetOutputWholeExtent (int , int , int , int , int , int )` - Get/Set the WholeExtent of the output. This can be used to either clip or pad the video frame. This clipping/padding is done when the frame is copied to the output, and does not change the contents of the framebuffer. This is useful e.g. for expanding the output size to a power of two for texture mapping. The default is (0,-1,0,-1,0,-1) which causes the entire frame to be copied to the output.

- `obj.SetOutputWholeExtent (int a[6])` - Get/Set the WholeExtent of the output. This can be used to either clip or pad the video frame. This clipping/padding is done when the frame is copied to the output, and does not change the contents of the framebuffer. This is useful e.g. for expanding the output size to a power of two for texture mapping. The default is (0,-1,0,-1,0,-1) which causes the entire frame to be copied to the output.

- `int = obj. GetOutputWholeExtent ()` - Get/Set the WholeExtent of the output. This can be used to either clip or pad the video frame. This clipping/padding is done when the frame is copied to the output, and does not change the contents of the framebuffer. This is useful e.g. for expanding the output size to a power of two for texture mapping. The default is (0,-1,0,-1,0,-1) which causes the entire frame to be copied to the output.

- `obj.SetDataSpacing (double , double , double )` - Set/Get the pixel spacing. Default: (1.0,1.0,1.0)

- `obj.SetDataSpacing (double a[3])` - Set/Get the pixel spacing. Default: (1.0,1.0,1.0)

- `double = obj. GetDataSpacing ()` - Set/Get the pixel spacing. Default: (1.0,1.0,1.0)

- `obj.SetDataOrigin (double , double , double )` - Set/Get the coordinates of the lower, left corner of the frame. Default: (0.0,0.0,0.0)

- `obj.SetDataOrigin (double a[3])` - Set/Get the coordinates of the lower, left corner of the frame. Default: (0.0,0.0,0.0)

- `double = obj. GetDataOrigin ()` - Set/Get the coordinates of the lower, left corner of the frame. Default: (0.0,0.0,0.0)

- `obj.SetOpacity (float )` - For RGBA output only (4 scalar components), set the opacity. This will not modify the existing contents of the framebuffer, only subsequently grabbed frames.

- `float = obj.GetOpacity ()` - For RGBA output only (4 scalar components), set the opacity. This will not modify the existing contents of the framebuffer, only subsequently grabbed frames.

- `int = obj.GetFrameCount ()` - This value is incremented each time a frame is grabbed. reset it to zero (or any other value) at any time.

- `obj.SetFrameCount (int )` - This value is incremented each time a frame is grabbed. reset it to zero (or any other value) at any time.

- `int = obj.GetFrameIndex ()` - Get the frame index relative to the 'beginning of the tape'. This value wraps back to zero if it increases past the FrameBufferSize.

- `double = obj.GetFrameTimeStamp (int frame)` - Get a time stamp in seconds (resolution of milliseconds) for a video frame. Time began on Jan 1, 1970. You can specify a number (negative or positive) to specify the position of the video frame relative to the current frame.

- `double = obj.GetFrameTimeStamp ()` - Get a time stamp in seconds (resolution of milliseconds) for the Output. Time began on Jan 1, 1970. This timestamp is only valid after the Output has been Updated.
- `obj.Initialize ()` - Initialize the hardware. This is called automatically on the first Update or Grab.
- `int = obj.GetInitialized ()` - Initialize the hardware. This is called automatically on the first Update or Grab.
- `obj.ReleaseSystemResources ()` - Release the video driver. This method must be called before application exit, or else the application might hang during exit.
- `obj.InternalGrab ()` - The internal function which actually does the grab. You will definitely want to override this if you develop a vtkVideoSource subclass.
- `obj.SetStartTimeStamp (double t)` - And internal variable which marks the beginning of a Record session. These methods are for internal use only.
- `double = obj.GetStartTimeStamp ()` - And internal variable which marks the beginning of a Record session. These methods are for internal use only.

34.52 vtkVRMLImporter

34.52.1 Usage

vtkVRMLImporter imports VRML 2.0 files into vtk.

To create an instance of class vtkVRMLImporter, simply invoke its constructor as follows

```
obj = vtkVRMLImporter
```

34.52.2 Methods

The class vtkVRMLImporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVRMLImporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVRMLImporter = obj.NewInstance ()`
- `vtkVRMLImporter = obj.SafeDownCast (vtkObject o)`
- `vtkObject = obj.GetVRMLDEFObject (string name)` - In the VRML spec you can DEF and USE nodes (name them), This routine will return the associated VTK object which was created as a result of the DEF mechanism Send in the name from the VRML file, get the VTK object. You will have to check and correctly cast the object since this only returns vtkObjects.
- `obj.enterNode (string )` - Needed by the yacc/lex grammar used
- `obj.exitNode ()` - Needed by the yacc/lex grammar used
- `obj.enterField (string )` - Needed by the yacc/lex grammar used
- `obj.exitField ()` - Needed by the yacc/lex grammar used
- `obj.useNode (string )` - Needed by the yacc/lex grammar used
- `obj.SetFileName (string )` - Specify the name of the file to read.
- `string = obj.GetFileName ()` - Specify the name of the file to read.

34.53 vtkWeightedTransformFilter

34.53.1 Usage

To create an instance of class vtkWeightedTransformFilter, simply invoke its constructor as follows

```
obj = vtkWeightedTransformFilter
```

34.53.2 Methods

The class vtkWeightedTransformFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWeightedTransformFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWeightedTransformFilter = obj.NewInstance ()`
- `vtkWeightedTransformFilter = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime also considering the filter's transforms.
- `obj.SetWeightArray (string )` - WeightArray is the string name of the DataArray in the input's FieldData that holds the weighting coefficients for each point. The filter will first look for the array in the input's PointData FieldData. If the array isn't there, the filter looks in the input's FieldData. The WeightArray can have tuples of any length, but must have a tuple for every point in the input data set. This array transforms points, normals, and vectors.
- `string = obj.GetWeightArray ()` - WeightArray is the string name of the DataArray in the input's FieldData that holds the weighting coefficients for each point. The filter will first look for the array in the input's PointData FieldData. If the array isn't there, the filter looks in the input's FieldData. The WeightArray can have tuples of any length, but must have a tuple for every point in the input data set. This array transforms points, normals, and vectors.
- `obj.SetTransformIndexArray (string )` - TransformIndexArray is the string name of the DataArray in the input's FieldData that holds the indices for the transforms for each point. These indices are used to select which transforms each weight of the DataArray refers. If the TransformIndexArray is not specified, the weights of each point are assumed to map directly to a transform. This DataArray must be of type UnsignedShort, which effectively limits the number of transforms to 65536 if a transform index array is used.

  The filter will first look for the array in the input's PointData FieldData. If the array isn't there, the filter looks in the input's FieldData. The TransformIndexArray can have tuples of any length, but must have a tuple for every point in the input data set. This array transforms points, normals, and vectors.
- `string = obj.GetTransformIndexArray ()` - TransformIndexArray is the string name of the DataArray in the input's FieldData that holds the indices for the transforms for each point. These indices are used to select which transforms each weight of the DataArray refers. If the TransformIndexArray is not specified, the weights of each point are assumed to map directly to a transform. This DataArray must be of type UnsignedShort, which effectively limits the number of transforms to 65536 if a transform index array is used.

  The filter will first look for the array in the input's PointData FieldData. If the array isn't there, the filter looks in the input's FieldData. The TransformIndexArray can have tuples of any length, but must have a tuple for every point in the input data set. This array transforms points, normals, and vectors.

- `obj.SetCellDataWeightArray (string )` - The CellDataWeightArray is analogous to the WeightArray, except for CellData. The array is searched for first in the CellData FieldData, then in the input's FieldData. The data array must have a tuple for each cell. This array is used to transform only normals and vectors.
- `string = obj.GetCellDataWeightArray ()` - The CellDataWeightArray is analogous to the WeightArray, except for CellData. The array is searched for first in the CellData FieldData, then in the input's FieldData. The data array must have a tuple for each cell. This array is used to transform only normals and vectors.
- `obj.SetCellDataTransformIndexArray (string )`
- `string = obj.GetCellDataTransformIndexArray ()`
- `obj.SetTransform (vtkAbstractTransform transform, int num)` - Set or Get one of the filter's transforms. The transform number must be less than the number of transforms allocated for the object. Setting a transform slot to NULL is equivalent to assigning an overriding weight of zero to that filter slot.
- `vtkAbstractTransform = obj.GetTransform (int num)` - Set or Get one of the filter's transforms. The transform number must be less than the number of transforms allocated for the object. Setting a transform slot to NULL is equivalent to assigning an overriding weight of zero to that filter slot.
- `obj.SetNumberOfTransforms (int num)` - Set the number of transforms for the filter. References to non-existent filter numbers in the data array is equivalent to a weight of zero (i.e., no contribution of that filter or weight). The maximum number of transforms is limited to 65536 if transform index arrays are used.
- `int = obj.GetNumberOfTransforms ()` - Set the number of transforms for the filter. References to non-existent filter numbers in the data array is equivalent to a weight of zero (i.e., no contribution of that filter or weight). The maximum number of transforms is limited to 65536 if transform index arrays are used.
- `obj.AddInputValuesOn ()` - If AddInputValues is true, the output values of this filter will be offset from the input values. The effect is exactly equivalent to having an identity transform of weight 1 added into each output point.
- `obj.AddInputValuesOff ()` - If AddInputValues is true, the output values of this filter will be offset from the input values. The effect is exactly equivalent to having an identity transform of weight 1 added into each output point.
- `obj.SetAddInputValues (int )` - If AddInputValues is true, the output values of this filter will be offset from the input values. The effect is exactly equivalent to having an identity transform of weight 1 added into each output point.
- `int = obj.GetAddInputValues ()` - If AddInputValues is true, the output values of this filter will be offset from the input values. The effect is exactly equivalent to having an identity transform of weight 1 added into each output point.

34.54 vtkX3DExporter

34.54.1 Usage

vtkX3DExporter is a render window exporter which writes out the renderered scene into an X3D file. X3D is an XML-based format for representation 3D scenes (similar to VRML). Check out http://www.web3d.org/x3d/ for more details. .SECTION Thanks X3DExporter is contributed by Christophe Mouton at EDF.

To create an instance of class vtkX3DExporter, simply invoke its constructor as follows

```
obj = vtkX3DExporter
```

34.54.2 Methods

The class vtkX3DExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkX3DExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkX3DExporter = obj.NewInstance ()`
- `vtkX3DExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Set/Get the output file name.
- `string = obj.GetFileName ()` - Set/Get the output file name.
- `obj.SetSpeed (double )` - Specify the Speed of navigation. Default is 4.
- `double = obj.GetSpeed ()` - Specify the Speed of navigation. Default is 4.
- `obj.SetBinary (int )` - Turn on binary mode
- `int = obj.GetBinaryMinValue ()` - Turn on binary mode
- `int = obj.GetBinaryMaxValue ()` - Turn on binary mode
- `obj.BinaryOn ()` - Turn on binary mode
- `obj.BinaryOff ()` - Turn on binary mode
- `int = obj.GetBinary ()` - Turn on binary mode
- `obj.SetFastest (int )` - In binary mode use fastest instead of best compression
- `int = obj.GetFastestMinValue ()` - In binary mode use fastest instead of best compression
- `int = obj.GetFastestMaxValue ()` - In binary mode use fastest instead of best compression
- `obj.FastestOn ()` - In binary mode use fastest instead of best compression
- `obj.FastestOff ()` - In binary mode use fastest instead of best compression
- `int = obj.GetFastest ()` - In binary mode use fastest instead of best compression

34.55 vtkXYPlotActor

34.55.1 Usage

vtkXYPlotActor creates an x-y plot of data from one or more input data sets or field data. The class plots dataset scalar values (y-axis) against the points (x-axis). The x-axis values are generated by taking the point ids, computing a cumulative arc length, or a normalized arc length. More than one input data set can be specified to generate multiple plots. Alternatively, if field data is supplied as input, the class plots one component against another. (The user must specify which component to use as the x-axis and which for the y-axis.)

To use this class to plot dataset(s), you must specify one or more input datasets containing scalar and point data. You'll probably also want to invoke a method to control how the point coordinates are converted into x values (by default point ids are used).

To use this class to plot field data, you must specify one or more input data objects with its associated field data. You'll also want to specify which component to use as the x-axis and which to use as the y-axis. Note that when plotting field data, the x and y values are used directly (i.e., there are no options to normalize the components).

Once you've set up the plot, you'll want to position it. The PositionCoordinate defines the lower-left location of the x-y plot (specified in normalized viewport coordinates) and the Position2Coordinate define the upper-right corner. (Note: the Position2Coordinate is relative to PositionCoordinate, so you can move the vtkXYPlotActor around the viewport by setting just the PositionCoordinate.) The combination of the two position coordinates specifies a rectangle in which the plot will lie.

Optional features include the ability to specify axes labels, label format and plot title. You can also manually specify the x and y plot ranges (by default they are computed automatically). The Border instance variable is used to create space between the boundary of the plot window (specified by PositionCoordinate and Position2Coordinate) and the plot itself.

The font property of the plot title can be modified through the TitleTextProperty attribute. The font property of the axes titles and labels can be modified through the AxisTitleTextProperty and AxisLabelTextProperty attributes. You may also use the GetXAxisActor2D or GetYAxisActor2D methods to access each individual axis actor to modify their font properties. In the same way, the GetLegendBoxActor method can be used to access the legend box actor to modify its font properties.

There are several advanced features as well. You can assign per curve properties (such as color and a plot symbol). (Note that each input dataset and/or data object creates a single curve.) Another option is to add a plot legend that graphically indicates the correspondance between the curve, curve symbols, and the data source. You can also exchange the x and y axes if you prefer you plot orientation that way.

To create an instance of class vtkXYPlotActor, simply invoke its constructor as follows

```
obj = vtkXYPlotActor
```

34.55.2 Methods

The class vtkXYPlotActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXYPlotActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXYPlotActor = obj.NewInstance ()`
- `vtkXYPlotActor = obj.SafeDownCast (vtkObject o)`
- `obj.AddInput (vtkDataSet in, string arrayName, int component)` - Add a dataset to the list of data to append. The array name specifies which point array to plot. The array must be a vtkDataArray subclass, i.e. a numeric array. If the array name is NULL, then the default scalars are used. The array can have multiple components, but only the first component is ploted.
- `obj.AddInput (vtkDataSet in)` - Remove a dataset from the list of data to append.
- `obj.RemoveInput (vtkDataSet in, string arrayName, int component)` - Remove a dataset from the list of data to append.
- `obj.RemoveInput (vtkDataSet in)` - This removes all of the data set inputs, but does not change the data object inputs.
- `obj.RemoveAllInputs ()` - This removes all of the data set inputs, but does not change the data object inputs.
- `vtkDataSetCollection = obj.GetInputList ()` - If plotting points by value, which component to use to determine the value. This sets a value per each input dataset (i.e., the ith dataset).

- `obj.SetPointComponent (int i, int comp)` - If plotting points by value, which component to use to determine the value. This sets a value per each input dataset (i.e., the ith dataset).

- `int = obj.GetPointComponent (int i)` - If plotting points by value, which component to use to determine the value. This sets a value per each input dataset (i.e., the ith dataset).

- `obj.SetXValues (int )` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `int = obj.GetXValuesMinValue ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `int = obj.GetXValuesMaxValue ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `int = obj.GetXValues ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `obj.SetXValuesToIndex ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `obj.SetXValuesToArcLength ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `obj.SetXValuesToNormalizedArcLength ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `obj.SetXValuesToValue ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length

along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)

- `string = obj.GetXValuesAsString ()` - Specify how the independent (x) variable is computed from the points. The independent variable can be the scalar/point index (i.e., point id), the accumulated arc length along the points, the normalized arc length, or by component value. If plotting datasets (e.g., points), the value that is used is specified by the PointComponent ivar. (Note: these methods also control how field data is plotted. Field data is usually plotted by value or index, if plotting length 1-dimensional length measures are used.)
- `obj.AddDataObjectInput (vtkDataObject in)` - Add a dataset to the list of data to append.
- `obj.RemoveDataObjectInput (vtkDataObject in)` - Remove a dataset from the list of data to append.
- `vtkDataObjectCollection = obj.GetDataObjectInputList ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `obj.SetDataObjectPlotMode (int )` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `int = obj.GetDataObjectPlotModeMinValue ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `int = obj.GetDataObjectPlotModeMaxValue ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `int = obj.GetDataObjectPlotMode ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `obj.SetDataObjectPlotModeToRows ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `obj.SetDataObjectPlotModeToColumns ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `string = obj.GetDataObjectPlotModeAsString ()` - Indicate whether to plot rows or columns. If plotting rows, then the dependent variables is taken from a specified row, versus rows (y).
- `obj.SetDataObjectXComponent (int i, int comp)` - Specify which component of the input data object to use as the independent variable for the ith input data object. (This ivar is ignored if plotting the index.) Note that the value is interpreted differently depending on DataObjectPlotMode. If the mode is Rows, then the value of DataObjectXComponent is the row number; otherwise it's the column number.
- `int = obj.GetDataObjectXComponent (int i)` - Specify which component of the input data object to use as the independent variable for the ith input data object. (This ivar is ignored if plotting the index.) Note that the value is interpreted differently depending on DataObjectPlotMode. If the mode is Rows, then the value of DataObjectXComponent is the row number; otherwise it's the column number.
- `obj.SetDataObjectYComponent (int i, int comp)` - Specify which component of the input data object to use as the dependent variable for the ith input data object. (This ivar is ignored if plotting the index.) Note that the value is interpreted differently depending on DataObjectPlotMode. If the mode is Rows, then the value of DataObjectYComponent is the row number; otherwise it's the column number.

- `int = obj.GetDataObjectYComponent (int i)` - Specify which component of the input data object to use as the dependent variable for the ith input data object. (This ivar is ignored if plotting the index.) Note that the value is interpreted differently depending on DataObjectPlotMode. If the mode is Rows, then the value of DataObjectYComponent is the row number; otherwise it's the column number.
- `obj.SetPlotColor (int i, double r, double g, double b)`
- `obj.SetPlotColor (int i, double color[3])`
- `double = obj.GetPlotColor (int i)`
- `obj.SetPlotSymbol (int i, vtkPolyData input)`
- `vtkPolyData = obj.GetPlotSymbol (int i)`
- `obj.SetPlotLabel (int i, string label)`
- `string = obj.GetPlotLabel (int i)`
- `int = obj.GetPlotCurvePoints ()`
- `obj.SetPlotCurvePoints (int )`
- `obj.PlotCurvePointsOn ()`
- `obj.PlotCurvePointsOff ()`
- `int = obj.GetPlotCurveLines ()`
- `obj.SetPlotCurveLines (int )`
- `obj.PlotCurveLinesOn ()`
- `obj.PlotCurveLinesOff ()`
- `obj.SetPlotLines (int i, int )`
- `int = obj.GetPlotLines (int i)`
- `obj.SetPlotPoints (int i, int )`
- `int = obj.GetPlotPoints (int i)`
- `obj.SetExchangeAxes (int )` - Enable/Disable exchange of the x-y axes (i.e., what was x becomes y, and vice-versa). Exchanging axes affects the labeling as well.
- `int = obj.GetExchangeAxes ()` - Enable/Disable exchange of the x-y axes (i.e., what was x becomes y, and vice-versa). Exchanging axes affects the labeling as well.
- `obj.ExchangeAxesOn ()` - Enable/Disable exchange of the x-y axes (i.e., what was x becomes y, and vice-versa). Exchanging axes affects the labeling as well.
- `obj.ExchangeAxesOff ()` - Enable/Disable exchange of the x-y axes (i.e., what was x becomes y, and vice-versa). Exchanging axes affects the labeling as well.
- `obj.SetReverseXAxis (int )` - Normally the x-axis is plotted from minimum to maximum. Setting this instance variable causes the x-axis to be plotted from maximum to minimum. Note that boolean always applies to the x-axis even if ExchangeAxes is set.
- `int = obj.GetReverseXAxis ()` - Normally the x-axis is plotted from minimum to maximum. Setting this instance variable causes the x-axis to be plotted from maximum to minimum. Note that boolean always applies to the x-axis even if ExchangeAxes is set.

- `obj.ReverseXAxisOn ()` - Normally the x-axis is plotted from minimum to maximum. Setting this instance variable causes the x-axis to be plotted from maximum to minimum. Note that boolean always applies to the x-axis even if ExchangeAxes is set.

- `obj.ReverseXAxisOff ()` - Normally the x-axis is plotted from minimum to maximum. Setting this instance variable causes the x-axis to be plotted from maximum to minimum. Note that boolean always applies to the x-axis even if ExchangeAxes is set.

- `obj.SetReverseYAxis (int )` - Normally the y-axis is plotted from minimum to maximum. Setting this instance variable causes the y-axis to be plotted from maximum to minimum. Note that boolean always applies to the y-axis even if ExchangeAxes is set.

- `int = obj.GetReverseYAxis ()` - Normally the y-axis is plotted from minimum to maximum. Setting this instance variable causes the y-axis to be plotted from maximum to minimum. Note that boolean always applies to the y-axis even if ExchangeAxes is set.

- `obj.ReverseYAxisOn ()` - Normally the y-axis is plotted from minimum to maximum. Setting this instance variable causes the y-axis to be plotted from maximum to minimum. Note that boolean always applies to the y-axis even if ExchangeAxes is set.

- `obj.ReverseYAxisOff ()` - Normally the y-axis is plotted from minimum to maximum. Setting this instance variable causes the y-axis to be plotted from maximum to minimum. Note that boolean always applies to the y-axis even if ExchangeAxes is set.

- `vtkLegendBoxActor = obj.GetLegendActor ()` - Retrieve handles to the legend box and glyph source. This is useful if you would like to change the default behavior of the legend box or glyph source. For example, the default glyph can be changed from a line to a vertex plus line, etc.)

- `vtkGlyphSource2D = obj.GetGlyphSource ()` - Retrieve handles to the legend box and glyph source. This is useful if you would like to change the default behavior of the legend box or glyph source. For example, the default glyph can be changed from a line to a vertex plus line, etc.)

- `obj.SetTitle (string )` - Set/Get the title of the x-y plot, and the title along the x and y axes.

- `string = obj.GetTitle ()` - Set/Get the title of the x-y plot, and the title along the x and y axes.

- `obj.SetXTitle (string )` - Set/Get the title of the x-y plot, and the title along the x and y axes.

- `string = obj.GetXTitle ()` - Set/Get the title of the x-y plot, and the title along the x and y axes.

- `obj.SetYTitle (string )` - Set/Get the title of the x-y plot, and the title along the x and y axes.

- `string = obj.GetYTitle ()` - Set/Get the title of the x-y plot, and the title along the x and y axes.

- `vtkAxisActor2D = obj.GetXAxisActor2D ()` - Retrieve handles to the X and Y axis (so that you can set their text properties for example)

- `vtkAxisActor2D = obj.GetYAxisActor2D ()` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `obj.SetXRange (double , double )` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `obj.SetXRange (double a[2])` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `double = obj. GetXRange ()` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `obj.SetYRange (double , double )` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `obj.SetYRange (double a[2])` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `double = obj. GetYRange ()` - Set the plot range (range of independent and dependent variables) to plot. Data outside of the range will be clipped. If the plot range of either the x or y variables is set to (v1,v2), where v1 == v2, then the range will be computed automatically. Note that the x-range values should be consistent with the way the independent variable is created (via INDEX, DISTANCE, or ARC_LENGTH).

- `obj.SetPlotRange (double xmin, double ymin, double xmax, double ymax)` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `obj.SetNumberOfXLabels (int )` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `int = obj.GetNumberOfXLabelsMinValue ()` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `int = obj.GetNumberOfXLabelsMaxValue ()` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `int = obj.GetNumberOfXLabels ()` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `obj.SetNumberOfYLabels (int )` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `int = obj.GetNumberOfYLabelsMinValue ()` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `int = obj.GetNumberOfYLabelsMaxValue ()` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `int = obj.GetNumberOfYLabels ()` - Set/Get the number of annotation labels to show along the x and y axes. This values is a suggestion: the number of labels may vary depending on the particulars of the data. The convenience method SetNumberOfLables() sets the number of x and y labels to the same value.

- `obj.SetNumberOfLabels (int num)` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.

- `obj.SetAdjustXLabels (int adjust)` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.

- `int = obj.GetAdjustXLabels ()` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.

- `obj.SetAdjustYLabels (int adjust)` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.

- `int = obj.GetAdjustYLabels ()` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.

- `obj.SetXTitlePosition (double position)` - Set/Get the position of the title of X or Y axis.

- `double = obj.GetXTitlePosition ()` - Set/Get the position of the title of X or Y axis.

- `obj.SetYTitlePosition (double position)` - Set/Get the position of the title of X or Y axis.

- `double = obj.GetYTitlePosition ()` - Set/Get the position of the title of X or Y axis.

- `obj.SetNumberOfXMinorTicks (int num)` - Set/Get the number of minor ticks in X or Y.

- `int = obj.GetNumberOfXMinorTicks ()` - Set/Get the number of minor ticks in X or Y.

- `obj.SetNumberOfYMinorTicks (int num)` - Set/Get the number of minor ticks in X or Y.

- `int = obj.GetNumberOfYMinorTicks ()` - Set/Get the number of minor ticks in X or Y.

- `obj.SetLegend (int )` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.

- `int = obj.GetLegend ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendOn ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.LegendOff ()` - Enable/Disable the creation of a legend. If on, the legend labels will be created automatically unless the per plot legend symbol has been set.
- `obj.SetTitlePosition (double , double )` - Set/Get the position of the title. This has no effect if AdjustTitlePosition is true.
- `obj.SetTitlePosition (double a[2])` - Set/Get the position of the title. This has no effect if AdjustTitlePosition is true.
- `double = obj. GetTitlePosition ()` - Set/Get the position of the title. This has no effect if AdjustTitlePosition is true.
- `obj.SetAdjustTitlePosition (int )` - If true, the xyplot actor will adjust the position of the title automatically to be upper-middle. Default is true.
- `int = obj.GetAdjustTitlePosition ()` - If true, the xyplot actor will adjust the position of the title automatically to be upper-middle. Default is true.
- `obj.AdjustTitlePositionOn ()` - If true, the xyplot actor will adjust the position of the title automatically to be upper-middle. Default is true.
- `obj.AdjustTitlePositionOff ()` - If true, the xyplot actor will adjust the position of the title automatically to be upper-middle. Default is true.
- `obj.SetAdjustTitlePositionMode (int )` - If AdjustTitlePosition is truem, the xyplot actor will adjust the position of the title automatically depending on the given mode, the mode is a combination of the Alignment flags. by default: vtkXYPlotActor::AlignHCenter — vtkXYPlotActor::Top — vtkXYPlotActor::AlignAxisVCenter
- `int = obj.GetAdjustTitlePositionMode ()` - If AdjustTitlePosition is truem, the xyplot actor will adjust the position of the title automatically depending on the given mode, the mode is a combination of the Alignment flags. by default: vtkXYPlotActor::AlignHCenter — vtkXYPlotActor::Top — vtkXYPlotActor::AlignAxisVCenter
- `obj.SetLegendPosition (double , double )` - Use these methods to control the position of the legend. The variables LegendPosition and LegendPosition2 define the lower-left and upper-right position of the legend. The coordinates are expressed as normalized values with respect to the rectangle defined by PositionCoordinate and Position2Coordinate. Note that LegendPosition2 is relative to LegendPosition.
- `obj.SetLegendPosition (double a[2])` - Use these methods to control the position of the legend. The variables LegendPosition and LegendPosition2 define the lower-left and upper-right position of the legend. The coordinates are expressed as normalized values with respect to the rectangle defined by PositionCoordinate and Position2Coordinate. Note that LegendPosition2 is relative to LegendPosition.
- `double = obj. GetLegendPosition ()` - Use these methods to control the position of the legend. The variables LegendPosition and LegendPosition2 define the lower-left and upper-right position of the legend. The coordinates are expressed as normalized values with respect to the rectangle defined by PositionCoordinate and Position2Coordinate. Note that LegendPosition2 is relative to LegendPosition.
- `obj.SetLegendPosition2 (double , double )` - Use these methods to control the position of the legend. The variables LegendPosition and LegendPosition2 define the lower-left and upper-right position of the legend. The coordinates are expressed as normalized values with respect to the rectangle defined by PositionCoordinate and Position2Coordinate. Note that LegendPosition2 is relative to LegendPosition.

- `obj.SetLegendPosition2 (double a[2])` - Use these methods to control the position of the legend. The variables LegendPosition and LegendPosition2 define the lower-left and upper-right position of the legend. The coordinates are expressed as normalized values with respect to the rectangle defined by PositionCoordinate and Position2Coordinate. Note that LegendPosition2 is relative to LegendPosition.
- `double = obj. GetLegendPosition2 ()` - Use these methods to control the position of the legend. The variables LegendPosition and LegendPosition2 define the lower-left and upper-right position of the legend. The coordinates are expressed as normalized values with respect to the rectangle defined by PositionCoordinate and Position2Coordinate. Note that LegendPosition2 is relative to LegendPosition.
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property.
- `obj.SetAxisTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property of all axes. Note that each axis can be controlled individually through the GetX/YAxisActor2D() methods.
- `vtkTextProperty = obj.GetAxisTitleTextProperty ()` - Set/Get the title text property of all axes. Note that each axis can be controlled individually through the GetX/YAxisActor2D() methods.
- `obj.SetAxisLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property of all axes. Note that each axis can be controlled individually through the GetX/YAxisActor2D() methods.
- `vtkTextProperty = obj.GetAxisLabelTextProperty ()` - Set/Get the labels text property of all axes. Note that each axis can be controlled individually through the GetX/YAxisActor2D() methods.
- `obj.SetLogx (int )` - Enable/Disable plotting of Log of x-values.
- `int = obj.GetLogx ()` - Enable/Disable plotting of Log of x-values.
- `obj.LogxOn ()` - Enable/Disable plotting of Log of x-values.
- `obj.LogxOff ()` - Enable/Disable plotting of Log of x-values.
- `obj.SetLabelFormat (string \_arg)` - Set/Get the format with which to print the labels . This sets both X and Y label formats. GetLabelFormat() returns X label format.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the X label.
- `obj.SetXLabelFormat (string \_arg)` - Set/Get the format with which to print the X label.
- `string = obj.GetXLabelFormat ()` - Set/Get the format with which to print the X label.
- `obj.SetYLabelFormat (string \_arg)` - Set/Get the format with which to print the Y label.
- `string = obj.GetYLabelFormat ()` - Set/Get the format with which to print the Y label.
- `obj.SetBorder (int )` - Set/Get the spacing between the plot window and the plot. The value is specified in pixels.
- `int = obj.GetBorderMinValue ()` - Set/Get the spacing between the plot window and the plot. The value is specified in pixels.
- `int = obj.GetBorderMaxValue ()` - Set/Get the spacing between the plot window and the plot. The value is specified in pixels.
- `int = obj.GetBorder ()` - Set/Get the spacing between the plot window and the plot. The value is specified in pixels.
- `int = obj.GetPlotPoints ()` - Set/Get whether the points are rendered. The point size can be set in the property object. This is a global flag which affects the plot only if per curve symbols are not defined.

- `obj.SetPlotPoints (int )` - Set/Get whether the points are rendered. The point size can be set in the property object. This is a global flag which affects the plot only if per curve symbols are not defined.
- `obj.PlotPointsOn ()` - Set/Get whether the points are rendered. The point size can be set in the property object. This is a global flag which affects the plot only if per curve symbols are not defined.
- `obj.PlotPointsOff ()` - Set/Get whether the points are rendered. The point size can be set in the property object. This is a global flag which affects the plot only if per curve symbols are not defined.
- `int = obj.GetPlotLines ()` - Set/Get whether the lines are rendered. The line width can be set in the property object.
- `obj.SetPlotLines (int )` - Set/Get whether the lines are rendered. The line width can be set in the property object.
- `obj.PlotLinesOn ()` - Set/Get whether the lines are rendered. The line width can be set in the property object.
- `obj.PlotLinesOff ()` - Set/Get whether the lines are rendered. The line width can be set in the property object.
- `obj.SetGlyphSize (double )` - Set/Get the factor that controls how big glyphs are in the plot. The number is expressed as a fraction of the length of the diagonal of the plot bounding box.
- `double = obj.GetGlyphSizeMinValue ()` - Set/Get the factor that controls how big glyphs are in the plot. The number is expressed as a fraction of the length of the diagonal of the plot bounding box.
- `double = obj.GetGlyphSizeMaxValue ()` - Set/Get the factor that controls how big glyphs are in the plot. The number is expressed as a fraction of the length of the diagonal of the plot bounding box.
- `double = obj.GetGlyphSize ()` - Set/Get the factor that controls how big glyphs are in the plot. The number is expressed as a fraction of the length of the diagonal of the plot bounding box.
- `obj.ViewportToPlotCoordinate (vtkViewport viewport)` - An alternate form of ViewportToPlotCoordinate() above. This method inputs the viewport coordinate pair (defined by the ivar ViewportCoordinate)and then stores them in the ivar PlotCoordinate.
- `obj.SetPlotCoordinate (double , double )` - An alternate form of ViewportToPlotCoordinate() above. This method inputs the viewport coordinate pair (defined by the ivar ViewportCoordinate)and then stores them in the ivar PlotCoordinate.
- `obj.SetPlotCoordinate (double  a[2])` - An alternate form of ViewportToPlotCoordinate() above. This method inputs the viewport coordinate pair (defined by the ivar ViewportCoordinate)and then stores them in the ivar PlotCoordinate.
- `double = obj. GetPlotCoordinate ()` - An alternate form of ViewportToPlotCoordinate() above. This method inputs the viewport coordinate pair (defined by the ivar ViewportCoordinate)and then stores them in the ivar PlotCoordinate.
- `obj.PlotToViewportCoordinate (vtkViewport viewport)` - An alternate form of PlotToViewportCoordinate() above. This method inputs the plot coordinate pair (defined in the ivar PlotCoordinate) and then stores them in the ivar ViewportCoordinate. (This method can be wrapped.)
- `obj.SetViewportCoordinate (double , double )` - An alternate form of PlotToViewportCoordinate() above. This method inputs the plot coordinate pair (defined in the ivar PlotCoordinate) and then stores them in the ivar ViewportCoordinate. (This method can be wrapped.)
- `obj.SetViewportCoordinate (double  a[2])` - An alternate form of PlotToViewportCoordinate() above. This method inputs the plot coordinate pair (defined in the ivar PlotCoordinate) and then stores them in the ivar ViewportCoordinate. (This method can be wrapped.)

- `double = obj. GetViewportCoordinate ()` - An alternate form of PlotToViewportCoordinate() above. This method inputs the plot coordinate pair (defined in the ivar PlotCoordinate) and then stores them in the ivar ViewportCoordinate. (This method can be wrapped.)
- `int = obj.IsInPlot (vtkViewport viewport, double u, double v)` - Is the specified viewport position within the plot area (as opposed to the region used by the plot plus the labels)?
- `obj.SetChartBox (int )` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the chart box.
- `int = obj.GetChartBox ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the chart box.
- `obj.ChartBoxOn ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the chart box.
- `obj.ChartBoxOff ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the chart box.
- `obj.SetChartBorder (int )` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `int = obj.GetChartBorder ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `obj.ChartBorderOn ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `obj.ChartBorderOff ()` - Set/Get the flag that controls whether a box will be drawn/filled corresponding to the legend box.
- `vtkProperty2D = obj.GetChartBoxProperty ()` - Get the box vtkProperty2D.
- `obj.SetShowReferenceXLine (int )` - Set/Get if the X reference line is visible. hidden by default
- `int = obj.GetShowReferenceXLine ()` - Set/Get if the X reference line is visible. hidden by default
- `obj.ShowReferenceXLineOn ()` - Set/Get if the X reference line is visible. hidden by default
- `obj.ShowReferenceXLineOff ()` - Set/Get if the X reference line is visible. hidden by default
- `obj.SetReferenceXValue (double )`
- `double = obj.GetReferenceXValue ()`
- `obj.SetShowReferenceYLine (int )` - Set/Get if the Y reference line is visible. hidden by default
- `int = obj.GetShowReferenceYLine ()` - Set/Get if the Y reference line is visible. hidden by default
- `obj.ShowReferenceYLineOn ()` - Set/Get if the Y reference line is visible. hidden by default
- `obj.ShowReferenceYLineOff ()` - Set/Get if the Y reference line is visible. hidden by default
- `obj.SetReferenceYValue (double )`
- `double = obj.GetReferenceYValue ()`
- `long = obj.GetMTime ()` - Take into account the modified time of internal helper classes.

Chapter 35

Visualization Toolkit Imaging Classes

35.1 vtkBooleanTexture

35.1.1 Usage

vtkBooleanTexture is a filter to generate a 2D texture map based on combinations of inside, outside, and on region boundary. The "region" is implicitly represented via 2D texture coordinates. These texture coordinates are normally generated using a filter like vtkImplicitTextureCoords, which generates the texture coordinates for any implicit function.

vtkBooleanTexture generates the map according to the s-t texture coordinates plus the notion of being in, on, or outside of a region. An in region is when the texture coordinate is between (0,0.5-thickness/2). An out region is where the texture coordinate is (0.5+thickness/2). An on region is between (0.5-thickness/2,0.5+thickness/2). The combination in, on, and out for each of the s-t texture coordinates results in 16 possible combinations (see text). For each combination, a different value of intensity and transparency can be assigned. To assign maximum intensity and/or opacity use the value 255. A minimum value of 0 results in a black region (for intensity) and a fully transparent region (for transparency).

To create an instance of class vtkBooleanTexture, simply invoke its constructor as follows

```
obj = vtkBooleanTexture
```

35.1.2 Methods

The class vtkBooleanTexture has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBooleanTexture class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBooleanTexture = obj.NewInstance ()`
- `vtkBooleanTexture = obj.SafeDownCast (vtkObject o)`
- `obj.SetXSize (int )` - Set the X texture map dimension.
- `int = obj.GetXSize ()` - Set the X texture map dimension.
- `obj.SetYSize (int )` - Set the Y texture map dimension.
- `int = obj.GetYSize ()` - Set the Y texture map dimension.
- `obj.SetThickness (int )` - Set the thickness of the "on" region.

- `int = obj.GetThickness ()` - Set the thickness of the "on" region.
- `obj.SetInIn (char , char )` - Specify intensity/transparency for "in/in" region.
- `obj.SetInIn (char  a[2])` - Specify intensity/transparency for "in/in" region.
- `char = obj. GetInIn ()` - Specify intensity/transparency for "in/in" region.
- `obj.SetInOut (char , char )` - Specify intensity/transparency for "in/out" region.
- `obj.SetInOut (char  a[2])` - Specify intensity/transparency for "in/out" region.
- `char = obj. GetInOut ()` - Specify intensity/transparency for "in/out" region.
- `obj.SetOutIn (char , char )` - Specify intensity/transparency for "out/in" region.
- `obj.SetOutIn (char  a[2])` - Specify intensity/transparency for "out/in" region.
- `char = obj. GetOutIn ()` - Specify intensity/transparency for "out/in" region.
- `obj.SetOutOut (char , char )` - Specify intensity/transparency for "out/out" region.
- `obj.SetOutOut (char  a[2])` - Specify intensity/transparency for "out/out" region.
- `char = obj. GetOutOut ()` - Specify intensity/transparency for "out/out" region.
- `obj.SetOnOn (char , char )` - Specify intensity/transparency for "on/on" region.
- `obj.SetOnOn (char  a[2])` - Specify intensity/transparency for "on/on" region.
- `char = obj. GetOnOn ()` - Specify intensity/transparency for "on/on" region.
- `obj.SetOnIn (char , char )` - Specify intensity/transparency for "on/in" region.
- `obj.SetOnIn (char  a[2])` - Specify intensity/transparency for "on/in" region.
- `char = obj. GetOnIn ()` - Specify intensity/transparency for "on/in" region.
- `obj.SetOnOut (char , char )` - Specify intensity/transparency for "on/out" region.
- `obj.SetOnOut (char  a[2])` - Specify intensity/transparency for "on/out" region.
- `char = obj. GetOnOut ()` - Specify intensity/transparency for "on/out" region.
- `obj.SetInOn (char , char )` - Specify intensity/transparency for "in/on" region.
- `obj.SetInOn (char  a[2])` - Specify intensity/transparency for "in/on" region.
- `char = obj. GetInOn ()` - Specify intensity/transparency for "in/on" region.
- `obj.SetOutOn (char , char )` - Specify intensity/transparency for "out/on" region.
- `obj.SetOutOn (char  a[2])` - Specify intensity/transparency for "out/on" region.
- `char = obj. GetOutOn ()` - Specify intensity/transparency for "out/on" region.

35.2 vtkExtractVOI

35.2.1 Usage

vtkExtractVOI is a filter that selects a portion of an input structured points dataset, or subsamples an input dataset. (The selected portion of interested is referred to as the Volume Of Interest, or VOI.) The output of this filter is a structured points dataset. The filter treats input data of any topological dimension (i.e., point, line, image, or volume) and can generate output data of any topological dimension.

To use this filter set the VOI ivar which are i-j-k min/max indices that specify a rectangular region in the data. (Note that these are 0-offset.) You can also specify a sampling rate to subsample the data.

Typical applications of this filter are to extract a slice from a volume for image processing, subsampling large volumes to reduce data size, or extracting regions of a volume with interesting data.

To create an instance of class vtkExtractVOI, simply invoke its constructor as follows

```
obj = vtkExtractVOI
```

35.2.2 Methods

The class vtkExtractVOI has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractVOI class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractVOI = obj.NewInstance ()`
- `vtkExtractVOI = obj.SafeDownCast (vtkObject o)`
- `obj.SetVOI (int , int , int , int , int , int )` - Specify i-j-k (min,max) pairs to extract. The resulting structured points dataset can be of any topological dimension (i.e., point, line, image, or volume).
- `obj.SetVOI (int  a[6])` - Specify i-j-k (min,max) pairs to extract. The resulting structured points dataset can be of any topological dimension (i.e., point, line, image, or volume).
- `int = obj. GetVOI ()` - Specify i-j-k (min,max) pairs to extract. The resulting structured points dataset can be of any topological dimension (i.e., point, line, image, or volume).
- `obj.SetSampleRate (int , int , int )` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.
- `obj.SetSampleRate (int  a[3])` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.
- `int = obj. GetSampleRate ()` - Set the sampling rate in the i, j, and k directions. If the rate is ¿ 1, then the resulting VOI will be subsampled representation of the input. For example, if the SampleRate=(2,2,2), every other point will be selected, resulting in a volume 1/8th the original size.

35.3 vtkFastSplatter

35.3.1 Usage

vtkFastSplatter takes any vtkPointSet as input (of which vtkPolyData and vtkUnstructuredGrid inherit). Each point in the data set is considered to be an impulse. These impulses are convolved with a given splat image. In other words, the splat image is added to the final image at every place where there is an input point.

Note that point and cell data are thrown away. If you want a sampling of unstructured points consider vtkGaussianSplatter or vtkShepardMethod.

Use input port 0 for the impulse data (vtkPointSet), and input port 1 for the splat image (vtkImageData) .SECTION Bugs

Any point outside of the extents of the image is thrown away, even if it is close enough such that it's convolution with the splat image would overlap the extents.

To create an instance of class vtkFastSplatter, simply invoke its constructor as follows

```
obj = vtkFastSplatter
```

35.3.2 Methods

The class vtkFastSplatter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFastSplatter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFastSplatter = obj.NewInstance ()`
- `vtkFastSplatter = obj.SafeDownCast (vtkObject o)`
- `obj.SetModelBounds (double , double , double , double , double , double )` - Set / get the (xmin,xmax, ymin,ymax, zmin,zmax) bounding box in which the sampling is performed. If any of the (min,max) bounds values are min ¿= max, then the bounds will be computed automatically from the input data. Otherwise, the user-specified bounds will be used.
- `obj.SetModelBounds (double a[6])` - Set / get the (xmin,xmax, ymin,ymax, zmin,zmax) bounding box in which the sampling is performed. If any of the (min,max) bounds values are min ¿= max, then the bounds will be computed automatically from the input data. Otherwise, the user-specified bounds will be used.
- `double = obj. GetModelBounds ()` - Set / get the (xmin,xmax, ymin,ymax, zmin,zmax) bounding box in which the sampling is performed. If any of the (min,max) bounds values are min ¿= max, then the bounds will be computed automatically from the input data. Otherwise, the user-specified bounds will be used.
- `obj.SetOutputDimensions (int , int , int )` - Set/get the dimensions of the output image
- `obj.SetOutputDimensions (int a[3])` - Set/get the dimensions of the output image
- `int = obj. GetOutputDimensions ()` - Set/get the dimensions of the output image
- `obj.SetLimitMode (int )` - Set/get the way voxel values will be limited. If this is set to None (the default), the output can have arbitrarily large values. If set to clamp, the output will be clamped to [MinValue,MaxValue]. If set to scale, the output will be linearly scaled between MinValue and MaxValue.

- `int = obj.GetLimitMode ()` - Set/get the way voxel values will be limited. If this is set to None (the default), the output can have arbitrarily large values. If set to clamp, the output will be clamped to [MinValue,MaxValue]. If set to scale, the output will be linearly scaled between MinValue and MaxValue.

- `obj.SetLimitModeToNone ()` - Set/get the way voxel values will be limited. If this is set to None (the default), the output can have arbitrarily large values. If set to clamp, the output will be clamped to [MinValue,MaxValue]. If set to scale, the output will be linearly scaled between MinValue and MaxValue.

- `obj.SetLimitModeToClamp ()` - Set/get the way voxel values will be limited. If this is set to None (the default), the output can have arbitrarily large values. If set to clamp, the output will be clamped to [MinValue,MaxValue]. If set to scale, the output will be linearly scaled between MinValue and MaxValue.

- `obj.SetLimitModeToScale ()` - Set/get the way voxel values will be limited. If this is set to None (the default), the output can have arbitrarily large values. If set to clamp, the output will be clamped to [MinValue,MaxValue]. If set to scale, the output will be linearly scaled between MinValue and MaxValue.

- `obj.SetLimitModeToFreezeScale ()` - See the LimitMode method.

- `obj.SetMinValue (double )` - See the LimitMode method.

- `double = obj.GetMinValue ()` - See the LimitMode method.

- `obj.SetMaxValue (double )` - See the LimitMode method.

- `double = obj.GetMaxValue ()` - See the LimitMode method.

- `int = obj.GetNumberOfPointsSplatted ()` - This returns the number of points splatted (as opposed to discarded for being outside the image) during the previous pass.

- `obj.SetSplatConnection (vtkAlgorithmOutput )` - Convenience function for connecting the splat algorithm source. This is provided mainly for convenience using the filter with ParaView, VTK users should prefer SetInputConnection(1, splat) instead.

35.4 vtkGaussianSplatter

35.4.1 Usage

vtkGaussianSplatter is a filter that injects input points into a structured points (volume) dataset. As each point is injected, it "splats" or distributes values to nearby voxels. Data is distributed using an elliptical, Gaussian distribution function. The distribution function is modified using scalar values (expands distribution) or normals (creates ellipsoidal distribution rather than spherical).

In general, the Gaussian distribution function f(x) around a given splat point p is given by

f(x) = ScaleFactor * exp(ExponentFactor*((r/Radius)**2))

where x is the current voxel sample point; r is the distance —x-p— ExponentFactor ¡= 0.0, and ScaleFactor can be multiplied by the scalar value of the point p that is currently being splatted.

If points normals are present (and NormalWarping is on), then the splat function becomes elliptical (as compared to the spherical one described by the previous equation). The Gaussian distribution function then becomes:

f(x) = ScaleFactor * exp(ExponentFactor*(((rxy/E)**2 + z**2)/R**2))

where E is a user-defined eccentricity factor that controls the elliptical shape of the splat; z is the distance of the current voxel sample point along normal N; and rxy is the distance of x in the direction prependicular to N.

This class is typically used to convert point-valued distributions into a volume representation. The volume is then usually iso-surfaced or volume rendered to generate a visualization. It can be used to create surfaces from point distributions, or to create structure (i.e., topology) when none exists.

To create an instance of class vtkGaussianSplatter, simply invoke its constructor as follows

```
obj = vtkGaussianSplatter
```

35.4.2 Methods

The class vtkGaussianSplatter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGaussianSplatter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGaussianSplatter = obj.NewInstance ()`
- `vtkGaussianSplatter = obj.SafeDownCast (vtkObject o)`
- `obj.SetSampleDimensions (int i, int j, int k)` - Set / get the dimensions of the sampling structured point set. Higher values produce better results but are much slower.
- `obj.SetSampleDimensions (int dim[3])` - Set / get the dimensions of the sampling structured point set. Higher values produce better results but are much slower.
- `int = obj. GetSampleDimensions ()` - Set / get the dimensions of the sampling structured point set. Higher values produce better results but are much slower.
- `obj.SetModelBounds (double , double , double , double , double , double )` - Set / get the (xmin,xmax, ymin,ymax, zmin,zmax) bounding box in which the sampling is performed. If any of the (min,max) bounds values are min ¿= max, then the bounds will be computed automatically from the input data. Otherwise, the user-specified bounds will be used.
- `obj.SetModelBounds (double a[6])` - Set / get the (xmin,xmax, ymin,ymax, zmin,zmax) bounding box in which the sampling is performed. If any of the (min,max) bounds values are min ¿= max, then the bounds will be computed automatically from the input data. Otherwise, the user-specified bounds will be used.
- `double = obj. GetModelBounds ()` - Set / get the (xmin,xmax, ymin,ymax, zmin,zmax) bounding box in which the sampling is performed. If any of the (min,max) bounds values are min ¿= max, then the bounds will be computed automatically from the input data. Otherwise, the user-specified bounds will be used.
- `obj.SetRadius (double )` - Set / get the radius of propagation of the splat. This value is expressed as a percentage of the length of the longest side of the sampling volume. Smaller numbers greatly reduce execution time.
- `double = obj.GetRadiusMinValue ()` - Set / get the radius of propagation of the splat. This value is expressed as a percentage of the length of the longest side of the sampling volume. Smaller numbers greatly reduce execution time.
- `double = obj.GetRadiusMaxValue ()` - Set / get the radius of propagation of the splat. This value is expressed as a percentage of the length of the longest side of the sampling volume. Smaller numbers greatly reduce execution time.

- `double = obj.GetRadius ()` - Set / get the radius of propagation of the splat. This value is expressed as a percentage of the length of the longest side of the sampling volume. Smaller numbers greatly reduce execution time.
- `obj.SetScaleFactor (double )` - Multiply Gaussian splat distribution by this value. If ScalarWarping is on, then the Scalar value will be multiplied by the ScaleFactor times the Gaussian function.
- `double = obj.GetScaleFactorMinValue ()` - Multiply Gaussian splat distribution by this value. If ScalarWarping is on, then the Scalar value will be multiplied by the ScaleFactor times the Gaussian function.
- `double = obj.GetScaleFactorMaxValue ()` - Multiply Gaussian splat distribution by this value. If ScalarWarping is on, then the Scalar value will be multiplied by the ScaleFactor times the Gaussian function.
- `double = obj.GetScaleFactor ()` - Multiply Gaussian splat distribution by this value. If ScalarWarping is on, then the Scalar value will be multiplied by the ScaleFactor times the Gaussian function.
- `obj.SetExponentFactor (double )` - Set / get the sharpness of decay of the splats. This is the exponent constant in the Gaussian equation. Normally this is a negative value.
- `double = obj.GetExponentFactor ()` - Set / get the sharpness of decay of the splats. This is the exponent constant in the Gaussian equation. Normally this is a negative value.
- `obj.SetNormalWarping (int )` - Turn on/off the generation of elliptical splats. If normal warping is on, then the input normals affect the distribution of the splat. This boolean is used in combination with the Eccentricity ivar.
- `int = obj.GetNormalWarping ()` - Turn on/off the generation of elliptical splats. If normal warping is on, then the input normals affect the distribution of the splat. This boolean is used in combination with the Eccentricity ivar.
- `obj.NormalWarpingOn ()` - Turn on/off the generation of elliptical splats. If normal warping is on, then the input normals affect the distribution of the splat. This boolean is used in combination with the Eccentricity ivar.
- `obj.NormalWarpingOff ()` - Turn on/off the generation of elliptical splats. If normal warping is on, then the input normals affect the distribution of the splat. This boolean is used in combination with the Eccentricity ivar.
- `obj.SetEccentricity (double )` - Control the shape of elliptical splatting. Eccentricity is the ratio of the major axis (aligned along normal) to the minor (axes) aligned along other two axes. So Eccentricity ¿ 1 creates needles with the long axis in the direction of the normal; Eccentricity¡1 creates pancakes perpendicular to the normal vector.
- `double = obj.GetEccentricityMinValue ()` - Control the shape of elliptical splatting. Eccentricity is the ratio of the major axis (aligned along normal) to the minor (axes) aligned along other two axes. So Eccentricity ¿ 1 creates needles with the long axis in the direction of the normal; Eccentricity¡1 creates pancakes perpendicular to the normal vector.
- `double = obj.GetEccentricityMaxValue ()` - Control the shape of elliptical splatting. Eccentricity is the ratio of the major axis (aligned along normal) to the minor (axes) aligned along other two axes. So Eccentricity ¿ 1 creates needles with the long axis in the direction of the normal; Eccentricity¡1 creates pancakes perpendicular to the normal vector.
- `double = obj.GetEccentricity ()` - Control the shape of elliptical splatting. Eccentricity is the ratio of the major axis (aligned along normal) to the minor (axes) aligned along other two axes. So Eccentricity ¿ 1 creates needles with the long axis in the direction of the normal; Eccentricity¡1 creates pancakes perpendicular to the normal vector.

- `obj.SetScalarWarping (int )` - Turn on/off the scaling of splats by scalar value.
- `int = obj.GetScalarWarping ()` - Turn on/off the scaling of splats by scalar value.
- `obj.ScalarWarpingOn ()` - Turn on/off the scaling of splats by scalar value.
- `obj.ScalarWarpingOff ()` - Turn on/off the scaling of splats by scalar value.
- `obj.SetCapping (int )` - Turn on/off the capping of the outer boundary of the volume to a specified cap value. This can be used to close surfaces (after iso-surfacing) and create other effects.
- `int = obj.GetCapping ()` - Turn on/off the capping of the outer boundary of the volume to a specified cap value. This can be used to close surfaces (after iso-surfacing) and create other effects.
- `obj.CappingOn ()` - Turn on/off the capping of the outer boundary of the volume to a specified cap value. This can be used to close surfaces (after iso-surfacing) and create other effects.
- `obj.CappingOff ()` - Turn on/off the capping of the outer boundary of the volume to a specified cap value. This can be used to close surfaces (after iso-surfacing) and create other effects.
- `obj.SetCapValue (double )` - Specify the cap value to use. (This instance variable only has effect if the ivar Capping is on.)
- `double = obj.GetCapValue ()` - Specify the cap value to use. (This instance variable only has effect if the ivar Capping is on.)
- `obj.SetAccumulationMode (int )` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.
- `int = obj.GetAccumulationModeMinValue ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.
- `int = obj.GetAccumulationModeMaxValue ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.
- `int = obj.GetAccumulationMode ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.
- `obj.SetAccumulationModeToMin ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.
- `obj.SetAccumulationModeToMax ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.
- `obj.SetAccumulationModeToSum ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.

- `string = obj.GetAccumulationModeAsString ()` - Specify the scalar accumulation mode. This mode expresses how scalar values are combined when splats are overlapped. The Max mode acts like a set union operation and is the most commonly used; the Min mode acts like a set intersection, and the sum is just weird.

- `obj.SetNullValue (double )` - Set the Null value for output points not receiving a contribution from the input points. (This is the initial value of the voxel samples.)

- `double = obj.GetNullValue ()` - Set the Null value for output points not receiving a contribution from the input points. (This is the initial value of the voxel samples.)

- `obj.ComputeModelBounds (vtkDataSet input, vtkImageData output, vtkInformation outInfo)` - Compute the size of the sample bounding box automatically from the input data. This is an internal helper function.

35.5 vtkImageAccumulate

35.5.1 Usage

vtkImageAccumulate - This filter divides component space into discrete bins. It then counts the number of pixels associated with each bin. The output is this "scatter plot" (histogram values for 1D). The dimensionality of the output depends on how many components the input pixels have. Input pixels with one component generate a 1D histogram. This filter can only handle images with 1 to 3 scalar components. The input can be any type, but the output is always int. Some statistics are computed on the pixel values at the same time. The SetStencil and ReverseStencil functions allow the statistics to be computed on an arbitrary portion of the input data. See the documentation for vtkImageStencilData for more information.

This filter also support ignoring pixel with value equal to 0. Using this option with vtkImageMask may result in results being slightly off since 0 could be a valid value from your input.

To create an instance of class vtkImageAccumulate, simply invoke its constructor as follows

```
obj = vtkImageAccumulate
```

35.5.2 Methods

The class vtkImageAccumulate has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageAccumulate class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkImageAccumulate = obj.NewInstance ()`

- `vtkImageAccumulate = obj.SafeDownCast (vtkObject o)`

- `obj.SetComponentSpacing (double , double , double )` - Set/Get - The component spacing is the dimension of each bin. This ends up being the spacing of the output "image". If the number of input scalar components are less than three, then some of these spacing values are ignored. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this spacing should be set to 100, 0, 0

- `obj.SetComponentSpacing (double a[3])` - Set/Get - The component spacing is the dimension of each bin. This ends up being the spacing of the output "image". If the number of input scalar components are less than three, then some of these spacing values are ignored. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this spacing should be set to 100, 0, 0

- `double = obj. GetComponentSpacing ()` - Set/Get - The component spacing is the dimension of each bin. This ends up being the spacing of the output "image". If the number of input scalar components are less than three, then some of these spacing values are ignored. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this spacing should be set to 100, 0, 0
- `obj.SetComponentOrigin (double , double , double )` - Set/Get - The component origin is the location of bin (0, 0, 0). Note that if the Component extent does not include the value (0,0,0), then this origin bin will not actually be in the output. The origin of the output ends up being the same as the componenet origin. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this origin should be set to 1000, 0, 0
- `obj.SetComponentOrigin (double a[3])` - Set/Get - The component origin is the location of bin (0, 0, 0). Note that if the Component extent does not include the value (0,0,0), then this origin bin will not actually be in the output. The origin of the output ends up being the same as the componenet origin. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this origin should be set to 1000, 0, 0
- `double = obj. GetComponentOrigin ()` - Set/Get - The component origin is the location of bin (0, 0, 0). Note that if the Component extent does not include the value (0,0,0), then this origin bin will not actually be in the output. The origin of the output ends up being the same as the componenet origin. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this origin should be set to 1000, 0, 0
- `obj.SetComponentExtent (int extent[6])` - Set/Get - The component extent sets the number/extent of the bins. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this extent should be set to 0, 9, 0, 0, 0, 0. The extent specifies inclusive min/max values. This implies that the top extent should be set to the number of bins - 1.
- `obj.SetComponentExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - Set/Get - The component extent sets the number/extent of the bins. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this extent should be set to 0, 9, 0, 0, 0, 0. The extent specifies inclusive min/max values. This implies that the top extent should be set to the number of bins - 1.
- `obj.GetComponentExtent (int extent[6])` - Set/Get - The component extent sets the number/extent of the bins. For a 1D histogram with 10 bins spanning the values 1000 to 2000, this extent should be set to 0, 9, 0, 0, 0, 0. The extent specifies inclusive min/max values. This implies that the top extent should be set to the number of bins - 1.
- `int = obj.GetComponentExtent ()` - Use a stencil to specify which voxels to accumulate.
- `obj.SetStencil (vtkImageStencilData stencil)` - Use a stencil to specify which voxels to accumulate.
- `vtkImageStencilData = obj.GetStencil ()` - Use a stencil to specify which voxels to accumulate.
- `obj.SetReverseStencil (int )` - Reverse the stencil.
- `int = obj.GetReverseStencilMinValue ()` - Reverse the stencil.
- `int = obj.GetReverseStencilMaxValue ()` - Reverse the stencil.
- `obj.ReverseStencilOn ()` - Reverse the stencil.
- `obj.ReverseStencilOff ()` - Reverse the stencil.
- `int = obj.GetReverseStencil ()` - Reverse the stencil.
- `double = obj. GetMin ()` - Get the statistics information for the data.
- `double = obj. GetMax ()` - Get the statistics information for the data.

- `double = obj. GetMean ()` - Get the statistics information for the data.
- `double = obj. GetStandardDeviation ()` - Get the statistics information for the data.
- `long = obj.GetVoxelCount ()` - Get the statistics information for the data.
- `obj.SetIgnoreZero (int )` - Should the data with value 0 be ignored?
- `int = obj.GetIgnoreZeroMinValue ()` - Should the data with value 0 be ignored?
- `int = obj.GetIgnoreZeroMaxValue ()` - Should the data with value 0 be ignored?
- `int = obj.GetIgnoreZero ()` - Should the data with value 0 be ignored?
- `obj.IgnoreZeroOn ()` - Should the data with value 0 be ignored?
- `obj.IgnoreZeroOff ()` - Should the data with value 0 be ignored?

35.6 vtkImageAnisotropicDiffusion2D

35.6.1 Usage

vtkImageAnisotropicDiffusion2D diffuses a 2d image iteratively. The neighborhood of the diffusion is determined by the instance flags. If "Edges" is on the 4 edge connected voxels are included, and if "Corners" is on, the 4 corner connected voxels are included. "DiffusionFactor" determines how far a pixel value moves toward its neighbors, and is insensitive to the number of neighbors chosen. The diffusion is anisotropic because it only occurs when a gradient measure is below "GradientThreshold". Two gradient measures exist and are toggled by the "GradientMagnitudeThreshold" flag. When "GradientMagnitudeThreshold" is on, the magnitude of the gradient, computed by central differences, above "DiffusionThreshold" a voxel is not modified. The alternative measure examines each neighbor independently. The gradient between the voxel and the neighbor must be below the "DiffusionThreshold" for diffusion to occur with THAT neighbor.

To create an instance of class vtkImageAnisotropicDiffusion2D, simply invoke its constructor as follows

```
obj = vtkImageAnisotropicDiffusion2D
```

35.6.2 Methods

The class vtkImageAnisotropicDiffusion2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageAnisotropicDiffusion2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageAnisotropicDiffusion2D = obj.NewInstance ()`
- `vtkImageAnisotropicDiffusion2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfIterations (int num)` - This method sets the number of interations which also affects the input neighborhood needed to compute one output pixel. Each iterations requires an extra pixel layer on the neighborhood. This is only relavent when you are trying to stream or are requesting a sub extent of the "wholeExtent".
- `int = obj.GetNumberOfIterations ()` - Get the number of iterations.
- `obj.SetDiffusionThreshold (double )` - Set/Get the difference threshold that stops diffusion. when the difference between two pixel is greater than this threshold, the pixels are not diffused. This causes diffusion to avoid sharp edges. If the GradientMagnitudeThreshold is set, then gradient magnitude is used for comparison instead of pixel differences.

- `double = obj.GetDiffusionThreshold ()` - Set/Get the difference threshold that stops diffusion. when the difference between two pixel is greater than this threshold, the pixels are not diffused. This causes diffusion to avoid sharp edges. If the GradientMagnitudeThreshold is set, then gradient magnitude is used for comparison instead of pixel differences.
- `obj.SetDiffusionFactor (double )` - The diffusion factor specifies how much neighboring pixels effect each other. No diffusion occurs with a factor of 0, and a diffusion factor of 1 causes the pixel to become the average of all its neighbors.
- `double = obj.GetDiffusionFactor ()` - The diffusion factor specifies how much neighboring pixels effect each other. No diffusion occurs with a factor of 0, and a diffusion factor of 1 causes the pixel to become the average of all its neighbors.
- `obj.SetFaces (int )` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `int = obj.GetFaces ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.FacesOn ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.FacesOff ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.SetEdges (int )` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `int = obj.GetEdges ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.EdgesOn ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.EdgesOff ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.SetCorners (int )` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `int = obj.GetCorners ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.CornersOn ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.CornersOff ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.SetGradientMagnitudeThreshold (int )` - Switch between gradient magnitude threshold and pixel gradient threshold.
- `int = obj.GetGradientMagnitudeThreshold ()` - Switch between gradient magnitude threshold and pixel gradient threshold.
- `obj.GradientMagnitudeThresholdOn ()` - Switch between gradient magnitude threshold and pixel gradient threshold.
- `obj.GradientMagnitudeThresholdOff ()` - Switch between gradient magnitude threshold and pixel gradient threshold.

35.7 vtkImageAnisotropicDiffusion3D

35.7.1 Usage

vtkImageAnisotropicDiffusion3D diffuses an volume iteratively. The neighborhood of the diffusion is determined by the instance flags. if "Faces" is on, the 6 voxels adjoined by faces are included in the neighborhood. If "Edges" is on the 12 edge connected voxels are included, and if "Corners" is on, the 8 corner connected voxels are included. "DiffusionFactor" determines how far a pixel value moves toward its neighbors, and is insensitive to the number of neighbors chosen. The diffusion is anisotropic because it only occurs when a gradient measure is below "GradientThreshold". Two gradient measures exist and are toggled by the "GradientMagnitudeThreshold" flag. When "GradientMagnitudeThreshold" is on, the magnitude of the

gradient, computed by central differences, above "DiffusionThreshold" a voxel is not modified. The alternative measure examines each neighbor independently. The gradient between the voxel and the neighbor must be below the "DiffusionThreshold" for diffusion to occur with THAT neighbor.

To create an instance of class vtkImageAnisotropicDiffusion3D, simply invoke its constructor as follows

```
obj = vtkImageAnisotropicDiffusion3D
```

35.7.2 Methods

The class vtkImageAnisotropicDiffusion3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageAnisotropicDiffusion3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageAnisotropicDiffusion3D = obj.NewInstance ()`
- `vtkImageAnisotropicDiffusion3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfIterations (int num)` - This method sets the number of interations which also affects the input neighborhood needed to compute one output pixel. Each iterations requires an extra pixel layer on the neighborhood. This is only relavent when you are trying to stream or are requesting a sub extent of the "wholeExtent".
- `int = obj.GetNumberOfIterations ()` - Get the number of iterations.
- `obj.SetDiffusionThreshold (double )` - Set/Get the difference threshold that stops diffusion. when the difference between two pixel is greater than this threshold, the pixels are not diffused. This causes diffusion to avoid sharp edges. If the GradientMagnitudeThreshold is set, then gradient magnitude is used for comparison instead of pixel differences.
- `double = obj.GetDiffusionThreshold ()` - Set/Get the difference threshold that stops diffusion. when the difference between two pixel is greater than this threshold, the pixels are not diffused. This causes diffusion to avoid sharp edges. If the GradientMagnitudeThreshold is set, then gradient magnitude is used for comparison instead of pixel differences.
- `obj.SetDiffusionFactor (double )` - Set/Get the difference factor
- `double = obj.GetDiffusionFactor ()` - Set/Get the difference factor
- `obj.SetFaces (int )` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `int = obj.GetFaces ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.FacesOn ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.FacesOff ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.SetEdges (int )` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `int = obj.GetEdges ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.EdgesOn ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.EdgesOff ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.SetCorners (int )` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `int = obj.GetCorners ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).

- `obj.CornersOn ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.CornersOff ()` - Choose neighbors to diffuse (6 faces, 12 edges, 8 corners).
- `obj.SetGradientMagnitudeThreshold (int )` - Switch between gradient magnitude threshold and pixel gradient threshold.
- `int = obj.GetGradientMagnitudeThreshold ()` - Switch between gradient magnitude threshold and pixel gradient threshold.
- `obj.GradientMagnitudeThresholdOn ()` - Switch between gradient magnitude threshold and pixel gradient threshold.
- `obj.GradientMagnitudeThresholdOff ()` - Switch between gradient magnitude threshold and pixel gradient threshold.

35.8 vtkImageAppend

35.8.1 Usage

vtkImageAppend takes the components from multiple inputs and merges them into one output. The output images are append along the "AppendAxis". Except for the append axis, all inputs must have the same extent. All inputs must have the same number of scalar components. A future extension might be to pad or clip inputs to have the same extent. The output has the same origin and spacing as the first input. The origin and spacing of all other inputs are ignored. All inputs must have the same scalar type.

To create an instance of class vtkImageAppend, simply invoke its constructor as follows

```
obj = vtkImageAppend
```

35.8.2 Methods

The class vtkImageAppend has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageAppend class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageAppend = obj.NewInstance ()`
- `vtkImageAppend = obj.SafeDownCast (vtkObject o)`
- `obj.ReplaceNthInputConnection (int idx, vtkAlgorithmOutput input)` - Replace one of the input connections with a new input. You can only replace input connections that you previously created with AddInputConnection() or, in the case of the first input, with SetInputConnection().
- `obj.SetInput (int num, vtkDataObject input)` - Set an Input of this filter. This method is only for support of old-style pipeline connections. When writing new code you should use SetInputConnection(), AddInputConnection(), and ReplaceNthInputConnection() instead.
- `obj.SetInput (vtkDataObject input)` - Set an Input of this filter. This method is only for support of old-style pipeline connections. When writing new code you should use SetInputConnection(), AddInputConnection(), and ReplaceNthInputConnection() instead.
- `vtkDataObject = obj.GetInput (int num)` - Get one input to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetInputConnection(0, num).

- `vtkDataObject = obj.GetInput ()` - Get one input to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetInputConnection(0, num).
- `int = obj.GetNumberOfInputs ()` - Get the number of inputs to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetNumberOfInputCon
- `obj.SetAppendAxis (int )` - This axis is expanded to hold the multiple images. The default AppendAxis is the X axis. If you want to create a volue from a series of XY images, then you should set the AppendAxis to 2 (Z axis).
- `int = obj.GetAppendAxis ()` - This axis is expanded to hold the multiple images. The default AppendAxis is the X axis. If you want to create a volue from a series of XY images, then you should set the AppendAxis to 2 (Z axis).
- `obj.SetPreserveExtents (int )` - By default "PreserveExtents" is off and the append axis is used. When "PreseveExtents" is on, the extent of the inputs is used to place the image in the output. The whole extent of the output is the union of the input whole extents. Any portion of the output not covered by the inputs is set to zero. The origin and spacing is taken from the first input.
- `int = obj.GetPreserveExtents ()` - By default "PreserveExtents" is off and the append axis is used. When "PreseveExtents" is on, the extent of the inputs is used to place the image in the output. The whole extent of the output is the union of the input whole extents. Any portion of the output not covered by the inputs is set to zero. The origin and spacing is taken from the first input.
- `obj.PreserveExtentsOn ()` - By default "PreserveExtents" is off and the append axis is used. When "PreseveExtents" is on, the extent of the inputs is used to place the image in the output. The whole extent of the output is the union of the input whole extents. Any portion of the output not covered by the inputs is set to zero. The origin and spacing is taken from the first input.
- `obj.PreserveExtentsOff ()` - By default "PreserveExtents" is off and the append axis is used. When "PreseveExtents" is on, the extent of the inputs is used to place the image in the output. The whole extent of the output is the union of the input whole extents. Any portion of the output not covered by the inputs is set to zero. The origin and spacing is taken from the first input.

35.9 vtkImageAppendComponents

35.9.1 Usage

vtkImageAppendComponents takes the components from two inputs and merges them into one output. If Input1 has M components, and Input2 has N components, the output will have M+N components with input1 components coming first.

To create an instance of class vtkImageAppendComponents, simply invoke its constructor as follows

```
obj = vtkImageAppendComponents
```

35.9.2 Methods

The class vtkImageAppendComponents has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageAppendComponents class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageAppendComponents = obj.NewInstance ()`

- `vtkImageAppendComponents = obj.SafeDownCast (vtkObject o)`
- `obj.ReplaceNthInputConnection (int idx, vtkAlgorithmOutput input)` - Replace one of the input connections with a new input. You can only replace input connections that you previously created with AddInputConnection() or, in the case of the first input, with SetInputConnection().
- `obj.SetInput (int num, vtkDataObject input)` - Set an Input of this filter. This method is only for support of old-style pipeline connections. When writing new code you should use SetInputConnection(), AddInputConnection(), and ReplaceNthInputConnection() instead.
- `obj.SetInput (vtkDataObject input)` - Set an Input of this filter. This method is only for support of old-style pipeline connections. When writing new code you should use SetInputConnection(), AddInputConnection(), and ReplaceNthInputConnection() instead.
- `vtkDataObject = obj.GetInput (int num)` - Get one input to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetInputConnection(0, num).
- `vtkDataObject = obj.GetInput ()` - Get one input to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetInputConnection(0, num).
- `int = obj.GetNumberOfInputs ()` - Get the number of inputs to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetNumberOfInputCon

35.10 vtkImageBlend

35.10.1 Usage

vtkImageBlend takes L, LA, RGB, or RGBA images as input and blends them according to the alpha values and/or the opacity setting for each input.

The spacing, origin, extent, and number of components of the output are the same as those for the first input. If the input has an alpha component, then this component is copied unchanged into the output. In addition, if the first input has either one component or two components i.e. if it is either L (greyscale) or LA (greyscale + alpha) then all other inputs must also be L or LA.

Different blending modes are available:

Normal (default) : This is the standard blending mode used by OpenGL and other graphics packages. The output always has the same number of components and the same extent as the first input. The alpha value of the first input is not used in the blending computation, instead it is copied directly to the output.

```
output <- input[0]
foreach input i {
  foreach pixel px {
    r <- input[i](px)(alpha) * opacity[i]
    f <- (255 - r)
    output(px) <- output(px) * f + input(px) * r
  }
}
```

Compound : Images are compounded together and each component is scaled by the sum of the alpha/opacity values. Use the CompoundThreshold method to set specify a threshold in compound mode. Pixels with opacity*alpha less or equal than this threshold are ignored. The alpha value of the first input, if present, is NOT copied to the alpha value of the output. The output always has the same number of components and the same extent as the first input.

```
output <- 0
foreach pixel px {
  sum <- 0
  foreach input i {
    r <- input[i](px)(alpha) * opacity(i)
    sum <- sum + r
    if r > threshold {
      output(px) <- output(px) + input(px) * r
    }
  }
  output(px) <- output(px) / sum
}
```

To create an instance of class vtkImageBlend, simply invoke its constructor as follows

```
obj = vtkImageBlend
```

35.10.2 Methods

The class vtkImageBlend has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageBlend class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageBlend = obj.NewInstance ()`
- `vtkImageBlend = obj.SafeDownCast (vtkObject o)`
- `obj.ReplaceNthInputConnection (int idx, vtkAlgorithmOutput input)` - Replace one of the input connections with a new input. You can only replace input connections that you previously created with AddInputConnection() or, in the case of the first input, with SetInputConnection().
- `obj.SetInput (int num, vtkDataObject input)` - Set an Input of this filter. This method is only for support of old-style pipeline connections. When writing new code you should use SetInputConnection(), AddInputConnection(), and ReplaceNthInputConnection() instead.
- `obj.SetInput (vtkDataObject input)` - Set an Input of this filter. This method is only for support of old-style pipeline connections. When writing new code you should use SetInputConnection(), AddInputConnection(), and ReplaceNthInputConnection() instead.
- `vtkDataObject = obj.GetInput (int num)` - Get one input to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetInputConnection(0, num).
- `vtkDataObject = obj.GetInput ()` - Get one input to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetInputConnection(0, num).
- `int = obj.GetNumberOfInputs ()` - Get the number of inputs to this filter. This method is only for support of old-style pipeline connections. When writing new code you should use vtkAlgorithm::GetNumberOfInputCon
- `obj.SetOpacity (int idx, double opacity)` - Set the opacity of an input image: the alpha values of the image are multiplied by the opacity. The opacity of image idx=0 is ignored.

- `double = obj.GetOpacity (int idx)` - Set the opacity of an input image: the alpha values of the image are multiplied by the opacity. The opacity of image idx=0 is ignored.
- `obj.SetStencil (vtkImageStencilData stencil)` - Set a stencil to apply when blending the data.
- `vtkImageStencilData = obj.GetStencil ()` - Set a stencil to apply when blending the data.
- `obj.SetBlendMode (int )` - Set the blend mode
- `int = obj.GetBlendModeMinValue ()` - Set the blend mode
- `int = obj.GetBlendModeMaxValue ()` - Set the blend mode
- `int = obj.GetBlendMode ()` - Set the blend mode
- `obj.SetBlendModeToNormal ()` - Set the blend mode
- `obj.SetBlendModeToCompound ()` - Set the blend mode
- `string = obj.GetBlendModeAsString (void )` - Set the blend mode
- `obj.SetCompoundThreshold (double )` - Specify a threshold in compound mode. Pixels with opacity*alpha less or equal the threshold are ignored.
- `double = obj.GetCompoundThreshold ()` - Specify a threshold in compound mode. Pixels with opacity*alpha less or equal the threshold are ignored.

35.11 vtkImageButterworthHighPass

35.11.1 Usage

This filter only works on an image after it has been converted to frequency domain by a vtkImageFFT filter. A vtkImageRFFT filter can be used to convert the output back into the spatial domain. vtkImageButterworthHighPass the frequency components around 0 are attenuated. Input and output are in doubles, with two components (complex numbers). out(i, j) = 1 / (1 + pow(CutOff/Freq(i,j), 2*Order));

To create an instance of class vtkImageButterworthHighPass, simply invoke its constructor as follows

```
obj = vtkImageButterworthHighPass
```

35.11.2 Methods

The class vtkImageButterworthHighPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageButterworthHighPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageButterworthHighPass = obj.NewInstance ()`
- `vtkImageButterworthHighPass = obj.SafeDownCast (vtkObject o)`
- `obj.SetCutOff (double , double , double )` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetCutOff (double a[3])` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).

- `obj.SetCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetXCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetYCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetZCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj. GetCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetXCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetYCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetZCutOff ()` - The order determines sharpness of the cutoff curve.
- `obj.SetOrder (int )` - The order determines sharpness of the cutoff curve.
- `int = obj.GetOrder ()` - The order determines sharpness of the cutoff curve.

35.12 vtkImageButterworthLowPass

35.12.1 Usage

This filter only works on an image after it has been converted to frequency domain by a vtkImageFFT filter. A vtkImageRFFT filter can be used to convert the output back into the spatial domain. vtkImageButterworthLowPass the high frequency components are attenuated. Input and output are in doubles, with two components (complex numbers). out(i, j) = (1 + pow(CutOff/Freq(i,j), 2*Order));

To create an instance of class vtkImageButterworthLowPass, simply invoke its constructor as follows

```
obj = vtkImageButterworthLowPass
```

35.12.2 Methods

The class vtkImageButterworthLowPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageButterworthLowPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageButterworthLowPass = obj.NewInstance ()`
- `vtkImageButterworthLowPass = obj.SafeDownCast (vtkObject o)`
- `obj.SetCutOff (double , double , double )` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetCutOff (double  a[3])` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).

- `obj.SetCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetXCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetYCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetZCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj. GetCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetXCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetYCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetZCutOff ()` - The order determines sharpness of the cutoff curve.
- `obj.SetOrder (int )` - The order determines sharpness of the cutoff curve.
- `int = obj.GetOrder ()` - The order determines sharpness of the cutoff curve.

35.13 vtkImageCacheFilter

35.13.1 Usage

vtkImageCacheFilter keep a number of vtkImageDataObjects from previous updates to satisfy future updates without needing to update the input. It does not change the data at all. It just makes the pipeline more efficient at the expense of using extra memory.

To create an instance of class vtkImageCacheFilter, simply invoke its constructor as follows

```
obj = vtkImageCacheFilter
```

35.13.2 Methods

The class vtkImageCacheFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCacheFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCacheFilter = obj.NewInstance ()`
- `vtkImageCacheFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetCacheSize (int size)` - This is the maximum number of images that can be retained in memory. it defaults to 10.
- `int = obj.GetCacheSize ()` - This is the maximum number of images that can be retained in memory. it defaults to 10.

35.14 vtkImageCanvasSource2D

35.14.1 Usage

vtkImageCanvasSource2D is a source that starts as a blank image. you may add to the image with two-dimensional drawing routines. It can paint multi-spectral images.

To create an instance of class vtkImageCanvasSource2D, simply invoke its constructor as follows

```
obj = vtkImageCanvasSource2D
```

35.14.2 Methods

The class vtkImageCanvasSource2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCanvasSource2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCanvasSource2D = obj.NewInstance ()`
- `vtkImageCanvasSource2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetDrawColor (double , double , double , double )` - Set/Get DrawColor. This is the value that is used when filling data or drawing lines. Default is (0,0,0,0)
- `obj.SetDrawColor (double  a[4])` - Set/Get DrawColor. This is the value that is used when filling data or drawing lines. Default is (0,0,0,0)
- `double = obj. GetDrawColor ()` - Set/Get DrawColor. This is the value that is used when filling data or drawing lines. Default is (0,0,0,0)
- `obj.SetDrawColor (double a)` - Set DrawColor to (a, b, 0, 0)
- `obj.SetDrawColor (double a, double b)` - Set DrawColor to (a, b, c, 0)
- `obj.SetDrawColor (double a, double b, double c)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.FillBox (int min0, int max0, int min1, int max1)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.FillTube (int x0, int y0, int x1, int y1, double radius)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.FillTriangle (int x0, int y0, int x1, int y1, int x2, int y2)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.DrawCircle (int c0, int c1, double radius)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.DrawPoint (int p0, int p1)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.DrawSegment (int x0, int y0, int x1, int y1)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor
- `obj.DrawSegment3D (double p0, double p1)` - Set the pixels inside the box (min0, max0, min1, max1) to the current DrawColor

- `obj.DrawSegment3D (double x1, double y1, double z1, double x2, double y2, double z2)` - Draw subimage of the input image in the canvas at position x0 and y0. The subimage is defined with sx, sy, width, and height.
- `obj.DrawImage (int x0, int y0, vtkImageData i)` - Draw subimage of the input image in the canvas at position x0 and y0. The subimage is defined with sx, sy, width, and height.
- `obj.DrawImage (int x0, int y0, vtkImageData , int sx, int sy, int width, int height)` - Draw subimage of the input image in the canvas at position x0 and y0. The subimage is defined with sx, sy, width, and height.
- `obj.FillPixel (int x, int y)` - Fill a colored area with another color. (like connectivity) All pixels connected (and with the same value) to pixel (x, y) get replaced by the current "DrawColor".
- `obj.SetExtent (int extent)` - These methods set the WholeExtent of the output It sets the size of the canvas. Extent is a min max 3D box. Minimums and maximums are inclusive.
- `obj.SetExtent (int x1, int x2, int y1, int y2, int z1, int z2)` - These methods set the WholeExtent of the output It sets the size of the canvas. Extent is a min max 3D box. Minimums and maximums are inclusive.
- `obj.SetDefaultZ (int )` - The drawing operations can only draw into one 2D XY plane at a time. If the canvas is a 3D volume, then this z value is used as the default for 2D operations. The default is 0.
- `int = obj.GetDefaultZ ()` - The drawing operations can only draw into one 2D XY plane at a time. If the canvas is a 3D volume, then this z value is used as the default for 2D operations. The default is 0.
- `obj.SetRatio (double , double , double )` - Set/Get Ratio. This is the value that is used to pre-multiply each (x, y, z) drawing coordinates (including DefaultZ). The default is (1, 1, 1)
- `obj.SetRatio (double a[3])` - Set/Get Ratio. This is the value that is used to pre-multiply each (x, y, z) drawing coordinates (including DefaultZ). The default is (1, 1, 1)
- `double = obj. GetRatio ()` - Set/Get Ratio. This is the value that is used to pre-multiply each (x, y, z) drawing coordinates (including DefaultZ). The default is (1, 1, 1)
- `obj.SetNumberOfScalarComponents (int i)` - Set the number of scalar components
- `int = obj.GetNumberOfScalarComponents () const` - Set the number of scalar components
- `obj.SetScalarTypeToFloat ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToDouble ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToInt ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToUnsignedInt ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToLong ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToUnsignedLong ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToShort ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToUnsignedShort ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToUnsignedChar ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarTypeToChar ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `obj.SetScalarType (int )` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility
- `int = obj.GetScalarType () const` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

35.15 vtkImageCast

35.15.1 Usage

vtkImageCast filter casts the input type to match the output type in the image processing pipeline. The filter does nothing if the input already has the correct type. To specify the "CastTo" type, use "SetOutputScalarType" method.

To create an instance of class vtkImageCast, simply invoke its constructor as follows

```
obj = vtkImageCast
```

35.15.2 Methods

The class vtkImageCast has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCast class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCast = obj.NewInstance ()`
- `vtkImageCast = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputScalarType (int )` - Set the desired output scalar type to cast to.
- `int = obj.GetOutputScalarType ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToFloat ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToDouble ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToInt ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToLong ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToShort ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToUnsignedChar ()` - Set the desired output scalar type to cast to.
- `obj.SetOutputScalarTypeToChar ()` - Set the desired output scalar type to cast to.
- `obj.SetClampOverflow (int )` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default ClampOverflow is off.
- `int = obj.GetClampOverflow ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default ClampOverflow is off.
- `obj.ClampOverflowOn ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default ClampOverflow is off.
- `obj.ClampOverflowOff ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default ClampOverflow is off.

35.16 vtkImageChangeInformation

35.16.1 Usage

vtkImageChangeInformation modify the spacing, origin, or extent of the data without changing the data itself. The data is not resampled by this filter, only the information accompanying the data is modified.

To create an instance of class vtkImageChangeInformation, simply invoke its constructor as follows

```
obj = vtkImageChangeInformation
```

35.16.2 Methods

The class vtkImageChangeInformation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageChangeInformation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageChangeInformation = obj.NewInstance ()`
- `vtkImageChangeInformation = obj.SafeDownCast (vtkObject o)`
- `obj.SetInformationInput (vtkImageData )` - Copy the information from another data set. By default, the information is copied from the input.
- `vtkImageData = obj.GetInformationInput ()` - Copy the information from another data set. By default, the information is copied from the input.
- `obj.SetOutputExtentStart (int , int , int )` - Specify new starting values for the extent explicitly. These values are used as WholeExtent[0], WholeExtent[2] and WholeExtent[4] of the output. The default is to the use the extent start of the Input, or of the InformationInput if InformationInput is set.
- `obj.SetOutputExtentStart (int a[3])` - Specify new starting values for the extent explicitly. These values are used as WholeExtent[0], WholeExtent[2] and WholeExtent[4] of the output. The default is to the use the extent start of the Input, or of the InformationInput if InformationInput is set.
- `int = obj. GetOutputExtentStart ()` - Specify new starting values for the extent explicitly. These values are used as WholeExtent[0], WholeExtent[2] and WholeExtent[4] of the output. The default is to the use the extent start of the Input, or of the InformationInput if InformationInput is set.
- `obj.SetOutputSpacing (double , double , double )` - Specify a new data spacing explicitly. The default is to use the spacing of the Input, or of the InformationInput if InformationInput is set.
- `obj.SetOutputSpacing (double a[3])` - Specify a new data spacing explicitly. The default is to use the spacing of the Input, or of the InformationInput if InformationInput is set.
- `double = obj. GetOutputSpacing ()` - Specify a new data spacing explicitly. The default is to use the spacing of the Input, or of the InformationInput if InformationInput is set.
- `obj.SetOutputOrigin (double , double , double )` - Specify a new data origin explicitly. The default is to use the origin of the Input, or of the InformationInput if InformationInput is set.
- `obj.SetOutputOrigin (double a[3])` - Specify a new data origin explicitly. The default is to use the origin of the Input, or of the InformationInput if InformationInput is set.
- `double = obj. GetOutputOrigin ()` - Specify a new data origin explicitly. The default is to use the origin of the Input, or of the InformationInput if InformationInput is set.
- `obj.SetCenterImage (int )` - Set the Origin of the output so that image coordinate (0,0,0) lies at the Center of the data set. This will override SetOutputOrigin. This is often a useful operation to apply before using vtkImageReslice to apply a transformation to an image.
- `obj.CenterImageOn ()` - Set the Origin of the output so that image coordinate (0,0,0) lies at the Center of the data set. This will override SetOutputOrigin. This is often a useful operation to apply before using vtkImageReslice to apply a transformation to an image.

- `obj.CenterImageOff ()` - Set the Origin of the output so that image coordinate (0,0,0) lies at the Center of the data set. This will override SetOutputOrigin. This is often a useful operation to apply before using vtkImageReslice to apply a transformation to an image.
- `int = obj.GetCenterImage ()` - Set the Origin of the output so that image coordinate (0,0,0) lies at the Center of the data set. This will override SetOutputOrigin. This is often a useful operation to apply before using vtkImageReslice to apply a transformation to an image.
- `obj.SetExtentTranslation (int , int , int )` - Apply a translation to the extent.
- `obj.SetExtentTranslation (int a[3])` - Apply a translation to the extent.
- `int = obj. GetExtentTranslation ()` - Apply a translation to the extent.
- `obj.SetSpacingScale (double , double , double )` - Apply a scale factor to the spacing.
- `obj.SetSpacingScale (double a[3])` - Apply a scale factor to the spacing.
- `double = obj. GetSpacingScale ()` - Apply a scale factor to the spacing.
- `obj.SetOriginTranslation (double , double , double )` - Apply a translation to the origin.
- `obj.SetOriginTranslation (double a[3])` - Apply a translation to the origin.
- `double = obj. GetOriginTranslation ()` - Apply a translation to the origin.
- `obj.SetOriginScale (double , double , double )` - Apply a scale to the origin. The scale is applied before the translation.
- `obj.SetOriginScale (double a[3])` - Apply a scale to the origin. The scale is applied before the translation.
- `double = obj. GetOriginScale ()` - Apply a scale to the origin. The scale is applied before the translation.

35.17 vtkImageCheckerboard

35.17.1 Usage

vtkImageCheckerboard displays two images as one using a checkerboard pattern. This filter can be used to compare two images. The checkerboard pattern is controlled by the NumberOfDivisions ivar. This controls the number of checkerboard divisions in the whole extent of the image.

To create an instance of class vtkImageCheckerboard, simply invoke its constructor as follows

```
obj = vtkImageCheckerboard
```

35.17.2 Methods

The class vtkImageCheckerboard has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCheckerboard class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCheckerboard = obj.NewInstance ()`
- `vtkImageCheckerboard = obj.SafeDownCast (vtkObject o)`

- `obj.SetNumberOfDivisions (int , int , int )` - Set/Get the number of divisions along each axis.
- `obj.SetNumberOfDivisions (int  a[3])` - Set/Get the number of divisions along each axis.
- `int = obj. GetNumberOfDivisions ()` - Set/Get the number of divisions along each axis.
- `obj.SetInput1 (vtkDataObject in)` - Set the two inputs to this filter
- `obj.SetInput2 (vtkDataObject in)`

35.18 vtkImageCityBlockDistance

35.18.1 Usage

vtkImageCityBlockDistance creates a distance map using the city block (Manhatten) distance measure. The input is a mask. Zero values are considered boundaries. The output pixel is the minimum of the input pixel and the distance to a boundary (or neighbor value + 1 unit). distance values are calculated in pixels. The filter works by taking 6 passes (for 3d distance map): 2 along each axis (forward and backward). Each pass keeps a running minimum distance. For some reason, I preserve the sign if the distance. If the input mask is initially negative, the output distances will be negative. Distances maps can have inside (negative regions) and outsides (positive regions).

To create an instance of class vtkImageCityBlockDistance, simply invoke its constructor as follows

```
obj = vtkImageCityBlockDistance
```

35.18.2 Methods

The class vtkImageCityBlockDistance has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCityBlockDistance class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCityBlockDistance = obj.NewInstance ()`
- `vtkImageCityBlockDistance = obj.SafeDownCast (vtkObject o)`

35.19 vtkImageClip

35.19.1 Usage

vtkImageClip will make an image smaller. The output must have an image extent which is the subset of the input. The filter has two modes of operation: 1: By default, the data is not copied in this filter. Only the whole extent is modified. 2: If ClipDataOn is set, then you will get no more that the clipped extent.

To create an instance of class vtkImageClip, simply invoke its constructor as follows

```
obj = vtkImageClip
```

35.19.2 Methods

The class vtkImageClip has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageClip class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageClip = obj.NewInstance ()`
- `vtkImageClip = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputWholeExtent (int extent[6], vtkInformation outInfo)` - The whole extent of the output has to be set explicitly.
- `obj.SetOutputWholeExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - The whole extent of the output has to be set explicitly.
- `obj.GetOutputWholeExtent (int extent[6])` - The whole extent of the output has to be set explicitly.
- `int = obj.GetOutputWholeExtent ()`
- `obj.ResetOutputWholeExtent ()`
- `obj.SetClipData (int )` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `int = obj.GetClipData ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.ClipDataOn ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.ClipDataOff ()` - By default, ClipData is off, and only the WholeExtent is modified. the data's extent may actually be larger. When this flag is on, the data extent will be no more than the OutputWholeExtent.
- `obj.SetOutputWholeExtent (int piece, int numPieces)` - Hack set output by piece

35.20 vtkImageConnector

35.20.1 Usage

vtkImageConnector is a helper class for connectivity filters. It is not meant to be used directly. It implements a stack and breadth first search necessary for some connectivity filters. Filtered axes sets the dimensionality of the neighbor comparison, and cannot be more than three dimensions. As implemented, only voxels which share faces are considered neighbors.

To create an instance of class vtkImageConnector, simply invoke its constructor as follows

```
obj = vtkImageConnector
```

35.20.2 Methods

The class vtkImageConnector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageConnector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageConnector = obj.NewInstance ()`
- `vtkImageConnector = obj.SafeDownCast (vtkObject o)`
- `obj.RemoveAllSeeds ()`
- `obj.SetConnectedValue (char )` - Values used by the MarkRegion method
- `char = obj.GetConnectedValue ()` - Values used by the MarkRegion method
- `obj.SetUnconnectedValue (char )` - Values used by the MarkRegion method
- `char = obj.GetUnconnectedValue ()` - Values used by the MarkRegion method
- `obj.MarkData (vtkImageData data, int dimensionality, int ext[6])` - Input a data of 0's and "UnconnectedValue"s. Seeds of this object are used to find connected pixels. All pixels connected to seeds are set to ConnectedValue. The data has to be unsigned char.

35.21 vtkImageConstantPad

35.21.1 Usage

vtkImageConstantPad changes the image extent of its input. Any pixels outside of the original image extent are filled with a constant value (default is 0.0).

To create an instance of class vtkImageConstantPad, simply invoke its constructor as follows

```
obj = vtkImageConstantPad
```

35.21.2 Methods

The class vtkImageConstantPad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageConstantPad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageConstantPad = obj.NewInstance ()`
- `vtkImageConstantPad = obj.SafeDownCast (vtkObject o)`
- `obj.SetConstant (double )` - Set/Get the pad value.
- `double = obj.GetConstant ()` - Set/Get the pad value.

35.22 vtkImageContinuousDilate3D

35.22.1 Usage

vtkImageContinuousDilate3D replaces a pixel with the maximum over an ellipsoidal neighborhood. If KernelSize of an axis is 1, no processing is done on that axis.

To create an instance of class vtkImageContinuousDilate3D, simply invoke its constructor as follows

```
obj = vtkImageContinuousDilate3D
```

35.22.2 Methods

The class vtkImageContinuousDilate3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageContinuousDilate3D class.

- `string = obj.GetClassName ()` - Construct an instance of vtkImageContinuousDilate3D filter. By default zero values are dilated.
- `int = obj.IsA (string name)` - Construct an instance of vtkImageContinuousDilate3D filter. By default zero values are dilated.
- `vtkImageContinuousDilate3D = obj.NewInstance ()` - Construct an instance of vtkImageContinuousDilate3D filter. By default zero values are dilated.
- `vtkImageContinuousDilate3D = obj.SafeDownCast (vtkObject o)` - Construct an instance of vtkImageContinuousDilate3D filter. By default zero values are dilated.
- `obj.SetKernelSize (int size0, int size1, int size2)` - This method sets the size of the neighborhood. It also sets the default middle of the neighborhood and computes the elliptical foot print.

35.23 vtkImageContinuousErode3D

35.23.1 Usage

vtkImageContinuousErode3D replaces a pixel with the minimum over an ellipsoidal neighborhood. If KernelSize of an axis is 1, no processing is done on that axis.

To create an instance of class vtkImageContinuousErode3D, simply invoke its constructor as follows

```
obj = vtkImageContinuousErode3D
```

35.23.2 Methods

The class vtkImageContinuousErode3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageContinuousErode3D class.

- `string = obj.GetClassName ()` - Construct an instance of vtkImageContinuousErode3D filter. By default zero values are eroded.
- `int = obj.IsA (string name)` - Construct an instance of vtkImageContinuousErode3D filter. By default zero values are eroded.
- `vtkImageContinuousErode3D = obj.NewInstance ()` - Construct an instance of vtkImageContinuousErode3D filter. By default zero values are eroded.

- `vtkImageContinuousErode3D = obj.SafeDownCast (vtkObject o)` - Construct an instance of vtkImageContinuousErode3D filter. By default zero values are eroded.
- `obj.SetKernelSize (int size0, int size1, int size2)` - This method sets the size of the neighborhood. It also sets the default middle of the neighborhood and computes the elliptical foot print.

35.24 vtkImageConvolve

35.24.1 Usage

vtkImageConvolve convolves the image with a 3D NxNxN kernel or a 2D NxN kernal. The output image is cropped to the same size as the input.

To create an instance of class vtkImageConvolve, simply invoke its constructor as follows

```
obj = vtkImageConvolve
```

35.24.2 Methods

The class vtkImageConvolve has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageConvolve class.

- `string = obj.GetClassName ()` - Construct an instance of vtkImageConvolve filter.
- `int = obj.IsA (string name)` - Construct an instance of vtkImageConvolve filter.
- `vtkImageConvolve = obj.NewInstance ()` - Construct an instance of vtkImageConvolve filter.
- `vtkImageConvolve = obj.SafeDownCast (vtkObject o)` - Construct an instance of vtkImageConvolve filter.
- `int = obj. GetKernelSize ()` - Get the kernel size
- `obj.SetKernel3x3 (double kernel[9])` - Set the kernel to be a given 3x3 or 5x5 or 7x7 kernel.
- `obj.SetKernel5x5 (double kernel[25])` - Set the kernel to be a given 3x3 or 5x5 or 7x7 kernel.
- `obj.GetKernel3x3 (double kernel[9])` - Return an array that contains the kernel.
- `obj.GetKernel5x5 (double kernel[25])` - Return an array that contains the kernel.
- `obj.SetKernel3x3x3 (double kernel[27])` - Set the kernel to be a 3x3x3 or 5x5x5 or 7x7x7 kernel.
- `obj.GetKernel3x3x3 (double kernel[27])` - Return an array that contains the kernel

35.25 vtkImageCorrelation

35.25.1 Usage

vtkImageCorrelation finds the correlation between two data sets. SetDimensionality determines whether the Correlation will be 3D, 2D or 1D. The default is a 2D Correlation. The Output type will be double. The output size will match the size of the first input. The second input is considered the correlation kernel.

To create an instance of class vtkImageCorrelation, simply invoke its constructor as follows

```
obj = vtkImageCorrelation
```

35.25.2 Methods

The class vtkImageCorrelation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCorrelation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCorrelation = obj.NewInstance ()`
- `vtkImageCorrelation = obj.SafeDownCast (vtkObject o)`
- `obj.SetDimensionality (int )` - Determines how the input is interpreted (set of 2d slices ...). The default is 2.
- `int = obj.GetDimensionalityMinValue ()` - Determines how the input is interpreted (set of 2d slices ...). The default is 2.
- `int = obj.GetDimensionalityMaxValue ()` - Determines how the input is interpreted (set of 2d slices ...). The default is 2.
- `int = obj.GetDimensionality ()` - Determines how the input is interpreted (set of 2d slices ...). The default is 2.
- `obj.SetInput1 (vtkDataObject in)` - Set the correlation kernel.
- `obj.SetInput2 (vtkDataObject in)`

35.26 vtkImageCursor3D

35.26.1 Usage

vtkImageCursor3D will draw a cursor on a 2d image or 3d volume.

To create an instance of class vtkImageCursor3D, simply invoke its constructor as follows

```
obj = vtkImageCursor3D
```

35.26.2 Methods

The class vtkImageCursor3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageCursor3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageCursor3D = obj.NewInstance ()`
- `vtkImageCursor3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetCursorPosition (double , double , double )` - Sets/Gets the center point of the 3d cursor.
- `obj.SetCursorPosition (double  a[3])` - Sets/Gets the center point of the 3d cursor.
- `double = obj. GetCursorPosition ()` - Sets/Gets the center point of the 3d cursor.

- `obj.SetCursorValue (double )` - Sets/Gets what pixel value to draw the cursor in.
- `double = obj.GetCursorValue ()` - Sets/Gets what pixel value to draw the cursor in.
- `obj.SetCursorRadius (int )` - Sets/Gets the radius of the cursor. The radius determines how far the axis lines project out from the cursors center.
- `int = obj.GetCursorRadius ()` - Sets/Gets the radius of the cursor. The radius determines how far the axis lines project out from the cursors center.

35.27 vtkImageDataStreamer

35.27.1 Usage

To satisfy a request, this filter calls update on its input many times with smaller update extents. All processing up stream streams smaller pieces.

To create an instance of class vtkImageDataStreamer, simply invoke its constructor as follows

```
obj = vtkImageDataStreamer
```

35.27.2 Methods

The class vtkImageDataStreamer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDataStreamer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDataStreamer = obj.NewInstance ()`
- `vtkImageDataStreamer = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfStreamDivisions (int )` - Set how many pieces to divide the input into. void SetNumberOfStreamDivisions(int num); int GetNumberOfStreamDivisions();
- `int = obj.GetNumberOfStreamDivisions ()` - Set how many pieces to divide the input into. void SetNumberOfStreamDivisions(int num); int GetNumberOfStreamDivisions();
- `obj.Update ()`
- `obj.UpdateWholeExtent ()`
- `obj.SetExtentTranslator (vtkExtentTranslator )` - Get the extent translator that will be used to split the requests
- `vtkExtentTranslator = obj.GetExtentTranslator ()` - Get the extent translator that will be used to split the requests

35.28 vtkImageDecomposeFilter

35.28.1 Usage

This superclass molds the vtkImageIterateFilter superclass so it iterates over the axes. The filter uses dimensionality to determine how many axes to execute (starting from x). The filter also provides convenience methods for permuting information retrieved from input, output and vtkImageData.

To create an instance of class vtkImageDecomposeFilter, simply invoke its constructor as follows

```
obj = vtkImageDecomposeFilter
```

35.28.2 Methods

The class vtkImageDecomposeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDecomposeFilter class.

- `string = obj.GetClassName ()` - Construct an instance of vtkImageDecomposeFilter filter with default dimensionality 3.
- `int = obj.IsA (string name)` - Construct an instance of vtkImageDecomposeFilter filter with default dimensionality 3.
- `vtkImageDecomposeFilter = obj.NewInstance ()` - Construct an instance of vtkImageDecomposeFilter filter with default dimensionality 3.
- `vtkImageDecomposeFilter = obj.SafeDownCast (vtkObject o)` - Construct an instance of vtkImageDecomposeFilter filter with default dimensionality 3.
- `obj.SetDimensionality (int dim)` - Dimensionality is the number of axes which are considered during execution. To process images dimensionality would be set to 2.
- `int = obj.GetDimensionality ()` - Dimensionality is the number of axes which are considered during execution. To process images dimensionality would be set to 2.

35.29 vtkImageDifference

35.29.1 Usage

vtkImageDifference takes two rgb unsigned char images and compares them. It allows the images to be slightly different. If AllowShift is on, then each pixel can be shifted by one pixel. Threshold is the allowable error for each pixel.

This is not a symetric filter and the difference computed is not symetric when AllowShift is on. Specifically in that case a pixel in SetImage input will be compared to the matching pixel in the input as well as to the input's eight connected neighbors. BUT... the opposite is not true. So for example if a valid image (SetImage) has a single white pixel in it, it will not find a match in the input image if the input image is black (because none of the nine suspect pixels are white). In contrast, if there is a single white pixel in the input image and the valid image (SetImage) is all black it will match with no error because all it has to do is find black pixels and even though the input image has a white pixel, its neighbors are not white.

To create an instance of class vtkImageDifference, simply invoke its constructor as follows

```
obj = vtkImageDifference
```

35.29.2 Methods

The class vtkImageDifference has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDifference class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDifference = obj.NewInstance ()`
- `vtkImageDifference = obj.SafeDownCast (vtkObject o)`
- `obj.SetImage (vtkDataObject image)` - Specify the Image to compare the input to.

- `vtkImageData = obj.GetImage ()` - Specify the Image to compare the input to.
- `double = obj.GetError (void )` - Return the total error in comparing the two images.
- `obj.GetError (double e)` - Return the total error in comparing the two images.
- `double = obj.GetThresholdedError (void )` - Return the total thresholded error in comparing the two images. The thresholded error is the error for a given pixel minus the threshold and clamped at a minimum of zero.
- `obj.GetThresholdedError (double e)` - Return the total thresholded error in comparing the two images. The thresholded error is the error for a given pixel minus the threshold and clamped at a minimum of zero.
- `obj.SetThreshold (int )` - Specify a threshold tolerance for pixel differences.
- `int = obj.GetThreshold ()` - Specify a threshold tolerance for pixel differences.
- `obj.SetAllowShift (int )` - Specify whether the comparison will allow a shift of one pixel between the images. If set, then the minimum difference between input images will be used to determine the difference. Otherwise, the difference is computed directly between pixels of identical row/column values.
- `int = obj.GetAllowShift ()` - Specify whether the comparison will allow a shift of one pixel between the images. If set, then the minimum difference between input images will be used to determine the difference. Otherwise, the difference is computed directly between pixels of identical row/column values.
- `obj.AllowShiftOn ()` - Specify whether the comparison will allow a shift of one pixel between the images. If set, then the minimum difference between input images will be used to determine the difference. Otherwise, the difference is computed directly between pixels of identical row/column values.
- `obj.AllowShiftOff ()` - Specify whether the comparison will allow a shift of one pixel between the images. If set, then the minimum difference between input images will be used to determine the difference. Otherwise, the difference is computed directly between pixels of identical row/column values.
- `obj.SetAveraging (int )` - Specify whether the comparison will include comparison of averaged 3x3 data between the images. For graphics renderings you normally would leave this on. For imaging operations it should be off.
- `int = obj.GetAveraging ()` - Specify whether the comparison will include comparison of averaged 3x3 data between the images. For graphics renderings you normally would leave this on. For imaging operations it should be off.
- `obj.AveragingOn ()` - Specify whether the comparison will include comparison of averaged 3x3 data between the images. For graphics renderings you normally would leave this on. For imaging operations it should be off.
- `obj.AveragingOff ()` - Specify whether the comparison will include comparison of averaged 3x3 data between the images. For graphics renderings you normally would leave this on. For imaging operations it should be off.

35.30 vtkImageDilateErode3D

35.30.1 Usage

vtkImageDilateErode3D will dilate one value and erode another. It uses an elliptical foot print, and only erodes/dilates on the boundary of the two values. The filter is restricted to the X, Y, and Z axes for now. It can degenerate to a 2 or 1 dimensional filter by setting the kernel size to 1 for a specific axis.

To create an instance of class vtkImageDilateErode3D, simply invoke its constructor as follows

```
obj = vtkImageDilateErode3D
```

35.30.2 Methods

The class vtkImageDilateErode3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDilateErode3D class.

- `string = obj.GetClassName ()` - Construct an instance of vtkImageDilateErode3D filter. By default zero values are dilated.
- `int = obj.IsA (string name)` - Construct an instance of vtkImageDilateErode3D filter. By default zero values are dilated.
- `vtkImageDilateErode3D = obj.NewInstance ()` - Construct an instance of vtkImageDilateErode3D filter. By default zero values are dilated.
- `vtkImageDilateErode3D = obj.SafeDownCast (vtkObject o)` - Construct an instance of vtkImageDilateErode3D filter. By default zero values are dilated.
- `obj.SetKernelSize (int size0, int size1, int size2)` - This method sets the size of the neighborhood. It also sets the default middle of the neighborhood and computes the elliptical foot print.
- `obj.SetDilateValue (double )` - Set/Get the Dilate and Erode values to be used by this filter.
- `double = obj.GetDilateValue ()` - Set/Get the Dilate and Erode values to be used by this filter.
- `obj.SetErodeValue (double )` - Set/Get the Dilate and Erode values to be used by this filter.
- `double = obj.GetErodeValue ()` - Set/Get the Dilate and Erode values to be used by this filter.

35.31 vtkImageDivergence

35.31.1 Usage

vtkImageDivergence takes a 3D vector field and creates a scalar field which which represents the rate of change of the vector field. The definition of Divergence: Given V = P(x,y,z), Q(x,y,z), R(x,y,z), Divergence = dP/dx + dQ/dy + dR/dz.

To create an instance of class vtkImageDivergence, simply invoke its constructor as follows

```
obj = vtkImageDivergence
```

35.31.2 Methods

The class vtkImageDivergence has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDivergence class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDivergence = obj.NewInstance ()`
- `vtkImageDivergence = obj.SafeDownCast (vtkObject o)`

35.32 vtkImageDotProduct

35.32.1 Usage

vtkImageDotProduct interprets the scalar components of two images as vectors and takes the dot product vector by vector (pixel by pixel).

To create an instance of class vtkImageDotProduct, simply invoke its constructor as follows

```
obj = vtkImageDotProduct
```

35.32.2 Methods

The class vtkImageDotProduct has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageDotProduct class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageDotProduct = obj.NewInstance ()`
- `vtkImageDotProduct = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput1 (vtkDataObject in)` - Set the two inputs to this filter
- `obj.SetInput2 (vtkDataObject in)`

35.33 vtkImageEllipsoidSource

35.33.1 Usage

vtkImageEllipsoidSource creates a binary image of a ellipsoid. It was created as an example of a simple source, and to test the mask filter. It is also used internally in vtkImageDilateErode3D.

To create an instance of class vtkImageEllipsoidSource, simply invoke its constructor as follows

```
obj = vtkImageEllipsoidSource
```

35.33.2 Methods

The class vtkImageEllipsoidSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageEllipsoidSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageEllipsoidSource = obj.NewInstance ()`
- `vtkImageEllipsoidSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetWholeExtent (int extent[6])` - Set/Get the extent of the whole output image.
- `obj.SetWholeExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - Set/Get the extent of the whole output image.
- `obj.GetWholeExtent (int extent[6])` - Set/Get the extent of the whole output image.
- `int = obj.GetWholeExtent ()` - Set/Get the center of the ellipsoid.
- `obj.SetCenter (double , double , double )` - Set/Get the center of the ellipsoid.
- `obj.SetCenter (double  a[3])` - Set/Get the center of the ellipsoid.
- `double = obj. GetCenter ()` - Set/Get the center of the ellipsoid.
- `obj.SetRadius (double , double , double )` - Set/Get the radius of the ellipsoid.
- `obj.SetRadius (double  a[3])` - Set/Get the radius of the ellipsoid.
- `double = obj. GetRadius ()` - Set/Get the radius of the ellipsoid.
- `obj.SetInValue (double )` - Set/Get the inside pixel values.
- `double = obj.GetInValue ()` - Set/Get the inside pixel values.
- `obj.SetOutValue (double )` - Set/Get the outside pixel values.
- `double = obj.GetOutValue ()` - Set/Get the outside pixel values.
- `obj.SetOutputScalarType (int )` - Set what type of scalar data this source should generate.
- `int = obj.GetOutputScalarType ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToFloat ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToDouble ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToLong ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToInt ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToShort ()` - Set what type of scalar data this source should generate.

- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToChar ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedChar ()`

35.34 vtkImageEuclideanDistance

35.34.1 Usage

vtkImageEuclideanDistance implements the Euclidean DT using Saito's algorithm. The distance map produced contains the square of the Euclidean distance values.

The algorithm has a o(n$\hat{}$(D+1)) complexity over nxnx...xn images in D dimensions. It is very efficient on relatively small images. Cuisenaire's algorithms should be used instead if n ¿¿ 500. These are not implemented yet.

For the special case of images where the slice-size is a multiple of 2N$\hat{}$ with a large N (typically for 256x256 slices), Saito's algorithm encounters a lot of cache conflicts during the 3rd iteration which can slow it very significantly. In that case, one should use ::SetAlgorithmToSaitoCached() instead for better performance.

References:

T. Saito and J.I. Toriwaki. New algorithms for Euclidean distance transformations of an n-dimensional digitised picture with applications. Pattern Recognition, 27(11). pp. 1551–1565, 1994.

O. Cuisenaire. Distance Transformation: fast algorithms and applications to medical image processing. PhD Thesis, Universite catholique de Louvain, October 1999. http://ltswww.epfl.ch/ cuisenai/papers/oc_thesis.pdf

To create an instance of class vtkImageEuclideanDistance, simply invoke its constructor as follows

```
obj = vtkImageEuclideanDistance
```

35.34.2 Methods

The class vtkImageEuclideanDistance has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageEuclideanDistance class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageEuclideanDistance = obj.NewInstance ()`
- `vtkImageEuclideanDistance = obj.SafeDownCast (vtkObject o)`
- `int = obj.SplitExtent (int splitExt[6], int startExt[6], int num, int total)` - Used internally for streaming and threads. Splits output update extent into num pieces. This method needs to be called num times. Results must not overlap for consistent starting extent. Subclass can override this method. This method returns the number of peices resulting from a successful split. This can be from 1 to "total". If 1 is returned, the extent cannot be split.
- `obj.SetInitialize (int )` - Used to set all non-zero voxels to MaximumDistance before starting the distance transformation. Setting Initialize off keeps the current value in the input image as starting point. This allows to superimpose several distance maps.
- `int = obj.GetInitialize ()` - Used to set all non-zero voxels to MaximumDistance before starting the distance transformation. Setting Initialize off keeps the current value in the input image as starting point. This allows to superimpose several distance maps.

- `obj.InitializeOn ()` - Used to set all non-zero voxels to MaximumDistance before starting the distance transformation. Setting Initialize off keeps the current value in the input image as starting point. This allows to superimpose several distance maps.
- `obj.InitializeOff ()` - Used to set all non-zero voxels to MaximumDistance before starting the distance transformation. Setting Initialize off keeps the current value in the input image as starting point. This allows to superimpose several distance maps.
- `obj.SetConsiderAnisotropy (int )` - Used to define whether Spacing should be used in the computation of the distances
- `int = obj.GetConsiderAnisotropy ()` - Used to define whether Spacing should be used in the computation of the distances
- `obj.ConsiderAnisotropyOn ()` - Used to define whether Spacing should be used in the computation of the distances
- `obj.ConsiderAnisotropyOff ()` - Used to define whether Spacing should be used in the computation of the distances
- `obj.SetMaximumDistance (double )` - Any distance bigger than this-¿MaximumDistance will not ne computed but set to this-¿MaximumDistance instead.
- `double = obj.GetMaximumDistance ()` - Any distance bigger than this-¿MaximumDistance will not ne computed but set to this-¿MaximumDistance instead.
- `obj.SetAlgorithm (int )` - Selects a Euclidean DT algorithm. 1. Saito 2. Saito-cached More algorithms will be added later on.
- `int = obj.GetAlgorithm ()` - Selects a Euclidean DT algorithm. 1. Saito 2. Saito-cached More algorithms will be added later on.
- `obj.SetAlgorithmToSaito ()` - Selects a Euclidean DT algorithm. 1. Saito 2. Saito-cached More algorithms will be added later on.
- `obj.SetAlgorithmToSaitoCached ()`

35.35 vtkImageEuclideanToPolar

35.35.1 Usage

For each pixel with vector components x,y, this filter outputs theta in component0, and radius in component1.
To create an instance of class vtkImageEuclideanToPolar, simply invoke its constructor as follows

```
obj = vtkImageEuclideanToPolar
```

35.35.2 Methods

The class vtkImageEuclideanToPolar has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageEuclideanToPolar class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageEuclideanToPolar = obj.NewInstance ()`
- `vtkImageEuclideanToPolar = obj.SafeDownCast (vtkObject o)`

- `obj.SetThetaMaximum (double )` - Theta is an angle. Maximum specifies when it maps back to 0. ThetaMaximum defaults to 255 instead of 2PI, because unsigned char is expected as input. The output type must be the same as input type.
- `double = obj.GetThetaMaximum ()` - Theta is an angle. Maximum specifies when it maps back to 0. ThetaMaximum defaults to 255 instead of 2PI, because unsigned char is expected as input. The output type must be the same as input type.

35.36 vtkImageExport

35.36.1 Usage

vtkImageExport provides a way of exporting image data at the end of a pipeline to a third-party system or to a simple C array. Applications can use this to get direct access to the image data in memory. A callback interface is provided to allow connection of the VTK pipeline to a third-party pipeline. This interface conforms to the interface of vtkImageImport. In Python it is possible to use this class to write the image data into a python string that has been pre-allocated to be the correct size.

To create an instance of class vtkImageExport, simply invoke its constructor as follows

```
obj = vtkImageExport
```

35.36.2 Methods

The class vtkImageExport has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageExport class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageExport = obj.NewInstance ()`
- `vtkImageExport = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataMemorySize ()` - Get the number of bytes required for the output C array.
- `obj.GetDataDimensions (int ptr)` - Get the (x,y,z) index dimensions of the data. Please note that C arrays are indexed in decreasing order, i.e. array[z][y][x].
- `int = obj.GetDataDimensions ()` - Get the number of scalar components of the data. Please note that when you index into a C array, the scalar component index comes last, i.e. array[z][y][x][c].
- `int = obj.GetDataNumberOfScalarComponents ()` - Get the number of scalar components of the data. Please note that when you index into a C array, the scalar component index comes last, i.e. array[z][y][x][c].
- `int = obj.GetDataScalarType ()` - Get the scalar type of the data. The scalar type of the C array must match the scalar type of the data.
- `string = obj.GetDataScalarTypeAsString ()` - Get miscellaneous additional information about the data.
- `int = obj.GetDataExtent ()` - Get miscellaneous additional information about the data.
- `obj.GetDataExtent (int ptr)` - Get miscellaneous additional information about the data.
- `double = obj.GetDataSpacing ()` - Get miscellaneous additional information about the data.

- `obj.GetDataSpacing (double ptr)` - Get miscellaneous additional information about the data.
- `double = obj.GetDataOrigin ()` - Get miscellaneous additional information about the data.
- `obj.GetDataOrigin (double ptr)` - Get miscellaneous additional information about the data.
- `obj.ImageLowerLeftOn ()` - Set/Get whether the data goes to the exported memory starting in the lower left corner or upper left corner. Default: On. When this flag is Off, the image will be flipped vertically before it is exported. WARNING: this flag is used only with the Export() method, it is ignored by GetPointerToData().
- `obj.ImageLowerLeftOff ()` - Set/Get whether the data goes to the exported memory starting in the lower left corner or upper left corner. Default: On. When this flag is Off, the image will be flipped vertically before it is exported. WARNING: this flag is used only with the Export() method, it is ignored by GetPointerToData().
- `int = obj.GetImageLowerLeft ()` - Set/Get whether the data goes to the exported memory starting in the lower left corner or upper left corner. Default: On. When this flag is Off, the image will be flipped vertically before it is exported. WARNING: this flag is used only with the Export() method, it is ignored by GetPointerToData().
- `obj.SetImageLowerLeft (int )` - Set/Get whether the data goes to the exported memory starting in the lower left corner or upper left corner. Default: On. When this flag is Off, the image will be flipped vertically before it is exported. WARNING: this flag is used only with the Export() method, it is ignored by GetPointerToData().
- `obj.Export ()` - The main interface: update the pipeline and export the image to the memory pointed to by SetExportVoidPointer(). You can also specify a void pointer when you call Export().

35.37 vtkImageExtractComponents

35.37.1 Usage

vtkImageExtractComponents takes an input with any number of components and outputs some of them. It does involve a copy of the data.

To create an instance of class vtkImageExtractComponents, simply invoke its constructor as follows

```
obj = vtkImageExtractComponents
```

35.37.2 Methods

The class vtkImageExtractComponents has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageExtractComponents class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageExtractComponents = obj.NewInstance ()`
- `vtkImageExtractComponents = obj.SafeDownCast (vtkObject o)`
- `obj.SetComponents (int c1)` - Set/Get the components to extract.
- `obj.SetComponents (int c1, int c2)` - Set/Get the components to extract.
- `obj.SetComponents (int c1, int c2, int c3)` - Set/Get the components to extract.

- `int = obj. GetComponents ()` - Set/Get the components to extract.
- `int = obj.GetNumberOfComponents ()` - Get the number of components to extract. This is set implicitly by the SetComponents() method.

35.38 vtkImageFFT

35.38.1 Usage

vtkImageFFT implements a fast Fourier transform. The input can have real or complex data in any components and data types, but the output is always complex doubles with real values in component0, and imaginary values in component1. The filter is fastest for images that have power of two sizes. The filter uses a butterfly fitlers for each prime factor of the dimension. This makes images with prime number dimensions (i.e. 17x17) much slower to compute. Multi dimensional (i.e volumes) FFT's are decomposed so that each axis executes in series.

To create an instance of class vtkImageFFT, simply invoke its constructor as follows

```
obj = vtkImageFFT
```

35.38.2 Methods

The class vtkImageFFT has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageFFT class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageFFT = obj.NewInstance ()`
- `vtkImageFFT = obj.SafeDownCast (vtkObject o)`
- `int = obj.SplitExtent (int splitExt[6], int startExt[6], int num, int total)` - Used internally for streaming and threads. Splits output update extent into num pieces. This method needs to be called num times. Results must not overlap for consistent starting extent. Subclass can override this method. This method returns the number of pieces resulting from a successful split. This can be from 1 to "total". If 1 is returned, the extent cannot be split.

35.39 vtkImageFlip

35.39.1 Usage

vtkImageFlip will reflect the data along the filtered axis. This filter is actually a thin wrapper around vtkImageReslice.

To create an instance of class vtkImageFlip, simply invoke its constructor as follows

```
obj = vtkImageFlip
```

35.39.2 Methods

The class vtkImageFlip has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageFlip class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageFlip = obj.NewInstance ()`
- `vtkImageFlip = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilteredAxis (int )` - Specify which axis will be flipped. This must be an integer between 0 (for x) and 2 (for z). Initial value is 0.
- `int = obj.GetFilteredAxis ()` - Specify which axis will be flipped. This must be an integer between 0 (for x) and 2 (for z). Initial value is 0.
- `obj.SetFlipAboutOrigin (int )` - By default the image will be flipped about its center, and the Origin, Spacing and Extent of the output will be identical to the input. However, if you have a coordinate system associated with the image and you want to use the flip to convert +ve values along one axis to -ve values (and vice versa) then you actually want to flip the image about coordinate (0,0,0) instead of about the center of the image. This method will adjust the Origin of the output such that the flip occurs about (0,0,0). Note that this method only changes the Origin (and hence the coordinate system) the output data: the actual pixel values are the same whether or not this method is used. Also note that the Origin in this method name refers to (0,0,0) in the coordinate system associated with the image, it does not refer to the Origin ivar that is associated with a vtkImageData.
- `int = obj.GetFlipAboutOrigin ()` - By default the image will be flipped about its center, and the Origin, Spacing and Extent of the output will be identical to the input. However, if you have a coordinate system associated with the image and you want to use the flip to convert +ve values along one axis to -ve values (and vice versa) then you actually want to flip the image about coordinate (0,0,0) instead of about the center of the image. This method will adjust the Origin of the output such that the flip occurs about (0,0,0). Note that this method only changes the Origin (and hence the coordinate system) the output data: the actual pixel values are the same whether or not this method is used. Also note that the Origin in this method name refers to (0,0,0) in the coordinate system associated with the image, it does not refer to the Origin ivar that is associated with a vtkImageData.
- `obj.FlipAboutOriginOn ()` - By default the image will be flipped about its center, and the Origin, Spacing and Extent of the output will be identical to the input. However, if you have a coordinate system associated with the image and you want to use the flip to convert +ve values along one axis to -ve values (and vice versa) then you actually want to flip the image about coordinate (0,0,0) instead of about the center of the image. This method will adjust the Origin of the output such that the flip occurs about (0,0,0). Note that this method only changes the Origin (and hence the coordinate system) the output data: the actual pixel values are the same whether or not this method is used. Also note that the Origin in this method name refers to (0,0,0) in the coordinate system associated with the image, it does not refer to the Origin ivar that is associated with a vtkImageData.
- `obj.FlipAboutOriginOff ()` - By default the image will be flipped about its center, and the Origin, Spacing and Extent of the output will be identical to the input. However, if you have a coordinate system associated with the image and you want to use the flip to convert +ve values along one axis to -ve values (and vice versa) then you actually want to flip the image about coordinate (0,0,0) instead of about the center of the image. This method will adjust the Origin of the output such that the flip occurs about (0,0,0). Note that this method only changes the Origin (and hence the coordinate system) the output data: the actual pixel values are the same whether or not this method is used. Also note that the Origin in this method name refers to (0,0,0) in the coordinate system associated with the image, it does not refer to the Origin ivar that is associated with a vtkImageData.
- `obj.SetFilteredAxes (int axis)` - Keep the mis-named Axes variations around for compatibility with old scripts. Axis is singular, not plural...

- `int = obj.GetFilteredAxes ()` - PreserveImageExtentOff wasn't covered by test scripts and its implementation was broken. It is deprecated now and it has no effect (i.e. the ImageExtent is always preserved).
- `obj.SetPreserveImageExtent (int )` - PreserveImageExtentOff wasn't covered by test scripts and its implementation was broken. It is deprecated now and it has no effect (i.e. the ImageExtent is always preserved).
- `int = obj.GetPreserveImageExtent ()` - PreserveImageExtentOff wasn't covered by test scripts and its implementation was broken. It is deprecated now and it has no effect (i.e. the ImageExtent is always preserved).
- `obj.PreserveImageExtentOn ()` - PreserveImageExtentOff wasn't covered by test scripts and its implementation was broken. It is deprecated now and it has no effect (i.e. the ImageExtent is always preserved).
- `obj.PreserveImageExtentOff ()` - PreserveImageExtentOff wasn't covered by test scripts and its implementation was broken. It is deprecated now and it has no effect (i.e. the ImageExtent is always preserved).

35.40 vtkImageFourierCenter

35.40.1 Usage

Is used for dispaying images in frequency space. FFT converts spatial images into frequency space, but puts the zero frequency at the origin. This filter shifts the zero frequency to the center of the image. Input and output are assumed to be doubles.

To create an instance of class vtkImageFourierCenter, simply invoke its constructor as follows

```
obj = vtkImageFourierCenter
```

35.40.2 Methods

The class vtkImageFourierCenter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageFourierCenter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageFourierCenter = obj.NewInstance ()`
- `vtkImageFourierCenter = obj.SafeDownCast (vtkObject o)`

35.41 vtkImageFourierFilter

35.41.1 Usage

vtkImageFourierFilter is a class of filters that use complex numbers this superclass is a container for methods that manipulate these structure including fast Fourier transforms. Complex numbers may become a class. This should really be a helper class.

To create an instance of class vtkImageFourierFilter, simply invoke its constructor as follows

```
obj = vtkImageFourierFilter
```

35.41.2 Methods

The class vtkImageFourierFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageFourierFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageFourierFilter = obj.NewInstance ()`
- `vtkImageFourierFilter = obj.SafeDownCast (vtkObject o)`

35.42 vtkImageGaussianSmooth

35.42.1 Usage

vtkImageGaussianSmooth implements a convolution of the input image with a gaussian. Supports from one to three dimensional convolutions.

To create an instance of class vtkImageGaussianSmooth, simply invoke its constructor as follows

```
obj = vtkImageGaussianSmooth
```

35.42.2 Methods

The class vtkImageGaussianSmooth has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageGaussianSmooth class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageGaussianSmooth = obj.NewInstance ()`
- `vtkImageGaussianSmooth = obj.SafeDownCast (vtkObject o)`
- `obj.SetStandardDeviations (double , double , double )` - Sets/Gets the Standard deviation of the gaussian in pixel units.
- `obj.SetStandardDeviations (double  a[3])` - Sets/Gets the Standard deviation of the gaussian in pixel units.
- `obj.SetStandardDeviation (double std)` - Sets/Gets the Standard deviation of the gaussian in pixel units.
- `obj.SetStandardDeviations (double a, double b)` - Sets/Gets the Standard deviation of the gaussian in pixel units.
- `double = obj. GetStandardDeviations ()` - Sets/Gets the Standard deviation of the gaussian in pixel units.
- `obj.SetStandardDeviation (double a, double b)` - Sets/Gets the Standard deviation of the gaussian in pixel units. These methods are provided for compatibility with old scripts
- `obj.SetStandardDeviation (double a, double b, double c)` - Sets/Gets the Radius Factors of the gaussian (no unit). The radius factors determine how far out the gaussian kernel will go before being clamped to zero.

- `obj.SetRadiusFactors (double , double , double )` - Sets/Gets the Radius Factors of the gaussian (no unit). The radius factors determine how far out the gaussian kernel will go before being clamped to zero.
- `obj.SetRadiusFactors (double  a[3])` - Sets/Gets the Radius Factors of the gaussian (no unit). The radius factors determine how far out the gaussian kernel will go before being clamped to zero.
- `obj.SetRadiusFactors (double f, double f2)` - Sets/Gets the Radius Factors of the gaussian (no unit). The radius factors determine how far out the gaussian kernel will go before being clamped to zero.
- `obj.SetRadiusFactor (double f)` - Sets/Gets the Radius Factors of the gaussian (no unit). The radius factors determine how far out the gaussian kernel will go before being clamped to zero.
- `double = obj. GetRadiusFactors ()` - Sets/Gets the Radius Factors of the gaussian (no unit). The radius factors determine how far out the gaussian kernel will go before being clamped to zero.
- `obj.SetDimensionality (int )` - Set/Get the dimensionality of this filter. This determines whether a one, two, or three dimensional gaussian is performed.
- `int = obj.GetDimensionality ()` - Set/Get the dimensionality of this filter. This determines whether a one, two, or three dimensional gaussian is performed.

35.43 vtkImageGaussianSource

35.43.1 Usage

vtkImageGaussianSource just produces images with pixel values determined by a Gaussian.

To create an instance of class vtkImageGaussianSource, simply invoke its constructor as follows

```
obj = vtkImageGaussianSource
```

35.43.2 Methods

The class vtkImageGaussianSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageGaussianSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageGaussianSource = obj.NewInstance ()`
- `vtkImageGaussianSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetWholeExtent (int xMinx, int xMax, int yMin, int yMax, int zMin, int zMax)` - Set/Get the extent of the whole output image.
- `obj.SetCenter (double , double , double )` - Set/Get the center of the Gaussian.
- `obj.SetCenter (double  a[3])` - Set/Get the center of the Gaussian.
- `double = obj. GetCenter ()` - Set/Get the center of the Gaussian.
- `obj.SetMaximum (double )` - Set/Get the Maximum value of the gaussian
- `double = obj.GetMaximum ()` - Set/Get the Maximum value of the gaussian
- `obj.SetStandardDeviation (double )` - Set/Get the standard deviation of the gaussian
- `double = obj.GetStandardDeviation ()` - Set/Get the standard deviation of the gaussian

35.44 vtkImageGradient

35.44.1 Usage

vtkImageGradient computes the gradient vector of an image. The vector results are stored as scalar components. The Dimensionality determines whether to perform a 2d or 3d gradient. The default is two dimensional XY gradient. OutputScalarType is always double. Gradient is computed using central differences.

To create an instance of class vtkImageGradient, simply invoke its constructor as follows

```
obj = vtkImageGradient
```

35.44.2 Methods

The class vtkImageGradient has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageGradient class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageGradient = obj.NewInstance ()`
- `vtkImageGradient = obj.SafeDownCast (vtkObject o)`
- `obj.SetDimensionality (int )` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionalityMinValue ()` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionalityMaxValue ()` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionality ()` - Determines how the input is interpreted (set of 2d slices ...)
- `obj.SetHandleBoundaries (int )` - Get/Set whether to handle boundaries. If enabled, boundary pixels are treated as duplicated so that central differencing works for the boundary pixels. If disabled, the output whole extent of the image is reduced by one pixel.
- `int = obj.GetHandleBoundaries ()` - Get/Set whether to handle boundaries. If enabled, boundary pixels are treated as duplicated so that central differencing works for the boundary pixels. If disabled, the output whole extent of the image is reduced by one pixel.
- `obj.HandleBoundariesOn ()` - Get/Set whether to handle boundaries. If enabled, boundary pixels are treated as duplicated so that central differencing works for the boundary pixels. If disabled, the output whole extent of the image is reduced by one pixel.
- `obj.HandleBoundariesOff ()` - Get/Set whether to handle boundaries. If enabled, boundary pixels are treated as duplicated so that central differencing works for the boundary pixels. If disabled, the output whole extent of the image is reduced by one pixel.

35.45 vtkImageGradientMagnitude

35.45.1 Usage

vtkImageGradientMagnitude computes the gradient magnitude of an image. Setting the dimensionality determines whether the gradient is computed on 2D images, or 3D volumes. The default is two dimensional XY images.

To create an instance of class vtkImageGradientMagnitude, simply invoke its constructor as follows

```
obj = vtkImageGradientMagnitude
```

35.45.2 Methods

The class vtkImageGradientMagnitude has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageGradientMagnitude class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageGradientMagnitude = obj.NewInstance ()`
- `vtkImageGradientMagnitude = obj.SafeDownCast (vtkObject o)`
- `obj.SetHandleBoundaries (int )` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `int = obj.GetHandleBoundaries ()` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `obj.HandleBoundariesOn ()` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `obj.HandleBoundariesOff ()` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `obj.SetDimensionality (int )` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionalityMinValue ()` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionalityMaxValue ()` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionality ()` - Determines how the input is interpreted (set of 2d slices ...)

35.46 vtkImageGridSource

35.46.1 Usage

vtkImageGridSource produces an image of a grid. The default output type is double.

To create an instance of class vtkImageGridSource, simply invoke its constructor as follows

```
obj = vtkImageGridSource
```

35.46.2 Methods

The class vtkImageGridSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageGridSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageGridSource = obj.NewInstance ()`
- `vtkImageGridSource = obj.SafeDownCast (vtkObject o)`

- `obj.SetGridSpacing (int , int , int )` - Set/Get the grid spacing in pixel units. Default (10,10,0). A value of zero means no grid.
- `obj.SetGridSpacing (int a[3])` - Set/Get the grid spacing in pixel units. Default (10,10,0). A value of zero means no grid.
- `int = obj. GetGridSpacing ()` - Set/Get the grid spacing in pixel units. Default (10,10,0). A value of zero means no grid.
- `obj.SetGridOrigin (int , int , int )` - Set/Get the grid origin, in ijk integer values. Default (0,0,0).
- `obj.SetGridOrigin (int a[3])` - Set/Get the grid origin, in ijk integer values. Default (0,0,0).
- `int = obj. GetGridOrigin ()` - Set/Get the grid origin, in ijk integer values. Default (0,0,0).
- `obj.SetLineValue (double )` - Set the grey level of the lines. Default 1.0.
- `double = obj.GetLineValue ()` - Set the grey level of the lines. Default 1.0.
- `obj.SetFillValue (double )` - Set the grey level of the fill. Default 0.0.
- `double = obj.GetFillValue ()` - Set the grey level of the fill. Default 0.0.
- `obj.SetDataScalarType (int )` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `obj.SetDataScalarTypeToDouble ()` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `obj.SetDataScalarTypeToInt ()` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `obj.SetDataScalarTypeToShort ()` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `obj.SetDataScalarTypeToUnsignedShort ()` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `obj.SetDataScalarTypeToUnsignedChar ()` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `int = obj.GetDataScalarType ()` - Set/Get the data type of pixels in the imported data. As a convenience, the OutputScalarType is set to the same value.
- `string = obj.GetDataScalarTypeAsString ()` - Set/Get the extent of the whole output image, Default: (0,255,0,255,0,0)
- `obj.SetDataExtent (int , int , int , int , int , int )` - Set/Get the extent of the whole output image, Default: (0,255,0,255,0,0)
- `obj.SetDataExtent (int a[6])` - Set/Get the extent of the whole output image, Default: (0,255,0,255,0,0)
- `int = obj. GetDataExtent ()` - Set/Get the extent of the whole output image, Default: (0,255,0,255,0,0)
- `obj.SetDataSpacing (double , double , double )` - Set/Get the pixel spacing.
- `obj.SetDataSpacing (double a[3])` - Set/Get the pixel spacing.
- `double = obj. GetDataSpacing ()` - Set/Get the pixel spacing.
- `obj.SetDataOrigin (double , double , double )` - Set/Get the origin of the data.
- `obj.SetDataOrigin (double a[3])` - Set/Get the origin of the data.
- `double = obj. GetDataOrigin ()` - Set/Get the origin of the data.

35.47 vtkImageHSIToRGB

35.47.1 Usage

For each pixel with hue, saturation and intensity components this filter outputs the color coded as red, green, blue. Output type must be the same as input type.

To create an instance of class vtkImageHSIToRGB, simply invoke its constructor as follows

```
obj = vtkImageHSIToRGB
```

35.47.2 Methods

The class vtkImageHSIToRGB has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageHSIToRGB class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageHSIToRGB = obj.NewInstance ()`
- `vtkImageHSIToRGB = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaximum (double )` - Hue is an angle. Maximum specifies when it maps back to 0. Hue-Maximum defaults to 255 instead of 2PI, because unsigned char is expected as input. Maximum also specifies the maximum of the Saturation, and R, G, B.
- `double = obj.GetMaximum ()` - Hue is an angle. Maximum specifies when it maps back to 0. Hue-Maximum defaults to 255 instead of 2PI, because unsigned char is expected as input. Maximum also specifies the maximum of the Saturation, and R, G, B.

35.48 vtkImageHSVToRGB

35.48.1 Usage

For each pixel with hue, saturation and value components this filter outputs the color coded as red, green, blue. Output type must be the same as input type.

To create an instance of class vtkImageHSVToRGB, simply invoke its constructor as follows

```
obj = vtkImageHSVToRGB
```

35.48.2 Methods

The class vtkImageHSVToRGB has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageHSVToRGB class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageHSVToRGB = obj.NewInstance ()`
- `vtkImageHSVToRGB = obj.SafeDownCast (vtkObject o)`

- `obj.SetMaximum (double )` - Hue is an angle. Maximum specifies when it maps back to 0. Hue-Maximum defaults to 255 instead of 2PI, because unsigned char is expected as input. Maximum also specifies the maximum of the Saturation, and R, G, B.
- `double = obj.GetMaximum ()` - Hue is an angle. Maximum specifies when it maps back to 0. Hue-Maximum defaults to 255 instead of 2PI, because unsigned char is expected as input. Maximum also specifies the maximum of the Saturation, and R, G, B.

35.49 vtkImageHybridMedian2D

35.49.1 Usage

vtkImageHybridMedian2D is a median filter that preserves thin lines and corners. It operates on a 5x5 pixel neighborhood. It computes two values initially: the median of the + neighbors and the median of the x neighbors. It then computes the median of these two values plus the center pixel. This result of this second median is the output pixel value.

To create an instance of class vtkImageHybridMedian2D, simply invoke its constructor as follows

```
obj = vtkImageHybridMedian2D
```

35.49.2 Methods

The class vtkImageHybridMedian2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageHybridMedian2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageHybridMedian2D = obj.NewInstance ()`
- `vtkImageHybridMedian2D = obj.SafeDownCast (vtkObject o)`

35.50 vtkImageIdealHighPass

35.50.1 Usage

This filter only works on an image after it has been converted to frequency domain by a vtkImageFFT filter. A vtkImageRFFT filter can be used to convert the output back into the spatial domain. vtkImageIdealHighPass just sets a portion of the image to zero. The sharp cutoff in the frequence domain produces ringing in the spatial domain. Input and Output must be doubles. Dimensionality is set when the axes are set. Defaults to 2D on X and Y axes.

To create an instance of class vtkImageIdealHighPass, simply invoke its constructor as follows

```
obj = vtkImageIdealHighPass
```

35.50.2 Methods

The class vtkImageIdealHighPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageIdealHighPass class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkImageIdealHighPass = obj.NewInstance ()`
- `vtkImageIdealHighPass = obj.SafeDownCast (vtkObject o)`
- `obj.SetCutOff (double , double , double )` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetCutOff (double a[3])` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetXCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetYCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetZCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj. GetCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetXCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetYCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetZCutOff ()`

35.51 vtkImageIdealLowPass

35.51.1 Usage

This filter only works on an image after it has been converted to frequency domain by a vtkImageFFT filter. A vtkImageRFFT filter can be used to convert the output back into the spatial domain. vtkImageIdealLowPass just sets a portion of the image to zero. The result is an image with a lot of ringing. Input and Output must be doubles. Dimensionality is set when the axes are set. Defaults to 2D on X and Y axes.

To create an instance of class vtkImageIdealLowPass, simply invoke its constructor as follows

```
obj = vtkImageIdealLowPass
```

35.51.2 Methods

The class vtkImageIdealLowPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageIdealLowPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageIdealLowPass = obj.NewInstance ()`

- `vtkImageIdealLowPass = obj.SafeDownCast (vtkObject o)`
- `obj.SetCutOff (double , double , double )` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetCutOff (double a[3])` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetXCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetYCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `obj.SetZCutOff (double v)` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj. GetCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetXCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetYCutOff ()` - Set/Get the cutoff frequency for each axis. The values are specified in the order X, Y, Z, Time. Units: Cycles per world unit (as defined by the data spacing).
- `double = obj.GetZCutOff ()`

35.52 vtkImageImport

35.52.1 Usage

vtkImageImport provides methods needed to import image data from a source independent of VTK, such as a simple C array or a third-party pipeline. Note that the VTK convention is for the image voxel index (0,0,0) to be the lower-left corner of the image, while most 2D image formats use the upper-left corner. You can use vtkImageFlip to correct the orientation after the image has been loaded into VTK. Note that is also possible to import the raw data from a Python string instead of from a C array. The array applies on scalar point data only, not on cell data.

To create an instance of class vtkImageImport, simply invoke its constructor as follows

```
obj = vtkImageImport
```

35.52.2 Methods

The class vtkImageImport has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageImport class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageImport = obj.NewInstance ()`

- `vtkImageImport = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataScalarType (int )` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `obj.SetDataScalarTypeToDouble ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `obj.SetDataScalarTypeToFloat ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `obj.SetDataScalarTypeToInt ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `obj.SetDataScalarTypeToShort ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `obj.SetDataScalarTypeToUnsignedShort ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `obj.SetDataScalarTypeToUnsignedChar ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `int = obj.GetDataScalarType ()` - Set/Get the data type of pixels in the imported data. This is used as the scalar type of the Output. Default: Short.
- `string = obj.GetDataScalarTypeAsString ()` - Set/Get the number of scalar components, for RGB images this must be 3. Default: 1.
- `obj.SetNumberOfScalarComponents (int )` - Set/Get the number of scalar components, for RGB images this must be 3. Default: 1.
- `int = obj.GetNumberOfScalarComponents ()` - Set/Get the number of scalar components, for RGB images this must be 3. Default: 1.
- `obj.SetDataExtent (int , int , int , int , int , int )` - Get/Set the extent of the data buffer. The dimensions of your data must be equal to (extent[1]-extent[0]+1) * (extent[3]-extent[2]+1) * (extent[5]-DataExtent[4]+1). For example, for a 2D image use (0,width-1, 0,height-1, 0,0).
- `obj.SetDataExtent (int  a[6])` - Get/Set the extent of the data buffer. The dimensions of your data must be equal to (extent[1]-extent[0]+1) * (extent[3]-extent[2]+1) * (extent[5]-DataExtent[4]+1). For example, for a 2D image use (0,width-1, 0,height-1, 0,0).
- `int = obj. GetDataExtent ()` - Get/Set the extent of the data buffer. The dimensions of your data must be equal to (extent[1]-extent[0]+1) * (extent[3]-extent[2]+1) * (extent[5]-DataExtent[4]+1). For example, for a 2D image use (0,width-1, 0,height-1, 0,0).
- `obj.SetDataExtentToWholeExtent ()` - Set/Get the spacing (typically in mm) between image voxels. Default: (1.0, 1.0, 1.0).
- `obj.SetDataSpacing (double , double , double )` - Set/Get the spacing (typically in mm) between image voxels. Default: (1.0, 1.0, 1.0).
- `obj.SetDataSpacing (double  a[3])` - Set/Get the spacing (typically in mm) between image voxels. Default: (1.0, 1.0, 1.0).
- `double = obj. GetDataSpacing ()` - Set/Get the spacing (typically in mm) between image voxels. Default: (1.0, 1.0, 1.0).
- `obj.SetDataOrigin (double , double , double )` - Set/Get the origin of the data, i.e. the coordinates (usually in mm) of voxel (0,0,0). Default: (0.0, 0.0, 0.0).

- `obj.SetDataOrigin (double a[3])` - Set/Get the origin of the data, i.e. the coordinates (usually in mm) of voxel (0,0,0). Default: (0.0, 0.0, 0.0).
- `double = obj. GetDataOrigin ()` - Set/Get the origin of the data, i.e. the coordinates (usually in mm) of voxel (0,0,0). Default: (0.0, 0.0, 0.0).
- `obj.SetWholeExtent (int , int , int , int , int , int )` - Get/Set the whole extent of the image. This is the largest possible extent. Set the DataExtent to the extent of the image in the buffer pointed to by the ImportVoidPointer.
- `obj.SetWholeExtent (int a[6])` - Get/Set the whole extent of the image. This is the largest possible extent. Set the DataExtent to the extent of the image in the buffer pointed to by the ImportVoidPointer.
- `int = obj. GetWholeExtent ()` - Get/Set the whole extent of the image. This is the largest possible extent. Set the DataExtent to the extent of the image in the buffer pointed to by the ImportVoidPointer.
- `obj.SetScalarArrayName (string )` - Set/get the scalar array name for this data set. Initial value is "scalars".
- `string = obj.GetScalarArrayName ()` - Set/get the scalar array name for this data set. Initial value is "scalars".
- `int = obj.InvokePipelineModifiedCallbacks ()` - Invoke the appropriate callbacks
- `obj.InvokeUpdateInformationCallbacks ()` - Invoke the appropriate callbacks
- `obj.InvokeExecuteInformationCallbacks ()` - Invoke the appropriate callbacks
- `obj.InvokeExecuteDataCallbacks ()` - Invoke the appropriate callbacks
- `obj.LegacyCheckWholeExtent ()` - Invoke the appropriate callbacks

35.53 vtkImageImportExecutive

35.53.1 Usage

vtkImageImportExecutive

To create an instance of class vtkImageImportExecutive, simply invoke its constructor as follows

```
obj = vtkImageImportExecutive
```

35.53.2 Methods

The class vtkImageImportExecutive has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageImportExecutive class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageImportExecutive = obj.NewInstance ()`
- `vtkImageImportExecutive = obj.SafeDownCast (vtkObject o)`

35.54 vtkImageIslandRemoval2D

35.54.1 Usage

vtkImageIslandRemoval2D computes the area of separate islands in a mask image. It removes any island that has less than AreaThreshold pixels. Output has the same ScalarType as input. It generates the whole 2D output image for any output request.

To create an instance of class vtkImageIslandRemoval2D, simply invoke its constructor as follows

```
obj = vtkImageIslandRemoval2D
```

35.54.2 Methods

The class vtkImageIslandRemoval2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageIslandRemoval2D class.

- `string = obj.GetClassName ()` - Constructor: Sets default filter to be identity.
- `int = obj.IsA (string name)` - Constructor: Sets default filter to be identity.
- `vtkImageIslandRemoval2D = obj.NewInstance ()` - Constructor: Sets default filter to be identity.
- `vtkImageIslandRemoval2D = obj.SafeDownCast (vtkObject o)` - Constructor: Sets default filter to be identity.
- `obj.SetAreaThreshold (int )` - Set/Get the cutoff area for removal
- `int = obj.GetAreaThreshold ()` - Set/Get the cutoff area for removal
- `obj.SetSquareNeighborhood (int )` - Set/Get whether to use 4 or 8 neighbors
- `int = obj.GetSquareNeighborhood ()` - Set/Get whether to use 4 or 8 neighbors
- `obj.SquareNeighborhoodOn ()` - Set/Get whether to use 4 or 8 neighbors
- `obj.SquareNeighborhoodOff ()` - Set/Get whether to use 4 or 8 neighbors
- `obj.SetIslandValue (double )` - Set/Get the value to remove.
- `double = obj.GetIslandValue ()` - Set/Get the value to remove.
- `obj.SetReplaceValue (double )` - Set/Get the value to put in the place of removed pixels.
- `double = obj.GetReplaceValue ()` - Set/Get the value to put in the place of removed pixels.

35.55 vtkImageIterateFilter

35.55.1 Usage

vtkImageIterateFilter is a filter superclass that supports calling execute multiple times per update. The largest hack/open issue is that the input and output caches are temporarily changed to "fool" the subclasses. I believe the correct solution is to pass the in and out cache to the subclasses methods as arguments. Now the data is passes. Can the caches be passed, and data retrieved from the cache?

To create an instance of class vtkImageIterateFilter, simply invoke its constructor as follows

```
obj = vtkImageIterateFilter
```

35.55.2 Methods

The class vtkImageIterateFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageIterateFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageIterateFilter = obj.NewInstance ()`
- `vtkImageIterateFilter = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetIteration ()` - Get which iteration is current being performed. Normally the user will not access this method.
- `int = obj.GetNumberOfIterations ()` - Get which iteration is current being performed. Normally the user will not access this method.

35.56 vtkImageLaplacian

35.56.1 Usage

vtkImageLaplacian computes the Laplacian (like a second derivative) of a scalar image. The operation is the same as taking the divergence after a gradient. Boundaries are handled, so the input is the same as the output. Dimensionality determines how the input regions are interpreted. (images, or volumes). The Dimensionality defaults to two.

To create an instance of class vtkImageLaplacian, simply invoke its constructor as follows

```
obj = vtkImageLaplacian
```

35.56.2 Methods

The class vtkImageLaplacian has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageLaplacian class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageLaplacian = obj.NewInstance ()`
- `vtkImageLaplacian = obj.SafeDownCast (vtkObject o)`
- `obj.SetDimensionality (int )` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionalityMinValue ()` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionalityMaxValue ()` - Determines how the input is interpreted (set of 2d slices ...)
- `int = obj.GetDimensionality ()` - Determines how the input is interpreted (set of 2d slices ...)

35.57 vtkImageLogarithmicScale

35.57.1 Usage

vtkImageLogarithmicScale passes each pixel through the function c*log(1+x). It also handles negative values with the function -c*log(1-x).

To create an instance of class vtkImageLogarithmicScale, simply invoke its constructor as follows

```
obj = vtkImageLogarithmicScale
```

35.57.2 Methods

The class vtkImageLogarithmicScale has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageLogarithmicScale class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageLogarithmicScale = obj.NewInstance ()`
- `vtkImageLogarithmicScale = obj.SafeDownCast (vtkObject o)`
- `obj.SetConstant (double )` - Set/Get the scale factor for the logarithmic function.
- `double = obj.GetConstant ()` - Set/Get the scale factor for the logarithmic function.

35.58 vtkImageLogic

35.58.1 Usage

vtkImageLogic implements basic logic operations. SetOperation is used to select the filter's behavior. The filter can take two or one input. Inputs must have the same type.

To create an instance of class vtkImageLogic, simply invoke its constructor as follows

```
obj = vtkImageLogic
```

35.58.2 Methods

The class vtkImageLogic has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageLogic class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageLogic = obj.NewInstance ()`
- `vtkImageLogic = obj.SafeDownCast (vtkObject o)`
- `obj.SetOperation (int )` - Set/Get the Operation to perform.
- `int = obj.GetOperation ()` - Set/Get the Operation to perform.
- `obj.SetOperationToAnd ()` - Set/Get the Operation to perform.

- `obj.SetOperationToOr ()` - Set/Get the Operation to perform.
- `obj.SetOperationToXor ()` - Set/Get the Operation to perform.
- `obj.SetOperationToNand ()` - Set/Get the Operation to perform.
- `obj.SetOperationToNor ()` - Set/Get the Operation to perform.
- `obj.SetOperationToNot ()` - Set/Get the Operation to perform.
- `obj.SetOutputTrueValue (double )` - Set the value to use for true in the output.
- `double = obj.GetOutputTrueValue ()` - Set the value to use for true in the output.
- `obj.SetInput1 (vtkDataObject input)` - Set the Input1 of this filter.
- `obj.SetInput2 (vtkDataObject input)` - Set the Input2 of this filter.

35.59 vtkImageLuminance

35.59.1 Usage

vtkImageLuminance calculates luminance from an rgb input.

To create an instance of class vtkImageLuminance, simply invoke its constructor as follows

```
obj = vtkImageLuminance
```

35.59.2 Methods

The class vtkImageLuminance has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageLuminance class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageLuminance = obj.NewInstance ()`
- `vtkImageLuminance = obj.SafeDownCast (vtkObject o)`

35.60 vtkImageMagnify

35.60.1 Usage

vtkImageMagnify maps each pixel of the input onto a nxmx... region of the output. Location (0,0,...) remains in the same place. The magnification occurs via pixel replication, or if Interpolate is on, by bilinear interpolation. Initially, interpolation is off and magnification factors are set to 1 in all directions.

To create an instance of class vtkImageMagnify, simply invoke its constructor as follows

```
obj = vtkImageMagnify
```

35.60.2 Methods

The class vtkImageMagnify has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMagnify class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMagnify = obj.NewInstance ()`
- `vtkImageMagnify = obj.SafeDownCast (vtkObject o)`
- `obj.SetMagnificationFactors (int , int , int )` - Set/Get the integer magnification factors in the i-j-k directions. Initially, factors are set to 1 in all directions.
- `obj.SetMagnificationFactors (int a[3])` - Set/Get the integer magnification factors in the i-j-k directions. Initially, factors are set to 1 in all directions.
- `int = obj. GetMagnificationFactors ()` - Set/Get the integer magnification factors in the i-j-k directions. Initially, factors are set to 1 in all directions.
- `obj.SetInterpolate (int )` - Turn interpolation on and off (pixel replication is used when off). Initially, interpolation is off.
- `int = obj.GetInterpolate ()` - Turn interpolation on and off (pixel replication is used when off). Initially, interpolation is off.
- `obj.InterpolateOn ()` - Turn interpolation on and off (pixel replication is used when off). Initially, interpolation is off.
- `obj.InterpolateOff ()` - Turn interpolation on and off (pixel replication is used when off). Initially, interpolation is off.

35.61 vtkImageMagnitude

35.61.1 Usage

vtkImageMagnitude takes the magnitude of the components.

To create an instance of class vtkImageMagnitude, simply invoke its constructor as follows

```
obj = vtkImageMagnitude
```

35.61.2 Methods

The class vtkImageMagnitude has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMagnitude class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMagnitude = obj.NewInstance ()`
- `vtkImageMagnitude = obj.SafeDownCast (vtkObject o)`

35.62 vtkImageMandelbrotSource

35.62.1 Usage

vtkImageMandelbrotSource creates an unsigned char image of the Mandelbrot set. The values in the image are the number of iterations it takes for the magnitude of the value to get over 2. The equation repeated is $z = z\hat{2} + C$ (z and C are complex). Initial value of z is zero, and the real value of C is mapped onto the x axis, and the imaginary value of C is mapped onto the Y Axis. I was thinking of extending this source to generate Julia Sets (initial value of Z varies). This would be 4 possible parameters to vary, but there are no more 4d images :(The third dimension (z axis) is the imaginary value of the initial value.

To create an instance of class vtkImageMandelbrotSource, simply invoke its constructor as follows

```
obj = vtkImageMandelbrotSource
```

35.62.2 Methods

The class vtkImageMandelbrotSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMandelbrotSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMandelbrotSource = obj.NewInstance ()`
- `vtkImageMandelbrotSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetWholeExtent (int extent[6])` - Set/Get the extent of the whole output Volume.
- `obj.SetWholeExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - Set/Get the extent of the whole output Volume.
- `int = obj. GetWholeExtent ()` - Set/Get the extent of the whole output Volume.
- `obj.SetConstantSize (int )` - This flag determines whether the Size or spacing of a data set remain constant (when extent is changed). By default, size remains constant.
- `int = obj.GetConstantSize ()` - This flag determines whether the Size or spacing of a data set remain constant (when extent is changed). By default, size remains constant.
- `obj.ConstantSizeOn ()` - This flag determines whether the Size or spacing of a data set remain constant (when extent is changed). By default, size remains constant.
- `obj.ConstantSizeOff ()` - This flag determines whether the Size or spacing of a data set remain constant (when extent is changed). By default, size remains constant.
- `obj.SetProjectionAxes (int x, int y, int z)` - Set the projection from the 4D space (4 parameters / 2 imaginary numbers) to the axes of the 3D Volume. 0=C_Real, 1=C_Imaginary, 2=X_Real, 4=X_Imaginary
- `obj.SetProjectionAxes (int a[3])` - Set the projection from the 4D space (4 parameters / 2 imaginary numbers) to the axes of the 3D Volume. 0=C_Real, 1=C_Imaginary, 2=X_Real, 4=X_Imaginary
- `int = obj. GetProjectionAxes ()` - Set the projection from the 4D space (4 parameters / 2 imaginary numbers) to the axes of the 3D Volume. 0=C_Real, 1=C_Imaginary, 2=X_Real, 4=X_Imaginary
- `obj.SetOriginCX (double , double , double , double )` - Imaginary and real value for C (constant in equation) and X (initial value).

- `obj.SetOriginCX (double a[4])` - Imaginary and real value for C (constant in equation) and X (initial value).
- `double = obj. GetOriginCX ()` - Imaginary and real value for C (constant in equation) and X (initial value). void SetOriginCX(double cReal, double cImag, double xReal, double xImag);
- `obj.SetSampleCX (double , double , double , double )` - Imaginary and real value for C (constant in equation) and X (initial value).
- `obj.SetSampleCX (double a[4])` - Imaginary and real value for C (constant in equation) and X (initial value).
- `double = obj. GetSampleCX ()` - Imaginary and real value for C (constant in equation) and X (initial value). void SetOriginCX(double cReal, double cImag, double xReal, double xImag);
- `obj.SetSizeCX (double cReal, double cImag, double xReal, double xImag)` - Just a different way of setting the sample. This sets the size of the 4D volume. SampleCX is computed from size and extent. Size is ignored when a dimension i 0 (collapsed).
- `double = obj.GetSizeCX ()` - Just a different way of setting the sample. This sets the size of the 4D volume. SampleCX is computed from size and extent. Size is ignored when a dimension i 0 (collapsed).
- `obj.GetSizeCX (double s[4])` - Just a different way of setting the sample. This sets the size of the 4D volume. SampleCX is computed from size and extent. Size is ignored when a dimension i 0 (collapsed).
- `obj.SetMaximumNumberOfIterations (short )` - The maximum number of cycles run to see if the value goes over 2
- `GetMaximumNumberOfIterationsMinValue = obj.()` - The maximum number of cycles run to see if the value goes over 2
- `GetMaximumNumberOfIterationsMaxValue = obj.()` - The maximum number of cycles run to see if the value goes over 2
- `short = obj.GetMaximumNumberOfIterations ()` - The maximum number of cycles run to see if the value goes over 2
- `obj.Zoom (double factor)` - Convienence for Viewer. Pan 3D volume relative to spacing. Zoom constant factor.
- `obj.Pan (double x, double y, double z)` - Convienence for Viewer. Pan 3D volume relative to spacing. Zoom constant factor.
- `obj.CopyOriginAndSample (vtkImageMandelbrotSource source)` - Convienence for Viewer. Copy the OriginCX and the SpacingCX. What about other parameters ???
- `obj.SetSubsampleRate (int )` - Set/Get a subsample rate.
- `int = obj.GetSubsampleRateMinValue ()` - Set/Get a subsample rate.
- `int = obj.GetSubsampleRateMaxValue ()` - Set/Get a subsample rate.
- `int = obj.GetSubsampleRate ()` - Set/Get a subsample rate.

35.63 vtkImageMapToColors

35.63.1 Usage

The vtkImageMapToColors filter will take an input image of any valid scalar type, and map the first component of the image through a lookup table. The result is an image of type VTK_UNSIGNED_CHAR. If the lookup table is not set, or is set to NULL, then the input data will be passed through if it is already of type VTK_UNSIGNED_CHAR.

To create an instance of class vtkImageMapToColors, simply invoke its constructor as follows

```
obj = vtkImageMapToColors
```

35.63.2 Methods

The class vtkImageMapToColors has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMapToColors class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMapToColors = obj.NewInstance ()`
- `vtkImageMapToColors = obj.SafeDownCast (vtkObject o)`
- `obj.SetLookupTable (vtkScalarsToColors )` - Set the lookup table.
- `vtkScalarsToColors = obj.GetLookupTable ()` - Set the lookup table.
- `obj.SetOutputFormat (int )` - Set the output format, the default is RGBA.
- `int = obj.GetOutputFormat ()` - Set the output format, the default is RGBA.
- `obj.SetOutputFormatToRGBA ()` - Set the output format, the default is RGBA.
- `obj.SetOutputFormatToRGB ()` - Set the output format, the default is RGBA.
- `obj.SetOutputFormatToLuminanceAlpha ()` - Set the output format, the default is RGBA.
- `obj.SetOutputFormatToLuminance ()` - Set the output format, the default is RGBA.
- `obj.SetActiveComponent (int )` - Set the component to map for multi-component images (default: 0)
- `int = obj.GetActiveComponent ()` - Set the component to map for multi-component images (default: 0)
- `obj.SetPassAlphaToOutput (int )` - Use the alpha component of the input when computing the alpha component of the output (useful when converting monochrome+alpha data to RGBA)
- `obj.PassAlphaToOutputOn ()` - Use the alpha component of the input when computing the alpha component of the output (useful when converting monochrome+alpha data to RGBA)
- `obj.PassAlphaToOutputOff ()` - Use the alpha component of the input when computing the alpha component of the output (useful when converting monochrome+alpha data to RGBA)
- `int = obj.GetPassAlphaToOutput ()` - Use the alpha component of the input when computing the alpha component of the output (useful when converting monochrome+alpha data to RGBA)
- `long = obj.GetMTime ()` - We need to check the modified time of the lookup table too.

35.64 vtkImageMapToRGBA

35.64.1 Usage

This filter has been replaced by vtkImageMapToColors, which provided additional features. Use vtkImageMapToColors instead.

To create an instance of class vtkImageMapToRGBA, simply invoke its constructor as follows

```
obj = vtkImageMapToRGBA
```

35.64.2 Methods

The class vtkImageMapToRGBA has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMapToRGBA class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMapToRGBA = obj.NewInstance ()`
- `vtkImageMapToRGBA = obj.SafeDownCast (vtkObject o)`

35.65 vtkImageMapToWindowLevelColors

35.65.1 Usage

The vtkImageMapToWindowLevelColors filter will take an input image of any valid scalar type, and map the first component of the image through a lookup table. This resulting color will be modulated with value obtained by a window / level operation. The result is an image of type VTK_UNSIGNED_CHAR. If the lookup table is not set, or is set to NULL, then the input data will be passed through if it is already of type UNSIGNED_CHAR.

To create an instance of class vtkImageMapToWindowLevelColors, simply invoke its constructor as follows

```
obj = vtkImageMapToWindowLevelColors
```

35.65.2 Methods

The class vtkImageMapToWindowLevelColors has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMapToWindowLevelColors class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMapToWindowLevelColors = obj.NewInstance ()`
- `vtkImageMapToWindowLevelColors = obj.SafeDownCast (vtkObject o)`
- `obj.SetWindow (double )` - Set / Get the Window to use -¿ modulation will be performed on the color based on (S - (L - W/2))/W where S is the scalar value, L is the level and W is the window.
- `double = obj.GetWindow ()` - Set / Get the Window to use -¿ modulation will be performed on the color based on (S - (L - W/2))/W where S is the scalar value, L is the level and W is the window.

- `obj.SetLevel (double )` - Set / Get the Level to use -¿ modulation will be performed on the color based on (S - (L - W/2))/W where S is the scalar value, L is the level and W is the window.
- `double = obj.GetLevel ()` - Set / Get the Level to use -¿ modulation will be performed on the color based on (S - (L - W/2))/W where S is the scalar value, L is the level and W is the window.

35.66 vtkImageMask

35.66.1 Usage

vtkImageMask combines a mask with an image. Non zero mask implies the output pixel will be the same as the image. If a mask pixel is zero, then the output pixel is set to "MaskedValue". The filter also has the option to pass the mask through a boolean not operation before processing the image. This reverses the passed and replaced pixels. The two inputs should have the same "WholeExtent". The mask input should be unsigned char, and the image scalar type is the same as the output scalar type.

To create an instance of class vtkImageMask, simply invoke its constructor as follows

```
obj = vtkImageMask
```

35.66.2 Methods

The class vtkImageMask has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMask class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMask = obj.NewInstance ()`
- `vtkImageMask = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaskedOutputValue (int num, double v)` - SetGet the value of the output pixel replaced by mask.
- `obj.SetMaskedOutputValue (double v)` - SetGet the value of the output pixel replaced by mask.
- `obj.SetMaskedOutputValue (double v1, double v2)` - SetGet the value of the output pixel replaced by mask.
- `obj.SetMaskedOutputValue (double v1, double v2, double v3)` - SetGet the value of the output pixel replaced by mask.
- `int = obj.GetMaskedOutputValueLength ()` - Set/Get the alpha blending value for the mask The input image is assumed to be at alpha = 1.0 and the mask image uses this alpha to blend using an over operator.
- `obj.SetMaskAlpha (double )` - Set/Get the alpha blending value for the mask The input image is assumed to be at alpha = 1.0 and the mask image uses this alpha to blend using an over operator.
- `double = obj.GetMaskAlphaMinValue ()` - Set/Get the alpha blending value for the mask The input image is assumed to be at alpha = 1.0 and the mask image uses this alpha to blend using an over operator.
- `double = obj.GetMaskAlphaMaxValue ()` - Set/Get the alpha blending value for the mask The input image is assumed to be at alpha = 1.0 and the mask image uses this alpha to blend using an over operator.

- `double = obj.GetMaskAlpha ()` - Set/Get the alpha blending value for the mask The input image is assumed to be at alpha = 1.0 and the mask image uses this alpha to blend using an over operator.
- `obj.SetImageInput (vtkImageData in)` - Set the input to be masked.
- `obj.SetMaskInput (vtkImageData in)` - Set the mask to be used.
- `obj.SetNotMask (int )` - When Not Mask is on, the mask is passed through a boolean not before it is used to mask the image. The effect is to pass the pixels where the input mask is zero, and replace the pixels where the input value is non zero.
- `int = obj.GetNotMask ()` - When Not Mask is on, the mask is passed through a boolean not before it is used to mask the image. The effect is to pass the pixels where the input mask is zero, and replace the pixels where the input value is non zero.
- `obj.NotMaskOn ()` - When Not Mask is on, the mask is passed through a boolean not before it is used to mask the image. The effect is to pass the pixels where the input mask is zero, and replace the pixels where the input value is non zero.
- `obj.NotMaskOff ()` - When Not Mask is on, the mask is passed through a boolean not before it is used to mask the image. The effect is to pass the pixels where the input mask is zero, and replace the pixels where the input value is non zero.
- `obj.SetInput1 (vtkDataObject in)` - Set the two inputs to this filter
- `obj.SetInput2 (vtkDataObject in)`

35.67 vtkImageMaskBits

35.67.1 Usage

vtkImageMaskBits applies a bit-mask pattern to each component. The bit-mask can be applied using a variety of boolean bitwise operators.

To create an instance of class vtkImageMaskBits, simply invoke its constructor as follows

```
obj = vtkImageMaskBits
```

35.67.2 Methods

The class vtkImageMaskBits has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMaskBits class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMaskBits = obj.NewInstance ()`
- `vtkImageMaskBits = obj.SafeDownCast (vtkObject o)`
- `obj.SetMasks (int , int , int , int )` - Set/Get the bit-masks. Default is 0xffffffff.
- `obj.SetMasks (int  a[4])` - Set/Get the bit-masks. Default is 0xffffffff.
- `obj.SetMask (int mask)` - Set/Get the bit-masks. Default is 0xffffffff.
- `obj.SetMasks (int mask1, int mask2)` - Set/Get the bit-masks. Default is 0xffffffff.

- `obj.SetMasks (int mask1, int mask2, int mask3)` - Set/Get the bit-masks. Default is 0xffffffff.
- `int = obj. GetMasks ()` - Set/Get the bit-masks. Default is 0xffffffff.
- `obj.SetOperation (int )` - Set/Get the boolean operator. Default is AND.
- `int = obj.GetOperation ()` - Set/Get the boolean operator. Default is AND.
- `obj.SetOperationToAnd ()` - Set/Get the boolean operator. Default is AND.
- `obj.SetOperationToOr ()` - Set/Get the boolean operator. Default is AND.
- `obj.SetOperationToXor ()` - Set/Get the boolean operator. Default is AND.
- `obj.SetOperationToNand ()` - Set/Get the boolean operator. Default is AND.
- `obj.SetOperationToNor ()` - Set/Get the boolean operator. Default is AND.

35.68 vtkImageMathematics

35.68.1 Usage

vtkImageMathematics implements basic mathematic operations SetOperation is used to select the filters behavior. The filter can take two or one input.

To create an instance of class vtkImageMathematics, simply invoke its constructor as follows

```
obj = vtkImageMathematics
```

35.68.2 Methods

The class vtkImageMathematics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMathematics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMathematics = obj.NewInstance ()`
- `vtkImageMathematics = obj.SafeDownCast (vtkObject o)`
- `obj.SetOperation (int )` - Set/Get the Operation to perform.
- `int = obj.GetOperation ()` - Set/Get the Operation to perform.
- `obj.SetOperationToAdd ()` - Set each pixel in the output image to the sum of the corresponding pixels in Input1 and Input2.
- `obj.SetOperationToSubtract ()` - Set each pixel in the output image to the difference of the corresponding pixels in Input1 and Input2 (output = Input1 - Input2).
- `obj.SetOperationToMultiply ()` - Set each pixel in the output image to the product of the corresponding pixels in Input1 and Input2.
- `obj.SetOperationToDivide ()` - Set each pixel in the output image to the quotient of the corresponding pixels in Input1 and Input2 (Output = Input1 / Input2).
- `obj.SetOperationToConjugate ()`

- `obj.SetOperationToComplexMultiply ()`
- `obj.SetOperationToInvert ()` - Set each pixel in the output image to 1 over the corresponding pixel in Input1 and Input2 (output = 1 / Input1). Input2 is not used.
- `obj.SetOperationToSin ()` - Set each pixel in the output image to the sine of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToCos ()` - Set each pixel in the output image to the cosine of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToExp ()` - Set each pixel in the output image to the exponential of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToLog ()` - Set each pixel in the output image to the log of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToAbsoluteValue ()` - Set each pixel in the output image to the absolute value of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToSquare ()` - Set each pixel in the output image to the square of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToSquareRoot ()` - Set each pixel in the output image to the square root of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToMin ()` - Set each pixel in the output image to the minimum of the corresponding pixels in Input1 and Input2. (Output = min(Input1, Input2))
- `obj.SetOperationToMax ()` - Set each pixel in the output image to the maximum of the corresponding pixels in Input1 and Input2. (Output = max(Input1, Input2))
- `obj.SetOperationToATAN ()` - Set each pixel in the output image to the arctangent of the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToATAN2 ()`
- `obj.SetOperationToMultiplyByK ()` - Set each pixel in the output image to the product of ConstantK with the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToAddConstant ()` - Set each pixel in the output image to the product of ConstantC with the corresponding pixel in Input1. Input2 is not used.
- `obj.SetOperationToReplaceCByK ()` - Find every pixel in Input1 that equals ConstantC and set the corresponding pixels in the Output to ConstantK. Input2 is not used.
- `obj.SetConstantK (double )` - A constant used by some operations (typically multiplicative). Default is 1.
- `double = obj.GetConstantK ()` - A constant used by some operations (typically multiplicative). Default is 1.
- `obj.SetConstantC (double )` - A constant used by some operations (typically additive). Default is 0.
- `double = obj.GetConstantC ()` - A constant used by some operations (typically additive). Default is 0.
- `obj.SetDivideByZeroToC (int )` - How to handle divide by zero. Default is 0.
- `int = obj.GetDivideByZeroToC ()` - How to handle divide by zero. Default is 0.

- `obj.DivideByZeroToCOn ()` - How to handle divide by zero. Default is 0.
- `obj.DivideByZeroToCOff ()` - How to handle divide by zero. Default is 0.
- `obj.SetInput1 (vtkDataObject in)` - Set the two inputs to this filter. For some operations, the second input is not used.
- `obj.SetInput2 (vtkDataObject in)`

35.69 vtkImageMedian3D

35.69.1 Usage

vtkImageMedian3D a Median filter that replaces each pixel with the median value from a rectangular neighborhood around that pixel. Neighborhoods can be no more than 3 dimensional. Setting one axis of the neighborhood kernelSize to 1 changes the filter into a 2D median.

To create an instance of class vtkImageMedian3D, simply invoke its constructor as follows

```
obj = vtkImageMedian3D
```

35.69.2 Methods

The class vtkImageMedian3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMedian3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMedian3D = obj.NewInstance ()`
- `vtkImageMedian3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetKernelSize (int size0, int size1, int size2)` - This method sets the size of the neighborhood. It also sets the default middle of the neighborhood
- `int = obj.GetNumberOfElements ()` - Return the number of elements in the median mask

35.70 vtkImageMirrorPad

35.70.1 Usage

vtkImageMirrorPad makes an image larger by filling extra pixels with a mirror image of the original image (mirror at image boundaries).

To create an instance of class vtkImageMirrorPad, simply invoke its constructor as follows

```
obj = vtkImageMirrorPad
```

35.70.2 Methods

The class vtkImageMirrorPad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMirrorPad class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkImageMirrorPad = obj.NewInstance ()`
- `vtkImageMirrorPad = obj.SafeDownCast (vtkObject o)`

35.71 vtkImageNoiseSource

35.71.1 Usage

vtkImageNoiseSource just produces images filled with noise. The only option now is uniform noise specified by a min and a max. There is one major problem with this source. Every time it executes, it will output different pixel values. This has important implications when a stream requests overlapping regions. The same pixels will have different values on different updates.

To create an instance of class vtkImageNoiseSource, simply invoke its constructor as follows

```
obj = vtkImageNoiseSource
```

35.71.2 Methods

The class vtkImageNoiseSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageNoiseSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageNoiseSource = obj.NewInstance ()`
- `vtkImageNoiseSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetMinimum (double )` - Set/Get the minimum and maximum values for the generated noise.
- `double = obj.GetMinimum ()` - Set/Get the minimum and maximum values for the generated noise.
- `obj.SetMaximum (double )` - Set/Get the minimum and maximum values for the generated noise.
- `double = obj.GetMaximum ()` - Set/Get the minimum and maximum values for the generated noise.
- `obj.SetWholeExtent (int xMinx, int xMax, int yMin, int yMax, int zMin, int zMax)` - Set how large of an image to generate.
- `obj.SetWholeExtent (int ext[6])`

35.72 vtkImageNonMaximumSuppression

35.72.1 Usage

vtkImageNonMaximumSuppression Sets to zero any pixel that is not a peak. If a pixel has a neighbor along the vector that has larger magnitude, the smaller pixel is set to zero. The filter takes two inputs: a magnitude and a vector. Output is magnitude information and is always in doubles. Typically this filter is used with vtkImageGradient and vtkImageGradientMagnitude as inputs.

To create an instance of class vtkImageNonMaximumSuppression, simply invoke its constructor as follows

```
obj = vtkImageNonMaximumSuppression
```

35.72.2 Methods

The class vtkImageNonMaximumSuppression has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageNonMaximumSuppression class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageNonMaximumSuppression = obj.NewInstance ()`
- `vtkImageNonMaximumSuppression = obj.SafeDownCast (vtkObject o)`
- `obj.SetMagnitudeInput (vtkImageData input)` - Set the magnitude and vector inputs.
- `obj.SetVectorInput (vtkImageData input)` - Set the magnitude and vector inputs.
- `obj.SetHandleBoundaries (int )` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `int = obj.GetHandleBoundaries ()` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `obj.HandleBoundariesOn ()` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `obj.HandleBoundariesOff ()` - If "HandleBoundariesOn" then boundary pixels are duplicated So central differences can get values.
- `obj.SetDimensionality (int )` - Determines how the input is interpreted (set of 2d slices or a 3D volume)
- `int = obj.GetDimensionalityMinValue ()` - Determines how the input is interpreted (set of 2d slices or a 3D volume)
- `int = obj.GetDimensionalityMaxValue ()` - Determines how the input is interpreted (set of 2d slices or a 3D volume)
- `int = obj.GetDimensionality ()` - Determines how the input is interpreted (set of 2d slices or a 3D volume)

35.73 vtkImageNormalize

35.73.1 Usage

For each point, vtkImageNormalize normalizes the vector defined by the scalar components. If the magnitude of this vector is zero, the output vector is zero also.

To create an instance of class vtkImageNormalize, simply invoke its constructor as follows

```
obj = vtkImageNormalize
```

35.73.2 Methods

The class vtkImageNormalize has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageNormalize class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageNormalize = obj.NewInstance ()`
- `vtkImageNormalize = obj.SafeDownCast (vtkObject o)`

35.74 vtkImageOpenClose3D

35.74.1 Usage

vtkImageOpenClose3D performs opening or closing by having two vtkImageErodeDilates in series. The size of operation is determined by the method SetKernelSize, and the operator is an ellipse. OpenValue and CloseValue determine how the filter behaves. For binary images Opening and closing behaves as expected. Close value is first dilated, and then eroded. Open value is first eroded, and then dilated. Degenerate two dimensional opening/closing can be achieved by setting the one axis the 3D KernelSize to 1. Values other than open value and close value are not touched. This enables the filter to processes segmented images containing more than two tags.

To create an instance of class vtkImageOpenClose3D, simply invoke its constructor as follows

```
obj = vtkImageOpenClose3D
```

35.74.2 Methods

The class vtkImageOpenClose3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageOpenClose3D class.

- `string = obj.GetClassName ()` - Default open value is 0, and default close value is 255.
- `int = obj.IsA (string name)` - Default open value is 0, and default close value is 255.
- `vtkImageOpenClose3D = obj.NewInstance ()` - Default open value is 0, and default close value is 255.
- `vtkImageOpenClose3D = obj.SafeDownCast (vtkObject o)` - Default open value is 0, and default close value is 255.
- `long = obj.GetMTime ()` - This method considers the sub filters MTimes when computing this objects modified time.
- `obj.DebugOn ()` - Turn debugging output on. (in sub filters also)
- `obj.DebugOff ()` - Turn debugging output on. (in sub filters also)
- `obj.Modified ()` - Pass modified message to sub filters.
- `obj.SetKernelSize (int size0, int size1, int size2)` - Selects the size of gaps or objects removed.

- `obj.SetOpenValue (double value)` - Determines the value that will opened. Open value is first eroded, and then dilated.
- `double = obj.GetOpenValue ()` - Determines the value that will opened. Open value is first eroded, and then dilated.
- `obj.SetCloseValue (double value)` - Determines the value that will closed. Close value is first dilated, and then eroded
- `double = obj.GetCloseValue ()` - Determines the value that will closed. Close value is first dilated, and then eroded
- `vtkImageDilateErode3D = obj.GetFilter0 ()` - Needed for Progress functions
- `vtkImageDilateErode3D = obj.GetFilter1 ()` - Needed for Progress functions

35.75 vtkImagePadFilter

35.75.1 Usage

vtkImagePadFilter Changes the image extent of an image. If the image extent is larger than the input image extent, the extra pixels are filled by an algorithm determined by the subclass. The image extent of the output has to be specified.

To create an instance of class vtkImagePadFilter, simply invoke its constructor as follows

```
obj = vtkImagePadFilter
```

35.75.2 Methods

The class vtkImagePadFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImagePadFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImagePadFilter = obj.NewInstance ()`
- `vtkImagePadFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputWholeExtent (int extent[6])` - The image extent of the output has to be set explicitly.
- `obj.SetOutputWholeExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - The image extent of the output has to be set explicitly.
- `obj.GetOutputWholeExtent (int extent[6])` - The image extent of the output has to be set explicitly.
- `int = obj.GetOutputWholeExtent ()` - Set/Get the number of output scalar components.
- `obj.SetOutputNumberOfScalarComponents (int )` - Set/Get the number of output scalar components.
- `int = obj.GetOutputNumberOfScalarComponents ()` - Set/Get the number of output scalar components.

35.76 vtkImagePermute

35.76.1 Usage

vtkImagePermute reorders the axes of the input. Filtered axes specify the input axes which become X, Y, Z. The input has to have the same scalar type of the output. The filter does copy the data when it executes. This filter is actually a very thin wrapper around vtkImageReslice.

To create an instance of class vtkImagePermute, simply invoke its constructor as follows

```
obj = vtkImagePermute
```

35.76.2 Methods

The class vtkImagePermute has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImagePermute class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImagePermute = obj.NewInstance ()`
- `vtkImagePermute = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilteredAxes (int x, int y, int z)` - The filtered axes are the input axes that get relabeled to X,Y,Z.
- `obj.SetFilteredAxes (int xyz[3])` - The filtered axes are the input axes that get relabeled to X,Y,Z.
- `int = obj. GetFilteredAxes ()` - The filtered axes are the input axes that get relabeled to X,Y,Z.

35.77 vtkImageQuantizeRGBToIndex

35.77.1 Usage

vtkImageQuantizeRGBToIndex takes a 3 component RGB image as input and produces a one component index image as output, along with a lookup table that contains the color definitions for the index values. This filter works on the entire input extent - it does not perform streaming, and it does not supported threaded execution (because it has to process the entire image).

To use this filter, you typically set the number of colors (between 2 and 65536), execute it, and then retrieve the lookup table. The colors can then be using the lookup table and the image index.

To create an instance of class vtkImageQuantizeRGBToIndex, simply invoke its constructor as follows

```
obj = vtkImageQuantizeRGBToIndex
```

35.77.2 Methods

The class vtkImageQuantizeRGBToIndex has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageQuantizeRGBToIndex class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkImageQuantizeRGBToIndex = obj.NewInstance ()`
- `vtkImageQuantizeRGBToIndex = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfColors (int )` - Set / Get the number of color index values to produce - must be a number between 2 and 65536.
- `int = obj.GetNumberOfColorsMinValue ()` - Set / Get the number of color index values to produce - must be a number between 2 and 65536.
- `int = obj.GetNumberOfColorsMaxValue ()` - Set / Get the number of color index values to produce - must be a number between 2 and 65536.
- `int = obj.GetNumberOfColors ()` - Set / Get the number of color index values to produce - must be a number between 2 and 65536.
- `vtkLookupTable = obj.GetLookupTable ()` - Get the resulting lookup table that contains the color definitions corresponding to the index values in the output image.
- `double = obj.GetInitializeExecuteTime ()`
- `double = obj.GetBuildTreeExecuteTime ()`
- `double = obj.GetLookupIndexExecuteTime ()`

35.78 vtkImageRange3D

35.78.1 Usage

vtkImageRange3D replaces a pixel with the maximum minus minimum over an ellipsoidal neighborhood. If KernelSize of an axis is 1, no processing is done on that axis.

To create an instance of class vtkImageRange3D, simply invoke its constructor as follows

```
obj = vtkImageRange3D
```

35.78.2 Methods

The class vtkImageRange3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageRange3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageRange3D = obj.NewInstance ()`
- `vtkImageRange3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetKernelSize (int size0, int size1, int size2)` - This method sets the size of the neighborhood. It also sets the default middle of the neighborhood and computes the elliptical foot print.

35.79 vtkImageRectilinearWipe

35.79.1 Usage

vtkImageRectilinearWipe makes a rectilinear combination of two images. The two input images must correspond in size, scalar type and number of components. The resulting image has four possible configurations called: Quad - alternate input 0 and input 1 horizontally and vertically. Select this with SetWipeModeToQuad. The Position specifies the location of the quad intersection. Corner - 3 of one input and 1 of the other. Select the location of input 0 with with SetWipeModeToLowerLeft, SetWipeModeToLowerRight, SetWipeModeToUpperLeft and SetWipeModeToUpperRight. The Position selects the location of the corner. Horizontal - alternate input 0 and input 1 with a vertical split. Select this with SetWipeModeToHorizontal. Position[0] specifies the location of the vertical transition between input 0 and input 1. Vertical - alternate input 0 and input 1 with a horizontal split. Only the y The intersection point of the rectilinear points is controlled with the Point ivar.

To create an instance of class vtkImageRectilinearWipe, simply invoke its constructor as follows

```
obj = vtkImageRectilinearWipe
```

35.79.2 Methods

The class vtkImageRectilinearWipe has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageRectilinearWipe class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageRectilinearWipe = obj.NewInstance ()`
- `vtkImageRectilinearWipe = obj.SafeDownCast (vtkObject o)`
- `obj.SetPosition (int , int )` - Set/Get the location of the image transition. Note that position is specified in pixels.
- `obj.SetPosition (int  a[2])` - Set/Get the location of the image transition. Note that position is specified in pixels.
- `int = obj. GetPosition ()` - Set/Get the location of the image transition. Note that position is specified in pixels.
- `obj.SetInput1 (vtkDataObject in)` - Set the two inputs to this filter.
- `obj.SetInput2 (vtkDataObject in)` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.
- `obj.SetWipe (int )` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1

of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `int = obj.GetWipeMinValue ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `int = obj.GetWipeMaxValue ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `int = obj.GetWipe ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToQuad ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToHorizontal ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToVertical ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToLowerLeft ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToLowerRight ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToUpperLeft ()` - Specify the wipe mode. This mode determnis how input 0 and input 1 are combined to produce the output. Each mode uses one or both of the values stored in Position. SetWipeToQuad - alternate input 0 and input 1 horizontally and vertically. The Position specifies the location of the quad intersection. SetWipeToLowerLeftLowerRight,UpperLeft.UpperRight - 3 of one input and 1 of the other. Select the location of input 0 to the LowerLeftLowerRight,UpperLeft,UpperRight. Position selects the location of the corner. SetWipeToHorizontal - alternate input 0 and input 1 with a vertical split. Position[0] specifies the location of the vertical transition between input 0 and input 1. SetWipeToVertical - alternate input 0 and input 1 with a horizontal split. Position[1] specifies the location of the horizonal transition between input 0 and input 1.

- `obj.SetWipeToUpperRight ()`

35.80 vtkImageResample

35.80.1 Usage

This filter produces an output with different spacing (and extent) than the input. Linear interpolation can be used to resample the data. The Output spacing can be set explicitly or relative to input spacing with the SetAxisMagnificationFactor method.

To create an instance of class vtkImageResample, simply invoke its constructor as follows

```
obj = vtkImageResample
```

35.80.2 Methods

The class vtkImageResample has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageResample class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageResample = obj.NewInstance ()`
- `vtkImageResample = obj.SafeDownCast (vtkObject o)`
- `obj.SetAxisOutputSpacing (int axis, double spacing)` - Set desired spacing. Zero is a reserved value indicating spacing has not been set.
- `obj.SetAxisMagnificationFactor (int axis, double factor)` - Set/Get Magnification factors. Zero is a reserved value indicating values have not been computed.
- `double = obj.GetAxisMagnificationFactor (int axis, vtkInformation inInfo)` - Set/Get Magnification factors. Zero is a reserved value indicating values have not been computed.
- `obj.SetDimensionality (int )` - Dimensionality is the number of axes which are considered during execution. To process images dimensionality would be set to 2. This has the same effect as setting the magnification of the third axis to 1.0
- `int = obj.GetDimensionality ()` - Dimensionality is the number of axes which are considered during execution. To process images dimensionality would be set to 2. This has the same effect as setting the magnification of the third axis to 1.0

35.81 vtkImageReslice

35.81.1 Usage

vtkImageReslice is the swiss-army-knife of image geometry filters: It can permute, rotate, flip, scale, resample, deform, and pad image data in any combination with reasonably high efficiency. Simple operations such as permutation, resampling and padding are done with similar efficiently to the specialized vtkImagePermute, vtkImageResample, and vtkImagePad filters. There are a number of tasks that vtkImageReslice is well suited for: ¡p¿1) Application of simple rotations, scales, and translations to an image. It is often a good idea to use vtkImageChangeInformation to center the image first, so that scales and rotations occur around the center rather than around the lower-left corner of the image. ¡p¿2) Resampling of one data set to match the voxel sampling of a second data set via the SetInformationInput() method, e.g. for the purpose of comparing two images or combining two images. A transformation, either linear or nonlinear, can be applied at the same time via the SetResliceTransform method if the two images are not in the same coordinate space. ¡p¿3) Extraction of slices from an image volume. The most convenient way to do this is to use SetResliceAxesDirectionCosines() to specify the orientation of the slice. The direction cosines give the x, y, and z axes for the output volume. The method SetOutputDimensionality(2) is used to specify that want to output a slice rather than a volume. The SetResliceAxesOrigin() command is used to provide an (x,y,z) point that the slice will pass through. You can use both the ResliceAxes and the ResliceTransform at the same time, in order to extract slices from a volume that you have applied a transformation to.

To create an instance of class vtkImageReslice, simply invoke its constructor as follows

```
obj = vtkImageReslice
```

35.81.2 Methods

The class vtkImageReslice has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageReslice class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageReslice = obj.NewInstance ()`
- `vtkImageReslice = obj.SafeDownCast (vtkObject o)`
- `obj.SetResliceAxes (vtkMatrix4x4 )` - This method is used to set up the axes for the output voxels. The output Spacing, Origin, and Extent specify the locations of the voxels within the coordinate system defined by the axes. The ResliceAxes are used most often to permute the data, e.g. to extract ZY or XZ slices of a volume as 2D XY images. ¡p¿The first column of the matrix specifies the x-axis vector (the fourth element must be set to zero), the second column specifies the y-axis, and the third column the z-axis. The fourth column is the origin of the axes (the fourth element must be set to one). ¡p¿An alternative to SetResliceAxes() is to use SetResliceAxesDirectionCosines() to set the directions of the axes and SetResliceAxesOrigin() to set the origin of the axes.
- `vtkMatrix4x4 = obj.GetResliceAxes ()` - This method is used to set up the axes for the output voxels. The output Spacing, Origin, and Extent specify the locations of the voxels within the coordinate system defined by the axes. The ResliceAxes are used most often to permute the data, e.g. to extract ZY or XZ slices of a volume as 2D XY images. ¡p¿The first column of the matrix specifies the x-axis vector (the fourth element must be set to zero), the second column specifies the y-axis, and the third column the z-axis. The fourth column is the origin of the axes (the fourth element must be set to one). ¡p¿An alternative to SetResliceAxes() is to use SetResliceAxesDirectionCosines() to set the directions of the axes and SetResliceAxesOrigin() to set the origin of the axes.
- `obj.SetResliceAxesDirectionCosines (double x0, double x1, double x2, double y0, double y1, double y` - Specify the direction cosines for the ResliceAxes (i.e. the first three elements of each of the first three columns of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create a new matrix if none exists.
- `obj.SetResliceAxesDirectionCosines (double x[3], double y[3], double z[3])` - Specify the direction cosines for the ResliceAxes (i.e. the first three elements of each of the first three columns of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create a new matrix if none exists.
- `obj.SetResliceAxesDirectionCosines (double xyz[9])` - Specify the direction cosines for the ResliceAxes (i.e. the first three elements of each of the first three columns of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create a new matrix if none exists.
- `obj.GetResliceAxesDirectionCosines (double x[3], double y[3], double z[3])` - Specify the direction cosines for the ResliceAxes (i.e. the first three elements of each of the first three columns of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create a new matrix if none exists.
- `obj.GetResliceAxesDirectionCosines (double xyz[9])` - Specify the direction cosines for the ResliceAxes (i.e. the first three elements of each of the first three columns of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create a new matrix if none exists.
- `double = obj.GetResliceAxesDirectionCosines ()` - Specify the direction cosines for the ResliceAxes (i.e. the first three elements of each of the first three columns of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create a new matrix if none exists.

- `obj.SetResliceAxesOrigin (double x, double y, double z)` - Specify the origin for the ResliceAxes (i.e. the first three elements of the final column of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create new matrix if none exists.

- `obj.SetResliceAxesOrigin (double xyz[3])` - Specify the origin for the ResliceAxes (i.e. the first three elements of the final column of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create new matrix if none exists.

- `obj.GetResliceAxesOrigin (double xyz[3])` - Specify the origin for the ResliceAxes (i.e. the first three elements of the final column of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create new matrix if none exists.

- `double = obj.GetResliceAxesOrigin ()` - Specify the origin for the ResliceAxes (i.e. the first three elements of the final column of the ResliceAxes matrix). This will modify the current ResliceAxes matrix, or create new matrix if none exists.

- `obj.SetResliceTransform (vtkAbstractTransform )` - Set a transform to be applied to the resampling grid that has been defined via the ResliceAxes and the output Origin, Spacing and Extent. Note that applying a transform to the resampling grid (which lies in the output coordinate system) is equivalent to applying the inverse of that transform to the input volume. Nonlinear transforms such as vtkGridTransform and vtkThinPlateSplineTransform can be used here.

- `vtkAbstractTransform = obj.GetResliceTransform ()` - Set a transform to be applied to the resampling grid that has been defined via the ResliceAxes and the output Origin, Spacing and Extent. Note that applying a transform to the resampling grid (which lies in the output coordinate system) is equivalent to applying the inverse of that transform to the input volume. Nonlinear transforms such as vtkGridTransform and vtkThinPlateSplineTransform can be used here.

- `obj.SetInformationInput (vtkImageData )` - Set a vtkImageData from which the default Spacing, Origin, and WholeExtent of the output will be copied. The spacing, origin, and extent will be permuted according to the ResliceAxes. Any values set via SetOutputSpacing, SetOutputOrigin, and SetOutputExtent will override these values. By default, the Spacing, Origin, and WholeExtent of the Input are used.

- `vtkImageData = obj.GetInformationInput ()` - Set a vtkImageData from which the default Spacing, Origin, and WholeExtent of the output will be copied. The spacing, origin, and extent will be permuted according to the ResliceAxes. Any values set via SetOutputSpacing, SetOutputOrigin, and SetOutputExtent will override these values. By default, the Spacing, Origin, and WholeExtent of the Input are used.

- `obj.SetTransformInputSampling (int )` - Specify whether to transform the spacing, origin and extent of the Input (or the InformationInput) according to the direction cosines and origin of the ResliceAxes before applying them as the default output spacing, origin and extent (default: On).

- `obj.TransformInputSamplingOn ()` - Specify whether to transform the spacing, origin and extent of the Input (or the InformationInput) according to the direction cosines and origin of the ResliceAxes before applying them as the default output spacing, origin and extent (default: On).

- `obj.TransformInputSamplingOff ()` - Specify whether to transform the spacing, origin and extent of the Input (or the InformationInput) according to the direction cosines and origin of the ResliceAxes before applying them as the default output spacing, origin and extent (default: On).

- `int = obj.GetTransformInputSampling ()` - Specify whether to transform the spacing, origin and extent of the Input (or the InformationInput) according to the direction cosines and origin of the ResliceAxes before applying them as the default output spacing, origin and extent (default: On).

- `obj.SetAutoCropOutput (int )` - Turn this on if you want to guarantee that the extent of the output will be large enough to ensure that none of the data will be cropped (default: Off).

- `obj.AutoCropOutputOn ()` - Turn this on if you want to guarantee that the extent of the output will be large enough to ensure that none of the data will be cropped (default: Off).
- `obj.AutoCropOutputOff ()` - Turn this on if you want to guarantee that the extent of the output will be large enough to ensure that none of the data will be cropped (default: Off).
- `int = obj.GetAutoCropOutput ()` - Turn this on if you want to guarantee that the extent of the output will be large enough to ensure that none of the data will be cropped (default: Off).
- `obj.SetWrap (int )` - Turn on wrap-pad feature (default: Off).
- `int = obj.GetWrap ()` - Turn on wrap-pad feature (default: Off).
- `obj.WrapOn ()` - Turn on wrap-pad feature (default: Off).
- `obj.WrapOff ()` - Turn on wrap-pad feature (default: Off).
- `obj.SetMirror (int )` - Turn on mirror-pad feature (default: Off). This will override the wrap-pad.
- `int = obj.GetMirror ()` - Turn on mirror-pad feature (default: Off). This will override the wrap-pad.
- `obj.MirrorOn ()` - Turn on mirror-pad feature (default: Off). This will override the wrap-pad.
- `obj.MirrorOff ()` - Turn on mirror-pad feature (default: Off). This will override the wrap-pad.
- `obj.SetBorder (int )` - Extend the apparent input border by a half voxel (default: On). This changes how interpolation is handled at the borders of the input image: if the center of an output voxel is beyond the edge of the input image, but is within a half voxel width of the edge (using the input voxel width), then the value of the output voxel is calculated as if the input's edge voxels were duplicated past the edges of the input. This has no effect if Mirror or Wrap are on.
- `int = obj.GetBorder ()` - Extend the apparent input border by a half voxel (default: On). This changes how interpolation is handled at the borders of the input image: if the center of an output voxel is beyond the edge of the input image, but is within a half voxel width of the edge (using the input voxel width), then the value of the output voxel is calculated as if the input's edge voxels were duplicated past the edges of the input. This has no effect if Mirror or Wrap are on.
- `obj.BorderOn ()` - Extend the apparent input border by a half voxel (default: On). This changes how interpolation is handled at the borders of the input image: if the center of an output voxel is beyond the edge of the input image, but is within a half voxel width of the edge (using the input voxel width), then the value of the output voxel is calculated as if the input's edge voxels were duplicated past the edges of the input. This has no effect if Mirror or Wrap are on.
- `obj.BorderOff ()` - Extend the apparent input border by a half voxel (default: On). This changes how interpolation is handled at the borders of the input image: if the center of an output voxel is beyond the edge of the input image, but is within a half voxel width of the edge (using the input voxel width), then the value of the output voxel is calculated as if the input's edge voxels were duplicated past the edges of the input. This has no effect if Mirror or Wrap are on.
- `obj.SetInterpolationMode (int )` - Set interpolation mode (default: nearest neighbor).
- `int = obj.GetInterpolationModeMinValue ()` - Set interpolation mode (default: nearest neighbor).
- `int = obj.GetInterpolationModeMaxValue ()` - Set interpolation mode (default: nearest neighbor).
- `int = obj.GetInterpolationMode ()` - Set interpolation mode (default: nearest neighbor).
- `obj.SetInterpolationModeToNearestNeighbor ()` - Set interpolation mode (default: nearest neighbor).

- `obj.SetInterpolationModeToLinear ()` - Set interpolation mode (default: nearest neighbor).
- `obj.SetInterpolationModeToCubic ()` - Set interpolation mode (default: nearest neighbor).
- `string = obj.GetInterpolationModeAsString ()` - Set interpolation mode (default: nearest neighbor).
- `obj.SetOptimization (int )` - Turn on and off optimizations (default on, they should only be turned off for testing purposes).
- `int = obj.GetOptimization ()` - Turn on and off optimizations (default on, they should only be turned off for testing purposes).
- `obj.OptimizationOn ()` - Turn on and off optimizations (default on, they should only be turned off for testing purposes).
- `obj.OptimizationOff ()` - Turn on and off optimizations (default on, they should only be turned off for testing purposes).
- `obj.SetBackgroundColor (double , double , double , double )` - Set the background color (for multi-component images).
- `obj.SetBackgroundColor (double a[4])` - Set the background color (for multi-component images).
- `double = obj. GetBackgroundColor ()` - Set the background color (for multi-component images).
- `obj.SetBackgroundLevel (double v)` - Set background grey level (for single-component images).
- `double = obj.GetBackgroundLevel ()` - Set background grey level (for single-component images).
- `obj.SetOutputSpacing (double , double , double )` - Set the voxel spacing for the output data. The default output spacing is the input spacing permuted through the ResliceAxes.
- `obj.SetOutputSpacing (double a[3])` - Set the voxel spacing for the output data. The default output spacing is the input spacing permuted through the ResliceAxes.
- `double = obj. GetOutputSpacing ()` - Set the voxel spacing for the output data. The default output spacing is the input spacing permuted through the ResliceAxes.
- `obj.SetOutputSpacingToDefault ()` - Set the voxel spacing for the output data. The default output spacing is the input spacing permuted through the ResliceAxes.
- `obj.SetOutputOrigin (double , double , double )` - Set the origin for the output data. The default output origin is the input origin permuted through the ResliceAxes.
- `obj.SetOutputOrigin (double a[3])` - Set the origin for the output data. The default output origin is the input origin permuted through the ResliceAxes.
- `double = obj. GetOutputOrigin ()` - Set the origin for the output data. The default output origin is the input origin permuted through the ResliceAxes.
- `obj.SetOutputOriginToDefault ()` - Set the origin for the output data. The default output origin is the input origin permuted through the ResliceAxes.
- `obj.SetOutputExtent (int , int , int , int , int , int )` - Set the extent for the output data. The default output extent is the input extent permuted through the ResliceAxes.
- `obj.SetOutputExtent (int a[6])` - Set the extent for the output data. The default output extent is the input extent permuted through the ResliceAxes.
- `int = obj. GetOutputExtent ()` - Set the extent for the output data. The default output extent is the input extent permuted through the ResliceAxes.

- `obj.SetOutputExtentToDefault ()` - Set the extent for the output data. The default output extent is the input extent permuted through the ResliceAxes.
- `obj.SetOutputDimensionality (int )` - Force the dimensionality of the output to either 1, 2, 3 or 0 (default: 3). If the dimensionality is 2D, then the Z extent of the output is forced to (0,0) and the Z origin of the output is forced to 0.0 (i.e. the output extent is confined to the xy plane). If the dimensionality is 1D, the output extent is confined to the x axis. For 0D, the output extent consists of a single voxel at (0,0,0).
- `int = obj.GetOutputDimensionality ()` - Force the dimensionality of the output to either 1, 2, 3 or 0 (default: 3). If the dimensionality is 2D, then the Z extent of the output is forced to (0,0) and the Z origin of the output is forced to 0.0 (i.e. the output extent is confined to the xy plane). If the dimensionality is 1D, the output extent is confined to the x axis. For 0D, the output extent consists of a single voxel at (0,0,0).
- `long = obj.GetMTime ()` - When determining the modified time of the filter, this check the modified time of the transform and matrix.
- `obj.ReportReferences (vtkGarbageCollector )` - Report object referenced by instances of this class.
- `obj.SetInterpolate (int t)` - Convenient methods for switching between nearest-neighbor and linear interpolation. InterpolateOn() is equivalent to SetInterpolationModeToLinear() and InterpolateOff() is equivalent to SetInterpolationModeToNearestNeighbor(). You should not use these methods if you use the SetInterpolationMode methods.
- `obj.InterpolateOn ()` - Convenient methods for switching between nearest-neighbor and linear interpolation. InterpolateOn() is equivalent to SetInterpolationModeToLinear() and InterpolateOff() is equivalent to SetInterpolationModeToNearestNeighbor(). You should not use these methods if you use the SetInterpolationMode methods.
- `obj.InterpolateOff ()` - Convenient methods for switching between nearest-neighbor and linear interpolation. InterpolateOn() is equivalent to SetInterpolationModeToLinear() and InterpolateOff() is equivalent to SetInterpolationModeToNearestNeighbor(). You should not use these methods if you use the SetInterpolationMode methods.
- `int = obj.GetInterpolate ()` - Convenient methods for switching between nearest-neighbor and linear interpolation. InterpolateOn() is equivalent to SetInterpolationModeToLinear() and InterpolateOff() is equivalent to SetInterpolationModeToNearestNeighbor(). You should not use these methods if you use the SetInterpolationMode methods.
- `obj.SetStencil (vtkImageStencilData stencil)` - Use a stencil to limit the calculations to a specific region of the output. Portions of the output that are 'outside' the stencil will be cleared to the background color.
- `vtkImageStencilData = obj.GetStencil ()` - Use a stencil to limit the calculations to a specific region of the output. Portions of the output that are 'outside' the stencil will be cleared to the background color.

35.82 vtkImageRFFT

35.82.1 Usage

vtkImageRFFT implements the reverse fast Fourier transform. The input can have real or complex data in any components and data types, but the output is always complex doubles with real values in component0, and imaginary values in component1. The filter is fastest for images that have power of two sizes. The filter uses a butterfly fitlers for each prime factor of the dimension. This makes images with prime number

dimensions (i.e. 17x17) much slower to compute. Multi dimensional (i.e volumes) FFT's are decomposed so that each axis executes in series. In most cases the RFFT will produce an image whose imaginary values are all zero's. In this case vtkImageExtractComponents can be used to remove this imaginary components leaving only the real image.

To create an instance of class vtkImageRFFT, simply invoke its constructor as follows

```
obj = vtkImageRFFT
```

35.82.2 Methods

The class vtkImageRFFT has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageRFFT class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageRFFT = obj.NewInstance ()`
- `vtkImageRFFT = obj.SafeDownCast (vtkObject o)`
- `int = obj.SplitExtent (int splitExt[6], int startExt[6], int num, int total)` - For streaming and threads. Splits output update extent into num pieces. This method needs to be called num times. Results must not overlap for consistent starting extent. Subclass can override this method. This method returns the number of pieces resulting from a successful split. This can be from 1 to "total". If 1 is returned, the extent cannot be split.

35.83 vtkImageRGBToHSI

35.83.1 Usage

For each pixel with red, blue, and green components this filter output the color coded as hue, saturation and intensity. Output type must be the same as input type.

To create an instance of class vtkImageRGBToHSI, simply invoke its constructor as follows

```
obj = vtkImageRGBToHSI
```

35.83.2 Methods

The class vtkImageRGBToHSI has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageRGBToHSI class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageRGBToHSI = obj.NewInstance ()`
- `vtkImageRGBToHSI = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaximum (double )` - Hue is an angle. Maximum specifies when it maps back to 0. Hue-Maximum defaults to 255 instead of 2PI, because unsigned char is expected as input. Maximum also specifies the maximum of the Saturation.
- `double = obj.GetMaximum ()` - Hue is an angle. Maximum specifies when it maps back to 0. Hue-Maximum defaults to 255 instead of 2PI, because unsigned char is expected as input. Maximum also specifies the maximum of the Saturation.

35.84 vtkImageRGBToHSV

35.84.1 Usage

For each pixel with red, blue, and green components this filter output the color coded as hue, saturation and value. Output type must be the same as input type.

To create an instance of class vtkImageRGBToHSV, simply invoke its constructor as follows

```
obj = vtkImageRGBToHSV
```

35.84.2 Methods

The class vtkImageRGBToHSV has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageRGBToHSV class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageRGBToHSV = obj.NewInstance ()`
- `vtkImageRGBToHSV = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaximum (double )`
- `double = obj.GetMaximum ()`

35.85 vtkImageSeedConnectivity

35.85.1 Usage

vtkImageSeedConnectivity marks pixels connected to user supplied seeds. The input must be unsigned char, and the output is also unsigned char. If a seed supplied by the user does not have pixel value "InputTrueValue", then the image is scanned +x, +y, +z until a pixel is encountered with value "InputTrueValue". This new pixel is used as the seed . Any pixel with out value "InputTrueValue" is consider off. The output pixels values are 0 for any off pixel in input, "OutputTrueValue" for any pixels connected to seeds, and "OutputUnconnectedValue" for any on pixels not connected to seeds. The same seeds are used for all images in the image set.

To create an instance of class vtkImageSeedConnectivity, simply invoke its constructor as follows

```
obj = vtkImageSeedConnectivity
```

35.85.2 Methods

The class vtkImageSeedConnectivity has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSeedConnectivity class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSeedConnectivity = obj.NewInstance ()`
- `vtkImageSeedConnectivity = obj.SafeDownCast (vtkObject o)`

- `obj.RemoveAllSeeds ()` - Methods for manipulating the seed pixels.
- `obj.AddSeed (int num, int index)` - Methods for manipulating the seed pixels.
- `obj.AddSeed (int i0, int i1, int i2)` - Methods for manipulating the seed pixels.
- `obj.AddSeed (int i0, int i1)` - Methods for manipulating the seed pixels.
- `obj.SetInputConnectValue (int )` - Set/Get what value is considered as connecting pixels.
- `int = obj.GetInputConnectValue ()` - Set/Get what value is considered as connecting pixels.
- `obj.SetOutputConnectedValue (int )` - Set/Get the value to set connected pixels to.
- `int = obj.GetOutputConnectedValue ()` - Set/Get the value to set connected pixels to.
- `obj.SetOutputUnconnectedValue (int )` - Set/Get the value to set unconnected pixels to.
- `int = obj.GetOutputUnconnectedValue ()` - Set/Get the value to set unconnected pixels to.
- `vtkImageConnector = obj.GetConnector ()` - Get the vtkImageCOnnector used by this filter.
- `obj.SetDimensionality (int )` - Set the number of axes to use in connectivity.
- `int = obj.GetDimensionality ()` - Set the number of axes to use in connectivity.

35.86 vtkImageSeparableConvolution

35.86.1 Usage

vtkImageSeparableConvolution performs a convolution along the X, Y, and Z axes of an image, based on the three different 1D convolution kernels. The kernels must be of odd size, and are considered to be centered at (int)((kernelsize - 1) / 2.0). If a kernel is NULL, that dimension is skipped. This filter is designed to efficiently convolve separable filters that can be decomposed into 1 or more 1D convolutions. It also handles arbitrarly large kernel sizes, and uses edge replication to handle boundaries.

To create an instance of class vtkImageSeparableConvolution, simply invoke its constructor as follows

```
obj = vtkImageSeparableConvolution
```

35.86.2 Methods

The class vtkImageSeparableConvolution has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSeparableConvolution class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSeparableConvolution = obj.NewInstance ()`
- `vtkImageSeparableConvolution = obj.SafeDownCast (vtkObject o)`
- `obj.SetXKernel (vtkFloatArray )`
- `vtkFloatArray = obj.GetXKernel ()`
- `obj.SetYKernel (vtkFloatArray )`
- `vtkFloatArray = obj.GetYKernel ()`

- `obj.SetZKernel (vtkFloatArray )`
- `vtkFloatArray = obj.GetZKernel ()`
- `long = obj.GetMTime ()` - Overload standard modified time function. If kernel arrays are modified, then this object is modified as well.

35.87 vtkImageShiftScale

35.87.1 Usage

With vtkImageShiftScale Pixels are shifted (a constant value added) and then scaled (multiplied by a scalar. As a convenience, this class allows you to set the output scalar type similar to vtkImageCast. This is because shift scale operations frequently convert data types.

To create an instance of class vtkImageShiftScale, simply invoke its constructor as follows

```
obj = vtkImageShiftScale
```

35.87.2 Methods

The class vtkImageShiftScale has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageShiftScale class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageShiftScale = obj.NewInstance ()`
- `vtkImageShiftScale = obj.SafeDownCast (vtkObject o)`
- `obj.SetShift (double )` - Set/Get the shift value. This value is added to each pixel
- `double = obj.GetShift ()` - Set/Get the shift value. This value is added to each pixel
- `obj.SetScale (double )` - Set/Get the scale value. Each pixel is multiplied by this value.
- `double = obj.GetScale ()` - Set/Get the scale value. Each pixel is multiplied by this value.
- `obj.SetOutputScalarType (int )` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `int = obj.GetOutputScalarType ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToDouble ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToFloat ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToLong ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToInt ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.

- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToShort ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToChar ()` - Set the desired output scalar type. The result of the shift and scale operations is cast to the type specified.
- `obj.SetOutputScalarTypeToUnsignedChar ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default, ClampOverflow is off.
- `obj.SetClampOverflow (int )` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default, ClampOverflow is off.
- `int = obj.GetClampOverflow ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default, ClampOverflow is off.
- `obj.ClampOverflowOn ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default, ClampOverflow is off.
- `obj.ClampOverflowOff ()` - When the ClampOverflow flag is on, the data is thresholded so that the output value does not exceed the max or min of the data type. By default, ClampOverflow is off.

35.88 vtkImageShrink3D

35.88.1 Usage

vtkImageShrink3D shrinks an image by sub sampling on a uniform grid (integer multiples).

To create an instance of class vtkImageShrink3D, simply invoke its constructor as follows

```
obj = vtkImageShrink3D
```

35.88.2 Methods

The class vtkImageShrink3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageShrink3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageShrink3D = obj.NewInstance ()`
- `vtkImageShrink3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetShrinkFactors (int , int , int )` - Set/Get the shrink factors
- `obj.SetShrinkFactors (int  a[3])` - Set/Get the shrink factors
- `int = obj. GetShrinkFactors ()` - Set/Get the shrink factors
- `obj.SetShift (int , int , int )` - Set/Get the pixel to use as origin.

- `obj.SetShift (int a[3])` - Set/Get the pixel to use as origin.
- `int = obj. GetShift ()` - Set/Get the pixel to use as origin.
- `obj.SetAveraging (int )` - Choose Mean, Minimum, Maximum, Median or sub sampling. The neighborhood operations are not centered on the sampled pixel. This may cause a half pixel shift in your output image. You can changed "Shift" to get around this. vtkImageGaussianSmooth or vtkImageMean with strides.
- `int = obj.GetAveraging ()` - Choose Mean, Minimum, Maximum, Median or sub sampling. The neighborhood operations are not centered on the sampled pixel. This may cause a half pixel shift in your output image. You can changed "Shift" to get around this. vtkImageGaussianSmooth or vtkImageMean with strides.
- `obj.AveragingOn ()` - Choose Mean, Minimum, Maximum, Median or sub sampling. The neighborhood operations are not centered on the sampled pixel. This may cause a half pixel shift in your output image. You can changed "Shift" to get around this. vtkImageGaussianSmooth or vtkImageMean with strides.
- `obj.AveragingOff ()` - Choose Mean, Minimum, Maximum, Median or sub sampling. The neighborhood operations are not centered on the sampled pixel. This may cause a half pixel shift in your output image. You can changed "Shift" to get around this. vtkImageGaussianSmooth or vtkImageMean with strides.
- `obj.SetMean (int )`
- `int = obj.GetMean ()`
- `obj.MeanOn ()`
- `obj.MeanOff ()`
- `obj.SetMinimum (int )`
- `int = obj.GetMinimum ()`
- `obj.MinimumOn ()`
- `obj.MinimumOff ()`
- `obj.SetMaximum (int )`
- `int = obj.GetMaximum ()`
- `obj.MaximumOn ()`
- `obj.MaximumOff ()`
- `obj.SetMedian (int )`
- `int = obj.GetMedian ()`
- `obj.MedianOn ()`
- `obj.MedianOff ()`

35.89 vtkImageSinusoidSource

35.89.1 Usage

vtkImageSinusoidSource just produces images with pixel values determined by a sinusoid.

To create an instance of class vtkImageSinusoidSource, simply invoke its constructor as follows

```
obj = vtkImageSinusoidSource
```

35.89.2 Methods

The class vtkImageSinusoidSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSinusoidSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSinusoidSource = obj.NewInstance ()`
- `vtkImageSinusoidSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetWholeExtent (int xMinx, int xMax, int yMin, int yMax, int zMin, int zMax)` - Set/Get the extent of the whole output image.
- `obj.SetDirection (double , double , double )` - Set/Get the direction vector which determines the sinusoidal orientation. The magnitude is ignored.
- `obj.SetDirection (double dir[3])` - Set/Get the direction vector which determines the sinusoidal orientation. The magnitude is ignored.
- `double = obj. GetDirection ()` - Set/Get the direction vector which determines the sinusoidal orientation. The magnitude is ignored.
- `obj.SetPeriod (double )` - Set/Get the period of the sinusoid in pixels.
- `double = obj.GetPeriod ()` - Set/Get the period of the sinusoid in pixels.
- `obj.SetPhase (double )` - Set/Get the phase: 0-¿2Pi. 0 =¿ Cosine, pi/2 =¿ Sine.
- `double = obj.GetPhase ()` - Set/Get the phase: 0-¿2Pi. 0 =¿ Cosine, pi/2 =¿ Sine.
- `obj.SetAmplitude (double )` - Set/Get the magnitude of the sinusoid.
- `double = obj.GetAmplitude ()` - Set/Get the magnitude of the sinusoid.

35.90 vtkImageSkeleton2D

35.90.1 Usage

vtkImageSkeleton2D should leave only single pixel width lines of non-zero-valued pixels (values of 1 are not allowed). It works by erosion on a 3x3 neighborhood with special rules. The number of iterations determines how far the filter can erode. There are three pruning levels: prune == 0 will leave traces on all angles... prune == 1 will not leave traces on 135 degree angles, but will on 90. prune == 2 does not leave traces on any angles leaving only closed loops. Prune defaults to zero. The output scalar type is the same as the input.

To create an instance of class vtkImageSkeleton2D, simply invoke its constructor as follows

```
obj = vtkImageSkeleton2D
```

35.90.2 Methods

The class vtkImageSkeleton2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSkeleton2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSkeleton2D = obj.NewInstance ()`
- `vtkImageSkeleton2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetPrune (int )` - When prune is on, only closed loops are left unchanged.
- `int = obj.GetPrune ()` - When prune is on, only closed loops are left unchanged.
- `obj.PruneOn ()` - When prune is on, only closed loops are left unchanged.
- `obj.PruneOff ()` - When prune is on, only closed loops are left unchanged.
- `obj.SetNumberOfIterations (int num)` - Sets the number of cycles in the erosion.

35.91 vtkImageSobel2D

35.91.1 Usage

vtkImageSobel2D computes a vector field from a scalar field by using Sobel functions. The number of vector components is 2 because the input is an image. Output is always doubles.

To create an instance of class vtkImageSobel2D, simply invoke its constructor as follows

```
obj = vtkImageSobel2D
```

35.91.2 Methods

The class vtkImageSobel2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSobel2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSobel2D = obj.NewInstance ()`
- `vtkImageSobel2D = obj.SafeDownCast (vtkObject o)`

35.92 vtkImageSobel3D

35.92.1 Usage

vtkImageSobel3D computes a vector field from a scalar field by using Sobel functions. The number of vector components is 3 because the input is a volume. Output is always doubles. A little creative liberty was used to extend the 2D sobel kernels into 3D.

To create an instance of class vtkImageSobel3D, simply invoke its constructor as follows

```
obj = vtkImageSobel3D
```

35.92.2 Methods

The class vtkImageSobel3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSobel3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSobel3D = obj.NewInstance ()`
- `vtkImageSobel3D = obj.SafeDownCast (vtkObject o)`

35.93 vtkImageSpatialAlgorithm

35.93.1 Usage

vtkImageSpatialAlgorithm is a super class for filters that operate on an input neighborhood for each output pixel. It handles even sized neighborhoods, but their can be a half pixel shift associated with processing. This superclass has some logic for handling boundaries. It can split regions into boundary and non-boundary pieces and call different execute methods.

To create an instance of class vtkImageSpatialAlgorithm, simply invoke its constructor as follows

```
obj = vtkImageSpatialAlgorithm
```

35.93.2 Methods

The class vtkImageSpatialAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSpatialAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSpatialAlgorithm = obj.NewInstance ()`
- `vtkImageSpatialAlgorithm = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetKernelSize ()` - Get the Kernel size.
- `int = obj. GetKernelMiddle ()` - Get the Kernel middle.

35.94 vtkImageSpatialFilter

35.94.1 Usage

vtkImageSpatialFilter is a super class for filters that operate on an input neighborhood for each output pixel. It handles even sized neighborhoods, but their can be a half pixel shift associated with processing. This superclass has some logic for handling boundaries. It can split regions into boundary and non-boundary pieces and call different execute methods. .SECTION Warning This used to be the parent class for most imaging filter in VTK4.x, now this role has been replaced by vtkImageSpatialAlgorithm. You should consider using vtkImageSpatialAlgorithm instead, when writing filter for VTK5 and above. This class was kept to ensure full backward compatibility. .SECTION See also vtkSimpleImageToImageFilter vtkImageToImageFilter vtkImageSpatialAlgorithm

To create an instance of class vtkImageSpatialFilter, simply invoke its constructor as follows

```
obj = vtkImageSpatialFilter
```

35.94.2 Methods

The class vtkImageSpatialFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSpatialFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSpatialFilter = obj.NewInstance ()`
- `vtkImageSpatialFilter = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetKernelSize ()` - Get the Kernel size.
- `int = obj. GetKernelMiddle ()` - Get the Kernel middle.

35.95 vtkImageStencil

35.95.1 Usage

vtkImageStencil will combine two images together using a stencil. The stencil should be provided in the form of a vtkImageStencilData,

To create an instance of class vtkImageStencil, simply invoke its constructor as follows

```
obj = vtkImageStencil
```

35.95.2 Methods

The class vtkImageStencil has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageStencil class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageStencil = obj.NewInstance ()`
- `vtkImageStencil = obj.SafeDownCast (vtkObject o)`
- `obj.SetStencil (vtkImageStencilData stencil)` - Specify the stencil to use. The stencil can be created from a vtkImplicitFunction or a vtkPolyData.
- `vtkImageStencilData = obj.GetStencil ()` - Specify the stencil to use. The stencil can be created from a vtkImplicitFunction or a vtkPolyData.
- `obj.SetReverseStencil (int )` - Reverse the stencil.
- `obj.ReverseStencilOn ()` - Reverse the stencil.
- `obj.ReverseStencilOff ()` - Reverse the stencil.
- `int = obj.GetReverseStencil ()` - Reverse the stencil.
- `obj.SetBackgroundInput (vtkImageData input)` - NOTE: Not yet implemented, use SetBackgroundValue instead. Set the second input. This image will be used for the 'outside' of the stencil. If not set, the output voxels will be filled with BackgroundValue instead.

- `vtkImageData = obj.GetBackgroundInput ()` - NOTE: Not yet implemented, use SetBackgroundValue instead. Set the second input. This image will be used for the 'outside' of the stencil. If not set, the output voxels will be filled with BackgroundValue instead.
- `obj.SetBackgroundValue (double val)` - Set the default output value to use when the second input is not set.
- `double = obj.GetBackgroundValue ()` - Set the default output value to use when the second input is not set.
- `obj.SetBackgroundColor (double , double , double , double )` - Set the default color to use when the second input is not set. This is like SetBackgroundValue, but for multi-component images.
- `obj.SetBackgroundColor (double a[4])` - Set the default color to use when the second input is not set. This is like SetBackgroundValue, but for multi-component images.
- `double = obj. GetBackgroundColor ()` - Set the default color to use when the second input is not set. This is like SetBackgroundValue, but for multi-component images.

35.96 vtkImageStencilData

35.96.1 Usage

vtkImageStencilData describes an image stencil in a manner which is efficient both in terms of speed and storage space. The stencil extents are stored for each x-row across the image (multiple extents per row if necessary) and can be retrieved via the GetNextExtent() method.

To create an instance of class vtkImageStencilData, simply invoke its constructor as follows

```
obj = vtkImageStencilData
```

35.96.2 Methods

The class vtkImageStencilData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageStencilData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageStencilData = obj.NewInstance ()`
- `vtkImageStencilData = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()`
- `obj.DeepCopy (vtkDataObject o)`
- `obj.ShallowCopy (vtkDataObject f)`
- `obj.InternalImageStencilDataCopy (vtkImageStencilData s)`
- `int = obj.GetDataObjectType ()` - The extent type is 3D, just like vtkImageData.
- `int = obj.GetExtentType ()` - The extent type is 3D, just like vtkImageData.
- `obj.InsertNextExtent (int r1, int r2, int yIdx, int zIdx)` - This method is used by vtkImageStencilDataSource to add an x sub extent [r1,r2] for the x row (yIdx,zIdx). The specified sub extent must not intersect any other sub extents along the same x row. As well, r1 and r2 must both be within the total x extent [Extent[0],Extent[1]].

- `obj.InsertAndMergeExtent (int r1, int r2, int yIdx, int zIdx)` - Similar to InsertNextExtent, except that the extent (r1,r2) at yIdx, zIdx is merged with other extents, (if any) on that row. So a unique extent may not necessarily be added. For instance, if an extent [5,11] already exists adding an extent, [7,9] will not affect the stencil. Likewise adding [10, 13] will replace the existing extent with [5,13].

- `obj.RemoveExtent (int r1, int r2, int yIdx, int zIdx)` - Remove the extent from (r1,r2) at yIdx, zIdx

- `obj.SetSpacing (double , double , double )` - Set the desired spacing for the stencil. This must be called before the stencil is Updated, ideally in the ExecuteInformation method of the imaging filter that is using the stencil.

- `obj.SetSpacing (double a[3])` - Set the desired spacing for the stencil. This must be called before the stencil is Updated, ideally in the ExecuteInformation method of the imaging filter that is using the stencil.

- `double = obj. GetSpacing ()` - Set the desired spacing for the stencil. This must be called before the stencil is Updated, ideally in the ExecuteInformation method of the imaging filter that is using the stencil.

- `obj.SetOrigin (double , double , double )` - Set the desired origin for the stencil. This must be called before the stencil is Updated, ideally in the ExecuteInformation method of the imaging filter that is using the stencil.

- `obj.SetOrigin (double a[3])` - Set the desired origin for the stencil. This must be called before the stencil is Updated, ideally in the ExecuteInformation method of the imaging filter that is using the stencil.

- `double = obj. GetOrigin ()` - Set the desired origin for the stencil. This must be called before the stencil is Updated, ideally in the ExecuteInformation method of the imaging filter that is using the stencil.

- `obj.SetExtent (int extent[6])` - Set the extent of the data. This is should be called only by vtkImageStencilSource, as it is part of the basic pipeline functionality.

- `obj.SetExtent (int x1, int x2, int y1, int y2, int z1, int z2)` - Set the extent of the data. This is should be called only by vtkImageStencilSource, as it is part of the basic pipeline functionality.

- `int = obj. GetExtent ()` - Set the extent of the data. This is should be called only by vtkImageStencilSource, as it is part of the basic pipeline functionality.

- `obj.AllocateExtents ()` - Allocate space for the sub-extents. This is called by vtkImageStencilSource.

- `obj.Fill ()` - Fill the sub-extents.

- `obj.CopyInformationToPipeline (vtkInformation request, vtkInformation input, vtkInformation output,` - Override these to handle origin, spacing, scalar type, and scalar number of components. See vtkDataObject for details.

- `obj.CopyInformationFromPipeline (vtkInformation request)` - Override these to handle origin, spacing, scalar type, and scalar number of components. See vtkDataObject for details.

- `obj.Add (vtkImageStencilData )` - Add merges the stencil supplied as argument into Self.

- `obj.Subtract (vtkImageStencilData )` - Subtract removes the portion of the stencil, supplied as argument, that lies within Self from Self.

- `obj.Replace (vtkImageStencilData )` - Replaces the portion of the stencil, supplied as argument, that lies within Self from Self.
- `int = obj.Clip (int extent[6])` - Clip the stencil with the supplied extents. In other words, discard data outside the specified extents. Return 1 if something changed.

35.97 vtkImageStencilSource

35.97.1 Usage

vtkImageStencilSource is a superclass for filters that generate image stencils. Given a clipping object such as a vtkImplicitFunction, it will set up a list of clipping extents for each x-row through the image data. The extents for each x-row can be retrieved via the GetNextExtent() method after the extent lists have been built with the BuildExtents() method. For large images, using clipping extents is much more memory efficient (and slightly more time-efficient) than building a mask. This class can be subclassed to allow clipping with objects other than vtkImplicitFunction.

To create an instance of class vtkImageStencilSource, simply invoke its constructor as follows

```
obj = vtkImageStencilSource
```

35.97.2 Methods

The class vtkImageStencilSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageStencilSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageStencilSource = obj.NewInstance ()`
- `vtkImageStencilSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutput (vtkImageStencilData output)` - Get or set the output for this source.
- `vtkImageStencilData = obj.GetOutput ()` - Get or set the output for this source.

35.98 vtkImageThreshold

35.98.1 Usage

vtkImageThreshold can do binary or continuous thresholding for lower, upper or a range of data. The output data type may be different than the output, but defaults to the same type.

To create an instance of class vtkImageThreshold, simply invoke its constructor as follows

```
obj = vtkImageThreshold
```

35.98.2 Methods

The class vtkImageThreshold has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageThreshold class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkImageThreshold = obj.NewInstance ()`
- `vtkImageThreshold = obj.SafeDownCast (vtkObject o)`
- `obj.ThresholdByUpper (double thresh)` - The values greater than or equal to the value match.
- `obj.ThresholdByLower (double thresh)` - The values less than or equal to the value match.
- `obj.ThresholdBetween (double lower, double upper)` - The values in a range (inclusive) match
- `obj.SetReplaceIn (int )` - Determines whether to replace the pixel in range with InValue
- `int = obj.GetReplaceIn ()` - Determines whether to replace the pixel in range with InValue
- `obj.ReplaceInOn ()` - Determines whether to replace the pixel in range with InValue
- `obj.ReplaceInOff ()` - Determines whether to replace the pixel in range with InValue
- `obj.SetInValue (double val)` - Replace the in range pixels with this value.
- `double = obj.GetInValue ()` - Replace the in range pixels with this value.
- `obj.SetReplaceOut (int )` - Determines whether to replace the pixel out of range with OutValue
- `int = obj.GetReplaceOut ()` - Determines whether to replace the pixel out of range with OutValue
- `obj.ReplaceOutOn ()` - Determines whether to replace the pixel out of range with OutValue
- `obj.ReplaceOutOff ()` - Determines whether to replace the pixel out of range with OutValue
- `obj.SetOutValue (double val)` - Replace the in range pixels with this value.
- `double = obj.GetOutValue ()` - Replace the in range pixels with this value.
- `double = obj.GetUpperThreshold ()` - Get the Upper and Lower thresholds.
- `double = obj.GetLowerThreshold ()` - Get the Upper and Lower thresholds.
- `obj.SetOutputScalarType (int )` - Set the desired output scalar type to cast to
- `int = obj.GetOutputScalarType ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToDouble ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToFloat ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToLong ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToInt ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToShort ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToChar ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToSignedChar ()` - Set the desired output scalar type to cast to
- `obj.SetOutputScalarTypeToUnsignedChar ()`

35.99 vtkImageToImageStencil

35.99.1 Usage

vtkImageToImageStencil will convert a vtkImageData into an stencil that can be used with vtkImageStecil or other vtk classes that apply a stencil to an image.

To create an instance of class vtkImageToImageStencil, simply invoke its constructor as follows

```
obj = vtkImageToImageStencil
```

35.99.2 Methods

The class vtkImageToImageStencil has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageToImageStencil class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageToImageStencil = obj.NewInstance ()`
- `vtkImageToImageStencil = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData input)` - Specify the image data to convert into a stencil.
- `vtkImageData = obj.GetInput ()` - Specify the image data to convert into a stencil.
- `obj.ThresholdByUpper (double thresh)` - The values greater than or equal to the value match.
- `obj.ThresholdByLower (double thresh)` - The values less than or equal to the value match.
- `obj.ThresholdBetween (double lower, double upper)` - The values in a range (inclusive) match
- `obj.SetUpperThreshold (double )` - Get the Upper and Lower thresholds.
- `double = obj.GetUpperThreshold ()` - Get the Upper and Lower thresholds.
- `obj.SetLowerThreshold (double )` - Get the Upper and Lower thresholds.
- `double = obj.GetLowerThreshold ()` - Get the Upper and Lower thresholds.

35.100 vtkImageTranslateExtent

35.100.1 Usage

vtkImageTranslateExtent shift the whole extent, but does not change the data.

To create an instance of class vtkImageTranslateExtent, simply invoke its constructor as follows

```
obj = vtkImageTranslateExtent
```

35.100.2 Methods

The class vtkImageTranslateExtent has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageTranslateExtent class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageTranslateExtent = obj.NewInstance ()`
- `vtkImageTranslateExtent = obj.SafeDownCast (vtkObject o)`
- `obj.SetTranslation (int , int , int )` - Delta to change "WholeExtent". -1 changes 0-¿10 to -1-¿9.
- `obj.SetTranslation (int  a[3])` - Delta to change "WholeExtent". -1 changes 0-¿10 to -1-¿9.
- `int = obj. GetTranslation ()` - Delta to change "WholeExtent". -1 changes 0-¿10 to -1-¿9.

35.101 vtkImageVariance3D

35.101.1 Usage

vtkImageVariance3D replaces each pixel with a measurement of pixel variance in a elliptical neighborhood centered on that pixel. The value computed is not exactly the variance. The difference between the neighbor values and center value is computed and squared for each neighbor. These values are summed and divided by the total number of neighbors to produce the output value.

To create an instance of class vtkImageVariance3D, simply invoke its constructor as follows

```
obj = vtkImageVariance3D
```

35.101.2 Methods

The class vtkImageVariance3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageVariance3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageVariance3D = obj.NewInstance ()`
- `vtkImageVariance3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetKernelSize (int size0, int size1, int size2)` - This method sets the size of the neighborhood. It also sets the default middle of the neighborhood and computes the Elliptical foot print.

35.102 vtkImageWeightedSum

35.102.1 Usage

All weights are normalized so they will sum to 1. Images must have the same extents. Output is

.SECTION Thanks The original author of this class is Lauren O'Donnell (MIT) for Slicer

To create an instance of class vtkImageWeightedSum, simply invoke its constructor as follows

```
obj = vtkImageWeightedSum
```

35.102.2 Methods

The class vtkImageWeightedSum has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageWeightedSum class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageWeightedSum = obj.NewInstance ()`
- `vtkImageWeightedSum = obj.SafeDownCast (vtkObject o)`
- `obj.SetWeights (vtkDoubleArray )` - The weights control the contribution of each input to the sum. They will be normalized to sum to 1 before filter execution.
- `vtkDoubleArray = obj.GetWeights ()` - The weights control the contribution of each input to the sum. They will be normalized to sum to 1 before filter execution.
- `obj.SetWeight (vtkIdType id, double weight)` - Change a specific weight. Reallocation is done
- `int = obj.GetNormalizeByWeight ()` - Setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the weighted sum By default, NormalizeByWeight is on.
- `obj.SetNormalizeByWeight (int )` - Setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the weighted sum By default, NormalizeByWeight is on.
- `int = obj.GetNormalizeByWeightMinValue ()` - Setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the weighted sum By default, NormalizeByWeight is on.
- `int = obj.GetNormalizeByWeightMaxValue ()` - Setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the weighted sum By default, NormalizeByWeight is on.
- `obj.NormalizeByWeightOn ()` - Setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the weighted sum By default, NormalizeByWeight is on.
- `obj.NormalizeByWeightOff ()` - Setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the weighted sum By default, NormalizeByWeight is on.
- `double = obj.CalculateTotalWeight ()` - Compute the total value of all the weight

35.103 vtkImageWrapPad

35.103.1 Usage

vtkImageWrapPad performs a modulo operation on the output pixel index to determine the source input index. The new image extent of the output has to be specified. Input has to be the same scalar type as output.

To create an instance of class vtkImageWrapPad, simply invoke its constructor as follows

```
obj = vtkImageWrapPad
```

35.103.2 Methods

The class vtkImageWrapPad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageWrapPad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageWrapPad = obj.NewInstance ()`
- `vtkImageWrapPad = obj.SafeDownCast (vtkObject o)`

35.104 vtkImplicitFunctionToImageStencil

35.104.1 Usage

vtkImplicitFunctionToImageStencil will convert a vtkImplicitFunction into a stencil that can be used with vtkImageStencil or with other classes that apply a stencil to an image.

To create an instance of class vtkImplicitFunctionToImageStencil, simply invoke its constructor as follows

```
obj = vtkImplicitFunctionToImageStencil
```

35.104.2 Methods

The class vtkImplicitFunctionToImageStencil has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitFunctionToImageStencil class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitFunctionToImageStencil = obj.NewInstance ()`
- `vtkImplicitFunctionToImageStencil = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImplicitFunction )` - Specify the implicit function to convert into a stencil.
- `vtkImplicitFunction = obj.GetInput ()` - Specify the implicit function to convert into a stencil.
- `obj.SetInformationInput (vtkImageData )` - Set a vtkImageData that has the Spacing, Origin, and WholeExtent that will be used for the stencil. This input should be set to the image that you wish to apply the stencil to. If you use this method, then any values set with the SetOutputSpacing, SetOutputOrigin, and SetOutputWholeExtent methods will be ignored.
- `vtkImageData = obj.GetInformationInput ()` - Set a vtkImageData that has the Spacing, Origin, and WholeExtent that will be used for the stencil. This input should be set to the image that you wish to apply the stencil to. If you use this method, then any values set with the SetOutputSpacing, SetOutputOrigin, and SetOutputWholeExtent methods will be ignored.
- `obj.SetOutputOrigin (double , double , double )` - Set the Origin to be used for the stencil. It should be set to the Origin of the image you intend to apply the stencil to. The default value is (0,0,0).
- `obj.SetOutputOrigin (double  a[3])` - Set the Origin to be used for the stencil. It should be set to the Origin of the image you intend to apply the stencil to. The default value is (0,0,0).

- `double = obj. GetOutputOrigin ()` - Set the Origin to be used for the stencil. It should be set to the Origin of the image you intend to apply the stencil to. The default value is (0,0,0).
- `obj.SetOutputSpacing (double , double , double )` - Set the Spacing to be used for the stencil. It should be set to the Spacing of the image you intend to apply the stencil to. The default value is (1,1,1)
- `obj.SetOutputSpacing (double a[3])` - Set the Spacing to be used for the stencil. It should be set to the Spacing of the image you intend to apply the stencil to. The default value is (1,1,1)
- `double = obj. GetOutputSpacing ()` - Set the Spacing to be used for the stencil. It should be set to the Spacing of the image you intend to apply the stencil to. The default value is (1,1,1)
- `obj.SetOutputWholeExtent (int , int , int , int , int , int )` - Set the whole extent for the stencil (anything outside this extent will be considered to be "outside" the stencil). If this is not set, then the stencil will always use the requested UpdateExtent as the stencil extent.
- `obj.SetOutputWholeExtent (int a[6])` - Set the whole extent for the stencil (anything outside this extent will be considered to be "outside" the stencil). If this is not set, then the stencil will always use the requested UpdateExtent as the stencil extent.
- `int = obj. GetOutputWholeExtent ()` - Set the whole extent for the stencil (anything outside this extent will be considered to be "outside" the stencil). If this is not set, then the stencil will always use the requested UpdateExtent as the stencil extent.
- `obj.SetThreshold (double )` - Set the threshold value for the implicit function.
- `double = obj.GetThreshold ()` - Set the threshold value for the implicit function.

35.105 vtkPointLoad

35.105.1 Usage

vtkPointLoad is a source object that computes stress tensors on a volume. The tensors are computed from the application of a point load on a semi-infinite domain. (The analytical results are adapted from Saada - see text.) It also is possible to compute effective stress scalars if desired. This object serves as a specialized data generator for some of the examples in the text.

To create an instance of class vtkPointLoad, simply invoke its constructor as follows

```
obj = vtkPointLoad
```

35.105.2 Methods

The class vtkPointLoad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointLoad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointLoad = obj.NewInstance ()`
- `vtkPointLoad = obj.SafeDownCast (vtkObject o)`
- `obj.SetLoadValue (double )` - Set/Get value of applied load.
- `double = obj.GetLoadValue ()` - Set/Get value of applied load.

- `obj.SetSampleDimensions (int i, int j, int k)` - Specify the dimensions of the volume. A stress tensor will be computed for each point in the volume.
- `obj.SetSampleDimensions (int dim[3])` - Specify the dimensions of the volume. A stress tensor will be computed for each point in the volume.
- `int = obj. GetSampleDimensions ()` - Specify the dimensions of the volume. A stress tensor will be computed for each point in the volume.
- `obj.SetModelBounds (double , double , double , double , double , double )` - Specify the region in space over which the tensors are computed. The point load is assumed to be applied at top center of the volume.
- `obj.SetModelBounds (double a[6])` - Specify the region in space over which the tensors are computed. The point load is assumed to be applied at top center of the volume.
- `double = obj. GetModelBounds ()` - Specify the region in space over which the tensors are computed. The point load is assumed to be applied at top center of the volume.
- `obj.SetPoissonsRatio (double )` - Set/Get Poisson's ratio.
- `double = obj.GetPoissonsRatio ()` - Set/Get Poisson's ratio.
- `obj.SetComputeEffectiveStress (int )` - Turn on/off computation of effective stress scalar. These methods do nothing. The effective stress is always computed.
- `int = obj.GetComputeEffectiveStress ()` - Turn on/off computation of effective stress scalar. These methods do nothing. The effective stress is always computed.
- `obj.ComputeEffectiveStressOn ()` - Turn on/off computation of effective stress scalar. These methods do nothing. The effective stress is always computed.
- `obj.ComputeEffectiveStressOff ()` - Turn on/off computation of effective stress scalar. These methods do nothing. The effective stress is always computed.

35.106 vtkRTAnalyticSource

35.106.1 Usage

vtkRTAnalyticSource just produces images with pixel values determined by a Maximum*Gaussian*XMag*sin(XFreq*x)*sin(Y
Values are float scalars on point data with name "RTData".

To create an instance of class vtkRTAnalyticSource, simply invoke its constructor as follows

```
obj = vtkRTAnalyticSource
```

35.106.2 Methods

The class vtkRTAnalyticSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRTAnalyticSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRTAnalyticSource = obj.NewInstance ()`
- `vtkRTAnalyticSource = obj.SafeDownCast (vtkObject o)`

- `obj.SetWholeExtent (int xMinx, int xMax, int yMin, int yMax, int zMin, int zMax)` - Set/Get the extent of the whole output image. Initial value is -10,10,-10,10,-10,10
- `int = obj. GetWholeExtent ()` - Set/Get the extent of the whole output image. Initial value is -10,10,-10,10,-10,10
- `obj.SetCenter (double , double , double )` - Set/Get the center of function. Initial value is 0.0,0.0,0.0
- `obj.SetCenter (double  a[3])` - Set/Get the center of function. Initial value is 0.0,0.0,0.0
- `double = obj. GetCenter ()` - Set/Get the center of function. Initial value is 0.0,0.0,0.0
- `obj.SetMaximum (double )` - Set/Get the Maximum value of the function. Initial value is 255.0.
- `double = obj.GetMaximum ()` - Set/Get the Maximum value of the function. Initial value is 255.0.
- `obj.SetStandardDeviation (double )` - Set/Get the standard deviation of the function. Initial value is 0.5.
- `double = obj.GetStandardDeviation ()` - Set/Get the standard deviation of the function. Initial value is 0.5.
- `obj.SetXFreq (double )` - Set/Get the natural frequency in x. Initial value is 60.
- `double = obj.GetXFreq ()` - Set/Get the natural frequency in x. Initial value is 60.
- `obj.SetYFreq (double )` - Set/Get the natural frequency in y. Initial value is 30.
- `double = obj.GetYFreq ()` - Set/Get the natural frequency in y. Initial value is 30.
- `obj.SetZFreq (double )` - Set/Get the natural frequency in z. Initial value is 40.
- `double = obj.GetZFreq ()` - Set/Get the natural frequency in z. Initial value is 40.
- `obj.SetXMag (double )` - Set/Get the magnitude in x. Initial value is 10.
- `double = obj.GetXMag ()` - Set/Get the magnitude in x. Initial value is 10.
- `obj.SetYMag (double )` - Set/Get the magnitude in y. Initial value is 18.
- `double = obj.GetYMag ()` - Set/Get the magnitude in y. Initial value is 18.
- `obj.SetZMag (double )` - Set/Get the magnitude in z. Initial value is 5.
- `double = obj.GetZMag ()` - Set/Get the magnitude in z. Initial value is 5.
- `obj.SetSubsampleRate (int )` - Set/Get the sub-sample rate. Initial value is 1.
- `int = obj.GetSubsampleRate ()` - Set/Get the sub-sample rate. Initial value is 1.

35.107 vtkSampleFunction

35.107.1 Usage

vtkSampleFunction is a source object that evaluates an implicit function and normals at each point in a vtkStructuredPoints. The user can specify the sample dimensions and location in space to perform the sampling. To create closed surfaces (in conjunction with the vtkContourFilter), capping can be turned on to set a particular value on the boundaries of the sample space.

To create an instance of class vtkSampleFunction, simply invoke its constructor as follows

```
obj = vtkSampleFunction
```

35.107.2 Methods

The class vtkSampleFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSampleFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSampleFunction = obj.NewInstance ()`
- `vtkSampleFunction = obj.SafeDownCast (vtkObject o)`
- `obj.SetImplicitFunction (vtkImplicitFunction )` - Specify the implicit function to use to generate data.
- `vtkImplicitFunction = obj.GetImplicitFunction ()` - Specify the implicit function to use to generate data.
- `obj.SetOutputScalarType (int )` - Set what type of scalar data this source should generate.
- `int = obj.GetOutputScalarType ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToDouble ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToFloat ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToLong ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedLong ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToInt ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedInt ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToShort ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedShort ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToChar ()` - Set what type of scalar data this source should generate.
- `obj.SetOutputScalarTypeToUnsignedChar ()` - Control the type of the scalars object by explicitly providing a scalar object. THIS IS DEPRECATED, although it still works!!! Please use SetOutputScalarType instead.
- `obj.SetScalars (vtkDataArray da)` - Control the type of the scalars object by explicitly providing a scalar object. THIS IS DEPRECATED, although it still works!!! Please use SetOutputScalarType instead.
- `obj.SetSampleDimensions (int i, int j, int k)` - Specify the dimensions of the data on which to sample.
- `obj.SetSampleDimensions (int dim[3])` - Specify the dimensions of the data on which to sample.
- `int = obj. GetSampleDimensions ()` - Specify the dimensions of the data on which to sample.

- `obj.SetModelBounds (double , double , double , double , double , double )` - Specify the region in space over which the sampling occurs. The bounds is specified as (xMin,xMax, yMin,yMax, zMin,zMax).
- `obj.SetModelBounds (double a[6])` - Specify the region in space over which the sampling occurs. The bounds is specified as (xMin,xMax, yMin,yMax, zMin,zMax).
- `double = obj. GetModelBounds ()` - Specify the region in space over which the sampling occurs. The bounds is specified as (xMin,xMax, yMin,yMax, zMin,zMax).
- `obj.SetCapping (int )` - Turn on/off capping. If capping is on, then the outer boundaries of the structured point set are set to cap value. This can be used to insure surfaces are closed.
- `int = obj.GetCapping ()` - Turn on/off capping. If capping is on, then the outer boundaries of the structured point set are set to cap value. This can be used to insure surfaces are closed.
- `obj.CappingOn ()` - Turn on/off capping. If capping is on, then the outer boundaries of the structured point set are set to cap value. This can be used to insure surfaces are closed.
- `obj.CappingOff ()` - Turn on/off capping. If capping is on, then the outer boundaries of the structured point set are set to cap value. This can be used to insure surfaces are closed.
- `obj.SetCapValue (double )` - Set the cap value.
- `double = obj.GetCapValue ()` - Set the cap value.
- `obj.SetComputeNormals (int )` - Turn on/off the computation of normals (normals are float values).
- `int = obj.GetComputeNormals ()` - Turn on/off the computation of normals (normals are float values).
- `obj.ComputeNormalsOn ()` - Turn on/off the computation of normals (normals are float values).
- `obj.ComputeNormalsOff ()` - Turn on/off the computation of normals (normals are float values).
- `obj.SetScalarArrayName (string )` - Set/get the scalar array name for this data set. Initial value is "scalars".
- `string = obj.GetScalarArrayName ()` - Set/get the scalar array name for this data set. Initial value is "scalars".
- `obj.SetNormalArrayName (string )` - Set/get the normal array name for this data set. Initial value is "normals".
- `string = obj.GetNormalArrayName ()` - Set/get the normal array name for this data set. Initial value is "normals".
- `long = obj.GetMTime ()` - Return the MTime also considering the implicit function.

35.108 vtkShepardMethod

35.108.1 Usage

vtkShepardMethod is a filter used to visualize unstructured point data using Shepard's method. The method works by resampling the unstructured points onto a structured points set. The influence functions are described as "inverse distance weighted". Once the structured points are computed, the usual visualization techniques (e.g., iso-contouring or volume rendering) can be used visualize the structured points.

To create an instance of class vtkShepardMethod, simply invoke its constructor as follows

```
obj = vtkShepardMethod
```

35.108.2 Methods

The class vtkShepardMethod has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShepardMethod class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShepardMethod = obj.NewInstance ()`
- `vtkShepardMethod = obj.SafeDownCast (vtkObject o)`
- `double = obj.ComputeModelBounds (double origin[3], double ar[3])` - Compute ModelBounds from input geometry.
- `int = obj. GetSampleDimensions ()` - Specify i-j-k dimensions on which to sample input points.
- `obj.SetSampleDimensions (int i, int j, int k)` - Set the i-j-k dimensions on which to sample the distance function.
- `obj.SetSampleDimensions (int dim[3])` - Set the i-j-k dimensions on which to sample the distance function.
- `obj.SetMaximumDistance (double )` - Specify influence distance of each input point. This distance is a fraction of the length of the diagonal of the sample space. Thus, values of 1.0 will cause each input point to influence all points in the structured point dataset. Values less than 1.0 can improve performance significantly.
- `double = obj.GetMaximumDistanceMinValue ()` - Specify influence distance of each input point. This distance is a fraction of the length of the diagonal of the sample space. Thus, values of 1.0 will cause each input point to influence all points in the structured point dataset. Values less than 1.0 can improve performance significantly.
- `double = obj.GetMaximumDistanceMaxValue ()` - Specify influence distance of each input point. This distance is a fraction of the length of the diagonal of the sample space. Thus, values of 1.0 will cause each input point to influence all points in the structured point dataset. Values less than 1.0 can improve performance significantly.
- `double = obj.GetMaximumDistance ()` - Specify influence distance of each input point. This distance is a fraction of the length of the diagonal of the sample space. Thus, values of 1.0 will cause each input point to influence all points in the structured point dataset. Values less than 1.0 can improve performance significantly.
- `obj.SetModelBounds (double , double , double , double , double , double )` - Specify the position in space to perform the sampling.
- `obj.SetModelBounds (double  a[6])` - Specify the position in space to perform the sampling.
- `double = obj. GetModelBounds ()` - Specify the position in space to perform the sampling.
- `obj.SetNullValue (double )` - Set the Null value for output points not receiving a contribution from the input points.
- `double = obj.GetNullValue ()` - Set the Null value for output points not receiving a contribution from the input points.

35.109 vtkSimpleImageFilterExample

35.109.1 Usage

This is an example of a simple image-image filter. It copies it's input to it's output (point by point). It shows how templates can be used to support various data types. .SECTION See also vtkSimpleImageToImageFilter

To create an instance of class vtkSimpleImageFilterExample, simply invoke its constructor as follows

```
obj = vtkSimpleImageFilterExample
```

35.109.2 Methods

The class vtkSimpleImageFilterExample has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimpleImageFilterExample class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSimpleImageFilterExample = obj.NewInstance ()`
- `vtkSimpleImageFilterExample = obj.SafeDownCast (vtkObject o)`

35.110 vtkSurfaceReconstructionFilter

35.110.1 Usage

vtkSurfaceReconstructionFilter takes a list of points assumed to lie on the surface of a solid 3D object. A signed measure of the distance to the surface is computed and sampled on a regular grid. The grid can then be contoured at zero to extract the surface. The default values for neighborhood size and sample spacing should give reasonable results for most uses but can be set if desired. This procedure is based on the PhD work of Hugues Hoppe: http://www.research.microsoft.com/ hoppe

To create an instance of class vtkSurfaceReconstructionFilter, simply invoke its constructor as follows

```
obj = vtkSurfaceReconstructionFilter
```

35.110.2 Methods

The class vtkSurfaceReconstructionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSurfaceReconstructionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSurfaceReconstructionFilter = obj.NewInstance ()`
- `vtkSurfaceReconstructionFilter = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNeighborhoodSize ()` - Specify the number of neighbors each point has, used for estimating the local surface orientation. The default value of 20 should be OK for most applications, higher values can be specified if the spread of points is uneven. Values as low as 10 may yield adequate results for some surfaces. Higher values cause the algorithm to take longer. Higher values will cause errors on sharp boundaries.

- `obj.SetNeighborhoodSize (int )` - Specify the number of neighbors each point has, used for estimating the local surface orientation. The default value of 20 should be OK for most applications, higher values can be specified if the spread of points is uneven. Values as low as 10 may yield adequate results for some surfaces. Higher values cause the algorithm to take longer. Higher values will cause errors on sharp boundaries.
- `double = obj.GetSampleSpacing ()` - Specify the spacing of the 3D sampling grid. If not set, a reasonable guess will be made.
- `obj.SetSampleSpacing (double )` - Specify the spacing of the 3D sampling grid. If not set, a reasonable guess will be made.

35.111 vtkTriangularTexture

35.111.1 Usage

vtkTriangularTexture is a filter that generates a 2D texture map based on the paper "Opacity-modulating Triangular Textures for Irregular Surfaces," by Penny Rheingans, IEEE Visualization '96, pp. 219-225. The textures assume texture coordinates of (0,0), (1.0) and (.5, sqrt(3)/2). The sequence of texture values is the same along each edge of the triangular texture map. So, the assignment order of texture coordinates is arbitrary.

To create an instance of class vtkTriangularTexture, simply invoke its constructor as follows

```
obj = vtkTriangularTexture
```

35.111.2 Methods

The class vtkTriangularTexture has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTriangularTexture class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTriangularTexture = obj.NewInstance ()`
- `vtkTriangularTexture = obj.SafeDownCast (vtkObject o)`
- `obj.SetScaleFactor (double )` - Set a Scale Factor.
- `double = obj.GetScaleFactor ()` - Set a Scale Factor.
- `obj.SetXSize (int )` - Set the X texture map dimension. Default is 64.
- `int = obj.GetXSize ()` - Set the X texture map dimension. Default is 64.
- `obj.SetYSize (int )` - Set the Y texture map dimension. Default is 64.
- `int = obj.GetYSize ()` - Set the Y texture map dimension. Default is 64.
- `obj.SetTexturePattern (int )` - Set the texture pattern. 1 = opaque at centroid (default) 2 = opaque at vertices 3 = opaque in rings around vertices
- `int = obj.GetTexturePatternMinValue ()` - Set the texture pattern. 1 = opaque at centroid (default) 2 = opaque at vertices 3 = opaque in rings around vertices
- `int = obj.GetTexturePatternMaxValue ()` - Set the texture pattern. 1 = opaque at centroid (default) 2 = opaque at vertices 3 = opaque in rings around vertices
- `int = obj.GetTexturePattern ()` - Set the texture pattern. 1 = opaque at centroid (default) 2 = opaque at vertices 3 = opaque in rings around vertices

35.112 vtkVoxelModeller

35.112.1 Usage

vtkVoxelModeller is a filter that converts an arbitrary data set to a structured point (i.e., voxel) representation. It is very similar to vtkImplicitModeller, except that it doesn't record distance; instead it records occupancy. By default it supports a compact output of 0/1 VTK_BIT. Other vtk scalar types can be specified. The Foreground and Background values of the output can also be specified. NOTE: Not all vtk filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.

To create an instance of class vtkVoxelModeller, simply invoke its constructor as follows

```
obj = vtkVoxelModeller
```

35.112.2 Methods

The class vtkVoxelModeller has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVoxelModeller class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVoxelModeller = obj.NewInstance ()`
- `vtkVoxelModeller = obj.SafeDownCast (vtkObject o)`
- `double = obj.ComputeModelBounds (double origin[3], double ar[3])` - Compute the ModelBounds based on the input geometry.
- `obj.SetSampleDimensions (int i, int j, int k)` - Set the i-j-k dimensions on which to sample the distance function. Default is (50, 50, 50)
- `obj.SetSampleDimensions (int dim[3])` - Set the i-j-k dimensions on which to sample the distance function. Default is (50, 50, 50)
- `int = obj. GetSampleDimensions ()` - Set the i-j-k dimensions on which to sample the distance function. Default is (50, 50, 50)
- `obj.SetMaximumDistance (double )` - Specify distance away from surface of input geometry to sample. Smaller values make large increases in performance. Default is 1.0.
- `double = obj.GetMaximumDistanceMinValue ()` - Specify distance away from surface of input geometry to sample. Smaller values make large increases in performance. Default is 1.0.
- `double = obj.GetMaximumDistanceMaxValue ()` - Specify distance away from surface of input geometry to sample. Smaller values make large increases in performance. Default is 1.0.
- `double = obj.GetMaximumDistance ()` - Specify distance away from surface of input geometry to sample. Smaller values make large increases in performance. Default is 1.0.
- `obj.SetModelBounds (double bounds[6])` - Specify the position in space to perform the voxelization. Default is (0, 0, 0, 0, 0, 0)
- `obj.SetModelBounds (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Specify the position in space to perform the voxelization. Default is (0, 0, 0, 0, 0, 0)
- `double = obj. GetModelBounds ()` - Specify the position in space to perform the voxelization. Default is (0, 0, 0, 0, 0, 0)

- `obj.SetScalarType (int )` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToFloat ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToDouble ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToInt ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToUnsignedInt ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToLong ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToUnsignedLong ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToShort ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToUnsignedShort ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToUnsignedChar ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToChar ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetScalarTypeToBit ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `int = obj.GetScalarType ()` - Control the scalar type of the output image. The default is VTK_BIT. NOTE: Not all filters/readers/writers support the VTK_BIT scalar type. You may want to use VTK_CHAR as an alternative.
- `obj.SetForegroundValue (double )` - Set the Foreground/Background values of the output. The Foreground value is set when a voxel is occupied. The Background value is set when a voxel is not occupied. The default ForegroundValue is 1. The default BackgroundValue is 0.
- `double = obj.GetForegroundValue ()` - Set the Foreground/Background values of the output. The Foreground value is set when a voxel is occupied. The Background value is set when a voxel is not occupied. The default ForegroundValue is 1. The default BackgroundValue is 0.

- `obj.SetBackgroundValue (double )` - Set the Foreground/Background values of the output. The Foreground value is set when a voxel is occupied. The Background value is set when a voxel is not occupied. The default ForegroundValue is 1. The default BackgroundValue is 0.
- `double = obj.GetBackgroundValue ()` - Set the Foreground/Background values of the output. The Foreground value is set when a voxel is occupied. The Background value is set when a voxel is not occupied. The default ForegroundValue is 1. The default BackgroundValue is 0.

Chapter 36

Visualization Toolkit Infovis Classes

36.1 vtkAddMembershipArray

36.1.1 Usage

This filter takes an input selection, vtkDataSetAttribute information, and data object and adds a bit array to the output vtkDataSetAttributes indicating whether each index was selected or not.

To create an instance of class vtkAddMembershipArray, simply invoke its constructor as follows

```
obj = vtkAddMembershipArray
```

36.1.2 Methods

The class vtkAddMembershipArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAddMembershipArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAddMembershipArray = obj.NewInstance ()`
- `vtkAddMembershipArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetFieldType ()` - The field type to add the membership array to.
- `obj.SetFieldType (int )` - The field type to add the membership array to.
- `int = obj.GetFieldTypeMinValue ()` - The field type to add the membership array to.
- `int = obj.GetFieldTypeMaxValue ()` - The field type to add the membership array to.
- `obj.SetOutputArrayName (string )` - The name of the array added to the output vtkDataSetAttributes indicating membership. Defaults to "membership".
- `string = obj.GetOutputArrayName ()` - The name of the array added to the output vtkDataSetAttributes indicating membership. Defaults to "membership".
- `obj.SetInputArrayName (string )`
- `string = obj.GetInputArrayName ()`
- `obj.SetInputValues (vtkAbstractArray )`
- `vtkAbstractArray = obj.GetInputValues ()`

36.2 vtkAdjacencyMatrixToEdgeTable

36.2.1 Usage

Treats a dense 2-way array of doubles as an adacency matrix and converts it into a vtkTable suitable for use as an edge table with vtkTableToGraph.

To create an instance of class vtkAdjacencyMatrixToEdgeTable, simply invoke its constructor as follows

```
obj = vtkAdjacencyMatrixToEdgeTable
```

36.2.2 Methods

The class vtkAdjacencyMatrixToEdgeTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAdjacencyMatrixToEdgeTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAdjacencyMatrixToEdgeTable = obj.NewInstance ()`
- `vtkAdjacencyMatrixToEdgeTable = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetSourceDimension ()` - Specifies whether rows or columns become the "source" in the output edge table. 0 = rows, 1 = columns. Default: 0
- `obj.SetSourceDimension (vtkIdType )` - Specifies whether rows or columns become the "source" in the output edge table. 0 = rows, 1 = columns. Default: 0
- `string = obj.GetValueArrayName ()` - Controls the name of the output table column that contains edge weights. Default: "value"
- `obj.SetValueArrayName (string )` - Controls the name of the output table column that contains edge weights. Default: "value"
- `vtkIdType = obj.GetMinimumCount ()` - Specifies the minimum number of adjacent edges to include for each source vertex. Default: 0
- `obj.SetMinimumCount (vtkIdType )` - Specifies the minimum number of adjacent edges to include for each source vertex. Default: 0
- `double = obj.GetMinimumThreshold ()` - Specifies a minimum threshold that an edge weight must exceed to be included in the output. Default: 0.5
- `obj.SetMinimumThreshold (double )` - Specifies a minimum threshold that an edge weight must exceed to be included in the output. Default: 0.5

36.3 vtkAppendPoints

36.3.1 Usage

vtkAppendPoints is a filter that appends the points and assoicated data of one or more polygonal (vtkPolyData) datasets. This filter can optionally add a new array marking the input index that the point came from.

To create an instance of class vtkAppendPoints, simply invoke its constructor as follows

```
obj = vtkAppendPoints
```

36.3.2 Methods

The class vtkAppendPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAppendPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAppendPoints = obj.NewInstance ()`
- `vtkAppendPoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetInputIdArrayName (string )` - Sets the output array name to fill with the input connection index for each point. This provides a way to trace a point back to a particular input. If this is NULL (the default), the array is not generated.
- `string = obj.GetInputIdArrayName ()` - Sets the output array name to fill with the input connection index for each point. This provides a way to trace a point back to a particular input. If this is NULL (the default), the array is not generated.

36.4 vtkApplyColors

36.4.1 Usage

vtkApplyColors performs a coloring of the dataset using default colors, lookup tables, annotations, and/or a selection. The output is a four-component vtkUnsignedCharArray containing RGBA tuples for each element in the dataset. The first input is the dataset to be colored, which may be a vtkTable, vtkGraph subclass, or vtkDataSet subclass. The API of this algorithm refers to "points" and "cells". For vtkGraph, the "points" refer to the graph vertices and "cells" refer to graph edges. For vtkTable, "points" refer to table rows. For vtkDataSet subclasses, the meaning is obvious.

The second (optional) input is a vtkAnnotationLayers object, which stores a list of annotation layers, with each layer holding a list of vtkAnnotation objects. The annotation specifies a subset of data along with other properties, including color. For annotations with color properties, this algorithm will use the color to color elements, using a "top one wins" strategy.

The third (optional) input is a vtkSelection object, meant for specifying the current selection. You can control the color of the selection.

The algorithm takes two input arrays, specified with SetInputArrayToProcess(0, 0, 0, vtkDataObject::FIELD_ASSOCIATION_POINTS, name) and SetInputArrayToProcess(1, 0, 0, vtkDataObject::FIELD_ASSOCIATION_ name). These set the point and cell data arrays to use to color the data with the associated lookup table. For vtkGraph, vtkTable inputs, you would use FIELD_ASSOCIATION_VERTICES, FIELD_ASSOCIATION_EDGES, or FIELD_ASSOCIATION_ROWS as appropriate.

To use the color array generated here, you should do the following:

mapper-¿SetScalarModeToUseCellFieldData(); mapper-¿SelectColorArray("vtkApplyColors color"); mapper-¿SetScalarVisibility(true);

Colors are assigned with the following priorities: ¡ol¿ ¡li¿ If an item is part of the selection, it is colored with that color. ¡li¿ Otherwise, if the item is part of an annotation, it is colored with the color of the final (top) annotation in the set of layers. ¡li¿ Otherwise, if the lookup table is used, it is colored using the lookup table color for the data value of the element. ¡li¿ Otherwise it will be colored with the default color. ¡/ol¿

Note: The opacity of an unselected item is defined by the multiplication of default opacity, lookup table opacity, and annotation opacity, where opacity is taken as a number from 0 to 1. So items will never be more opaque than any of these three opacities. Selected items are always given the selection opacity directly.

To create an instance of class vtkApplyColors, simply invoke its constructor as follows

```
obj = vtkApplyColors
```

36.4.2 Methods

The class vtkApplyColors has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkApplyColors class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkApplyColors = obj.NewInstance ()`
- `vtkApplyColors = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointLookupTable (vtkScalarsToColors lut)` - The lookup table to use for point colors. This is only used if input array 0 is set and UsePointLookupTable is on.
- `vtkScalarsToColors = obj.GetPointLookupTable ()` - The lookup table to use for point colors. This is only used if input array 0 is set and UsePointLookupTable is on.
- `obj.SetUsePointLookupTable (bool )` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `bool = obj.GetUsePointLookupTable ()` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.UsePointLookupTableOn ()` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.UsePointLookupTableOff ()` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.SetScalePointLookupTable (bool )` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `bool = obj.GetScalePointLookupTable ()` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `obj.ScalePointLookupTableOn ()` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `obj.ScalePointLookupTableOff ()` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `obj.SetDefaultPointColor (double , double , double )` - The default point color for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `obj.SetDefaultPointColor (double  a[3])` - The default point color for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `double = obj. GetDefaultPointColor ()` - The default point color for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `obj.SetDefaultPointOpacity (double )` - The default point opacity for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `double = obj.GetDefaultPointOpacity ()` - The default point opacity for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `obj.SetSelectedPointColor (double , double , double )` - The point color for all selected elements of the data. This is used if the selection input is available.

- `obj.SetSelectedPointColor (double a[3])` - The point color for all selected elements of the data. This is used if the selection input is available.
- `double = obj. GetSelectedPointColor ()` - The point color for all selected elements of the data. This is used if the selection input is available.
- `obj.SetSelectedPointOpacity (double )` - The point opacity for all selected elements of the data. This is used if the selection input is available.
- `double = obj.GetSelectedPointOpacity ()` - The point opacity for all selected elements of the data. This is used if the selection input is available.
- `obj.SetPointColorOutputArrayName (string )` - The output array name for the point color RGBA array. Default is "vtkApplyColors color".
- `string = obj.GetPointColorOutputArrayName ()` - The output array name for the point color RGBA array. Default is "vtkApplyColors color".
- `obj.SetCellLookupTable (vtkScalarsToColors lut)` - The lookup table to use for cell colors. This is only used if input array 1 is set and UseCellLookupTable is on.
- `vtkScalarsToColors = obj.GetCellLookupTable ()` - The lookup table to use for cell colors. This is only used if input array 1 is set and UseCellLookupTable is on.
- `obj.SetUseCellLookupTable (bool )` - If on, uses the cell lookup table to set the colors of unannotated, unselected elements of the data.
- `bool = obj.GetUseCellLookupTable ()` - If on, uses the cell lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.UseCellLookupTableOn ()` - If on, uses the cell lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.UseCellLookupTableOff ()` - If on, uses the cell lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.SetScaleCellLookupTable (bool )` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `bool = obj.GetScaleCellLookupTable ()` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `obj.ScaleCellLookupTableOn ()` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `obj.ScaleCellLookupTableOff ()` - If on, uses the range of the data to scale the lookup table range. Otherwise, uses the range defined in the lookup table.
- `obj.SetDefaultCellColor (double , double , double )` - The default cell color for all unannotated, unselected elements of the data. This is used if UseCellLookupTable is off.
- `obj.SetDefaultCellColor (double a[3])` - The default cell color for all unannotated, unselected elements of the data. This is used if UseCellLookupTable is off.
- `double = obj. GetDefaultCellColor ()` - The default cell color for all unannotated, unselected elements of the data. This is used if UseCellLookupTable is off.
- `obj.SetDefaultCellOpacity (double )` - The default cell opacity for all unannotated, unselected elements of the data. This is used if UseCellLookupTable is off.
- `double = obj.GetDefaultCellOpacity ()` - The default cell opacity for all unannotated, unselected elements of the data. This is used if UseCellLookupTable is off.

- `obj.SetSelectedCellColor (double , double , double )` - The cell color for all selected elements of the data. This is used if the selection input is available.
- `obj.SetSelectedCellColor (double a[3])` - The cell color for all selected elements of the data. This is used if the selection input is available.
- `double = obj. GetSelectedCellColor ()` - The cell color for all selected elements of the data. This is used if the selection input is available.
- `obj.SetSelectedCellOpacity (double )` - The cell opacity for all selected elements of the data. This is used if the selection input is available.
- `double = obj.GetSelectedCellOpacity ()` - The cell opacity for all selected elements of the data. This is used if the selection input is available.
- `obj.SetCellColorOutputArrayName (string )` - The output array name for the cell color RGBA array. Default is "vtkApplyColors color".
- `string = obj.GetCellColorOutputArrayName ()` - The output array name for the cell color RGBA array. Default is "vtkApplyColors color".
- `obj.SetUseCurrentAnnotationColor (bool )` - Use the annotation to color the current annotation (i.e. the current selection). Otherwise use the selection color attributes of this filter.
- `bool = obj.GetUseCurrentAnnotationColor ()` - Use the annotation to color the current annotation (i.e. the current selection). Otherwise use the selection color attributes of this filter.
- `obj.UseCurrentAnnotationColorOn ()` - Use the annotation to color the current annotation (i.e. the current selection). Otherwise use the selection color attributes of this filter.
- `obj.UseCurrentAnnotationColorOff ()` - Use the annotation to color the current annotation (i.e. the current selection). Otherwise use the selection color attributes of this filter.

36.5 vtkApplyIcons

36.5.1 Usage

vtkApplyIcons performs a iconing of the dataset using default icons, lookup tables, annotations, and/or a selection. The output is a vtkIntArray containing the icon index for each element in the dataset. The first input is the dataset to be iconed, which may be a vtkTable, vtkGraph subclass, or vtkDataSet subclass.

The second (optional) input is a vtkAnnotationLayers object, which stores a list of annotation layers, with each layer holding a list of vtkAnnotation objects. The annotation specifies a subset of data along with other properties, including icon. For annotations with icon properties, this algorithm will use the icon index of annotated elements, using a "top one wins" strategy.

The third (optional) input is a vtkSelection object, meant for specifying the current selection. You can control the icon of the selection, or whether there is a set of selected icons at a particular offset in the icon sheet.

The algorithm takes an input array, specified with SetInputArrayToProcess(0, 0, 0, vtkDataObject::FIELD_ASSOCIATIO name) This sets data arrays to use to icon the data with the associated lookup table. For vtkGraph and vtkTable inputs, you would use FIELD_ASSOCIATION_VERTICES, FIELD_ASSOCIATION_EDGES, or FIELD_ASSOCIATION_ROWS as appropriate. The icon array will be added to the same set of attributes that the input array came from. If there is no input array, the icon array will be applied to the attributes associated with the AttributeType parameter.

Icons are assigned with the following priorities: ¡ol¿ ¡li¿ If an item is part of the selection, it is glyphed with that icon. ¡li¿ Otherwise, if the item is part of an annotation, it is glyphed with the icon of the final (top) annotation in the set of layers. ¡li¿ Otherwise, if a lookup table is used, it is glyphed using the lookup table icon for the data value of the element. ¡li¿ Otherwise it will be glyphed with the default icon. ¡/ol¿

To create an instance of class vtkApplyIcons, simply invoke its constructor as follows

```
obj = vtkApplyIcons
```

36.5.2 Methods

The class vtkApplyIcons has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkApplyIcons class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkApplyIcons = obj.NewInstance ()`
- `vtkApplyIcons = obj.SafeDownCast (vtkObject o)`
- `obj.SetIconType (double v, int icon)` - Edits the lookup table to use for point icons. This is only used if input array 0 is set and UsePointLookupTable is on.
- `obj.SetIconType (string v, int icon)` - Edits the lookup table to use for point icons. This is only used if input array 0 is set and UsePointLookupTable is on.
- `obj.ClearAllIconTypes ()` - Edits the lookup table to use for point icons. This is only used if input array 0 is set and UsePointLookupTable is on.
- `obj.SetUseLookupTable (bool )` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `bool = obj.GetUseLookupTable ()` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.UseLookupTableOn ()` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.UseLookupTableOff ()` - If on, uses the point lookup table to set the colors of unannotated, unselected elements of the data.
- `obj.SetDefaultIcon (int )` - The default point icon for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `int = obj.GetDefaultIcon ()` - The default point icon for all unannotated, unselected elements of the data. This is used if UsePointLookupTable is off.
- `obj.SetSelectedIcon (int )` - The point icon for all selected elements of the data. This is used if the annotation input has a current selection.
- `int = obj.GetSelectedIcon ()` - The point icon for all selected elements of the data. This is used if the annotation input has a current selection.
- `obj.SetIconOutputArrayName (string )` - The output array name for the point icon index array. Default is "vtkApplyIcons icon".
- `string = obj.GetIconOutputArrayName ()` - The output array name for the point icon index array. Default is "vtkApplyIcons icon".
- `obj.SetSelectionMode (int )` - Changes the behavior of the icon to use for selected items. ¡ul¿ ¡li¿SELECTED_ICON uses SelectedIcon as the icon for all selected elements. ¡li¿SELECTED_OFFSET uses SelectedIcon as an offset to add to all selected elements. ¡li¿ANNOTATION_ICON uses the ICON_INDEX() property of the current annotation. ¡li¿IGNORE_SELECTION does not change the icon based on the current selection. ¡/ul¿ The default is IGNORE_SELECTION.

- `int = obj.GetSelectionMode ()` - Changes the behavior of the icon to use for selected items. ¡ul¿ ¡li¿SELECTED_ICON uses SelectedIcon as the icon for all selected elements. ¡li¿SELECTED_OFFSET uses SelectedIcon as an offset to add to all selected elements. ¡li¿ANNOTATION_ICON uses the ICON_INDEX() property of the current annotation. ¡li¿IGNORE_SELECTION does not change the icon based on the current selection. ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetSelectionModeToSelectedIcon ()` - Changes the behavior of the icon to use for selected items. ¡ul¿ ¡li¿SELECTED_ICON uses SelectedIcon as the icon for all selected elements. ¡li¿SELECTED_OFFSET uses SelectedIcon as an offset to add to all selected elements. ¡li¿ANNOTATION_ICON uses the ICON_INDEX() property of the current annotation. ¡li¿IGNORE_SELECTION does not change the icon based on the current selection. ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetSelectionModeToSelectedOffset ()` - Changes the behavior of the icon to use for selected items. ¡ul¿ ¡li¿SELECTED_ICON uses SelectedIcon as the icon for all selected elements. ¡li¿SELECTED_OFFSET uses SelectedIcon as an offset to add to all selected elements. ¡li¿ANNOTATION_ICON uses the ICON_INDEX() property of the current annotation. ¡li¿IGNORE_SELECTION does not change the icon based on the current selection. ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetSelectionModeToAnnotationIcon ()` - Changes the behavior of the icon to use for selected items. ¡ul¿ ¡li¿SELECTED_ICON uses SelectedIcon as the icon for all selected elements. ¡li¿SELECTED_OFFSET uses SelectedIcon as an offset to add to all selected elements. ¡li¿ANNOTATION_ICON uses the ICON_INDEX() property of the current annotation. ¡li¿IGNORE_SELECTION does not change the icon based on the current selection. ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetSelectionModeToIgnoreSelection ()` - The attribute type to append the icon array to, used only if the input array is not specified or does not exist. This is set to one of the AttributeTypes enum in vtkDataObject (e.g. POINT, CELL, VERTEX EDGE, FIELD).
- `obj.SetAttributeType (int )` - The attribute type to append the icon array to, used only if the input array is not specified or does not exist. This is set to one of the AttributeTypes enum in vtkDataObject (e.g. POINT, CELL, VERTEX EDGE, FIELD).
- `int = obj.GetAttributeType ()` - The attribute type to append the icon array to, used only if the input array is not specified or does not exist. This is set to one of the AttributeTypes enum in vtkDataObject (e.g. POINT, CELL, VERTEX EDGE, FIELD).

36.6 vtkArcParallelEdgeStrategy

36.6.1 Usage

Parallel edges are drawn as arcs, and self-loops are drawn as ovals. When only one edge connects two vertices it is drawn as a straight line.

To create an instance of class vtkArcParallelEdgeStrategy, simply invoke its constructor as follows

```
obj = vtkArcParallelEdgeStrategy
```

36.6.2 Methods

The class vtkArcParallelEdgeStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArcParallelEdgeStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArcParallelEdgeStrategy = obj.NewInstance ()`

- `vtkArcParallelEdgeStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out.
- `int = obj.GetNumberOfSubdivisions ()` - Get/Set the number of subdivisions on each edge.
- `obj.SetNumberOfSubdivisions (int )` - Get/Set the number of subdivisions on each edge.

36.7 vtkAreaLayout

36.7.1 Usage

vtkAreaLayout assigns sector regions to each vertex in the tree, creating a tree ring. The data is added as a data array with four components per tuple representing the location and size of the sector using the format (StartAngle, EndAngle, innerRadius, outerRadius).

This algorithm relies on a helper class to perform the actual layout. This helper class is a subclass of vtkAreaLayoutStrategy.

.SECTION Thanks Thanks to Jason Shepherd from Sandia National Laboratories for help developing this class.

To create an instance of class vtkAreaLayout, simply invoke its constructor as follows

```
obj = vtkAreaLayout
```

36.7.2 Methods

The class vtkAreaLayout has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAreaLayout class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAreaLayout = obj.NewInstance ()`
- `vtkAreaLayout = obj.SafeDownCast (vtkObject o)`
- `obj.SetSizeArrayName (string name)` - The name for the array created for the area for each vertex. The rectangles are stored in a quadruple float array (startAngle, endAngle, innerRadius, outerRadius). For rectangular layouts, this is (minx, maxx, miny, maxy).
- `string = obj.GetAreaArrayName ()` - The name for the array created for the area for each vertex. The rectangles are stored in a quadruple float array (startAngle, endAngle, innerRadius, outerRadius). For rectangular layouts, this is (minx, maxx, miny, maxy).
- `obj.SetAreaArrayName (string )` - The name for the array created for the area for each vertex. The rectangles are stored in a quadruple float array (startAngle, endAngle, innerRadius, outerRadius). For rectangular layouts, this is (minx, maxx, miny, maxy).
- `bool = obj.GetEdgeRoutingPoints ()` - Whether to output a second output tree with vertex locations appropriate for routing bundled edges. Default is on.
- `obj.SetEdgeRoutingPoints (bool )` - Whether to output a second output tree with vertex locations appropriate for routing bundled edges. Default is on.
- `obj.EdgeRoutingPointsOn ()` - Whether to output a second output tree with vertex locations appropriate for routing bundled edges. Default is on.

- `obj.EdgeRoutingPointsOff ()` - Whether to output a second output tree with vertex locations appropriate for routing bundled edges. Default is on.
- `vtkAreaLayoutStrategy = obj.GetLayoutStrategy ()` - The strategy to use when laying out the tree map.
- `obj.SetLayoutStrategy (vtkAreaLayoutStrategy strategy)` - The strategy to use when laying out the tree map.
- `long = obj.GetMTime ()` - Get the modification time of the layout algorithm.
- `vtkIdType = obj.FindVertex (float pnt[2])` - Get the vertex whose area contains the point, or return -1 if no vertex area covers the point.
- `obj.GetBoundingArea (vtkIdType id, float sinfo)` - The bounding area information for a certain vertex id.

36.8 vtkAreaLayoutStrategy

36.8.1 Usage

All subclasses of this class perform a area layout on a tree. This involves assigning a region to each vertex in the tree, and placing that information in a data array with four components per tuple representing (innerRadius, outerRadius, startAngle, endAngle).

Instances of subclasses of this class may be assigned as the layout strategy to vtkAreaLayout

.SECTION Thanks Thanks to Jason Shepherd from Sandia National Laboratories for help developing this class.

To create an instance of class vtkAreaLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkAreaLayoutStrategy
```

36.8.2 Methods

The class vtkAreaLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAreaLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAreaLayoutStrategy = obj.NewInstance ()`
- `vtkAreaLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout (vtkTree inputTree, vtkDataArray areaArray, vtkDataArray sizeArray)` - Perform the layout of the input tree, and store the sector bounds of each vertex as a tuple in a data array. For radial layout, this is (innerRadius, outerRadius, startAngle, endAngle). For rectangular layout, this is (xmin, xmax, ymin, ymax).

  The sizeArray may be NULL, or may contain the desired size of each vertex in the tree.
- `obj.LayoutEdgePoints (vtkTree inputTree, vtkDataArray areaArray, vtkDataArray sizeArray, vtkTree ed`
- `vtkIdType = obj.FindVertex (vtkTree tree, vtkDataArray array, float pnt[2])` - Returns the vertex id that contains pnt (or -1 if no one contains it)
- `obj.SetShrinkPercentage (double )`

- `double = obj.GetShrinkPercentageMinValue ()`
- `double = obj.GetShrinkPercentageMaxValue ()`
- `double = obj.GetShrinkPercentage ()`

36.9 vtkArrayNorm

36.9.1 Usage

Given an input matrix (vtkTypedArray¡double¿), computes the L-norm for each vector along either dimension, storing the results in a dense output vector (1D vtkDenseArray¡double¿). The caller may optionally request the inverse norm as output (useful for subsequent normalization), and may limit the computation to a "window" of vector elements, to avoid data copying.

.SECTION Thanks Developed by Timothy M. Shead (tshead@sandia.gov) at Sandia National Laboratories.

To create an instance of class vtkArrayNorm, simply invoke its constructor as follows

```
obj = vtkArrayNorm
```

36.9.2 Methods

The class vtkArrayNorm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayNorm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayNorm = obj.NewInstance ()`
- `vtkArrayNorm = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Controls the dimension along which norms will be computed. For input matrices, For input matrices, use "0" (rows) or "1" (columns). Default: 0
- `obj.SetDimension (int )` - Controls the dimension along which norms will be computed. For input matrices, For input matrices, use "0" (rows) or "1" (columns). Default: 0
- `int = obj.GetL ()` - Controls the L-value. Default: 2
- `obj.SetL (int value)` - Controls the L-value. Default: 2
- `obj.SetInvert (int )` - Controls whether to invert output values. Default: false
- `int = obj.GetInvert ()` - Controls whether to invert output values. Default: false

36.10 vtkAssignCoordinates

36.10.1 Usage

Given two(or three) arrays take the values in those arrays and simply assign them to the coordinates of the vertices. Yes you could do this with the array calculator, but your mom wears army boots so we're not going to.

To create an instance of class vtkAssignCoordinates, simply invoke its constructor as follows

```
obj = vtkAssignCoordinates
```

36.10.2 Methods

The class vtkAssignCoordinates has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssignCoordinates class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssignCoordinates = obj.NewInstance ()`
- `vtkAssignCoordinates = obj.SafeDownCast (vtkObject o)`
- `obj.SetXCoordArrayName (string )` - Set the x coordinate array name.
- `string = obj.GetXCoordArrayName ()` - Set the x coordinate array name.
- `obj.SetYCoordArrayName (string )` - Set the y coordinate array name.
- `string = obj.GetYCoordArrayName ()` - Set the y coordinate array name.
- `obj.SetZCoordArrayName (string )` - Set the z coordinate array name.
- `string = obj.GetZCoordArrayName ()` - Set the z coordinate array name.
- `obj.SetJitter (bool )` - Set if you want a random jitter

36.11 vtkAssignCoordinatesLayoutStrategy

36.11.1 Usage

Uses vtkAssignCoordinates to use values from arrays as the x, y, and z coordinates.

To create an instance of class vtkAssignCoordinatesLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkAssignCoordinatesLayoutStrategy
```

36.11.2 Methods

The class vtkAssignCoordinatesLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssignCoordinatesLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssignCoordinatesLayoutStrategy = obj.NewInstance ()`
- `vtkAssignCoordinatesLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetXCoordArrayName (string name)` - The array to use for the x coordinate values.
- `string = obj.GetXCoordArrayName ()` - The array to use for the x coordinate values.
- `obj.SetYCoordArrayName (string name)` - The array to use for the y coordinate values.
- `string = obj.GetYCoordArrayName ()` - The array to use for the y coordinate values.

- `obj.SetZCoordArrayName (string name)` - The array to use for the z coordinate values.
- `string = obj.GetZCoordArrayName ()` - The array to use for the z coordinate values.
- `obj.Layout ()` - Perform the random layout.

36.12 vtkAttributeClustering2DLayoutStrategy

36.12.1 Usage

This class is a density grid based force directed layout strategy. Also please note that 'fast' is relative to quite slow. :) The layout running time is O(V+E) with an extremely high constant. .SECTION Thanks Thanks to Godzilla for not eating my computer so that this class could be written.

To create an instance of class vtkAttributeClustering2DLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkAttributeClustering2DLayoutStrategy
```

36.12.2 Methods

The class vtkAttributeClustering2DLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAttributeClustering2DLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAttributeClustering2DLayoutStrategy = obj.NewInstance ()`
- `vtkAttributeClustering2DLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetVertexAttribute ()` - The name of the array on the vertices, whose values will be used for determining clusters.
- `obj.SetVertexAttribute (string )` - The name of the array on the vertices, whose values will be used for determining clusters.
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `obj.SetInitialTemperature (float )` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperature ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)

- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)

- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)

- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetRestDistance (float )` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `float = obj.GetRestDistance ()` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()`

36.13 vtkBivariateLinearTableThreshold

36.13.1 Usage

Class for filtering the rows of a two numeric columns of a vtkTable. The columns are treated as the two variables of a line. This filter will then iterate through the rows of the table determining if X,Y values pairs are above/below/between/near one or more lines.

The "between" mode checks to see if a row is contained within the convex hull of all of the specified lines. The "near" mode checks if a row is within a distance threshold two one of the specified lines. This class is used in conjunction with various plotting classes, so it is useful to rescale the X,Y axes to a particular range of values. Distance comparisons can be performed in the scaled space by setting the CustomRanges ivar and enabling UseNormalizedDistance.

To create an instance of class vtkBivariateLinearTableThreshold, simply invoke its constructor as follows

```
obj = vtkBivariateLinearTableThreshold
```

36.13.2 Methods

The class vtkBivariateLinearTableThreshold has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBivariateLinearTableThreshold class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBivariateLinearTableThreshold = obj.NewInstance ()`
- `vtkBivariateLinearTableThreshold = obj.SafeDownCast (vtkObject o)`
- `obj.SetInclusive (int )` - Include the line in the threshold. Essentially whether the threshold operation uses ¿ versus ¿=.
- `int = obj.GetInclusive ()` - Include the line in the threshold. Essentially whether the threshold operation uses ¿ versus ¿=.
- `obj.AddColumnToThreshold (vtkIdType column, vtkIdType component)` - Add a numeric column to the pair of columns to be thresholded. Call twice.

- `int = obj.GetNumberOfColumnsToThreshold ()` - Return how many columns have been added. Hopefully 2.
- `obj.ClearColumnsToThreshold ()` - Reset the columns to be thresholded.
- `vtkIdTypeArray = obj.GetSelectedRowIds (int selection)` - Get the output as a table of row ids.
- `obj.Initialize ()` - Reset the columns to threshold, column ranges, etc.
- `obj.AddLineEquation (double p1, double p2)` - Add a line for thresholding from two x,y points.
- `obj.AddLineEquation (double p, double slope)` - Add a line for thresholding in point-slope form.
- `obj.AddLineEquation (double a, double b, double c)` - Add a line for thresholding in implicit form (ax + by + c = 0)
- `obj.ClearLineEquations ()` - Reset the list of line equations.
- `int = obj.GetLinearThresholdType ()` - Set the threshold type. Above: find all rows that are above the specified lines. Below: find all rows that are below the specified lines. Near: find all rows that are near the specified lines. Between: find all rows that are between the specified lines.
- `obj.SetLinearThresholdType (int )` - Set the threshold type. Above: find all rows that are above the specified lines. Below: find all rows that are below the specified lines. Near: find all rows that are near the specified lines. Between: find all rows that are between the specified lines.
- `obj.SetLinearThresholdTypeToAbove ()` - Set the threshold type. Above: find all rows that are above the specified lines. Below: find all rows that are below the specified lines. Near: find all rows that are near the specified lines. Between: find all rows that are between the specified lines.
- `obj.SetLinearThresholdTypeToBelow ()` - Set the threshold type. Above: find all rows that are above the specified lines. Below: find all rows that are below the specified lines. Near: find all rows that are near the specified lines. Between: find all rows that are between the specified lines.
- `obj.SetLinearThresholdTypeToNear ()` - Set the threshold type. Above: find all rows that are above the specified lines. Below: find all rows that are below the specified lines. Near: find all rows that are near the specified lines. Between: find all rows that are between the specified lines.
- `obj.SetLinearThresholdTypeToBetween ()` - Manually access the maximum/minimum x,y values. This is used in conjunction with UseNormalizedDistance when determining if a row passes the threshold.
- `obj.SetColumnRanges (double , double )` - Manually access the maximum/minimum x,y values. This is used in conjunction with UseNormalizedDistance when determining if a row passes the threshold.
- `obj.SetColumnRanges (double a[2])` - Manually access the maximum/minimum x,y values. This is used in conjunction with UseNormalizedDistance when determining if a row passes the threshold.
- `double = obj. GetColumnRanges ()` - Manually access the maximum/minimum x,y values. This is used in conjunction with UseNormalizedDistance when determining if a row passes the threshold.
- `obj.SetDistanceThreshold (double )` - The Cartesian distance within which a point will pass the near threshold.
- `double = obj.GetDistanceThreshold ()` - The Cartesian distance within which a point will pass the near threshold.
- `obj.SetUseNormalizedDistance (int )` - Renormalize the space of the data such that the X and Y axes are "square" over the specified ColumnRanges. This essentially scales the data space so that ColumnRanges[1]-ColumnRanges[0] = 1.0 and ColumnRanges[3]-ColumnRanges[2] = 1.0. Used for scatter plot distance calculations. Be sure to set DistanceThreshold accordingly, when used.

- `int = obj.GetUseNormalizedDistance ()` - Renormalize the space of the data such that the X and Y axes are "square" over the specified ColumnRanges. This essentially scales the data space so that ColumnRanges[1]-ColumnRanges[0] = 1.0 and ColumnRanges[3]-ColumnRanges[2] = 1.0. Used for scatter plot distance calculations. Be sure to set DistanceThreshold accordingly, when used.
- `obj.UseNormalizedDistanceOn ()` - Renormalize the space of the data such that the X and Y axes are "square" over the specified ColumnRanges. This essentially scales the data space so that ColumnRanges[1]-ColumnRanges[0] = 1.0 and ColumnRanges[3]-ColumnRanges[2] = 1.0. Used for scatter plot distance calculations. Be sure to set DistanceThreshold accordingly, when used.
- `obj.UseNormalizedDistanceOff ()` - Renormalize the space of the data such that the X and Y axes are "square" over the specified ColumnRanges. This essentially scales the data space so that ColumnRanges[1]-ColumnRanges[0] = 1.0 and ColumnRanges[3]-ColumnRanges[2] = 1.0. Used for scatter plot distance calculations. Be sure to set DistanceThreshold accordingly, when used.

36.14 vtkBivariateStatisticsAlgorithm

36.14.1 Usage

This class specializes statistics algorithms to the bivariate case, where a number of pairs of columns of interest can be selected in the input data set. This is done by the means of the following functions:

ResetColumns() - reset the list of columns of interest. Add/RemoveColum(namColX, namColY) - try to add/remove column pair (namColX, namColy) to/from the list. SetColumnStatus (namCol, status) - mostly for UI wrapping purposes, try to add/remove (depending on status) namCol from a list of buffered columns, from which all possible pairs are generated. The verb "try" is used in the sense that neither attempting to repeat an existing entry nor to remove a non-existent entry will work.

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkBivariateStatisticsAlgorithm, simply invoke its constructor as follows

```
obj = vtkBivariateStatisticsAlgorithm
```

36.14.2 Methods

The class vtkBivariateStatisticsAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBivariateStatisticsAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBivariateStatisticsAlgorithm = obj.NewInstance ()`
- `vtkBivariateStatisticsAlgorithm = obj.SafeDownCast (vtkObject o)`
- `obj.AddColumnPair (string namColX, string namColY)` - Convenience method to create a request with a single column name pair (namColX, namColY) in a single call; this is the preferred method to select columns pairs, ensuring selection consistency (a pair of columns per request).

  Unlike SetColumnStatus(), you need not call RequestSelectedColumns() after AddColumnPair().

  Warning: namColX and namColY are only checked for their validity as strings; no check is made that either are valid column names.
- `int = obj.RequestSelectedColumns ()` - Use the current column status values to produce a new request for statistics to be produced when RequestData() is called. Unlike the superclass implementation, this version adds a new request for every possible pairing of the selected columns instead of a single request containing all the columns.

36.15 vtkBoxLayoutStrategy

36.15.1 Usage

vtkBoxLayoutStrategy recursively partitions the space for children vertices in a tree-map into square regions (or regions very close to a square).

.SECTION Thanks Thanks to Brian Wylie from Sandia National Laboratories for creating this class.

To create an instance of class vtkBoxLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkBoxLayoutStrategy
```

36.15.2 Methods

The class vtkBoxLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoxLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBoxLayoutStrategy = obj.NewInstance ()`
- `vtkBoxLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout (vtkTree inputTree, vtkDataArray coordsArray, vtkDataArray sizeArray)` - Perform the layout of a tree and place the results as 4-tuples in coordsArray (Xmin, Xmax, Ymin, Ymax).

36.16 vtkChacoGraphReader

36.16.1 Usage

vtkChacoGraphReader reads in files in the Chaco format into a vtkGraph. An example is the following ¡code¿ 10 13 2 6 10 1 3 2 4 8 3 5 4 6 10 1 5 7 6 8 3 7 9 8 10 1 5 9 ¡/code¿ The first line specifies the number of vertices and edges in the graph. Each additional line contains the vertices adjacent to a particular vertex. In this example, vertex 1 is adjacent to 2, 6 and 10, vertex 2 is adjacent to 1 and 3, etc. Since Chaco ids start at 1 and VTK ids start at 0, the vertex ids in the vtkGraph will be 1 less than the Chaco ids.

To create an instance of class vtkChacoGraphReader, simply invoke its constructor as follows

```
obj = vtkChacoGraphReader
```

36.16.2 Methods

The class vtkChacoGraphReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkChacoGraphReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkChacoGraphReader = obj.NewInstance ()`
- `vtkChacoGraphReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()` - The Chaco file name.
- `obj.SetFileName (string )` - The Chaco file name.

36.17 vtkCircularLayoutStrategy

36.17.1 Usage

Assigns points to the vertices around a circle with unit radius.

To create an instance of class vtkCircularLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkCircularLayoutStrategy
```

36.17.2 Methods

The class vtkCircularLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCircularLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCircularLayoutStrategy = obj.NewInstance ()`
- `vtkCircularLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout ()` - Perform the layout.

36.18 vtkClustering2DLayoutStrategy

36.18.1 Usage

This class is a density grid based force directed layout strategy. Also please note that 'fast' is relative to quite slow. :) The layout running time is O(V+E) with an extremely high constant. .SECTION Thanks Thanks to Godzilla for not eating my computer so that this class could be written.

To create an instance of class vtkClustering2DLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkClustering2DLayoutStrategy
```

36.18.2 Methods

The class vtkClustering2DLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClustering2DLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkClustering2DLayoutStrategy = obj.NewInstance ()`
- `vtkClustering2DLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.

- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.

- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `obj.SetInitialTemperature (float )` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperature ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetRestDistance (float )` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `float = obj.GetRestDistance ()` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()`

36.19 vtkCollapseGraph

36.19.1 Usage

vtkCollapseGraph "collapses" vertices onto their neighbors, while maintaining connectivity. Two inputs are required - a graph (directed or undirected), and a vertex selection that can be converted to indices.

Conceptually, each of the vertices specified in the input selection expands, "swallowing" adacent vertices. Edges to-or-from the "swallowed" vertices become edges to-or-from the expanding vertices, maintaining the overall graph connectivity.

In the case of directed graphs, expanding vertices only swallow vertices that are connected via out edges. This rule provides intuitive behavior when working with trees, so that "child" vertices collapse into their parents when the parents are part of the input selection.

Input port 0: graph Input port 1: selection

To create an instance of class vtkCollapseGraph, simply invoke its constructor as follows

```
obj = vtkCollapseGraph
```

36.19.2 Methods

The class vtkCollapseGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollapseGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollapseGraph = obj.NewInstance ()`
- `vtkCollapseGraph = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraphConnection (vtkAlgorithmOutput )`
- `obj.SetSelectionConnection (vtkAlgorithmOutput )`

36.20 vtkCollapseVerticesByArray

36.20.1 Usage

vtkCollapseVerticesByArray is a class which collapses the graph using a vertex array as the key. So if the graph has vertices sharing common traits then this class combines all these vertices into one. This class does not perform aggregation on vertex data but allow to do so for edge data. Users can choose one or more edge data arrays for aggregation using AddAggregateEdgeArray function.

.SECTION Thanks

To create an instance of class vtkCollapseVerticesByArray, simply invoke its constructor as follows

```
obj = vtkCollapseVerticesByArray
```

36.20.2 Methods

The class vtkCollapseVerticesByArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollapseVerticesByArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollapseVerticesByArray = obj.NewInstance ()`
- `vtkCollapseVerticesByArray = obj.SafeDownCast (vtkObject o)`
- `bool = obj.GetAllowSelfLoops ()` - Boolean to allow self loops during collapse.
- `obj.SetAllowSelfLoops (bool )` - Boolean to allow self loops during collapse.
- `obj.AllowSelfLoopsOn ()` - Boolean to allow self loops during collapse.
- `obj.AllowSelfLoopsOff ()` - Boolean to allow self loops during collapse.
- `obj.AddAggregateEdgeArray (string arrName)` - Add arrays on which aggregation of data is allowed. Default if replaced by the last value.
- `obj.ClearAggregateEdgeArray ()` - Clear the list of arrays on which aggregation was set to allow.
- `string = obj.GetVertexArray ()` - Set the array using which perform the collapse.
- `obj.SetVertexArray (string )` - Set the array using which perform the collapse.

36.21 vtkCommunity2DLayoutStrategy

36.21.1 Usage

This class is a density grid based force directed layout strategy. Also please note that 'fast' is relative to quite slow. :) The layout running time is O(V+E) with an extremely high constant. .SECTION Thanks Thanks to Godzilla for not eating my computer so that this class could be written.

To create an instance of class vtkCommunity2DLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkCommunity2DLayoutStrategy
```

36.21.2 Methods

The class vtkCommunity2DLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCommunity2DLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCommunity2DLayoutStrategy = obj.NewInstance ()`
- `vtkCommunity2DLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `obj.SetInitialTemperature (float )` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `float = obj.GetInitialTemperature ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetRestDistance (float )` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `float = obj.GetRestDistance ()` - Manually set the resting distance. Otherwise the distance is computed automatically.

- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()` - Get/Set the community array name
- `string = obj.GetCommunityArrayName ()` - Get/Set the community array name
- `obj.SetCommunityArrayName (string )` - Get/Set the community array name
- `obj.SetCommunityStrength (float )` - Set the community 'strength'. The default is '1' which means vertices in the same community will be placed close together, values closer to .1 (minimum) will mean a layout closer to traditional force directed.
- `float = obj.GetCommunityStrengthMinValue ()` - Set the community 'strength'. The default is '1' which means vertices in the same community will be placed close together, values closer to .1 (minimum) will mean a layout closer to traditional force directed.
- `float = obj.GetCommunityStrengthMaxValue ()` - Set the community 'strength'. The default is '1' which means vertices in the same community will be placed close together, values closer to .1 (minimum) will mean a layout closer to traditional force directed.
- `float = obj.GetCommunityStrength ()` - Set the community 'strength'. The default is '1' which means vertices in the same community will be placed close together, values closer to .1 (minimum) will mean a layout closer to traditional force directed.

36.22 vtkComputeHistogram2DOutliers

36.22.1 Usage

This class takes a table and one or more vtkImageData histograms as input and computes the outliers in that data. In general it does so by identifying histogram bins that are removed by a median (salt and pepper) filter and below a threshold. This threshold is automatically identified to retrieve a number of outliers close to a user-determined value. This value is set by calling SetPreferredNumberOfOutliers(int).

The image data input can come either as a multiple vtkImageData via the repeatable INPUT_HISTOGRAM_IMAGE_DATA port, or as a single vtkMultiBlockDataSet containing vtkImageData objects as blocks. One or the other must be set, not both (or neither).

The output can be retrieved as a set of row ids in a vtkSelection or as a vtkTable containing the actual outlier row data.

To create an instance of class vtkComputeHistogram2DOutliers, simply invoke its constructor as follows

```
obj = vtkComputeHistogram2DOutliers
```

36.22.2 Methods

The class vtkComputeHistogram2DOutliers has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkComputeHistogram2DOutliers class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkComputeHistogram2DOutliers = obj.NewInstance ()`

- `vtkComputeHistogram2DOutliers = obj.SafeDownCast (vtkObject o)`
- `obj.SetPreferredNumberOfOutliers (int )`
- `int = obj.GetPreferredNumberOfOutliers ()`
- `vtkTable = obj.GetOutputTable ()`
- `obj.SetInputTableConnection (vtkAlgorithmOutput cxn)` - Set the input histogram data as a (repeatable) vtkImageData
- `obj.SetInputHistogramImageDataConnection (vtkAlgorithmOutput cxn)` - Set the input histogram data as a vtkMultiBlockData set containing multiple vtkImageData objects.
- `obj.SetInputHistogramMultiBlockConnection (vtkAlgorithmOutput cxn)`

36.23 vtkConeLayoutStrategy

36.23.1 Usage

vtkConeLayoutStrategy positions the nodes of a tree(forest) in 3D space based on the cone-tree approach first described by Robertson, Mackinlay and Card in Proc. CHI'91. This implementation incorporates refinements to the layout developed by Carriere and Kazman, and by Auber.

The input graph must be a forest (i.e. a set of trees, or a single tree); in the case of a forest, the input will be converted to a single tree by introducing a new root node, and connecting each root in the input forest to the meta-root. The tree is then laid out, after which the meta-root is removed.

The cones are positioned so that children lie in planes parallel to the X-Y plane, with the axis of cones parallel to Z, and with Z coordinate increasing with distance of nodes from the root.

.SECTION Thanks Thanks to David Duke from the University of Leeds for providing this implementation.

To create an instance of class vtkConeLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkConeLayoutStrategy
```

36.23.2 Methods

The class vtkConeLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConeLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConeLayoutStrategy = obj.NewInstance ()`
- `vtkConeLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetCompactness (float )` - Determine the compactness, the ratio between the average width of a cone in the tree, and the height of the cone. The default setting is 0.75 which (empirically) seems reasonable, but this will need adapting depending on the data.
- `float = obj.GetCompactness ()` - Determine the compactness, the ratio between the average width of a cone in the tree, and the height of the cone. The default setting is 0.75 which (empirically) seems reasonable, but this will need adapting depending on the data.
- `obj.SetCompression (int )` - Determine if layout should be compressed, i.e. the layout puts children closer together, possibly allowing sub-trees to overlap. This is useful if the tree is actually the spanning tree of a graph. For "real" trees, non-compressed layout is best, and is the default.

- `int = obj.GetCompression ()` - Determine if layout should be compressed, i.e. the layout puts children closer together, possibly allowing sub-trees to overlap. This is useful if the tree is actually the spanning tree of a graph. For "real" trees, non-compressed layout is best, and is the default.
- `obj.CompressionOn ()` - Determine if layout should be compressed, i.e. the layout puts children closer together, possibly allowing sub-trees to overlap. This is useful if the tree is actually the spanning tree of a graph. For "real" trees, non-compressed layout is best, and is the default.
- `obj.CompressionOff ()` - Determine if layout should be compressed, i.e. the layout puts children closer together, possibly allowing sub-trees to overlap. This is useful if the tree is actually the spanning tree of a graph. For "real" trees, non-compressed layout is best, and is the default.
- `obj.SetSpacing (float )` - Set the spacing parameter that affects space between layers of the tree. If compression is on, Spacing is the actual distance between layers. If compression is off, actual distance also includes a factor of the compactness and maximum cone radius.
- `float = obj.GetSpacing ()` - Set the spacing parameter that affects space between layers of the tree. If compression is on, Spacing is the actual distance between layers. If compression is off, actual distance also includes a factor of the compactness and maximum cone radius.
- `obj.Layout ()` - Perform the layout.

36.24 vtkConstrained2DLayoutStrategy

36.24.1 Usage

This class is a density grid based force directed layout strategy. Also please note that 'fast' is relative to quite slow. :) The layout running time is O(V+E) with an extremely high constant. .SECTION Thanks We would like to thank Mothra for distracting Godzilla while we wrote this class.

To create an instance of class vtkConstrained2DLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkConstrained2DLayoutStrategy
```

36.24.2 Methods

The class vtkConstrained2DLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConstrained2DLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConstrained2DLayoutStrategy = obj.NewInstance ()`
- `vtkConstrained2DLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.

- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)
- `obj.SetInitialTemperature (float )` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `float = obj.GetInitialTemperature ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)

- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetRestDistance (float )` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `float = obj.GetRestDistance ()` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()` - Set/Get the input constraint array name. If no input array name is set then the name 'constraint' is used.
- `obj.SetInputArrayName (string )` - Set/Get the input constraint array name. If no input array name is set then the name 'constraint' is used.
- `string = obj.GetInputArrayName ()` - Set/Get the input constraint array name. If no input array name is set then the name 'constraint' is used.

36.25 vtkContingencyStatistics

36.25.1 Usage

Given a pair of columns of interest, this class provides the following functionalities, depending on the execution mode it is executed in: * Learn: calculate contigency tables and corresponding discrete bivariate probability distribution. * Assess: given two columns of interest with the same number of entries as input in port INPUT_DATA, and a corresponding bivariate probability distribution,

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkContingencyStatistics, simply invoke its constructor as follows

```
obj = vtkContingencyStatistics
```

36.25.2 Methods

The class vtkContingencyStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContingencyStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkContingencyStatistics = obj.NewInstance ()`
- `vtkContingencyStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model NB: not implemented

36.26 vtkCorrelativeStatistics

36.26.1 Usage

Given a selection of pairs of columns of interest, this class provides the following functionalities, depending on the execution mode it is executed in: * Learn: calculate means, unbiased variance and covariance estimators of column pairs, and corresponding linear regressions and linear correlation coefficient. More precisely, Learn calculates the sums; if finalize is set to true (default), the final statistics are calculated with the function CalculateFromSums. Otherwise, only raw sums are output; this option is made for efficient parallel calculations. Note that CalculateFromSums is a static function, so that it can be used directly with no need to instantiate a vtkCorrelativeStatistics object. * Assess: given two data vectors X and Y with the same number of entries as input in port INPUT_DATA, and reference means, variances, and covariance, along with an acceptable threshold t¿1, assess all pairs of values of (X,Y) whose relative PDF (assuming a bivariate Gaussian model) is below t.

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkCorrelativeStatistics, simply invoke its constructor as follows

```
obj = vtkCorrelativeStatistics
```

36.26.2 Methods

The class vtkCorrelativeStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCorrelativeStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCorrelativeStatistics = obj.NewInstance ()`
- `vtkCorrelativeStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model

36.27 vtkCosmicTreeLayoutStrategy

36.27.1 Usage

This layout strategy takes an input tree and places all the children of a node into a containing circle. The placement is such that each child placed can be represented with a circle tangent to the containing circle and (usually) 2 other children. The interior of the circle is left empty so that graph edges drawn on top of the tree will not obfuscate the tree. However, when one child is much larger than all the others, it may

encroach on the center of the containing circle; that's OK, because it's large enough not to be obscured by edges drawn atop it.

.SECTION Thanks Thanks to the galaxy and David Thompson hierarchically nested inside it for inspiring this layout strategy.

To create an instance of class vtkCosmicTreeLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkCosmicTreeLayoutStrategy
```

36.27.2 Methods

The class vtkCosmicTreeLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCosmicTreeLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCosmicTreeLayoutStrategy = obj.NewInstance ()`
- `vtkCosmicTreeLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout ()` - Perform the layout.
- `obj.SetSizeLeafNodesOnly (int )` - Should node size specifications be obeyed at leaf nodes only or (with scaling as required to meet constraints) at every node in the tree? This defaults to true, so that leaf nodes are scaled according to the size specification provided, and the parent node sizes are calculated by the algorithm.
- `int = obj.GetSizeLeafNodesOnly ()` - Should node size specifications be obeyed at leaf nodes only or (with scaling as required to meet constraints) at every node in the tree? This defaults to true, so that leaf nodes are scaled according to the size specification provided, and the parent node sizes are calculated by the algorithm.
- `obj.SizeLeafNodesOnlyOn ()` - Should node size specifications be obeyed at leaf nodes only or (with scaling as required to meet constraints) at every node in the tree? This defaults to true, so that leaf nodes are scaled according to the size specification provided, and the parent node sizes are calculated by the algorithm.
- `obj.SizeLeafNodesOnlyOff ()` - Should node size specifications be obeyed at leaf nodes only or (with scaling as required to meet constraints) at every node in the tree? This defaults to true, so that leaf nodes are scaled according to the size specification provided, and the parent node sizes are calculated by the algorithm.
- `obj.SetLayoutDepth (int )` - How many levels of the tree should be laid out? For large trees, you may wish to set the root and maximum depth in order to retrieve the layout for the visible portion of the tree. When this value is zero or negative, all nodes below and including the LayoutRoot will be presented. This defaults to 0.
- `int = obj.GetLayoutDepth ()` - How many levels of the tree should be laid out? For large trees, you may wish to set the root and maximum depth in order to retrieve the layout for the visible portion of the tree. When this value is zero or negative, all nodes below and including the LayoutRoot will be presented. This defaults to 0.
- `obj.SetLayoutRoot (vtkIdType )` - What is the top-most tree node to lay out? This node will become the largest containing circle in the layout. Use this in combination with SetLayoutDepth to retrieve the layout of a subtree of interest for rendering. Setting LayoutRoot to a negative number signals that the root node of the tree should be used as the root node of the layout. This defaults to -1.

- `vtkIdType = obj.GetLayoutRoot ()` - What is the top-most tree node to lay out? This node will become the largest containing circle in the layout. Use this in combination with SetLayoutDepth to retrieve the layout of a subtree of interest for rendering. Setting LayoutRoot to a negative number signals that the root node of the tree should be used as the root node of the layout. This defaults to -1.
- `obj.SetNodeSizeArrayName (string )` - Set the array to be used for sizing nodes. If this is set to an empty string or NULL (the default), then all leaf nodes (or all nodes, when SizeLeafNodesOnly is false) will be assigned a unit size.
- `string = obj.GetNodeSizeArrayName ()` - Set the array to be used for sizing nodes. If this is set to an empty string or NULL (the default), then all leaf nodes (or all nodes, when SizeLeafNodesOnly is false) will be assigned a unit size.

36.28 vtkDataObjectToTable

36.28.1 Usage

This filter is used to extract either the field, cell or point data of any data object as a table.

To create an instance of class vtkDataObjectToTable, simply invoke its constructor as follows

```
obj = vtkDataObjectToTable
```

36.28.2 Methods

The class vtkDataObjectToTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectToTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectToTable = obj.NewInstance ()`
- `vtkDataObjectToTable = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetFieldType ()` - The field type to copy into the output table. Should be one of FIELD_DATA, POINT_DATA, CELL_DATA, VERTEX_DATA, EDGE_DATA.
- `obj.SetFieldType (int )` - The field type to copy into the output table. Should be one of FIELD_DATA, POINT_DATA, CELL_DATA, VERTEX_DATA, EDGE_DATA.
- `int = obj.GetFieldTypeMinValue ()` - The field type to copy into the output table. Should be one of FIELD_DATA, POINT_DATA, CELL_DATA, VERTEX_DATA, EDGE_DATA.
- `int = obj.GetFieldTypeMaxValue ()` - The field type to copy into the output table. Should be one of FIELD_DATA, POINT_DATA, CELL_DATA, VERTEX_DATA, EDGE_DATA.

36.29 vtkDelimitedTextReader

36.29.1 Usage

vtkDelimitedTextReader is an interface for pulling in data from a flat, delimited ascii or unicode text file (delimiter can be any character).

The behavior of the reader with respect to ascii or unicode input is controlled by the SetUnicodeCharacterSet() method. By default (without calling SetUnicodeCharacterSet()), the reader will expect to read

ascii text and will output vtkStdString columns. Use the Set and Get methods to set delimiters that do not contain UTF8 in the name when operating the reader in default ascii mode. If the SetUnicodeCharacterSet() method is called, the reader will output vtkUnicodeString columns in the output table. In addition, it is necessary to use the Set and Get methods that contain UTF8 in the name to specify delimiters when operating in unicode mode.

This class emits ProgressEvent for every 100 lines it reads.

.SECTION Thanks Thanks to Andy Wilson, Brian Wylie, Tim Shead, and Thomas Otahal from Sandia National Laboratories for implementing this class.

To create an instance of class vtkDelimitedTextReader, simply invoke its constructor as follows

```
obj = vtkDelimitedTextReader
```

36.29.2 Methods

The class vtkDelimitedTextReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDelimitedTextReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDelimitedTextReader = obj.NewInstance ()`
- `vtkDelimitedTextReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()`
- `obj.SetFileName (string )`
- `string = obj.GetUnicodeCharacterSet ()` - Specifies the character set used in the input file. Valid character set names will be drawn from the list maintained by the Internet Assigned Name Authority at

  http://www.iana.org/assignments/character-sets

  Where multiple aliases are provided for a character set, the preferred MIME name will be used. vtkUnicodeDelimitedTextReader currently supports "US-ASCII", "UTF-8", "UTF-16", "UTF-16BE", and "UTF-16LE" character sets.

- `obj.SetUnicodeCharacterSet (string )` - Specifies the character set used in the input file. Valid character set names will be drawn from the list maintained by the Internet Assigned Name Authority at

  http://www.iana.org/assignments/character-sets

  Where multiple aliases are provided for a character set, the preferred MIME name will be used. vtkUnicodeDelimitedTextReader currently supports "US-ASCII", "UTF-8", "UTF-16", "UTF-16BE", and "UTF-16LE" character sets.

- `obj.SetUTF8RecordDelimiters (string delimiters)` - Specify the character(s) that will be used to separate records. The order of characters in the string does not matter. Defaults to " ◦
  n".

- `string = obj.GetUTF8RecordDelimiters ()` - Specify the character(s) that will be used to separate records. The order of characters in the string does not matter. Defaults to " ◦
  n".

- `obj.SetFieldDelimiterCharacters (string )` - Specify the character(s) that will be used to separate fields. For example, set this to "," for a comma-separated value file. Set it to ".:;" for a file where columns can be separated by a period, colon or semicolon. The order of the characters in the string does not matter. Defaults to a comma.
- `string = obj.GetFieldDelimiterCharacters ()` - Specify the character(s) that will be used to separate fields. For example, set this to "," for a comma-separated value file. Set it to ".:;" for a file where columns can be separated by a period, colon or semicolon. The order of the characters in the string does not matter. Defaults to a comma.
- `obj.SetUTF8FieldDelimiters (string delimiters)`
- `string = obj.GetUTF8FieldDelimiters ()`
- `char = obj.GetStringDelimiter ()` - Get/set the character that will begin and end strings. Microsoft Excel, for example, will export the following format:

  "First Field","Second Field","Field, With, Commas","Fourth Field"

  The third field has a comma in it. By using a string delimiter, this will be correctly read. The delimiter defaults to "".
- `obj.SetStringDelimiter (char )` - Get/set the character that will begin and end strings. Microsoft Excel, for example, will export the following format:

  "First Field","Second Field","Field, With, Commas","Fourth Field"

  The third field has a comma in it. By using a string delimiter, this will be correctly read. The delimiter defaults to "".
- `obj.SetUTF8StringDelimiters (string delimiters)`
- `string = obj.GetUTF8StringDelimiters ()`
- `obj.SetUseStringDelimiter (bool )` - Set/get whether to use the string delimiter. Defaults to on.
- `bool = obj.GetUseStringDelimiter ()` - Set/get whether to use the string delimiter. Defaults to on.
- `obj.UseStringDelimiterOn ()` - Set/get whether to use the string delimiter. Defaults to on.
- `obj.UseStringDelimiterOff ()` - Set/get whether to use the string delimiter. Defaults to on.
- `bool = obj.GetHaveHeaders ()` - Set/get whether to treat the first line of the file as headers.
- `obj.SetHaveHeaders (bool )` - Set/get whether to treat the first line of the file as headers.
- `obj.SetMergeConsecutiveDelimiters (bool )` - Set/get whether to merge successive delimiters. Use this if (for example) your fields are separated by spaces but you don't know exactly how many.
- `bool = obj.GetMergeConsecutiveDelimiters ()` - Set/get whether to merge successive delimiters. Use this if (for example) your fields are separated by spaces but you don't know exactly how many.
- `obj.MergeConsecutiveDelimitersOn ()` - Set/get whether to merge successive delimiters. Use this if (for example) your fields are separated by spaces but you don't know exactly how many.
- `obj.MergeConsecutiveDelimitersOff ()` - Set/get whether to merge successive delimiters. Use this if (for example) your fields are separated by spaces but you don't know exactly how many.
- `vtkIdType = obj.GetMaxRecords ()` - Specifies the maximum number of records to read from the file. Limiting the number of records to read is useful for previewing the contents of a file.
- `obj.SetMaxRecords (vtkIdType )` - Specifies the maximum number of records to read from the file. Limiting the number of records to read is useful for previewing the contents of a file.

- `obj.SetDetectNumericColumns (bool )` - When set to true, the reader will detect numeric columns and create vtkDoubleArray or vtkIntArray for those instead of vtkStringArray. Default is off.
- `bool = obj.GetDetectNumericColumns ()` - When set to true, the reader will detect numeric columns and create vtkDoubleArray or vtkIntArray for those instead of vtkStringArray. Default is off.
- `obj.DetectNumericColumnsOn ()` - When set to true, the reader will detect numeric columns and create vtkDoubleArray or vtkIntArray for those instead of vtkStringArray. Default is off.
- `obj.DetectNumericColumnsOff ()` - When set to true, the reader will detect numeric columns and create vtkDoubleArray or vtkIntArray for those instead of vtkStringArray. Default is off.
- `obj.SetPedigreeIdArrayName (string )` - The name of the array for generating or assigning pedigree ids (default "id").
- `string = obj.GetPedigreeIdArrayName ()` - The name of the array for generating or assigning pedigree ids (default "id").
- `obj.SetGeneratePedigreeIds (bool )` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `bool = obj.GetGeneratePedigreeIds ()` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `obj.GeneratePedigreeIdsOn ()` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `obj.GeneratePedigreeIdsOff ()` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `obj.SetOutputPedigreeIds (bool )` - If on, assigns pedigree ids to output. Defaults to off.
- `bool = obj.GetOutputPedigreeIds ()` - If on, assigns pedigree ids to output. Defaults to off.
- `obj.OutputPedigreeIdsOn ()` - If on, assigns pedigree ids to output. Defaults to off.
- `obj.OutputPedigreeIdsOff ()` - If on, assigns pedigree ids to output. Defaults to off.
- `vtkStdString = obj.GetLastError ()` - Returns a human-readable description of the most recent error, if any. Otherwise, returns an empty string. Note that the result is only valid after calling Update().

36.30 vtkDescriptiveStatistics

36.30.1 Usage

Given a selection of columns of interest in an input data table, this class provides the following functionalities, depending on the execution mode it is executed in: * Learn: calculate extremal values, arithmetic mean, unbiased variance estimator, skewness estimator, and both sample and G2 estimation of the kurtosis excess. More precisely, Learn calculates the sums; if finalize is set to true (default), the final statistics are calculated with CalculateFromSums. Otherwise, only raw sums are output; this option is made for efficient parallel calculations. Note that CalculateFromSums is a static function, so that it can be used directly with no need to instantiate a vtkDescriptiveStatistics object. * Assess: given an input data set in port INPUT_DATA, and a reference value x along with an acceptable deviation d¿0, assess all entries in the data set which are outside of [x-d,x+d].

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkDescriptiveStatistics, simply invoke its constructor as follows

```
obj = vtkDescriptiveStatistics
```

36.30.2 Methods

The class vtkDescriptiveStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDescriptiveStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDescriptiveStatistics = obj.NewInstance ()`
- `vtkDescriptiveStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetUnbiasedVariance (int )` - Set/get whether the unbiased estimator for the variance should be used, or if the population variance will be calculated. The default is that the unbiased estimator will be used.
- `int = obj.GetUnbiasedVariance ()` - Set/get whether the unbiased estimator for the variance should be used, or if the population variance will be calculated. The default is that the unbiased estimator will be used.
- `obj.UnbiasedVarianceOn ()` - Set/get whether the unbiased estimator for the variance should be used, or if the population variance will be calculated. The default is that the unbiased estimator will be used.
- `obj.UnbiasedVarianceOff ()` - Set/get whether the unbiased estimator for the variance should be used, or if the population variance will be calculated. The default is that the unbiased estimator will be used.
- `obj.SetSignedDeviations (int )` - Set/get whether the deviations returned should be signed, or should only have their magnitude reported. The default is that signed deviations will be computed.
- `int = obj.GetSignedDeviations ()` - Set/get whether the deviations returned should be signed, or should only have their magnitude reported. The default is that signed deviations will be computed.
- `obj.SignedDeviationsOn ()` - Set/get whether the deviations returned should be signed, or should only have their magnitude reported. The default is that signed deviations will be computed.
- `obj.SignedDeviationsOff ()` - Set/get whether the deviations returned should be signed, or should only have their magnitude reported. The default is that signed deviations will be computed.
- `obj.SetNominalParameter (string name)` - A convenience method (in particular for UI wrapping) to set the name of the column that contains the nominal value for the Assess option.
- `obj.SetDeviationParameter (string name)` - A convenience method (in particular for UI wrapping) to set the name of the column that contains the deviation for the Assess option.
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model

36.31 vtkDotProductSimilarity

36.31.1 Usage

Treats matrices as collections of vectors and computes dot-product similarity metrics between vectors.

The results are returned as an edge-table that lists the index of each vector and their computed similarity. The output edge-table is typically used with vtkTableToGraph to create a similarity graph.

This filter can be used with one or two input matrices. If you provide a single matrix as input, every vector in the matrix is compared with every other vector. If you provide two matrices, every vector in the first matrix is compared with every vector in the second matrix.

Note that this filter *only* computes the dot-product between each pair of vectors; if you want to compute the cosine of the angles between vectors, you will need to normalize the inputs yourself.

Inputs: Input port 0: (required) A vtkDenseArray¡double¿ with two dimensions (a matrix). Input port 1: (optional) A vtkDenseArray¡double¿ with two dimensions (a matrix).

Outputs: Output port 0: A vtkTable containing "source", "target", and "similarity" columns.

To create an instance of class vtkDotProductSimilarity, simply invoke its constructor as follows

```
obj = vtkDotProductSimilarity
```

36.31.2 Methods

The class vtkDotProductSimilarity has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDotProductSimilarity class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDotProductSimilarity = obj.NewInstance ()`
- `vtkDotProductSimilarity = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetVectorDimension ()` - Controls whether to compute similarities for row-vectors or column-vectors. 0 = rows, 1 = columns.
- `obj.SetVectorDimension (vtkIdType )` - Controls whether to compute similarities for row-vectors or column-vectors. 0 = rows, 1 = columns.
- `int = obj.GetUpperDiagonal ()` - When computing similarities for a single input matrix, controls whether the results will include the upper diagonal of the similarity matrix. Default: true.
- `obj.SetUpperDiagonal (int )` - When computing similarities for a single input matrix, controls whether the results will include the upper diagonal of the similarity matrix. Default: true.
- `int = obj.GetDiagonal ()` - When computing similarities for a single input matrix, controls whether the results will include the diagonal of the similarity matrix. Default: false.
- `obj.SetDiagonal (int )` - When computing similarities for a single input matrix, controls whether the results will include the diagonal of the similarity matrix. Default: false.
- `int = obj.GetLowerDiagonal ()` - When computing similarities for a single input matrix, controls whether the results will include the lower diagonal of the similarity matrix. Default: false.
- `obj.SetLowerDiagonal (int )` - When computing similarities for a single input matrix, controls whether the results will include the lower diagonal of the similarity matrix. Default: false.
- `int = obj.GetFirstSecond ()` - When computing similarities for two input matrices, controls whether the results will include comparisons from the first matrix to the second matrix.
- `obj.SetFirstSecond (int )` - When computing similarities for two input matrices, controls whether the results will include comparisons from the first matrix to the second matrix.
- `int = obj.GetSecondFirst ()` - When computing similarities for two input matrices, controls whether the results will include comparisons from the second matrix to the first matrix.

- `obj.SetSecondFirst (int )` - When computing similarities for two input matrices, controls whether the results will include comparisons from the second matrix to the first matrix.
- `double = obj.GetMinimumThreshold ()` - Specifies a minimum threshold that a similarity must exceed to be included in the output.
- `obj.SetMinimumThreshold (double )` - Specifies a minimum threshold that a similarity must exceed to be included in the output.
- `vtkIdType = obj.GetMinimumCount ()` - Specifies a minimum number of edges to include for each vector.
- `obj.SetMinimumCount (vtkIdType )` - Specifies a minimum number of edges to include for each vector.
- `vtkIdType = obj.GetMaximumCount ()` - Specifies a maximum number of edges to include for each vector.
- `obj.SetMaximumCount (vtkIdType )` - Specifies a maximum number of edges to include for each vector.

36.32 vtkEdgeCenters

36.32.1 Usage

vtkEdgeCenters is a filter that takes as input any graph and generates on output points at the center of the cells in the dataset. These points can be used for placing glyphs (vtkGlyph3D) or labeling (vtkLabeledDataMapper). (The center is the parametric center of the cell, not necessarily the geometric or bounding box center.) The edge attributes will be associated with the points on output.

To create an instance of class vtkEdgeCenters, simply invoke its constructor as follows

```
obj = vtkEdgeCenters
```

36.32.2 Methods

The class vtkEdgeCenters has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgeCenters class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgeCenters = obj.NewInstance ()`
- `vtkEdgeCenters = obj.SafeDownCast (vtkObject o)`
- `obj.SetVertexCells (int )` - Enable/disable the generation of vertex cells.
- `int = obj.GetVertexCells ()` - Enable/disable the generation of vertex cells.
- `obj.VertexCellsOn ()` - Enable/disable the generation of vertex cells.
- `obj.VertexCellsOff ()` - Enable/disable the generation of vertex cells.

36.33 vtkEdgeLayout

36.33.1 Usage

This class is a shell for many edge layout strategies which may be set using the SetLayoutStrategy() function. The layout strategies do the actual work.

To create an instance of class vtkEdgeLayout, simply invoke its constructor as follows

```
obj = vtkEdgeLayout
```

36.33.2 Methods

The class vtkEdgeLayout has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgeLayout class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgeLayout = obj.NewInstance ()`
- `vtkEdgeLayout = obj.SafeDownCast (vtkObject o)`
- `obj.SetLayoutStrategy (vtkEdgeLayoutStrategy strategy)` - The layout strategy to use during graph layout.
- `vtkEdgeLayoutStrategy = obj.GetLayoutStrategy ()` - The layout strategy to use during graph layout.
- `long = obj.GetMTime ()` - Get the modification time of the layout algorithm.

36.34 vtkEdgeLayoutStrategy

36.34.1 Usage

All edge layouts should subclass from this class. vtkEdgeLayoutStrategy works as a plug-in to the vtkEdgeLayout algorithm.

To create an instance of class vtkEdgeLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkEdgeLayoutStrategy
```

36.34.2 Methods

The class vtkEdgeLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgeLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgeLayoutStrategy = obj.NewInstance ()`
- `vtkEdgeLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraph (vtkGraph graph)` - Setting the graph for the layout strategy

- `obj.Initialize ()` - This method allows the layout strategy to do initialization of data structures or whatever else it might want to do.
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out.
- `obj.SetEdgeWeightArrayName (string )` - Set/Get the field to use for the edge weights.
- `string = obj.GetEdgeWeightArrayName ()` - Set/Get the field to use for the edge weights.

36.35 vtkExpandSelectedGraph

36.35.1 Usage

The first input is a vtkSelection containing the selected vertices. The second input is a vtkGraph. This filter 'grows' the selection set in one of the following ways 1) SetBFSDistance controls how many 'hops' the selection is grown from each seed point in the selection set (defaults to 1) 2) IncludeShortestPaths controls whether this filter tries to 'connect' the vertices in the selection set by computing the shortest path between the vertices (if such a path exists) Note: IncludeShortestPaths is currently non-functional

To create an instance of class vtkExpandSelectedGraph, simply invoke its constructor as follows

```
obj = vtkExpandSelectedGraph
```

36.35.2 Methods

The class vtkExpandSelectedGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExpandSelectedGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExpandSelectedGraph = obj.NewInstance ()`
- `vtkExpandSelectedGraph = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraphConnection (vtkAlgorithmOutput in)` - A convenience method for setting the second input (i.e. the graph).
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Specify the first vtkSelection input and the second vtkGraph input.
- `obj.SetBFSDistance (int )` - Set/Get BFSDistance which controls how many 'hops' the selection is grown from each seed point in the selection set (defaults to 1)
- `int = obj.GetBFSDistance ()` - Set/Get BFSDistance which controls how many 'hops' the selection is grown from each seed point in the selection set (defaults to 1)
- `obj.SetIncludeShortestPaths (bool )` - Set/Get IncludeShortestPaths controls whether this filter tries to 'connect' the vertices in the selection set by computing the shortest path between the vertices (if such a path exists) Note: IncludeShortestPaths is currently non-functional
- `bool = obj.GetIncludeShortestPaths ()` - Set/Get IncludeShortestPaths controls whether this filter tries to 'connect' the vertices in the selection set by computing the shortest path between the vertices (if such a path exists) Note: IncludeShortestPaths is currently non-functional
- `obj.IncludeShortestPathsOn ()` - Set/Get IncludeShortestPaths controls whether this filter tries to 'connect' the vertices in the selection set by computing the shortest path between the vertices (if such a path exists) Note: IncludeShortestPaths is currently non-functional

- `obj.IncludeShortestPathsOff ()` - Set/Get IncludeShortestPaths controls whether this filter tries to 'connect' the vertices in the selection set by computing the shortest path between the vertices (if such a path exists) Note: IncludeShortestPaths is currently non-functional
- `obj.SetDomain (string )` - Set/Get the vertex domain to use in the expansion.
- `string = obj.GetDomain ()` - Set/Get the vertex domain to use in the expansion.
- `obj.SetUseDomain (bool )` - Whether or not to use the domain when deciding to add a vertex to the expansion. Defaults to false.
- `bool = obj.GetUseDomain ()` - Whether or not to use the domain when deciding to add a vertex to the expansion. Defaults to false.
- `obj.UseDomainOn ()` - Whether or not to use the domain when deciding to add a vertex to the expansion. Defaults to false.
- `obj.UseDomainOff ()` - Whether or not to use the domain when deciding to add a vertex to the expansion. Defaults to false.

36.36 vtkExtractHistogram2D

36.36.1 Usage

This class computes a 2D histogram between two columns of an input vtkTable. Just as with a 1D histogram, a 2D histogram breaks up the input domain into bins, and each pair of values (row in the table) fits into a single bin and increments a row counter for that bin.

To use this class, set the input with a table and call AddColumnPair(nameX,nameY), where nameX and nameY are the names of the two columns to be used.

In addition to the number of bins (in X and Y), the domain of the histogram can be customized by toggling the UseCustomHistogramExtents flag and setting the CustomHistogramExtents variable to the desired value.

To create an instance of class vtkExtractHistogram2D, simply invoke its constructor as follows

```
obj = vtkExtractHistogram2D
```

36.36.2 Methods

The class vtkExtractHistogram2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractHistogram2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractHistogram2D = obj.NewInstance ()`
- `vtkExtractHistogram2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfBins (int , int )` - Set/get the number of bins to be used per dimension (x,y)
- `obj.SetNumberOfBins (int  a[2])` - Set/get the number of bins to be used per dimension (x,y)
- `int = obj. GetNumberOfBins ()` - Set/get the number of bins to be used per dimension (x,y)
- `obj.SetComponentsToProcess (int , int )` - Set/get the components of the arrays in the two input columns to be used during histogram computation. Defaults to component 0.

- `obj.SetComponentsToProcess (int a[2])` - Set/get the components of the arrays in the two input columns to be used during histogram computation. Defaults to component 0.
- `int = obj. GetComponentsToProcess ()` - Set/get the components of the arrays in the two input columns to be used during histogram computation. Defaults to component 0.
- `obj.SetCustomHistogramExtents (double , double , double , double )` - Set/get a custom domain for histogram computation. UseCustomHistogramExtents must be called for these to actually be used.
- `obj.SetCustomHistogramExtents (double a[4])` - Set/get a custom domain for histogram computation. UseCustomHistogramExtents must be called for these to actually be used.
- `double = obj. GetCustomHistogramExtents ()` - Set/get a custom domain for histogram computation. UseCustomHistogramExtents must be called for these to actually be used.
- `obj.SetUseCustomHistogramExtents (int )` - Use the extents in CustomHistogramExtents when computing the histogram, rather than the simple range of the input columns.
- `int = obj.GetUseCustomHistogramExtents ()` - Use the extents in CustomHistogramExtents when computing the histogram, rather than the simple range of the input columns.
- `obj.UseCustomHistogramExtentsOn ()` - Use the extents in CustomHistogramExtents when computing the histogram, rather than the simple range of the input columns.
- `obj.UseCustomHistogramExtentsOff ()` - Use the extents in CustomHistogramExtents when computing the histogram, rather than the simple range of the input columns.
- `obj.SetScalarType (int )` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `obj.SetScalarTypeToUnsignedInt ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `obj.SetScalarTypeToUnsignedLong ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `obj.SetScalarTypeToUnsignedShort ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `obj.SetScalarTypeToUnsignedChar ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `obj.SetScalarTypeToFloat ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `obj.SetScalarTypeToDouble ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `int = obj.GetScalarType ()` - Control the scalar type of the output histogram. If the input is relatively small, you can save space by using a smaller data type. Defaults to unsigned integer.
- `double = obj.GetMaximumBinCount ()` - Access the count of the histogram bin containing the largest number of input rows.
- `int = obj.GetBinRange (vtkIdType binX, vtkIdType binY, double range[4])` - Compute the range of the bin located at position (binX,binY) in the 2D histogram.
- `int = obj.GetBinRange (vtkIdType bin, double range[4])` - Get the range of the of the bin located at 1D position index bin in the 2D histogram array.

- `obj.GetBinWidth (double bw[2])` - Get the width of all of the bins. Also stored in the spacing ivar of the histogram image output.
- `vtkImageData = obj.GetOutputHistogramImage ()` - Gets the data object at the histogram image output port and casts it to a vtkImageData.
- `obj.SetSwapColumns (int )`
- `int = obj.GetSwapColumns ()`
- `obj.SwapColumnsOn ()`
- `obj.SwapColumnsOff ()`
- `obj.SetRowMask (vtkDataArray )` - Get/Set an optional mask that can ignore rows of the table
- `vtkDataArray = obj.GetRowMask ()` - Get/Set an optional mask that can ignore rows of the table
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model. Not used.

36.37 vtkExtractSelectedGraph

36.37.1 Usage

The first input is a vtkGraph to take a subgraph from. The second input (optional) is a vtkSelection containing selected indices. The third input (optional) is a vtkAnnotationsLayers whose annotations contain selected specifying selected indices. The vtkSelection may have FIELD_TYPE set to POINTS (a vertex selection) or CELLS (an edge selection). A vertex selection preserves all edges that connect selected vertices. An edge selection preserves all vertices that are adjacent to at least one selected edge. Alternately, you may indicate that an edge selection should maintain the full set of vertices, by turning RemoveIsolatedVertices off.

To create an instance of class vtkExtractSelectedGraph, simply invoke its constructor as follows

```
