obj = vtkExtractSelectedGraph
```

36.37.2 Methods

The class vtkExtractSelectedGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractSelectedGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractSelectedGraph = obj.NewInstance ()`
- `vtkExtractSelectedGraph = obj.SafeDownCast (vtkObject o)`
- `obj.SetSelectionConnection (vtkAlgorithmOutput in)` - A convenience method for setting the second input (i.e. the selection).
- `obj.SetAnnotationLayersConnection (vtkAlgorithmOutput in)` - A convenience method for setting the third input (i.e. the annotation layers).
- `obj.SetRemoveIsolatedVertices (bool )` - If set, removes vertices with no adjacent edges in an edge selection. A vertex selection ignores this flag and always returns the full set of selected vertices. Default is on.

- `bool = obj.GetRemoveIsolatedVertices ()` - If set, removes vertices with no adjacent edges in an edge selection. A vertex selection ignores this flag and always returns the full set of selected vertices. Default is on.
- `obj.RemoveIsolatedVerticesOn ()` - If set, removes vertices with no adjacent edges in an edge selection. A vertex selection ignores this flag and always returns the full set of selected vertices. Default is on.
- `obj.RemoveIsolatedVerticesOff ()` - If set, removes vertices with no adjacent edges in an edge selection. A vertex selection ignores this flag and always returns the full set of selected vertices. Default is on.
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Specify the first vtkGraph input and the second vtkSelection input.

36.38 vtkFast2DLayoutStrategy

36.38.1 Usage

This class is a density grid based force directed layout strategy. Also please note that 'fast' is relative to quite slow. :) The layout running time is O(V+E) with an extremely high constant. .SECTION Thanks Thanks to Godzilla for not eating my computer so that this class could be written.

To create an instance of class vtkFast2DLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkFast2DLayoutStrategy
```

36.38.2 Methods

The class vtkFast2DLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFast2DLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFast2DLayoutStrategy = obj.NewInstance ()`
- `vtkFast2DLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `obj.SetInitialTemperature (float )` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperature ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)

- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)

- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetRestDistance (float )` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `float = obj.GetRestDistance ()` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()`

36.39 vtkFixedWidthTextReader

36.39.1 Usage

vtkFixedWidthTextReader reads in a table from a text file where each column occupies a certain number of characters.

This class emits ProgressEvent for every 100 lines it reads.

To create an instance of class vtkFixedWidthTextReader, simply invoke its constructor as follows

```
obj = vtkFixedWidthTextReader
```

36.39.2 Methods

The class vtkFixedWidthTextReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedWidthTextReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedWidthTextReader = obj.NewInstance ()`
- `vtkFixedWidthTextReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()`
- `obj.SetFileName (string )`
- `obj.SetFieldWidth (int )` - Set/get the field width
- `int = obj.GetFieldWidth ()` - Set/get the field width

- `obj.SetStripWhiteSpace (bool )` - If set, this flag will cause the reader to strip whitespace from the beginning and ending of each field. Defaults to off.
- `bool = obj.GetStripWhiteSpace ()` - If set, this flag will cause the reader to strip whitespace from the beginning and ending of each field. Defaults to off.
- `obj.StripWhiteSpaceOn ()` - If set, this flag will cause the reader to strip whitespace from the beginning and ending of each field. Defaults to off.
- `obj.StripWhiteSpaceOff ()` - If set, this flag will cause the reader to strip whitespace from the beginning and ending of each field. Defaults to off.
- `bool = obj.GetHaveHeaders ()` - Set/get whether to treat the first line of the file as headers.
- `obj.SetHaveHeaders (bool )` - Set/get whether to treat the first line of the file as headers.
- `obj.HaveHeadersOn ()` - Set/get whether to treat the first line of the file as headers.
- `obj.HaveHeadersOff ()` - Set/get whether to treat the first line of the file as headers.

36.40 vtkForceDirectedLayoutStrategy

36.40.1 Usage

Lays out a graph in 2D or 3D using a force-directed algorithm. The user may specify whether to layout the graph randomly initially, the bounds, the number of dimensions (2 or 3), and the cool-down rate.

.SECTION Thanks Thanks to Brian Wylie for adding functionality for allowing this layout to be incremental.

To create an instance of class vtkForceDirectedLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkForceDirectedLayoutStrategy
```

36.40.2 Methods

The class vtkForceDirectedLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkForceDirectedLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkForceDirectedLayoutStrategy = obj.NewInstance ()`
- `vtkForceDirectedLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.

- `obj.SetGraphBounds (double , double , double , double , double , double )` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `obj.SetGraphBounds (double a[6])` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `double = obj. GetGraphBounds ()` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `obj.SetAutomaticBoundsComputation (int )` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `int = obj.GetAutomaticBoundsComputation ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.AutomaticBoundsComputationOn ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.AutomaticBoundsComputationOff ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '50' for no particular reason
- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '50' for no particular reason
- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '50' for no particular reason
- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '50' for no particular reason
- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '50' to match the default 'MaxNumberOfIterations'
- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '50' to match the default 'MaxNumberOfIterations'
- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '50' to match the default 'MaxNumberOfIterations'
- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '50' to match the default 'MaxNumberOfIterations'
- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.

- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.

- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.

- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified.

- `obj.SetThreeDimensionalLayout (int )` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is off.

- `int = obj.GetThreeDimensionalLayout ()` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is off.

- `obj.ThreeDimensionalLayoutOn ()` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is off.

- `obj.ThreeDimensionalLayoutOff ()` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is off.

- `obj.SetRandomInitialPoints (int )` - Turn on/off use of random positions within the graph bounds as initial points.

- `int = obj.GetRandomInitialPoints ()` - Turn on/off use of random positions within the graph bounds as initial points.

- `obj.RandomInitialPointsOn ()` - Turn on/off use of random positions within the graph bounds as initial points.

- `obj.RandomInitialPointsOff ()` - Turn on/off use of random positions within the graph bounds as initial points.

- `obj.SetInitialTemperature (float )` - Set the initial temperature. If zero (the default) , the initial temperature will be computed automatically.

- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. If zero (the default) , the initial temperature will be computed automatically.

- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. If zero (the default) , the initial temperature will be computed automatically.

- `float = obj.GetInitialTemperature ()` - Set the initial temperature. If zero (the default) , the initial temperature will be computed automatically.

- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call

- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.

- `int = obj.IsLayoutComplete ()`

36.41 vtkGenerateIndexArray

36.41.1 Usage

Generates a new vtkIdTypeArray containing zero-base indices.

vtkGenerateIndexArray operates in one of two distinct "modes". By default, it simply generates an index array containing monotonically-increasing integers in the range [0, N), where N is appropriately sized for the field type that will store the results. This mode is useful for generating a unique ID field for datasets that have none.

The second "mode" uses an existing array from the input data object as a "reference". Distinct values from the reference array are sorted in ascending order, and an integer index in the range [0, N) is assigned to each. The resulting map is used to populate the output index array, mapping each value in the reference array to its corresponding index and storing the result in the output array. This mode is especially useful when generating tensors, since it allows us to "map" from an array with arbitrary contents to an index that can be used as tensor coordinates.

To create an instance of class vtkGenerateIndexArray, simply invoke its constructor as follows

```
obj = vtkGenerateIndexArray
```

36.41.2 Methods

The class vtkGenerateIndexArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenerateIndexArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenerateIndexArray = obj.NewInstance ()`
- `vtkGenerateIndexArray = obj.SafeDownCast (vtkObject o)`
- `obj.SetArrayName (string )` - Control the output index array name. Default: "index".
- `string = obj.GetArrayName ()` - Control the output index array name. Default: "index".
- `obj.SetFieldType (int )` - Control the location where the index array will be stored.
- `int = obj.GetFieldType ()` - Control the location where the index array will be stored.
- `obj.SetReferenceArrayName (string )` - Specifies an optional reference array for index-generation.
- `string = obj.GetReferenceArrayName ()` - Specifies an optional reference array for index-generation.
- `obj.SetPedigreeID (int )` - Specifies whether the index array should be marked as pedigree ids. Default: false.
- `int = obj.GetPedigreeID ()` - Specifies whether the index array should be marked as pedigree ids. Default: false.

36.42 vtkGeoEdgeStrategy

36.42.1 Usage

vtkGeoEdgeStrategy produces arcs for each edge in the input graph. This is useful for viewing lines on a sphere (e.g. the earth). The arcs may "jump" above the sphere's surface using ExplodeFactor.

To create an instance of class vtkGeoEdgeStrategy, simply invoke its constructor as follows

```
obj = vtkGeoEdgeStrategy
```

36.42.2 Methods

The class vtkGeoEdgeStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoEdgeStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoEdgeStrategy = obj.NewInstance ()`
- `vtkGeoEdgeStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetGlobeRadius (double )` - The base radius used to determine the earth's surface. Default is the earth's radius in meters. TODO: Change this to take in a vtkGeoTerrain to get altitude.
- `double = obj.GetGlobeRadius ()` - The base radius used to determine the earth's surface. Default is the earth's radius in meters. TODO: Change this to take in a vtkGeoTerrain to get altitude.
- `obj.SetExplodeFactor (double )` - Factor on which to "explode" the arcs away from the surface. A value of 0.0 keeps the values on the surface. Values larger than 0.0 push the arcs away from the surface by a distance proportional to the distance between the points. The default is 0.2.
- `double = obj.GetExplodeFactor ()` - Factor on which to "explode" the arcs away from the surface. A value of 0.0 keeps the values on the surface. Values larger than 0.0 push the arcs away from the surface by a distance proportional to the distance between the points. The default is 0.2.
- `obj.SetNumberOfSubdivisions (int )` - The number of subdivisions in the arc. The default is 20.
- `int = obj.GetNumberOfSubdivisions ()` - The number of subdivisions in the arc. The default is 20.
- `obj.Layout ()` - Perform the layout.

36.43 vtkGeoMath

36.43.1 Usage

vtkGeoMath provides some useful geographic calculations.

To create an instance of class vtkGeoMath, simply invoke its constructor as follows

```
obj = vtkGeoMath
```

36.43.2 Methods

The class vtkGeoMath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoMath class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoMath = obj.NewInstance ()`
- `vtkGeoMath = obj.SafeDownCast (vtkObject o)`

36.44 vtkGraphHierarchicalBundle

36.44.1 Usage

This algorithm creates a vtkPolyData from a vtkGraph. As opposed to vtkGraphToPolyData, which converts each arc into a straight line, each arc is converted to a polyline, following a tree structure. The filter requires both a vtkGraph and vtkTree as input. The tree vertices must be a superset of the graph vertices. A common example is when the graph vertices correspond to the leaves of the tree, but the internal vertices of the tree represent groupings of graph vertices. The algorithm matches the vertices using the array "PedigreeId". The user may alternately set the DirectMapping flag to indicate that the two structures must have directly corresponding offsets (i.e. node i in the graph must correspond to node i in the tree).

The vtkGraph defines the topology of the output vtkPolyData (i.e. the connections between nodes) while the vtkTree defines the geometry (i.e. the location of nodes and arc routes). Thus, the tree must have been assigned vertex locations, but the graph does not need locations, in fact they will be ignored. The edges approximately follow the path from the source to target nodes in the tree. A bundling parameter controls how closely the edges are bundled together along the tree structure.

You may follow this algorithm with vtkSplineFilter in order to make nicely curved edges.

To create an instance of class vtkGraphHierarchicalBundle, simply invoke its constructor as follows

```
obj = vtkGraphHierarchicalBundle
```

36.44.2 Methods

The class vtkGraphHierarchicalBundle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphHierarchicalBundle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphHierarchicalBundle = obj.NewInstance ()`
- `vtkGraphHierarchicalBundle = obj.SafeDownCast (vtkObject o)`
- `obj.SetBundlingStrength (double )` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `double = obj.GetBundlingStrengthMinValue ()` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `double = obj.GetBundlingStrengthMaxValue ()` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `double = obj.GetBundlingStrength ()` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `obj.SetDirectMapping (bool )` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `bool = obj.GetDirectMapping ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.

- `obj.DirectMappingOn ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `obj.DirectMappingOff ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Set the input type of the algorithm to vtkGraph.

36.45 vtkGraphHierarchicalBundleEdges

36.45.1 Usage

This algorithm creates a vtkPolyData from a vtkGraph. As opposed to vtkGraphToPolyData, which converts each arc into a straight line, each arc is converted to a polyline, following a tree structure. The filter requires both a vtkGraph and vtkTree as input. The tree vertices must be a superset of the graph vertices. A common example is when the graph vertices correspond to the leaves of the tree, but the internal vertices of the tree represent groupings of graph vertices. The algorithm matches the vertices using the array "PedigreeId". The user may alternately set the DirectMapping flag to indicate that the two structures must have directly corresponding offsets (i.e. node i in the graph must correspond to node i in the tree).

The vtkGraph defines the topology of the output vtkPolyData (i.e. the connections between nodes) while the vtkTree defines the geometry (i.e. the location of nodes and arc routes). Thus, the tree must have been assigned vertex locations, but the graph does not need locations, in fact they will be ignored. The edges approximately follow the path from the source to target nodes in the tree. A bundling parameter controls how closely the edges are bundled together along the tree structure.

You may follow this algorithm with vtkSplineFilter in order to make nicely curved edges.

To create an instance of class vtkGraphHierarchicalBundleEdges, simply invoke its constructor as follows

```
obj = vtkGraphHierarchicalBundleEdges
```

36.45.2 Methods

The class vtkGraphHierarchicalBundleEdges has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphHierarchicalBundleEdges class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphHierarchicalBundleEdges = obj.NewInstance ()`
- `vtkGraphHierarchicalBundleEdges = obj.SafeDownCast (vtkObject o)`
- `obj.SetBundlingStrength (double )` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `double = obj.GetBundlingStrengthMinValue ()` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `double = obj.GetBundlingStrengthMaxValue ()` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.

- `double = obj.GetBundlingStrength ()` - The level of arc bundling in the graph. A strength of 0 creates straight lines, while a strength of 1 forces arcs to pass directly through hierarchy node points. The default value is 0.8.
- `obj.SetDirectMapping (bool )` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `bool = obj.GetDirectMapping ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `obj.DirectMappingOn ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `obj.DirectMappingOff ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Set the input type of the algorithm to vtkGraph.

36.46 vtkGraphLayout

36.46.1 Usage

This class is a shell for many graph layout strategies which may be set using the SetLayoutStrategy() function. The layout strategies do the actual work.

.SECION Thanks Thanks to Brian Wylie from Sandia National Laboratories for adding incremental layout capabilities.

To create an instance of class vtkGraphLayout, simply invoke its constructor as follows

```
obj = vtkGraphLayout
```

36.46.2 Methods

The class vtkGraphLayout has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphLayout class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphLayout = obj.NewInstance ()`
- `vtkGraphLayout = obj.SafeDownCast (vtkObject o)`
- `obj.SetLayoutStrategy (vtkGraphLayoutStrategy strategy)` - The layout strategy to use during graph layout.
- `vtkGraphLayoutStrategy = obj.GetLayoutStrategy ()` - The layout strategy to use during graph layout.
- `int = obj.IsLayoutComplete ()` - Ask the layout algorithm if the layout is complete
- `long = obj.GetMTime ()` - Get the modification time of the layout algorithm.

- `double = obj.GetZRange ()` - Set the ZRange for the output data. If the initial layout is planar (i.e. all z coordinates are zero), the coordinates will be evenly spaced from 0.0 to ZRange. The default is zero, which has no effect.
- `obj.SetZRange (double )` - Set the ZRange for the output data. If the initial layout is planar (i.e. all z coordinates are zero), the coordinates will be evenly spaced from 0.0 to ZRange. The default is zero, which has no effect.
- `vtkAbstractTransform = obj.GetTransform ()` - Transform the graph vertices after the layout.
- `obj.SetTransform (vtkAbstractTransform t)` - Transform the graph vertices after the layout.
- `obj.SetUseTransform (bool )` - Whether to use the specified transform after layout.
- `bool = obj.GetUseTransform ()` - Whether to use the specified transform after layout.
- `obj.UseTransformOn ()` - Whether to use the specified transform after layout.
- `obj.UseTransformOff ()` - Whether to use the specified transform after layout.

36.47 vtkGraphLayoutStrategy

36.47.1 Usage

All graph layouts should subclass from this class. vtkGraphLayoutStrategy works as a plug-in to the vtkGraphLayout algorithm. The Layout() function should perform some reasonable "chunk" of the layout. This allows the user to be able to see the progress of the layout. Use IsLayoutComplete() to tell the user when there is no more layout to perform.

.SECTION Thanks Thanks to Brian Wylie from Sandia National Laboratories for adding incremental layout capabilities.

To create an instance of class vtkGraphLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkGraphLayoutStrategy
```

36.47.2 Methods

The class vtkGraphLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphLayoutStrategy = obj.NewInstance ()`
- `vtkGraphLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraph (vtkGraph graph)` - Setting the graph for the layout strategy
- `obj.Initialize ()` - This method allows the layout strategy to do initialization of data structures or whatever else it might want to do.
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()` - Whether to use edge weights in the layout or not.

- `obj.SetWeightEdges (bool state)` - Whether to use edge weights in the layout or not.
- `bool = obj.GetWeightEdges ()` - Whether to use edge weights in the layout or not.
- `obj.SetEdgeWeightField (string field)` - Set/Get the field to use for the edge weights.
- `string = obj.GetEdgeWeightField ()` - Set/Get the field to use for the edge weights.

36.48 vtkGroupLeafVertices

36.48.1 Usage

Use SetInputArrayToProcess(0, ...) to set the array to group on. Currently this array must be a vtkStringArray.

To create an instance of class vtkGroupLeafVertices, simply invoke its constructor as follows

```
obj = vtkGroupLeafVertices
```

36.48.2 Methods

The class vtkGroupLeafVertices has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGroupLeafVertices class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGroupLeafVertices = obj.NewInstance ()`
- `vtkGroupLeafVertices = obj.SafeDownCast (vtkObject o)`
- `obj.SetGroupDomain (string )` - The name of the domain that non-leaf vertices will be assigned to. If the input graph already contains vertices in this domain: - If the ids for this domain are numeric, starts assignment with max id - If the ids for this domain are strings, starts assignment with "group X" where "X" is the max id. Default is "group_vertex".
- `string = obj.GetGroupDomain ()` - The name of the domain that non-leaf vertices will be assigned to. If the input graph already contains vertices in this domain: - If the ids for this domain are numeric, starts assignment with max id - If the ids for this domain are strings, starts assignment with "group X" where "X" is the max id. Default is "group_vertex".

36.49 vtkISIReader

36.49.1 Usage

ISI is a tagged format for expressing bibliographic citations. Data is structured as a collection of records with each record composed of one-to-many fields. See

http://isibasic.com/help/helpprn.html#dialog_export_format

for details. vtkISIReader will convert an ISI file into a vtkTable, with the set of table columns determined dynamically from the contents of the file.

To create an instance of class vtkISIReader, simply invoke its constructor as follows

```
obj = vtkISIReader
```

36.49.2 Methods

The class vtkISIReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkISIReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkISIReader = obj.NewInstance ()`
- `vtkISIReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()` - Set/get the file to load
- `obj.SetFileName (string )` - Set/get the file to load
- `string = obj.GetDelimiter ()` - Set/get the delimiter to be used for concatenating field data (default: ";")
- `obj.SetDelimiter (string )` - Set/get the delimiter to be used for concatenating field data (default: ";")
- `int = obj.GetMaxRecords ()` - Set/get the maximum number of records to read from the file (zero = unlimited)
- `obj.SetMaxRecords (int )` - Set/get the maximum number of records to read from the file (zero = unlimited)

36.50 vtkKMeansDistanceFunctor

36.50.1 Usage

This is an abstract class (with a default concrete subclass) that implements algorithms used by the vtkKMeansStatistics filter that rely on a distance metric. If you wish to use a non-Euclidean distance metric (this could include working with strings that do not have a Euclidean distance metric, implementing k-mediods, or trying distance metrics in norms other than L2), you should subclass vtkKMeansDistanceFunctor.

To create an instance of class vtkKMeansDistanceFunctor, simply invoke its constructor as follows

```
obj = vtkKMeansDistanceFunctor
```

36.50.2 Methods

The class vtkKMeansDistanceFunctor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKMeansDistanceFunctor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKMeansDistanceFunctor = obj.NewInstance ()`
- `vtkKMeansDistanceFunctor = obj.SafeDownCast (vtkObject o)`
- `vtkVariantArray = obj.GetEmptyTuple (vtkIdType dimension)` - Return an empty tuple. These values are used as cluster center coordinates when no initial cluster centers are specified.

- `obj.PairwiseUpdate (vtkTable clusterCenters, vtkIdType row, vtkVariantArray data, vtkIdType dataCa` - This is called once per observation per run per iteration in order to assign the observation to its nearest cluster center after the distance functor has been evaluated for all the cluster centers.

  The distance functor is responsible for incrementally updating the cluster centers to account for the assignment.

- `obj.PerturbElement (vtkTable , vtkTable , vtkIdType , vtkIdType , vtkIdType , double )` - When a cluster center (1) has no observations that are closer to it than other cluster centers or (2) has exactly the same coordinates as another cluster center, its coordinates should be perturbed. This function should perform that perturbation.

  Since perturbation relies on a distance metric, this function is the responsibility of the distance functor.

- `vtkAbstractArray = obj.CreateCoordinateArray ()` - Return a vtkAbstractArray capable of holding cluster center coordinates. This is used by vtkPKMeansStatistics to hold cluster center coordinates sent to (received from) other processes.

- `int = obj.GetDataType ()` - Return the data type used to store cluster center coordinates.

36.51 vtkKMeansDistanceFunctorCalculator

36.51.1 Usage

This is a subclass of the default k-means distance functor that allows the user to specify a distance function as a string. The provided expression is evaluated whenever the parenthesis operator is invoked but this is much slower than the default distance calculation.

User-specified distance expressions should be written in terms of two vector variables named "x" and "y". The length of the vectors will be determined by the k-means request and all columns of interest in the request must contain values that may be converted to a floating point representation. (Strings and vtkObject pointers are not allowed.) An example distance expression is "sqrt((x0-y0)$\hat{}$2 + (x1-y1)$\hat{}$2)" which computes Euclidian distance in a plane defined by the first 2 coordinates of the vectors specified.

To create an instance of class vtkKMeansDistanceFunctorCalculator, simply invoke its constructor as follows

```
obj = vtkKMeansDistanceFunctorCalculator
```

36.51.2 Methods

The class vtkKMeansDistanceFunctorCalculator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKMeansDistanceFunctorCalculator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKMeansDistanceFunctorCalculator = obj.NewInstance ()`
- `vtkKMeansDistanceFunctorCalculator = obj.SafeDownCast (vtkObject o)`
- `obj.SetDistanceExpression (string )` - Set/get the distance function expression.
- `string = obj.GetDistanceExpression ()` - Set/get the distance function expression.
- `obj.SetFunctionParser (vtkFunctionParser )` - Set/get the string containing an expression which evaluates to the distance metric used for k-means computation. The scalar variables "x0", "x1", ... "xn" and "y0", "y1", ..., "yn" refer to the coordinates involved in the computation.

- `vtkFunctionParser = obj.GetFunctionParser ()` - Set/get the string containing an expression which evaluates to the distance metric used for k-means computation. The scalar variables "x0", "x1", ... "xn" and "y0", "y1", ..., "yn" refer to the coordinates involved in the computation.

36.52 vtkKMeansStatistics

36.52.1 Usage

This class takes as input an optional vtkTable on port LEARN_PARAMETERS specifying initial set(s) of cluster values of the following form:

```
     K     | Col1             |  ...    | ColN
-----------+------------------+---------+---------------
     M     |clustCoord(1, 1) |  ...    | clustCoord(1, N)
     M     |clustCoord(2, 1) |  ...    | clustCoord(2, N)
     .     |       .          |   .     |        .
     .     |       .          |   .     |        .
     .     |       .          |   .     |        .
     M     |clustCoord(M, 1) |  ...    | clustCoord(M, N)
     L     |clustCoord(1, 1) |  ...    | clustCoord(1, N)
     L     |clustCoord(2, 1) |  ...    | clustCoord(2, N)
     .     |       .          |   .     |        .
     .     |       .          |   .     |        .
     .     |       .          |   .     |        .
     L     |clustCoord(L, 1) |  ...    | clustCoord(L, N)
```

Because the desired value of K is often not known in advance and the results of the algorithm are dependent on the initial cluster centers, we provide a mechanism for the user to test multiple runs or sets of cluster centers within a single call to the Learn phase. The first column of the table identifies the number of clusters K in the particular run (the entries in this column should be of type vtkIdType), while the remaining columns are a subset of the columns contained in the table on port INPUT_DATA. We require that all user specified clusters be of the same dimension N and consequently, that the LEARN_PARAMETERS table have N+1 columns. Due to this restriction, only one request can be processed for each call to the Learn phase and subsequent requests are silently ignored. Note that, if the first column of the LEARN_PARAMETERS table is not of type vtkIdType, then the table will be ignored and a single run will be performed using the first DefaultNumberOfClusters input data observations as initial cluster centers.

When the user does not supply an initial set of clusters, then the first DefaultNumberOfClusters input data observations are used as initial cluster centers and a single run is performed.

This class provides the following functionalities, depending on the mode it is executed in: * Learn: calculates new cluster centers for each run. The output metadata on port OUTPUT_MODEL is a multiblock dataset containing at a minimum one vtkTable with columns specifying the following for each run: the run ID, number of clusters, number of iterations required for convergence, total error associated with the cluster (sum of squared Euclidean distance from each observation to its nearest cluster center), the cardinality of the cluster, and the new cluster coordinates.

*Derive: An additional vtkTable is stored in the multiblock dataset output on port OUTPUT_MODEL. This table contains columns that store for each run: the runID, number of clusters, total error for all clusters in the run, local rank, and global rank. The local rank is computed by comparing squared Euclidean errors of all runs with the same number of clusters. The global rank is computed analagously across all runs.

* Assess: This requires a multiblock dataset (as computed from Learn and Derive) on input port INPUT_MODEL and tabular data on input port INPUT_DATA that contains column names matching those of the tables on input port INPUT_MODEL. The assess mode reports the closest cluster center and associated squared Euclidean distance of each observation in port INPUT_DATA's table to the cluster centers for each run in the multiblock dataset provided on port INPUT_MODEL.

The code can handle a wide variety of data types as it operates on vtkAbstractArrays and is not limited to vtkDataArrays. A default distance functor that computes the sum of the squares of the Euclidean distance between two objects is provided (vtkKMeansDistanceFunctor). The default distance functor can be overridden to use alternative distance metrics.

.SECTION Thanks Thanks to Janine Bennett, David Thompson, and Philippe Pebay of Sandia National Laboratories for implementing this class.

To create an instance of class vtkKMeansStatistics, simply invoke its constructor as follows

```
obj = vtkKMeansStatistics
```

36.52.2 Methods

The class vtkKMeansStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKMeansStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKMeansStatistics = obj.NewInstance ()`
- `vtkKMeansStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetDistanceFunctor (vtkKMeansDistanceFunctor )` - Set the DistanceFunctor.
- `vtkKMeansDistanceFunctor = obj.GetDistanceFunctor ()` - Set the DistanceFunctor.
- `obj.SetDefaultNumberOfClusters (int )` - Set/get the DefaultNumberOfClusters, used when no initial cluster coordinates are specified.
- `int = obj.GetDefaultNumberOfClusters ()` - Set/get the DefaultNumberOfClusters, used when no initial cluster coordinates are specified.
- `obj.SetKValuesArrayName (string )` - Set/get the KValuesArrayName.
- `string = obj.GetKValuesArrayName ()` - Set/get the KValuesArrayName.
- `obj.SetMaxNumIterations (int )` - Set/get the MaxNumIterations used to terminate iterations on cluster center coordinates when the relative tolerance can not be met.
- `int = obj.GetMaxNumIterations ()` - Set/get the MaxNumIterations used to terminate iterations on cluster center coordinates when the relative tolerance can not be met.
- `obj.SetTolerance (double )` - Set/get the relative Tolerance used to terminate iterations on cluster center coordinates.
- `double = obj.GetTolerance ()` - Set/get the relative Tolerance used to terminate iterations on cluster center coordinates.
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model NB: not implemented

36.53 vtkMatricizeArray

36.53.1 Usage

Given a sparse input array of arbitrary dimension, creates a sparse output matrix (vtkSparseArray¡double¿) where each column is a slice along an arbitrary dimension from the source.

.SECTION Thanks Developed by Timothy M. Shead (tshead@sandia.gov) at Sandia National Laboratories.

To create an instance of class vtkMatricizeArray, simply invoke its constructor as follows

```
obj = vtkMatricizeArray
```

36.53.2 Methods

The class vtkMatricizeArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMatricizeArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMatricizeArray = obj.NewInstance ()`
- `vtkMatricizeArray = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetSliceDimension ()` - Returns the 0-numbered dimension that will be mapped to columns in the output
- `obj.SetSliceDimension (vtkIdType )` - Sets the 0-numbered dimension that will be mapped to columns in the output

36.54 vtkMergeColumns

36.54.1 Usage

vtkMergeColumns replaces two columns in a table with a single column containing data in both columns. The columns are set using

SetInputArrayToProcess(0, 0, 0, vtkDataObject::FIELD_ASSOCIATION_ROWS, "col1")

and

SetInputArrayToProcess(1, 0, 0, vtkDataObject::FIELD_ASSOCIATION_ROWS, "col2")

where "col1" and "col2" are the names of the columns to merge. The user may also specify the name of the merged column. The arrays must be of the same type. If the arrays are numeric, the values are summed in the merged column. If the arrays are strings, the values are concatenated. The strings are separated by a space if they are both nonempty.

To create an instance of class vtkMergeColumns, simply invoke its constructor as follows

```
obj = vtkMergeColumns
```

36.54.2 Methods

The class vtkMergeColumns has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeColumns class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkMergeColumns = obj.NewInstance ()`
- `vtkMergeColumns = obj.SafeDownCast (vtkObject o)`
- `obj.SetMergedColumnName (string )` - The name to give the merged column created by this filter.
- `string = obj.GetMergedColumnName ()` - The name to give the merged column created by this filter.

36.55 vtkMergeGraphs

36.55.1 Usage

vtkMergeGraphs combines information from two graphs into one. Both graphs must have pedigree ids assigned to the vertices. The output will contain the vertices/edges in the first graph, in addition to:
- vertices in the second graph whose pedigree id does not match a vertex in the first input
- edges in the second graph

The output will contain the same attribute structure as the input; fields associated only with the second input graph will not be passed to the output. When possible, the vertex/edge data for new vertices and edges will be populated with matching attributes on the second graph. To be considered a matching attribute, the array must have the same name, type, and number of components.

To create an instance of class vtkMergeGraphs, simply invoke its constructor as follows

```
obj = vtkMergeGraphs
```

36.55.2 Methods

The class vtkMergeGraphs has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeGraphs class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergeGraphs = obj.NewInstance ()`
- `vtkMergeGraphs = obj.SafeDownCast (vtkObject o)`
- `int = obj.ExtendGraph (vtkMutableGraphHelper g1, vtkGraph g2)` - This is the core functionality of the algorithm. Adds edges and vertices from g2 into g1.
- `obj.SetMaxEdges (vtkIdType )` - The maximum number of edges in the combined graph. Default is -1, which specifies that there should be no limit on the number of edges.
- `vtkIdType = obj.GetMaxEdges ()` - The maximum number of edges in the combined graph. Default is -1, which specifies that there should be no limit on the number of edges.

36.56 vtkMergeTables

36.56.1 Usage

Combines the columns of two tables into one larger table. The number of rows in the resulting table is the sum of the number of rows in each of the input tables. The number of columns in the output is generally the sum of the number of columns in each input table, except in the case where column names are duplicated in both tables. In this case, if MergeColumnsByName is on (the default), the two columns will be merged into

a single column of the same name. If MergeColumnsByName is off, both columns will exist in the output. You may set the FirstTablePrefix and SecondTablePrefix to define how the columns named are modified. One of these prefixes may be the empty string, but they must be different.

To create an instance of class vtkMergeTables, simply invoke its constructor as follows

```
obj = vtkMergeTables
```

36.56.2 Methods

The class vtkMergeTables has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergeTables class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergeTables = obj.NewInstance ()`
- `vtkMergeTables = obj.SafeDownCast (vtkObject o)`
- `obj.SetFirstTablePrefix (string )` - The prefix to give to same-named fields from the first table. Default is "Table1.".
- `string = obj.GetFirstTablePrefix ()` - The prefix to give to same-named fields from the first table. Default is "Table1.".
- `obj.SetSecondTablePrefix (string )` - The prefix to give to same-named fields from the second table. Default is "Table2.".
- `string = obj.GetSecondTablePrefix ()` - The prefix to give to same-named fields from the second table. Default is "Table2.".
- `obj.SetMergeColumnsByName (bool )` - If on, merges columns with the same name. If off, keeps both columns, but calls one FirstTablePrefix + name, and the other SecondTablePrefix + name. Default is on.
- `bool = obj.GetMergeColumnsByName ()` - If on, merges columns with the same name. If off, keeps both columns, but calls one FirstTablePrefix + name, and the other SecondTablePrefix + name. Default is on.
- `obj.MergeColumnsByNameOn ()` - If on, merges columns with the same name. If off, keeps both columns, but calls one FirstTablePrefix + name, and the other SecondTablePrefix + name. Default is on.
- `obj.MergeColumnsByNameOff ()` - If on, merges columns with the same name. If off, keeps both columns, but calls one FirstTablePrefix + name, and the other SecondTablePrefix + name. Default is on.
- `obj.SetPrefixAllButMerged (bool )` - If on, all columns will have prefixes except merged columns. If off, only unmerged columns with the same name will have prefixes. Default is off.
- `bool = obj.GetPrefixAllButMerged ()` - If on, all columns will have prefixes except merged columns. If off, only unmerged columns with the same name will have prefixes. Default is off.
- `obj.PrefixAllButMergedOn ()` - If on, all columns will have prefixes except merged columns. If off, only unmerged columns with the same name will have prefixes. Default is off.
- `obj.PrefixAllButMergedOff ()` - If on, all columns will have prefixes except merged columns. If off, only unmerged columns with the same name will have prefixes. Default is off.

36.57 vtkMultiCorrelativeStatistics

36.57.1 Usage

Given a selection of sets of columns of interest, this class provides the following functionalities, depending on the execution mode it is executed in: * Learn: calculates means, unbiased variance and covariance estimators of column pairs coefficient. More precisely, Learn calculates the averages and centered variance/covariance sums; if finalize is set to true (default), the final statistics are calculated. The output metadata on port OUTPUT_MODEL is a multiblock dataset containing at a minimum one vtkTable holding the raw sums in a sparse matrix style. If finalize is true, then one additional vtkTable will be present for each requested set of column correlations. These additional tables contain column averages, the upper triangular portion of the covariance matrix (in the upper right hand portion of the table) and the Cholesky decomposition of the covariance matrix (in the lower portion of the table beneath the covariance triangle). The leftmost column will be a vector of column averages. The last entry in the column averages vector is the number of samples. As an example, consider a request for a 3-column correlation with columns named ColA, ColB, and ColC. The resulting table will look like this:

```
Column  |Mean     |ColA     |ColB     |ColC
--------+---------+---------+---------+---------
ColA    |avg(A)   |cov(A,A) |cov(A,B) |cov(A,C)
ColB    |avg(B)   |chol(1,1)|cov(B,B) |cov(B,C)
ColC    |avg(C)   |chol(2,1)|chol(2,2)|cov(C,C)
Cholesky|length(A)|chol(3,1)|chol(3,2)|chol(3,3)
```

* Assess: given a set of results matrices as specified above in input port INPUT_MODEL and tabular data on input port INPUT_DATA that contains column names matching those of the tables on input port INPUT_MODEL, the assess mode computes the relative deviation of each observation in port INPUT_DATA's table according to the linear correlations implied by each table in port INPUT_MODEL.

.SECTION Thanks Thanks to Philippe Pebay, Jackson Mayo, and David Thompson of Sandia National Laboratories for implementing this class.

To create an instance of class vtkMultiCorrelativeStatistics, simply invoke its constructor as follows

```
obj = vtkMultiCorrelativeStatistics
```

36.57.2 Methods

The class vtkMultiCorrelativeStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiCorrelativeStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiCorrelativeStatistics = obj.NewInstance ()`
- `vtkMultiCorrelativeStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model

36.58 vtkMutableGraphHelper

36.58.1 Usage

vtkMutableGraphHelper has helper methods AddVertex and AddEdge which add vertices/edges to the underlying mutable graph. This is helpful in filters which need to (re)construct graphs which may be either directed or undirected.

To create an instance of class vtkMutableGraphHelper, simply invoke its constructor as follows

```
obj = vtkMutableGraphHelper
```

36.58.2 Methods

The class vtkMutableGraphHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMutableGraphHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMutableGraphHelper = obj.NewInstance ()`
- `vtkMutableGraphHelper = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraph (vtkGraph g)` - Set the underlying graph that you want to modify with this helper. The graph must be an instance of vtkMutableDirectedGraph or vtkMutableUndirectedGraph.
- `vtkGraph = obj.GetGraph ()` - Set the underlying graph that you want to modify with this helper. The graph must be an instance of vtkMutableDirectedGraph or vtkMutableUndirectedGraph.
- `vtkGraphEdge = obj.AddGraphEdge (vtkIdType u, vtkIdType v)` - Add an edge to the underlying mutable graph.
- `vtkIdType = obj.AddVertex ()` - Add a vertex to the underlying mutable graph.
- `obj.RemoveVertex (vtkIdType v)` - Remove a vertex from the underlying mutable graph.
- `obj.RemoveVertices (vtkIdTypeArray verts)` - Remove a collection of vertices from the underlying mutable graph.
- `obj.RemoveEdge (vtkIdType e)` - Remove an edge from the underlying mutable graph.
- `obj.RemoveEdges (vtkIdTypeArray edges)` - Remove a collection of edges from the underlying mutable graph.

36.59 vtkNetworkHierarchy

36.59.1 Usage

Use SetInputArrayToProcess(0, ...) to set the array to that has the network ip addresses. Currently this array must be a vtkStringArray.

To create an instance of class vtkNetworkHierarchy, simply invoke its constructor as follows

```
obj = vtkNetworkHierarchy
```

36.59.2 Methods

The class vtkNetworkHierarchy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkNetworkHierarchy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkNetworkHierarchy = obj.NewInstance ()`
- `vtkNetworkHierarchy = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetIPArrayName ()` - Used to store the ip array name
- `obj.SetIPArrayName (string )` - Used to store the ip array name

36.60 vtkOrderStatistics

36.60.1 Usage

Given a selection of columns of interest in an input data table, this class provides the following functionalities, depending on the execution mode it is executed in: * Learn: calculate 5-point statistics (minimum, 1st quartile, median, third quartile, maximum) and all other deciles (1,2,3,4,6,7,8,9). * Assess: given an input data set in port INPUT_DATA, and two percentiles p1 ¡ p2, assess all entries in the data set which are outside of [p1,p2].

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkOrderStatistics, simply invoke its constructor as follows

```
obj = vtkOrderStatistics
```

36.60.2 Methods

The class vtkOrderStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOrderStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOrderStatistics = obj.NewInstance ()`
- `vtkOrderStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfIntervals (vtkIdType )` - Set the number of quantiles (with uniform spacing).
- `vtkIdType = obj.GetNumberOfIntervals ()` - Get the number of quantiles (with uniform spacing).
- `obj.SetQuantileDefinition (int )` - Set the quantile definition.
- `vtkIdType = obj.GetQuantileDefinition ()` - Given a collection of models, calculate aggregate model NB: not implemented
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model NB: not implemented

36.61 vtkPairwiseExtractHistogram2D

36.61.1 Usage

This class computes a 2D histogram between all adjacent pairs of columns of an input vtkTable. Internally it creates multiple vtkExtractHistogram2D instances (one for each pair of adjacent table columns). It also manages updating histogram computations intelligently, only recomputing those histograms for whom a relevant property has been altered.

Note that there are two different outputs from this filter. One is a table for which each column contains a flattened 2D histogram array. The other is a vtkMultiBlockDataSet for which each block is a vtkImageData representation of the 2D histogram.

To create an instance of class vtkPairwiseExtractHistogram2D, simply invoke its constructor as follows

```
obj = vtkPairwiseExtractHistogram2D
```

36.61.2 Methods

The class vtkPairwiseExtractHistogram2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPairwiseExtractHistogram2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPairwiseExtractHistogram2D = obj.NewInstance ()`
- `vtkPairwiseExtractHistogram2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfBins (int , int )` - Set/get the bin dimensions of the histograms to compute
- `obj.SetNumberOfBins (int  a[2])` - Set/get the bin dimensions of the histograms to compute
- `int = obj. GetNumberOfBins ()` - Set/get the bin dimensions of the histograms to compute
- `obj.SetCustomColumnRangeIndex (int )` - Strange method for setting an index to be used for setting custom column range. This was (probably) necessary to get this class to interact with the ParaView client/server message passing interface.
- `obj.SetCustomColumnRangeByIndex (double , double )` - Strange method for setting an index to be used for setting custom column range. This was (probably) necessary to get this class to interact with the ParaView client/server message passing interface.
- `obj.SetCustomColumnRange (int col, double range[2])` - More standard way to set the custom range for a particular column. This makes sure that only the affected histograms know that they need to be updated.
- `obj.SetCustomColumnRange (int col, double rmin, double rmax)` - More standard way to set the custom range for a particular column. This makes sure that only the affected histograms know that they need to be updated.
- `obj.SetScalarType (int )` - Set the scalar type for each of the computed histograms.
- `obj.SetScalarTypeToUnsignedInt ()` - Set the scalar type for each of the computed histograms.
- `obj.SetScalarTypeToUnsignedLong ()` - Set the scalar type for each of the computed histograms.
- `obj.SetScalarTypeToUnsignedShort ()` - Set the scalar type for each of the computed histograms.
- `obj.SetScalarTypeToUnsignedChar ()` - Set the scalar type for each of the computed histograms.

- `int = obj.GetScalarType ()` - Set the scalar type for each of the computed histograms.
- `double = obj.GetMaximumBinCount (int idx)` - Get the maximum bin count for a single histogram
- `double = obj.GetMaximumBinCount ()` - Get the maximum bin count over all histograms
- `int = obj.GetBinRange (int idx, vtkIdType binX, vtkIdType binY, double range[4])` - Compute the range of the bin located at position (binX,binY) in the 2D histogram at idx.
- `int = obj.GetBinRange (int idx, vtkIdType bin, double range[4])` - Get the range of the of the bin located at 1D position index bin in the 2D histogram array at idx.
- `obj.GetBinWidth (int idx, double bw[2])` - Get the width of all of the bins. Also stored in the spacing ivar of the histogram image output at idx.
- `vtkImageData = obj.GetOutputHistogramImage (int idx)` - Get the vtkImageData output of the idx'th histogram filter
- `vtkExtractHistogram2D = obj.GetHistogramFilter (int idx)` - Get a pointer to the idx'th histogram filter.
- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model. Not used

36.62 vtkPassArrays

36.62.1 Usage

This filter preserves all the topology of the input, but only a subset of arrays are passed to the output. Add an array to be passed to the output data object with AddArray(). If RemoveArrays is on, the specified arrays will be the ones that are removed instead of the ones that are kept.

Arrays with special attributes (scalars, pedigree ids, etc.) will retain those attributes in the output.

By default, only those field types with at least one array specified through AddArray will be processed. If instead UseFieldTypes is turned on, you explicitly set which field types to process with AddFieldType.

Example 1:

```
passArray->AddArray(vtkDataObject::POINT, ''velocity'');
```

The output will have only that one array "velocity" in the point data, but cell and field data will be untouched.

Example 2:

```
passArray->AddArray(vtkDataObject::POINT, ''velocity'');
passArray->UseFieldTypesOn();
passArray->AddFieldType(vtkDataObject::POINT);
passArray->AddFieldType(vtkDataObject::CELL);
```

The point data would still contain the single array, but the cell data would be cleared since you did not specify any arrays to pass. Field data would still be untouched.

To create an instance of class vtkPassArrays, simply invoke its constructor as follows

```
obj = vtkPassArrays
```

36.62.2 Methods

The class vtkPassArrays has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPassArrays class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPassArrays = obj.NewInstance ()`
- `vtkPassArrays = obj.SafeDownCast (vtkObject o)`
- `obj.AddArray (int fieldType, string name)` - Adds an array to pass through. fieldType where the array that should be passed (point data, cell data, etc.). It should be one of the constants defined in the vtkDataObject::AttributeTypes enumeration.
- `obj.ClearArrays ()` - Clear all arrays to pass through.
- `obj.SetRemoveArrays (bool )` - Instead of passing only the specified arrays, remove the specified arrays and keep all other arrays. Default is off.
- `bool = obj.GetRemoveArrays ()` - Instead of passing only the specified arrays, remove the specified arrays and keep all other arrays. Default is off.
- `obj.RemoveArraysOn ()` - Instead of passing only the specified arrays, remove the specified arrays and keep all other arrays. Default is off.
- `obj.RemoveArraysOff ()` - Instead of passing only the specified arrays, remove the specified arrays and keep all other arrays. Default is off.
- `obj.SetUseFieldTypes (bool )` - Process only those field types explicitly specified with AddFieldType. Otherwise, processes field types associated with at least one specified array. Default is off.
- `bool = obj.GetUseFieldTypes ()` - Process only those field types explicitly specified with AddFieldType. Otherwise, processes field types associated with at least one specified array. Default is off.
- `obj.UseFieldTypesOn ()` - Process only those field types explicitly specified with AddFieldType. Otherwise, processes field types associated with at least one specified array. Default is off.
- `obj.UseFieldTypesOff ()` - Process only those field types explicitly specified with AddFieldType. Otherwise, processes field types associated with at least one specified array. Default is off.
- `obj.AddFieldType (int fieldType)` - Add a field type to process. fieldType where the array that should be passed (point data, cell data, etc.). It should be one of the constants defined in the vtkDataObject::AttributeTypes enumeration. NOTE: These are only used if UseFieldType is turned on.
- `obj.ClearFieldTypes ()` - Clear all field types to process.

36.63 vtkPassThrough

36.63.1 Usage

The output type is always the same as the input object type.

To create an instance of class vtkPassThrough, simply invoke its constructor as follows

```
obj = vtkPassThrough
```

36.63.2 Methods

The class vtkPassThrough has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPassThrough class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPassThrough = obj.NewInstance ()`
- `vtkPassThrough = obj.SafeDownCast (vtkObject o)`
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Specify the first input port as optional
- `obj.SetDeepCopyInput (int )` - Whether or not to deep copy the input. This can be useful if you want to create a copy of a data object. You can then disconnect this filter's input connections and it will act like a source. Defaults to OFF.
- `int = obj.GetDeepCopyInput ()` - Whether or not to deep copy the input. This can be useful if you want to create a copy of a data object. You can then disconnect this filter's input connections and it will act like a source. Defaults to OFF.
- `obj.DeepCopyInputOn ()` - Whether or not to deep copy the input. This can be useful if you want to create a copy of a data object. You can then disconnect this filter's input connections and it will act like a source. Defaults to OFF.
- `obj.DeepCopyInputOff ()` - Whether or not to deep copy the input. This can be useful if you want to create a copy of a data object. You can then disconnect this filter's input connections and it will act like a source. Defaults to OFF.

36.64 vtkPassThroughEdgeStrategy

36.64.1 Usage

Simply passes existing edge layout information from the input to the output without making changes.

To create an instance of class vtkPassThroughEdgeStrategy, simply invoke its constructor as follows

```
obj = vtkPassThroughEdgeStrategy
```

36.64.2 Methods

The class vtkPassThroughEdgeStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPassThroughEdgeStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPassThroughEdgeStrategy = obj.NewInstance ()`
- `vtkPassThroughEdgeStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out.

36.65 vtkPassThroughLayoutStrategy

36.65.1 Usage

Yes, this incredible strategy does absoluted nothing to the data so in affect passes through the graph untouched. This strategy is useful in the cases where the graph is already laid out.

To create an instance of class vtkPassThroughLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkPassThroughLayoutStrategy
```

36.65.2 Methods

The class vtkPassThroughLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPassThroughLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPassThroughLayoutStrategy = obj.NewInstance ()`
- `vtkPassThroughLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()`

36.66 vtkPBivariateLinearTableThreshold

36.66.1 Usage

Perform the table filtering operations provided by vtkBivariateLinearTableThreshold in parallel.

To create an instance of class vtkPBivariateLinearTableThreshold, simply invoke its constructor as follows

```
obj = vtkPBivariateLinearTableThreshold
```

36.66.2 Methods

The class vtkPBivariateLinearTableThreshold has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPBivariateLinearTableThreshold class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPBivariateLinearTableThreshold = obj.NewInstance ()`
- `vtkPBivariateLinearTableThreshold = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Set the vtkMultiProcessController to be used for combining filter results from the individual nodes.
- `vtkMultiProcessController = obj.GetController ()` - Set the vtkMultiProcessController to be used for combining filter results from the individual nodes.

36.67 vtkPCAStatistics

36.67.1 Usage

This class derives from the multi-correlative statistics algorithm and uses the covariance matrix and Cholesky decomposition computed by it. However, when it finalizes the statistics in Learn mode, the PCA class computes the SVD of the covariance matrix in order to obtain its eigenvectors.

In the assess mode, the input data are - projected into the basis defined by the eigenvectors, - the energy associated with each datum is computed, - or some combination thereof. Additionally, the user may specify some threshold energy or eigenvector entry below which the basis is truncated. This allows projection into a lower-dimensional state while minimizing (in a least squares sense) the projection error.

.SECTION Thanks Thanks to David Thompson, Philippe Pebay and Jackson Mayo from Sandia National Laboratories for implementing this class.

To create an instance of class vtkPCAStatistics, simply invoke its constructor as follows

```
obj = vtkPCAStatistics
```

36.67.2 Methods

The class vtkPCAStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPCAStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPCAStatistics = obj.NewInstance ()`
- `vtkPCAStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetNormalizationScheme (int )` - This determines how (or if) the covariance matrix cov is normalized before PCA.

  When set to NONE, no normalization is performed. This is the default.

  When set to TRIANGLE_SPECIFIED, each entry cov(i,j) is divided by V(i,j). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_SPECIFIED, each entry cov(i,j) is divided by sqrt(V(i)*V(j)). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_VARIANCE, each entry cov(i,j) is divided by sqrt(cov(i,i)*cov(j,j)). ¡b¿Warning¡/b¿: Although this is accepted practice in some fields, some people think you should not turn this option on unless there is a good physically-based reason for doing so. Much better instead to determine how component magnitudes should be compared using physical reasoning and use DIAGONAL_SPECIFIED, TRIANGLE_SPECIFIED, or perform some pre-processing to shift and scale input data columns appropriately than to expect magical results from a shady normalization hack.

- `int = obj.GetNormalizationScheme ()` - This determines how (or if) the covariance matrix cov is normalized before PCA.

  When set to NONE, no normalization is performed. This is the default.

  When set to TRIANGLE_SPECIFIED, each entry cov(i,j) is divided by V(i,j). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_SPECIFIED, each entry cov(i,j) is divided by sqrt(V(i)*V(j)). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_VARIANCE, each entry cov(i,j) is divided by sqrt(cov(i,i)*cov(j,j)). ¡b¿Warning¡/b¿: Although this is accepted practice in some fields, some people think you should not turn this option on

unless there is a good physically-based reason for doing so. Much better instead to determine how component magnitudes should be compared using physical reasoning and use DIAGONAL_SPECIFIED, TRIANGLE_SPECIFIED, or perform some pre-processing to shift and scale input data columns appropriately than to expect magical results from a shady normalization hack.

- `obj.SetNormalizationSchemeByName (string sname)` - This determines how (or if) the covariance matrix cov is normalized before PCA.

  When set to NONE, no normalization is performed. This is the default.

  When set to TRIANGLE_SPECIFIED, each entry cov(i,j) is divided by V(i,j). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_SPECIFIED, each entry cov(i,j) is divided by sqrt(V(i)*V(j)). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_VARIANCE, each entry cov(i,j) is divided by sqrt(cov(i,i)*cov(j,j)). ¡b¿Warning¡/b¿: Although this is accepted practice in some fields, some people think you should not turn this option on unless there is a good physically-based reason for doing so. Much better instead to determine how component magnitudes should be compared using physical reasoning and use DIAGONAL_SPECIFIED, TRIANGLE_SPECIFIED, or perform some pre-processing to shift and scale input data columns appropriately than to expect magical results from a shady normalization hack.

- `string = obj.GetNormalizationSchemeName (int scheme)` - This determines how (or if) the covariance matrix cov is normalized before PCA.

  When set to NONE, no normalization is performed. This is the default.

  When set to TRIANGLE_SPECIFIED, each entry cov(i,j) is divided by V(i,j). The list V of normalization factors must be set using the SetNormalization method before the filter is executed.

  When set to DIAGONAL_VARIANCE, each entry cov(i,j) is divided by sqrt(cov(i,i)*cov(j,j)). ¡b¿Warning¡/b¿: Although this is accepted practice in some fields, some people think you should not turn this option on unless there is a good physically-based reason for doing so. Much better instead to determine how component magnitudes should be compared using physical reasoning and use DIAGONAL_SPECIFIED, TRIANGLE_SPECIFIED, or perform some pre-processing to shift and scale input data columns appropriately than to expect magical results from a shady normalization hack.

- `vtkTable = obj.GetSpecifiedNormalization ()` - These methods allow you to set/get values used to normalize the covariance matrix before PCA. The normalization values apply to all requests, so you do not specify a single vector but a 3-column table.

  The first two columns contain the names of columns from input 0 and the third column contains the value to normalize the corresponding entry in the covariance matrix. The table must always have 3 columns even when the NormalizationScheme is DIAGONAL_SPECIFIED. When only diagonal entries are to be used, only table rows where the first two columns are identical to one another will be employed. If there are multiple rows specifying different values for the same pair of columns, the entry nearest the bottom of the table takes precedence.

  These functions are actually convenience methods that set/get the third input of the filter. Because the table is the third input, you may use other filters to produce a table of normalizations and have the pipeline take care of updates.

  Any missing entries will be set to 1.0 and a warning issued. An error will occur if the third input to the filter is not set and the NormalizationScheme is DIAGONAL_SPECIFIED or TRIANGLE_SPECIFIED.

- `obj.SetSpecifiedNormalization (vtkTable )` - These methods allow you to set/get values used to normalize the covariance matrix before PCA. The normalization values apply to all requests, so you do not specify a single vector but a 3-column table.

The first two columns contain the names of columns from input 0 and the third column contains the value to normalize the corresponding entry in the covariance matrix. The table must always have 3 columns even when the NormalizationScheme is DIAGONAL_SPECIFIED. When only diagonal entries are to be used, only table rows where the first two columns are identical to one another will be employed. If there are multiple rows specifying different values for the same pair of columns, the entry nearest the bottom of the table takes precedence.

These functions are actually convenience methods that set/get the third input of the filter. Because the table is the third input, you may use other filters to produce a table of normalizations and have the pipeline take care of updates.

Any missing entries will be set to 1.0 and a warning issued. An error will occur if the third input to the filter is not set and the NormalizationScheme is DIAGONAL_SPECIFIED or TRIANGLE_SPECIFIED.

- `obj.SetBasisScheme (int )` - This variable controls the dimensionality of output tuples in Assess mode. Consider the case where you have requested a PCA on D columns.

  When set to vtkPCAStatistics::FULL_BASIS, the entire set of basis vectors is used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of the same dimension as the input tuples. (That dimension is D, so there will be D additional columns added to the table for the request.)

  When set to vtkPCAStatistics::FIXED_BASIS_SIZE, only the first N basis vectors are used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of dimension min(N,D). You must set N prior to assessing data using the SetFixedBasisSize() method. When N ¡ D, this turns the PCA into a projection (instead of change of basis).

  When set to vtkPCAStatistics::FIXED_BASIS_ENERGY, the number of basis vectors used to derive new coordinates for each tuple will be the minimum number of columns N that satisfy

  $$\frac{\sum_{i=1}^{N} \lambda_i}{\sum_{i=1}^{D} \lambda_i} < T$$

  You must set T prior to assessing data using the SetFixedBasisEnergy() method. When T ¡ 1, this turns the PCA into a projection (instead of change of basis).

  By default BasisScheme is set to vtkPCAStatistics::FULL_BASIS.

- `int = obj.GetBasisScheme ()` - This variable controls the dimensionality of output tuples in Assess mode. Consider the case where you have requested a PCA on D columns.

  When set to vtkPCAStatistics::FULL_BASIS, the entire set of basis vectors is used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of the same dimension as the input tuples. (That dimension is D, so there will be D additional columns added to the table for the request.)

  When set to vtkPCAStatistics::FIXED_BASIS_SIZE, only the first N basis vectors are used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of dimension min(N,D). You must set N prior to assessing data using the SetFixedBasisSize() method. When N ¡ D, this turns the PCA into a projection (instead of change of basis).

  When set to vtkPCAStatistics::FIXED_BASIS_ENERGY, the number of basis vectors used to derive new coordinates for each tuple will be the minimum number of columns N that satisfy

  $$\frac{\sum_{i=1}^{N} \lambda_i}{\sum_{i=1}^{D} \lambda_i} < T$$

  You must set T prior to assessing data using the SetFixedBasisEnergy() method. When T ¡ 1, this turns the PCA into a projection (instead of change of basis).

  By default BasisScheme is set to vtkPCAStatistics::FULL_BASIS.

- `string = obj.GetBasisSchemeName (int schemeIndex)` - This variable controls the dimensionality of output tuples in Assess mode. Consider the case where you have requested a PCA on D columns.

  When set to vtkPCAStatistics::FULL_BASIS, the entire set of basis vectors is used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of the same dimension as the input tuples. (That dimension is D, so there will be D additional columns added to the table for the request.)

  When set to vtkPCAStatistics::FIXED_BASIS_SIZE, only the first N basis vectors are used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of dimension min(N,D). You must set N prior to assessing data using the SetFixedBasisSize() method. When N ¡ D, this turns the PCA into a projection (instead of change of basis).

  When set to vtkPCAStatistics::FIXED_BASIS_ENERGY, the number of basis vectors used to derive new coordinates for each tuple will be the minimum number of columns N that satisfy

  $$\frac{\sum_{i=1}^{N} \lambda_i}{\sum_{i=1}^{D} \lambda_i} < T$$

  You must set T prior to assessing data using the SetFixedBasisEnergy() method. When T ¡ 1, this turns the PCA into a projection (instead of change of basis).

  By default BasisScheme is set to vtkPCAStatistics::FULL_BASIS.

- `obj.SetBasisSchemeByName (string schemeName)` - This variable controls the dimensionality of output tuples in Assess mode. Consider the case where you have requested a PCA on D columns.

  When set to vtkPCAStatistics::FULL_BASIS, the entire set of basis vectors is used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of the same dimension as the input tuples. (That dimension is D, so there will be D additional columns added to the table for the request.)

  When set to vtkPCAStatistics::FIXED_BASIS_SIZE, only the first N basis vectors are used to derive new coordinates for each tuple being assessed. In this mode, you are guaranteed to have output tuples of dimension min(N,D). You must set N prior to assessing data using the SetFixedBasisSize() method. When N ¡ D, this turns the PCA into a projection (instead of change of basis).

  $$\frac{\sum_{i=1}^{N} \lambda_i}{\sum_{i=1}^{D} \lambda_i} < T$$

  You must set T prior to assessing data using the SetFixedBasisEnergy() method. When T ¡ 1, this turns the PCA into a projection (instead of change of basis).

  By default BasisScheme is set to vtkPCAStatistics::FULL_BASIS.

- `obj.SetFixedBasisSize (int )` - The number of basis vectors to use. See SetBasisScheme() for more information. When FixedBasisSize ¡= 0 (the default), the fixed basis size scheme is equivalent to the full basis scheme.

- `int = obj.GetFixedBasisSize ()` - The number of basis vectors to use. See SetBasisScheme() for more information. When FixedBasisSize ¡= 0 (the default), the fixed basis size scheme is equivalent to the full basis scheme.

- `obj.SetFixedBasisEnergy (double )` - The minimum energy the new basis should use, as a fraction. See SetBasisScheme() for more information. When FixedBasisEnergy ¿= 1 (the default), the fixed basis energy scheme is equivalent to the full basis scheme.

- `double = obj.GetFixedBasisEnergyMinValue ()` - The minimum energy the new basis should use, as a fraction. See SetBasisScheme() for more information. When FixedBasisEnergy ¿= 1 (the default), the fixed basis energy scheme is equivalent to the full basis scheme.

- `double = obj.GetFixedBasisEnergyMaxValue ()` - The minimum energy the new basis should use, as a fraction. See SetBasisScheme() for more information. When FixedBasisEnergy ¿= 1 (the default), the fixed basis energy scheme is equivalent to the full basis scheme.
- `double = obj.GetFixedBasisEnergy ()` - The minimum energy the new basis should use, as a fraction. See SetBasisScheme() for more information. When FixedBasisEnergy ¿= 1 (the default), the fixed basis energy scheme is equivalent to the full basis scheme.

36.68 vtkPComputeHistogram2DOutliers

36.68.1 Usage

This class does exactly the same this as vtkComputeHistogram2DOutliers, but does it in a multi-process environment. After each node computes their own local outliers, class does an AllGather that distributes the outliers to every node. This could probably just be a Gather onto the root node instead.

After this operation, the row selection will only contain local row ids, since I'm not sure how to deal with distributed ids.

To create an instance of class vtkPComputeHistogram2DOutliers, simply invoke its constructor as follows

```
obj = vtkPComputeHistogram2DOutliers
```

36.68.2 Methods

The class vtkPComputeHistogram2DOutliers has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPComputeHistogram2DOutliers class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPComputeHistogram2DOutliers = obj.NewInstance ()`
- `vtkPComputeHistogram2DOutliers = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )`
- `vtkMultiProcessController = obj.GetController ()`

36.69 vtkPContingencyStatistics

36.69.1 Usage

vtkPContingencyStatistics is vtkContingencyStatistics subclass for parallel datasets. It learns and derives the global statistical model on each node, but assesses each individual data points on the node that owns it.

To create an instance of class vtkPContingencyStatistics, simply invoke its constructor as follows

```
obj = vtkPContingencyStatistics
```

36.69.2 Methods

The class vtkPContingencyStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPContingencyStatistics class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkPContingencyStatistics = obj.NewInstance ()`
- `vtkPContingencyStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `obj.Learn (vtkTable inData, vtkTable inParameters, vtkDataObject outMeta)` - Execute the parallel calculations required by the Learn option.

36.70 vtkPCorrelativeStatistics

36.70.1 Usage

vtkPCorrelativeStatistics is vtkCorrelativeStatistics subclass for parallel datasets. It learns and derives the global statistical model on each node, but assesses each individual data points on the node that owns it.

To create an instance of class vtkPCorrelativeStatistics, simply invoke its constructor as follows

```
obj = vtkPCorrelativeStatistics
```

36.70.2 Methods

The class vtkPCorrelativeStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPCorrelativeStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPCorrelativeStatistics = obj.NewInstance ()`
- `vtkPCorrelativeStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `obj.Learn (vtkTable inData, vtkTable inParameters, vtkDataObject outMeta)` - Execute the parallel calculations required by the Learn option.

36.71 vtkPDescriptiveStatistics

36.71.1 Usage

vtkPDescriptiveStatistics is vtkDescriptiveStatistics subclass for parallel datasets. It learns and derives the global statistical model on each node, but assesses each individual data points on the node that owns it.

To create an instance of class vtkPDescriptiveStatistics, simply invoke its constructor as follows

```
obj = vtkPDescriptiveStatistics
```

36.71.2 Methods

The class vtkPDescriptiveStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPDescriptiveStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPDescriptiveStatistics = obj.NewInstance ()`
- `vtkPDescriptiveStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `obj.Learn (vtkTable inData, vtkTable inParameters, vtkDataObject outMeta)` - Execute the parallel calculations required by the Learn option.

36.72 vtkPerturbCoincidentVertices

36.72.1 Usage

This filter perturbs vertices in a graph that have coincident coordinates. In particular this happens all the time with graphs that are georeferenced, so we need a nice scheme to perturb the vertices so that when the user zooms in the vertices can be distiquished.

To create an instance of class vtkPerturbCoincidentVertices, simply invoke its constructor as follows

```
obj = vtkPerturbCoincidentVertices
```

36.72.2 Methods

The class vtkPerturbCoincidentVertices has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPerturbCoincidentVertices class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPerturbCoincidentVertices = obj.NewInstance ()`
- `vtkPerturbCoincidentVertices = obj.SafeDownCast (vtkObject o)`
- `obj.SetPerturbFactor (double )` - Specify the perturbation factor (defaults to 1.0)
- `double = obj.GetPerturbFactor ()` - Specify the perturbation factor (defaults to 1.0)

36.73 vtkPExtractHistogram2D

36.73.1 Usage

This class does exactly the same this as vtkExtractHistogram2D, but does it in a multi-process environment. After each node computes their own local histograms, this class does an AllReduce that distributes the sum of all local histograms onto each node.

To create an instance of class vtkPExtractHistogram2D, simply invoke its constructor as follows

```
obj = vtkPExtractHistogram2D
```

36.73.2 Methods

The class vtkPExtractHistogram2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPExtractHistogram2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPExtractHistogram2D = obj.NewInstance ()`
- `vtkPExtractHistogram2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )`
- `vtkMultiProcessController = obj.GetController ()`

36.74 vtkPKMeansStatistics

36.74.1 Usage

vtkPKMeansStatistics is vtkKMeansStatistics subclass for parallel datasets. It learns and derives the global statistical model on each node, but assesses each individual data points on the node that owns it.

To create an instance of class vtkPKMeansStatistics, simply invoke its constructor as follows

```
obj = vtkPKMeansStatistics
```

36.74.2 Methods

The class vtkPKMeansStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPKMeansStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPKMeansStatistics = obj.NewInstance ()`
- `vtkPKMeansStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.

- `obj.UpdateClusterCenters (vtkTable newClusterElements, vtkTable curClusterElements, vtkIdTypeArray` - Subroutine to update new cluster centers from the old centers.
- `vtkIdType = obj.GetTotalNumberOfObservations (vtkIdType numObservations)` - Subroutine to get the total number of data objects.
- `obj.CreateInitialClusterCenters (vtkIdType numToAllocate, vtkIdTypeArray numberOfClusters, vtkTable` - Subroutine to initialize cluster centerss if not provided by the user.

36.75 vtkPMultiCorrelativeStatistics

36.75.1 Usage

vtkPMultiCorrelativeStatistics is vtkMultiCorrelativeStatistics subclass for parallel datasets. It learns and derives the global statistical model on each node, but assesses each individual data points on the node that owns it.

To create an instance of class vtkPMultiCorrelativeStatistics, simply invoke its constructor as follows

```
obj = vtkPMultiCorrelativeStatistics
```

36.75.2 Methods

The class vtkPMultiCorrelativeStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPMultiCorrelativeStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPMultiCorrelativeStatistics = obj.NewInstance ()`
- `vtkPMultiCorrelativeStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.

36.76 vtkPPairwiseExtractHistogram2D

36.76.1 Usage

This class does exactly the same this as vtkPairwiseExtractHistogram2D, but does it in a multi-process environment. After each node computes their own local histograms, this class does an AllReduce that distributes the sum of all local histograms onto each node.

Because vtkPairwiseExtractHistogram2D is a light wrapper around a series of vtkExtractHistogram2D classes, this class just overrides the function that instantiates new histogram filters and returns the parallel version (vtkPExtractHistogram2D).

To create an instance of class vtkPPairwiseExtractHistogram2D, simply invoke its constructor as follows

```
obj = vtkPPairwiseExtractHistogram2D
```

36.76.2 Methods

The class vtkPPairwiseExtractHistogram2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPPairwiseExtractHistogram2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPPairwiseExtractHistogram2D = obj.NewInstance ()`
- `vtkPPairwiseExtractHistogram2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )`
- `vtkMultiProcessController = obj.GetController ()`

36.77 vtkPPCAStatistics

36.77.1 Usage

vtkPPCAStatistics is vtkPCAStatistics subclass for parallel datasets. It learns and derives the global statistical model on each node, but assesses each individual data points on the node that owns it.

To create an instance of class vtkPPCAStatistics, simply invoke its constructor as follows

```
obj = vtkPPCAStatistics
```

36.77.2 Methods

The class vtkPPCAStatistics has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPPCAStatistics class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPPCAStatistics = obj.NewInstance ()`
- `vtkPPCAStatistics = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the multiprocess controller. If no controller is set, single process is assumed.

36.78 vtkPruneTreeFilter

36.78.1 Usage

Removes a subtree rooted at a particular vertex in a vtkTree.

To create an instance of class vtkPruneTreeFilter, simply invoke its constructor as follows

```
obj = vtkPruneTreeFilter
```

36.78.2 Methods

The class vtkPruneTreeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPruneTreeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPruneTreeFilter = obj.NewInstance ()`
- `vtkPruneTreeFilter = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetParentVertex ()` - Set the parent vertex of the subtree to remove.
- `obj.SetParentVertex (vtkIdType )` - Set the parent vertex of the subtree to remove.

36.79 vtkRandomGraphSource

36.79.1 Usage

Generates a graph with a specified number of vertices, with the density of edges specified by either an exact number of edges or the probability of an edge. You may additionally specify whether to begin with a random tree (which enforces graph connectivity).

To create an instance of class vtkRandomGraphSource, simply invoke its constructor as follows

```
obj = vtkRandomGraphSource
```

36.79.2 Methods

The class vtkRandomGraphSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRandomGraphSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRandomGraphSource = obj.NewInstance ()`
- `vtkRandomGraphSource = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfVertices ()` - The number of vertices in the graph.
- `obj.SetNumberOfVertices (int )` - The number of vertices in the graph.
- `int = obj.GetNumberOfVerticesMinValue ()` - The number of vertices in the graph.
- `int = obj.GetNumberOfVerticesMaxValue ()` - The number of vertices in the graph.
- `int = obj.GetNumberOfEdges ()` - If UseEdgeProbability is off, creates a graph with the specified number of edges. Duplicate (parallel) edges are allowed.
- `obj.SetNumberOfEdges (int )` - If UseEdgeProbability is off, creates a graph with the specified number of edges. Duplicate (parallel) edges are allowed.
- `int = obj.GetNumberOfEdgesMinValue ()` - If UseEdgeProbability is off, creates a graph with the specified number of edges. Duplicate (parallel) edges are allowed.

- `int = obj.GetNumberOfEdgesMaxValue ()` - If UseEdgeProbability is off, creates a graph with the specified number of edges. Duplicate (parallel) edges are allowed.
- `double = obj.GetEdgeProbability ()` - If UseEdgeProbability is on, adds an edge with this probability between 0 and 1 for each pair of vertices in the graph.
- `obj.SetEdgeProbability (double )` - If UseEdgeProbability is on, adds an edge with this probability between 0 and 1 for each pair of vertices in the graph.
- `double = obj.GetEdgeProbabilityMinValue ()` - If UseEdgeProbability is on, adds an edge with this probability between 0 and 1 for each pair of vertices in the graph.
- `double = obj.GetEdgeProbabilityMaxValue ()` - If UseEdgeProbability is on, adds an edge with this probability between 0 and 1 for each pair of vertices in the graph.
- `obj.SetIncludeEdgeWeights (bool )` - When set, includes edge weights in an array named "edge_weights". Defaults to off. Weights are random between 0 and 1.
- `bool = obj.GetIncludeEdgeWeights ()` - When set, includes edge weights in an array named "edge_weights". Defaults to off. Weights are random between 0 and 1.
- `obj.IncludeEdgeWeightsOn ()` - When set, includes edge weights in an array named "edge_weights". Defaults to off. Weights are random between 0 and 1.
- `obj.IncludeEdgeWeightsOff ()` - When set, includes edge weights in an array named "edge_weights". Defaults to off. Weights are random between 0 and 1.
- `obj.SetEdgeWeightArrayName (string )` - The name of the edge weight array. Default "edge weight".
- `string = obj.GetEdgeWeightArrayName ()` - The name of the edge weight array. Default "edge weight".
- `obj.SetDirected (bool )` - When set, creates a directed graph, as opposed to an undirected graph.
- `bool = obj.GetDirected ()` - When set, creates a directed graph, as opposed to an undirected graph.
- `obj.DirectedOn ()` - When set, creates a directed graph, as opposed to an undirected graph.
- `obj.DirectedOff ()` - When set, creates a directed graph, as opposed to an undirected graph.
- `obj.SetUseEdgeProbability (bool )` - When set, uses the EdgeProbability parameter to determine the density of edges. Otherwise, NumberOfEdges is used.
- `bool = obj.GetUseEdgeProbability ()` - When set, uses the EdgeProbability parameter to determine the density of edges. Otherwise, NumberOfEdges is used.
- `obj.UseEdgeProbabilityOn ()` - When set, uses the EdgeProbability parameter to determine the density of edges. Otherwise, NumberOfEdges is used.
- `obj.UseEdgeProbabilityOff ()` - When set, uses the EdgeProbability parameter to determine the density of edges. Otherwise, NumberOfEdges is used.
- `obj.SetStartWithTree (bool )` - When set, builds a random tree structure first, then adds additional random edges.
- `bool = obj.GetStartWithTree ()` - When set, builds a random tree structure first, then adds additional random edges.
- `obj.StartWithTreeOn ()` - When set, builds a random tree structure first, then adds additional random edges.

- `obj.StartWithTreeOff ()` - When set, builds a random tree structure first, then adds additional random edges.
- `obj.SetAllowSelfLoops (bool )` - If this flag is set to true, edges where the source and target vertex are the same can be generated. The default is to forbid such loops.
- `bool = obj.GetAllowSelfLoops ()` - If this flag is set to true, edges where the source and target vertex are the same can be generated. The default is to forbid such loops.
- `obj.AllowSelfLoopsOn ()` - If this flag is set to true, edges where the source and target vertex are the same can be generated. The default is to forbid such loops.
- `obj.AllowSelfLoopsOff ()` - If this flag is set to true, edges where the source and target vertex are the same can be generated. The default is to forbid such loops.
- `obj.SetAllowParallelEdges (bool )` - When set, multiple edges from a source to a target vertex are allowed. The default is to forbid such loops.
- `bool = obj.GetAllowParallelEdges ()` - When set, multiple edges from a source to a target vertex are allowed. The default is to forbid such loops.
- `obj.AllowParallelEdgesOn ()` - When set, multiple edges from a source to a target vertex are allowed. The default is to forbid such loops.
- `obj.AllowParallelEdgesOff ()` - When set, multiple edges from a source to a target vertex are allowed. The default is to forbid such loops.
- `obj.SetGeneratePedigreeIds (bool )` - Add pedigree ids to vertex and edge data.
- `bool = obj.GetGeneratePedigreeIds ()` - Add pedigree ids to vertex and edge data.
- `obj.GeneratePedigreeIdsOn ()` - Add pedigree ids to vertex and edge data.
- `obj.GeneratePedigreeIdsOff ()` - Add pedigree ids to vertex and edge data.
- `obj.SetVertexPedigreeIdArrayName (string )` - The name of the vertex pedigree id array. Default "vertex id".
- `string = obj.GetVertexPedigreeIdArrayName ()` - The name of the vertex pedigree id array. Default "vertex id".
- `obj.SetEdgePedigreeIdArrayName (string )` - The name of the edge pedigree id array. Default "edge id".
- `string = obj.GetEdgePedigreeIdArrayName ()` - The name of the edge pedigree id array. Default "edge id".
- `obj.SetSeed (int )` - Control the seed used for pseudo-random-number generation. This ensures that vtkRandomGraphSource can produce repeatable results.
- `int = obj.GetSeed ()` - Control the seed used for pseudo-random-number generation. This ensures that vtkRandomGraphSource can produce repeatable results.

36.80 vtkRandomLayoutStrategy

36.80.1 Usage

Assigns points to the vertices of a graph randomly within a bounded range.

.SECION Thanks Thanks to Brian Wylie from Sandia National Laboratories for adding incremental layout capabilities.

To create an instance of class vtkRandomLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkRandomLayoutStrategy
```

36.80.2 Methods

The class vtkRandomLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRandomLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRandomLayoutStrategy = obj.NewInstance ()`
- `vtkRandomLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to compute point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to compute point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to compute point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeed ()` - Seed the random number generator used to compute point positions. This has a significant effect on their final positions when the layout is complete.
- `obj.SetGraphBounds (double , double , double , double , double , double )` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `obj.SetGraphBounds (double a[6])` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `double = obj. GetGraphBounds ()` - Set / get the region in space in which to place the final graph. The GraphBounds only affects the results if AutomaticBoundsComputation is off.
- `obj.SetAutomaticBoundsComputation (int )` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `int = obj.GetAutomaticBoundsComputation ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.AutomaticBoundsComputationOn ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.AutomaticBoundsComputationOff ()` - Turn on/off automatic graph bounds calculation. If this boolean is off, then the manually specified GraphBounds is used. If on, then the input's bounds us used as the graph bounds.
- `obj.SetThreeDimensionalLayout (int )` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is on.
- `int = obj.GetThreeDimensionalLayout ()` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is on.
- `obj.ThreeDimensionalLayoutOn ()` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is on.

- `obj.ThreeDimensionalLayoutOff ()` - Turn on/off layout of graph in three dimensions. If off, graph layout occurs in two dimensions. By default, three dimensional layout is on.
- `obj.SetGraph (vtkGraph graph)` - Set the graph to layout.
- `obj.Layout ()` - Perform the random layout.

36.81 vtkRemoveHiddenData

36.81.1 Usage

Output only those rows/vertices/edges of the input vtkDataObject that are visible, as defined by the vtkAnnotation::HIDE() flag of the input vtkAnnotationLayers. Inputs: Port 0 - vtkDataObject Port 1 - vtkAnnotationLayers (optional)

To create an instance of class vtkRemoveHiddenData, simply invoke its constructor as follows

```
obj = vtkRemoveHiddenData
```

36.81.2 Methods

The class vtkRemoveHiddenData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRemoveHiddenData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRemoveHiddenData = obj.NewInstance ()`
- `vtkRemoveHiddenData = obj.SafeDownCast (vtkObject o)`

36.82 vtkRemoveIsolatedVertices

36.82.1 Usage

To create an instance of class vtkRemoveIsolatedVertices, simply invoke its constructor as follows

```
obj = vtkRemoveIsolatedVertices
```

36.82.2 Methods

The class vtkRemoveIsolatedVertices has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRemoveIsolatedVertices class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRemoveIsolatedVertices = obj.NewInstance ()`
- `vtkRemoveIsolatedVertices = obj.SafeDownCast (vtkObject o)`

36.83 vtkRISReader

36.83.1 Usage

RIS is a tagged format for expressing bibliographic citations. Data is structured as a collection of records with each record composed of one-to-many fields. See

http://en.wikipedia.org/wiki/RIS_(file_format) http://www.refman.com/support/risformat_intro.asp http://www.adeptsc

for details. vtkRISReader will convert an RIS file into a vtkTable, with the set of table columns determined dynamically from the contents of the file.

To create an instance of class vtkRISReader, simply invoke its constructor as follows

```
obj = vtkRISReader
```

36.83.2 Methods

The class vtkRISReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRISReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRISReader = obj.NewInstance ()`
- `vtkRISReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()` - Set/get the file to load
- `obj.SetFileName (string )` - Set/get the file to load
- `string = obj.GetDelimiter ()` - Set/get the delimiter to be used for concatenating field data (default: ";")
- `obj.SetDelimiter (string )` - Set/get the delimiter to be used for concatenating field data (default: ";")
- `int = obj.GetMaxRecords ()` - Set/get the maximum number of records to read from the file (zero = unlimited)
- `obj.SetMaxRecords (int )` - Set/get the maximum number of records to read from the file (zero = unlimited)

36.84 vtkSCurveSpline

36.84.1 Usage

vtkSCurveSpline is a concrete implementation of vtkSpline using a SCurve basis.

To create an instance of class vtkSCurveSpline, simply invoke its constructor as follows

```
obj = vtkSCurveSpline
```

36.84.2 Methods

The class vtkSCurveSpline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSCurveSpline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSCurveSpline = obj.NewInstance ()`
- `vtkSCurveSpline = obj.SafeDownCast (vtkObject o)`
- `obj.Compute ()`
- `double = obj.Evaluate (double t)` - Evaluate a 1D SCurve spline.
- `obj.DeepCopy (vtkSpline s)` - Deep copy of SCurve spline data.
- `obj.SetNodeWeight (double )`
- `double = obj.GetNodeWeight ()`

36.85 vtkSimple2DLayoutStrategy

36.85.1 Usage

This class is an implementation of the work presented in: Fruchterman & Reingold "Graph Drawing by Force-directed Placement" Software-Practice and Experience 21(11) 1991). The class includes some optimizations but nothing too fancy.

.SECTION Thanks Thanks to Brian Wylie from Sandia National Laboratories for creating this class.

To create an instance of class vtkSimple2DLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkSimple2DLayoutStrategy
```

36.85.2 Methods

The class vtkSimple2DLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimple2DLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSimple2DLayoutStrategy = obj.NewInstance ()`
- `vtkSimple2DLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetRandomSeed (int )` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMinValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.
- `int = obj.GetRandomSeedMaxValue ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.

- `int = obj.GetRandomSeed ()` - Seed the random number generator used to jitter point positions. This has a significant effect on their final positions when the layout is complete.

- `obj.SetMaxNumberOfIterations (int )` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMinValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterationsMaxValue ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `int = obj.GetMaxNumberOfIterations ()` - Set/Get the maximum number of iterations to be used. The higher this number, the more iterations through the algorithm is possible, and thus, the more the graph gets modified. The default is '100' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetIterationsPerLayout (int )` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMinValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayoutMaxValue ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `int = obj.GetIterationsPerLayout ()` - Set/Get the number of iterations per layout. The only use for this ivar is for the application to do visualizations of the layout before it's complete. The default is '100' to match the default 'MaxNumberOfIterations' Note: Changing this parameter is just fine :)

- `obj.SetInitialTemperature (float )` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMinValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperatureMaxValue ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `float = obj.GetInitialTemperature ()` - Set the initial temperature. The temperature default is '5' for no particular reason Note: The strong recommendation is that you do not change this parameter. :)

- `obj.SetCoolDownRate (double )` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMinValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRateMaxValue ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `double = obj.GetCoolDownRate ()` - Set/Get the Cool-down rate. The higher this number is, the longer it will take to "cool-down", and thus, the more the graph will be modified. The default is '10' for no particular reason. Note: The strong recommendation is that you do not change this parameter. :)
- `obj.SetJitter (bool )` - Set Random jitter of the nodes at initialization to on or off. Note: It's strongly recommendation to have jitter ON even if you have initial coordinates in your graph. Default is ON
- `bool = obj.GetJitter ()` - Set Random jitter of the nodes at initialization to on or off. Note: It's strongly recommendation to have jitter ON even if you have initial coordinates in your graph. Default is ON
- `obj.SetRestDistance (float )` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `float = obj.GetRestDistance ()` - Manually set the resting distance. Otherwise the distance is computed automatically.
- `obj.Initialize ()` - This strategy sets up some data structures for faster processing of each Layout() call
- `obj.Layout ()` - This is the layout method where the graph that was set in SetGraph() is laid out. The method can either entirely layout the graph or iteratively lay out the graph. If you have an iterative layout please implement the IsLayoutComplete() method.
- `int = obj.IsLayoutComplete ()`

36.86 vtkSimple3DCirclesStrategy

36.86.1 Usage

Places vertices on circles depending on the graph vertices hierarchy level. The source graph could be vtkDirectedAcyclicGraph or vtkDirectedGraph if MarkedStartPoints array was added. The algorithm collects the standalone points, too and take them to a separated circle. If method is FixedRadiusMethod, the radius of the circles will be equal. If method is FixedDistanceMethod, the distance beetwen the points on circles will be equal.

In first step initial points are searched. A point is initial, if its in degree equal zero and out degree is greater than zero (or marked by MarkedStartVertices and out degree is greater than zero). Independent vertices (in and out degree equal zero) are collected separatelly. In second step the hierarchical level is generated for every vertex. In third step the hierarchical order is generated. If a vertex has no hierarchical level and it is not independent, the graph has loop so the algorithm exit with error message. Finally the vertices positions are calculated by the hierarchical order and by the vertices hierarchy levels.

To create an instance of class vtkSimple3DCirclesStrategy, simply invoke its constructor as follows

```
obj = vtkSimple3DCirclesStrategy
```

36.86.2 Methods

The class vtkSimple3DCirclesStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimple3DCirclesStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSimple3DCirclesStrategy = obj.NewInstance ()`
- `vtkSimple3DCirclesStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetMethod (int )` - Set or get cicrle generating method (FixedRadiusMethod/FixedDistanceMethod). Default is FixedRadiusMethod.
- `int = obj.GetMethod ()` - Set or get cicrle generating method (FixedRadiusMethod/FixedDistanceMethod). Default is FixedRadiusMethod.
- `obj.SetRadius (double )` - If Method is FixedRadiusMethod: Set or get the radius of the circles. If Method is FixedDistanceMethod: Set or get the distance of the points in the circle.
- `double = obj.GetRadius ()` - If Method is FixedRadiusMethod: Set or get the radius of the circles. If Method is FixedDistanceMethod: Set or get the distance of the points in the circle.
- `obj.SetHeight (double )` - Set or get the vertical (local z) distance between the circles. If AutoHeight is on, this is the minimal height between the circle layers
- `double = obj.GetHeight ()` - Set or get the vertical (local z) distance between the circles. If AutoHeight is on, this is the minimal height between the circle layers
- `obj.SetOrign (double , double , double )` - Set or get the orign of the geometry. This is the center of the first circle. SetOrign(x,y,z)
- `obj.SetOrign (double  a[3])` - Set or get the orign of the geometry. This is the center of the first circle. SetOrign(x,y,z)
- `double = obj. GetOrign ()` - Set or get the orign of the geometry. This is the center of the first circle. SetOrign(x,y,z)
- `obj.SetDirection (double dx, double dy, double dz)` - Set or get the normal vector of the circles plain. The height is growing in this direction. The direction must not be zero vector. The default vector is (0.0,0.0,1.0)
- `obj.SetDirection (double d[3])` - Set or get the normal vector of the circles plain. The height is growing in this direction. The direction must not be zero vector. The default vector is (0.0,0.0,1.0)
- `double = obj. GetDirection ()` - Set or get the normal vector of the circles plain. The height is growing in this direction. The direction must not be zero vector. The default vector is (0.0,0.0,1.0)

- `obj.SetMarkedStartVertices (vtkIntArray \_arg)` - Set or get initial vertices. If MarkedStartVertices is added, loop is accepted in the graph. (If all of the loop start vertices are marked in MarkedStartVertices array.) MarkedStartVertices size must be equal with the number of the vertices in the graph. Start vertices must be marked by MarkedValue. (E.g.: if MarkedValue=3 and MarkedStartPoints is 0, 3, 5, 3 , the start points ids will be 1,3.))

- `vtkIntArray = obj.GetMarkedStartVertices ()` - Set or get initial vertices. If MarkedStartVertices is added, loop is accepted in the graph. (If all of the loop start vertices are marked in MarkedStartVertices array.) MarkedStartVertices size must be equal with the number of the vertices in the graph. Start vertices must be marked by MarkedValue. (E.g.: if MarkedValue=3 and MarkedStartPoints is 0, 3, 5, 3 , the start points ids will be 1,3.))

- `obj.SetMarkedValue (int )` - Set or get MarkedValue. See: MarkedStartVertices.

- `int = obj.GetMarkedValue ()` - Set or get MarkedValue. See: MarkedStartVertices.

- `obj.SetForceToUseUniversalStartPointsFinder (int )` - Set or get ForceToUseUniversalStartPointsFinder. If ForceToUseUniversalStartPointsFinder is true, MarkedStartVertices won't be used. In this case the input graph must be vtkDirectedAcyclicGraph (Defualt: false).

- `int = obj.GetForceToUseUniversalStartPointsFinder ()` - Set or get ForceToUseUniversalStartPointsFinder. If ForceToUseUniversalStartPointsFinder is true, MarkedStartVertices won't be used. In this case the input graph must be vtkDirectedAcyclicGraph (Defualt: false).

- `obj.ForceToUseUniversalStartPointsFinderOn ()` - Set or get ForceToUseUniversalStartPointsFinder. If ForceToUseUniversalStartPointsFinder is true, MarkedStartVertices won't be used. In this case the input graph must be vtkDirectedAcyclicGraph (Defualt: false).

- `obj.ForceToUseUniversalStartPointsFinderOff ()` - Set or get ForceToUseUniversalStartPointsFinder. If ForceToUseUniversalStartPointsFinder is true, MarkedStartVertices won't be used. In this case the input graph must be vtkDirectedAcyclicGraph (Defualt: false).

- `obj.SetAutoHeight (int )` - Set or get auto height (Default: false). If AutoHeight is true, (r(i+1) - r(i-1))/Height will be smaller than tan(MinimumRadian). If you want equal distances and parallel circles, you should turn off AutoHeight.

- `int = obj.GetAutoHeight ()` - Set or get auto height (Default: false). If AutoHeight is true, (r(i+1) - r(i-1))/Height will be smaller than tan(MinimumRadian). If you want equal distances and parallel circles, you should turn off AutoHeight.

- `obj.AutoHeightOn ()` - Set or get auto height (Default: false). If AutoHeight is true, (r(i+1) - r(i-1))/Height will be smaller than tan(MinimumRadian). If you want equal distances and parallel circles, you should turn off AutoHeight.

- `obj.AutoHeightOff ()` - Set or get auto height (Default: false). If AutoHeight is true, (r(i+1) - r(i-1))/Height will be smaller than tan(MinimumRadian). If you want equal distances and parallel circles, you should turn off AutoHeight.

- `obj.SetMinimumRadian (double )` - Set or get minimum radian (used by auto height).

- `double = obj.GetMinimumRadian ()` - Set or get minimum radian (used by auto height).

- `obj.SetMinimumDegree (double degree)` - Set or get minimum degree (used by auto height). There is no separated minimum degree, so minimum radian will be changed.

- `double = obj.GetMinimumDegree (void )` - Set or get minimum degree (used by auto height). There is no separated minimum degree, so minimum radian will be changed.

- `obj.SetHierarchicalLayers (vtkIntArray \_arg)` - Set or get hierarchical layers id by vertices (An usual vertex's layer id is greater or equal to zero. If a vertex is standalone, its layer id is -2.) If no HierarchicalLayers array is defined, vtkSimple3DCirclesStrategy will generate it automatically (default).

- `vtkIntArray = obj.GetHierarchicalLayers ()` - Set or get hierarchical layers id by vertices (An usual vertex's layer id is greater or equal to zero. If a vertex is standalone, its layer id is -2.) If no HierarchicalLayers array is defined, vtkSimple3DCirclesStrategy will generate it automatically (default).

- `obj.SetHierarchicalOrder (vtkIdTypeArray \_arg)` - Set or get hierarchical ordering of vertices (The array starts from the first vertex's id. All id must be greater or equal to zero!) If no HierarchicalOrder is defined, vtkSimple3DCirclesStrategy will generate it automatically (default).

- `vtkIdTypeArray = obj.GetHierarchicalOrder ()` - Set or get hierarchical ordering of vertices (The array starts from the first vertex's id. All id must be greater or equal to zero!) If no HierarchicalOrder is defined, vtkSimple3DCirclesStrategy will generate it automatically (default).

- `obj.Layout (void )` - Standard layout method

- `obj.SetGraph (vtkGraph graph)` - Set graph (warning: HierarchicalOrder and HierarchicalLayers will set to zero. These reference counts will be decreased!)

36.87 vtkSliceAndDiceLayoutStrategy

36.87.1 Usage

Lays out a tree-map alternating between horizontal and vertical slices, taking into account the relative size of each vertex.

.SECTION Thanks Slice and dice algorithm comes from: Shneiderman, B. 1992. Tree visualization with tree-maps: 2-d space-filling approach. ACM Trans. Graph. 11, 1 (Jan. 1992), 92-99.

To create an instance of class vtkSliceAndDiceLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkSliceAndDiceLayoutStrategy
```

36.87.2 Methods

The class vtkSliceAndDiceLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSliceAndDiceLayoutStrategy class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkSliceAndDiceLayoutStrategy = obj.NewInstance ()`

- `vtkSliceAndDiceLayoutStrategy = obj.SafeDownCast (vtkObject o)`

- `obj.Layout (vtkTree inputTree, vtkDataArray coordsArray, vtkDataArray sizeArray)` - Perform the layout of a tree and place the results as 4-tuples in coordsArray (Xmin, Xmax, Ymin, Ymax).

36.88 vtkSpanTreeLayoutStrategy

36.88.1 Usage

vtkSpanTreeLayout is a strategy for drawing directed graphs that works by first extracting a spanning tree (more accurately, a spanning forest), and using this both to position graph vertices and to plan the placement of non-tree edges. The latter are drawn with the aid of edge points to produce a tidy drawing.

The approach is best suited to "quasi-trees", graphs where the number of edges is of the same order as the number of nodes; it is less well suited to denser graphs. The boolean flag DepthFirstSpanningTree determines whether a depth-first or breadth-first strategy is used to construct the underlying forest, and the choice of strategy affects the output layout significantly. Informal experiments suggest that the breadth-first strategy is better for denser graphs.

Different layouts could also be produced by plugging in alternative tree layout strategies. To work with the method of routing non-tree edges, any strategy should draw a tree so that levels are equally spaced along the z-axis, precluding for example the use of a radial or balloon layout.

vtkSpanTreeLayout is based on an approach to 3D graph layout first developed as part of the "tulip" tool by Dr. David Auber at LaBRI, U.Bordeaux: see www.tulip-software.org

This implementation departs from the original version in that: (a) it is reconstructed to use Titan/VTK data structures; (b) it uses a faster method for dealing with non-tree edges, requiring at most two edge points per edge (c) allows for plugging in different tree layout methods (d) allows selection of two different strategies for building the underlying layout tree, which can yield significantly different results depending on the data.

.SECTION Thanks Thanks to David Duke from the University of Leeds for providing this implementation.

To create an instance of class vtkSpanTreeLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkSpanTreeLayoutStrategy
```

36.88.2 Methods

The class vtkSpanTreeLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSpanTreeLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSpanTreeLayoutStrategy = obj.NewInstance ()`
- `vtkSpanTreeLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.SetDepthFirstSpanningTree (bool )` - If set, base the layout on a depth-first spanning tree, rather than the default breadth-first spanning tree. Switching between DFT and BFT may significantly change the layout, and choice must be made on a per-graph basis. Default value is off.
- `bool = obj.GetDepthFirstSpanningTree ()` - If set, base the layout on a depth-first spanning tree, rather than the default breadth-first spanning tree. Switching between DFT and BFT may significantly change the layout, and choice must be made on a per-graph basis. Default value is off.
- `obj.DepthFirstSpanningTreeOn ()` - If set, base the layout on a depth-first spanning tree, rather than the default breadth-first spanning tree. Switching between DFT and BFT may significantly change the layout, and choice must be made on a per-graph basis. Default value is off.
- `obj.DepthFirstSpanningTreeOff ()` - If set, base the layout on a depth-first spanning tree, rather than the default breadth-first spanning tree. Switching between DFT and BFT may significantly change the layout, and choice must be made on a per-graph basis. Default value is off.
- `obj.Layout ()` - Perform the layout.

36.89 vtkSparseArrayToTable

36.89.1 Usage

Converts any sparse array to a vtkTable containing one row for each value stored in the array. The table will contain one column of coordinates for each dimension in the source array, plus one column of array values. A common use-case for vtkSparseArrayToTable would be converting a sparse array into a table suitable for use as an input to vtkTableToGraph.

The coordinate columns in the output table will be named using the dimension labels from the source array, The value column name can be explicitly set using SetValueColumn().

.SECTION Thanks Developed by Timothy M. Shead (tshead@sandia.gov) at Sandia National Laboratories.

To create an instance of class vtkSparseArrayToTable, simply invoke its constructor as follows

```
obj = vtkSparseArrayToTable
```

36.89.2 Methods

The class vtkSparseArrayToTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSparseArrayToTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSparseArrayToTable = obj.NewInstance ()`
- `vtkSparseArrayToTable = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetValueColumn ()` - Specify the name of the output table column that contains array values. Default: "value"
- `obj.SetValueColumn (string )` - Specify the name of the output table column that contains array values. Default: "value"

36.90 vtkSplineGraphEdges

36.90.1 Usage

vtkSplineGraphEdges uses a vtkSpline to make edges into nicely sampled splines. By default, the filter will use an optimized b-spline. Otherwise, it will use a custom vtkSpline instance set by the user.

To create an instance of class vtkSplineGraphEdges, simply invoke its constructor as follows

```
obj = vtkSplineGraphEdges
```

36.90.2 Methods

The class vtkSplineGraphEdges has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplineGraphEdges class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSplineGraphEdges = obj.NewInstance ()`

- `vtkSplineGraphEdges = obj.SafeDownCast (vtkObject o)`
- `obj.SetSpline (vtkSpline s)` - If SplineType is CUSTOM, uses this spline.
- `vtkSpline = obj.GetSpline ()` - If SplineType is CUSTOM, uses this spline.
- `obj.SetSplineType (int )` - Spline type used by the filter. BSPLINE (0) - Use optimized b-spline (default). CUSTOM (1) - Use spline set with SetSpline.
- `int = obj.GetSplineType ()` - Spline type used by the filter. BSPLINE (0) - Use optimized b-spline (default). CUSTOM (1) - Use spline set with SetSpline.
- `obj.SetNumberOfSubdivisions (vtkIdType )` - The number of subdivisions in the spline.
- `vtkIdType = obj.GetNumberOfSubdivisions ()` - The number of subdivisions in the spline.

36.91 vtkSplitColumnComponents

36.91.1 Usage

Splits any columns in a table that have more than one component into individual columns. Single component columns are passed through without any data duplication. So if column names "Points" had three components this column would be split into "Points (0)", "Points (1)" and Points (2)".

To create an instance of class vtkSplitColumnComponents, simply invoke its constructor as follows

```
obj = vtkSplitColumnComponents
```

36.91.2 Methods

The class vtkSplitColumnComponents has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplitColumnComponents class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSplitColumnComponents = obj.NewInstance ()`
- `vtkSplitColumnComponents = obj.SafeDownCast (vtkObject o)`
- `obj.SetCalculateMagnitudes (bool )` - If on this filter will calculate an additional magnitude column for all columns it splits with two or more components. Default is on.
- `bool = obj.GetCalculateMagnitudes ()` - If on this filter will calculate an additional magnitude column for all columns it splits with two or more components. Default is on.

36.92 vtkSQLDatabaseGraphSource

36.92.1 Usage

This class combines vtkSQLDatabase, vtkSQLQuery, and vtkQueryToGraph to provide a convenience class for generating graphs from databases. Also this class can be easily wrapped and used within ParaView / OverView.

To create an instance of class vtkSQLDatabaseGraphSource, simply invoke its constructor as follows

```
obj = vtkSQLDatabaseGraphSource
```

36.92.2 Methods

The class vtkSQLDatabaseGraphSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLDatabaseGraphSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLDatabaseGraphSource = obj.NewInstance ()`
- `vtkSQLDatabaseGraphSource = obj.SafeDownCast (vtkObject o)`
- `vtkStdString = obj.GetURL ()`
- `obj.SetURL (vtkStdString \&url)`
- `obj.SetPassword (vtkStdString \&password)`
- `vtkStdString = obj.GetEdgeQuery ()`
- `obj.SetEdgeQuery (vtkStdString \&query)`
- `vtkStdString = obj.GetVertexQuery ()`
- `obj.SetVertexQuery (vtkStdString \&query)`
- `obj.AddLinkVertex (string column, string domain, int hidden)`
- `obj.ClearLinkVertices ()`
- `obj.AddLinkEdge (string column1, string column2)`
- `obj.ClearLinkEdges ()`
- `bool = obj.GetGenerateEdgePedigreeIds ()` - If on (default), generate edge pedigree ids. If off, assign an array to be edge pedigree ids.
- `obj.SetGenerateEdgePedigreeIds (bool )` - If on (default), generate edge pedigree ids. If off, assign an array to be edge pedigree ids.
- `obj.GenerateEdgePedigreeIdsOn ()` - If on (default), generate edge pedigree ids. If off, assign an array to be edge pedigree ids.
- `obj.GenerateEdgePedigreeIdsOff ()` - If on (default), generate edge pedigree ids. If off, assign an array to be edge pedigree ids.
- `obj.SetEdgePedigreeIdArrayName (string )` - Use this array name for setting or generating edge pedigree ids.
- `string = obj.GetEdgePedigreeIdArrayName ()` - Use this array name for setting or generating edge pedigree ids.
- `obj.SetDirected (bool )` - If on (default), generate a directed output graph. If off, generate an undirected output graph.
- `bool = obj.GetDirected ()` - If on (default), generate a directed output graph. If off, generate an undirected output graph.
- `obj.DirectedOn ()` - If on (default), generate a directed output graph. If off, generate an undirected output graph.
- `obj.DirectedOff ()` - If on (default), generate a directed output graph. If off, generate an undirected output graph.

36.93 vtkSQLDatabaseTableSource

36.93.1 Usage

This class combines vtkSQLDatabase, vtkSQLQuery, and vtkQueryToTable to provide a convenience class for generating tables from databases. Also this class can be easily wrapped and used within ParaView / OverView.

To create an instance of class vtkSQLDatabaseTableSource, simply invoke its constructor as follows

```
obj = vtkSQLDatabaseTableSource
```

36.93.2 Methods

The class vtkSQLDatabaseTableSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLDatabaseTableSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLDatabaseTableSource = obj.NewInstance ()`
- `vtkSQLDatabaseTableSource = obj.SafeDownCast (vtkObject o)`
- `vtkStdString = obj.GetURL ()`
- `obj.SetURL (vtkStdString \&url)`
- `obj.SetPassword (vtkStdString \&password)`
- `vtkStdString = obj.GetQuery ()`
- `obj.SetQuery (vtkStdString \&query)`
- `obj.SetPedigreeIdArrayName (string )` - The name of the array for generating or assigning pedigree ids (default "id").
- `string = obj.GetPedigreeIdArrayName ()` - The name of the array for generating or assigning pedigree ids (default "id").
- `obj.SetGeneratePedigreeIds (bool )` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `bool = obj.GetGeneratePedigreeIds ()` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `obj.GeneratePedigreeIdsOn ()` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.
- `obj.GeneratePedigreeIdsOff ()` - If on (default), generates pedigree ids automatically. If off, assign one of the arrays to be the pedigree id.

36.94 vtkSQLGraphReader

36.94.1 Usage

Creates a vtkGraph using one or two vtkSQLQuery's. The first (required) query must have one row for each arc in the graph. The query must have two columns which represent the source and target node ids.

The second (optional) query has one row for each node in the graph. The table must have a field whose values match those in the arc table. If the node table is not given, a node will be created for each unique source or target identifier in the arc table.

The source, target, and node ID fields must be of the same type, and must be either vtkStringArray or a subclass of vtkDataArray.

All columns in the queries, including the source, target, and node index fields, are copied into the arc data and node data of the resulting vtkGraph. If the node query is not given, the node data will contain a single "id" column with the same type as the source/target id arrays.

If parallel arcs are collected, not all the arc data is not copied into the output. Only the source and target id arrays will be transferred. An additional vtkIdTypeArray column called "weight" is created which contains the number of times each arc appeared in the input.

If the node query contains positional data, the user may specify the names of these fields. These arrays must be data arrays. The z-coordinate array is optional, and if not given the z-coordinates are set to zero.

To create an instance of class vtkSQLGraphReader, simply invoke its constructor as follows

```
obj = vtkSQLGraphReader
```

36.94.2 Methods

The class vtkSQLGraphReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLGraphReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLGraphReader = obj.NewInstance ()`
- `vtkSQLGraphReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetDirected (bool )` - When set, creates a directed graph, as opposed to an undirected graph.
- `bool = obj.GetDirected ()` - When set, creates a directed graph, as opposed to an undirected graph.
- `obj.DirectedOn ()` - When set, creates a directed graph, as opposed to an undirected graph.
- `obj.DirectedOff ()` - When set, creates a directed graph, as opposed to an undirected graph.
- `obj.SetVertexQuery (vtkSQLQuery q)` - The query that retrieves the node information.
- `vtkSQLQuery = obj.GetVertexQuery ()` - The query that retrieves the node information.
- `obj.SetEdgeQuery (vtkSQLQuery q)` - The query that retrieves the arc information.
- `vtkSQLQuery = obj.GetEdgeQuery ()` - The query that retrieves the arc information.
- `obj.SetSourceField (string )` - The name of the field in the arc query for the source node of each arc.
- `string = obj.GetSourceField ()` - The name of the field in the arc query for the source node of each arc.

- `obj.SetTargetField (string )` - The name of the field in the arc query for the target node of each arc.
- `string = obj.GetTargetField ()` - The name of the field in the arc query for the target node of each arc.
- `obj.SetVertexIdField (string )` - The name of the field in the node query for the node ID.
- `string = obj.GetVertexIdField ()` - The name of the field in the node query for the node ID.
- `obj.SetXField (string )` - The name of the field in the node query for the node's x coordinate.
- `string = obj.GetXField ()` - The name of the field in the node query for the node's x coordinate.
- `obj.SetYField (string )` - The name of the field in the node query for the node's y coordinate.
- `string = obj.GetYField ()` - The name of the field in the node query for the node's y coordinate.
- `obj.SetZField (string )` - The name of the field in the node query for the node's z coordinate.
- `string = obj.GetZField ()` - The name of the field in the node query for the node's z coordinate.
- `obj.SetCollapseEdges (bool )` - When set, creates a graph with no parallel arcs. Parallel arcs are combined into one arc. No cell fields are passed to the output, except the vtkGhostLevels array if it exists, but a new field "weight" is created that holds the number of duplicates of that arc in the input.
- `bool = obj.GetCollapseEdges ()` - When set, creates a graph with no parallel arcs. Parallel arcs are combined into one arc. No cell fields are passed to the output, except the vtkGhostLevels array if it exists, but a new field "weight" is created that holds the number of duplicates of that arc in the input.
- `obj.CollapseEdgesOn ()` - When set, creates a graph with no parallel arcs. Parallel arcs are combined into one arc. No cell fields are passed to the output, except the vtkGhostLevels array if it exists, but a new field "weight" is created that holds the number of duplicates of that arc in the input.
- `obj.CollapseEdgesOff ()` - When set, creates a graph with no parallel arcs. Parallel arcs are combined into one arc. No cell fields are passed to the output, except the vtkGhostLevels array if it exists, but a new field "weight" is created that holds the number of duplicates of that arc in the input.

36.95 vtkSquarifyLayoutStrategy

36.95.1 Usage

vtkSquarifyLayoutStrategy partitions the space for child vertices into regions that use all avaliable space and are as close to squares as possible. The algorithm also takes into account the relative vertex size.

.SECTION Thanks The squarified tree map algorithm comes from: Bruls, D.M., C. Huizing, J.J. van Wijk. Squarified Treemaps. In: W. de Leeuw, R. van Liere (eds.), Data Visualization 2000, Proceedings of the joint Eurographics and IEEE TCVG Symposium on Visualization, 2000, Springer, Vienna, p. 33-42.

To create an instance of class vtkSquarifyLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkSquarifyLayoutStrategy
```

36.95.2 Methods

The class vtkSquarifyLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSquarifyLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSquarifyLayoutStrategy = obj.NewInstance ()`
- `vtkSquarifyLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout (vtkTree inputTree, vtkDataArray coordsArray, vtkDataArray sizeArray)` - Perform the layout of a tree and place the results as 4-tuples in coordsArray (Xmin, Xmax, Ymin, Ymax).

36.96 vtkStackedTreeLayoutStrategy

36.96.1 Usage

Performs a tree ring layout or "icicle" layout on a tree. This involves assigning a sector region to each vertex in the tree, and placing that information in a data array with four components per tuple representing (innerRadius, outerRadius, startAngle, endAngle).

This class may be assigned as the layout strategy to vtkAreaLayout.

.SECTION Thanks Thanks to Jason Shepherd from Sandia National Laboratories for help developing this class.

To create an instance of class vtkStackedTreeLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkStackedTreeLayoutStrategy
```

36.96.2 Methods

The class vtkStackedTreeLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStackedTreeLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStackedTreeLayoutStrategy = obj.NewInstance ()`
- `vtkStackedTreeLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout (vtkTree inputTree, vtkDataArray sectorArray, vtkDataArray sizeArray)` - Perform the layout of the input tree, and store the sector bounds of each vertex as a tuple (innerRadius, outerRadius, startAngle, endAngle) in a data array.
- `obj.LayoutEdgePoints (vtkTree inputTree, vtkDataArray sectorArray, vtkDataArray sizeArray, vtkTree` - Fill edgeRoutingTree with points suitable for routing edges of an overlaid graph.
- `obj.SetInteriorRadius (double )` - Define the tree ring's interior radius.
- `double = obj.GetInteriorRadius ()` - Define the tree ring's interior radius.
- `obj.SetRingThickness (double )` - Define the thickness of each of the tree rings.

- `double = obj.GetRingThickness ()` - Define the thickness of each of the tree rings.
- `obj.SetRootStartAngle (double )` - Define the start angle for the root node. NOTE: It is assumed that the root end angle is greater than the root start angle and subtends no more than 360 degrees.
- `double = obj.GetRootStartAngle ()` - Define the start angle for the root node. NOTE: It is assumed that the root end angle is greater than the root start angle and subtends no more than 360 degrees.
- `obj.SetRootEndAngle (double )` - Define the end angle for the root node. NOTE: It is assumed that the root end angle is greater than the root start angle and subtends no more than 360 degrees.
- `double = obj.GetRootEndAngle ()` - Define the end angle for the root node. NOTE: It is assumed that the root end angle is greater than the root start angle and subtends no more than 360 degrees.
- `obj.SetUseRectangularCoordinates (bool )` - Define whether or not rectangular coordinates are being used (as opposed to polar coordinates).
- `bool = obj.GetUseRectangularCoordinates ()` - Define whether or not rectangular coordinates are being used (as opposed to polar coordinates).
- `obj.UseRectangularCoordinatesOn ()` - Define whether or not rectangular coordinates are being used (as opposed to polar coordinates).
- `obj.UseRectangularCoordinatesOff ()` - Define whether or not rectangular coordinates are being used (as opposed to polar coordinates).
- `obj.SetReverse (bool )` - Define whether to reverse the order of the tree stacks from low to high.
- `bool = obj.GetReverse ()` - Define whether to reverse the order of the tree stacks from low to high.
- `obj.ReverseOn ()` - Define whether to reverse the order of the tree stacks from low to high.
- `obj.ReverseOff ()` - Define whether to reverse the order of the tree stacks from low to high.
- `obj.SetInteriorLogSpacingValue (double )` - The spacing of tree levels in the edge routing tree. Levels near zero give more space to levels near the root, while levels near one (the default) create evenly-spaced levels. Levels above one give more space to levels near the leaves.
- `double = obj.GetInteriorLogSpacingValue ()` - The spacing of tree levels in the edge routing tree. Levels near zero give more space to levels near the root, while levels near one (the default) create evenly-spaced levels. Levels above one give more space to levels near the leaves.
- `vtkIdType = obj.FindVertex (vtkTree tree, vtkDataArray array, float pnt[2])` - Returns the vertex id that contains pnt (or -1 if no one contains it).

36.97 vtkStatisticsAlgorithm

36.97.1 Usage

All statistics algorithms can conceptually be operated with several options: * Learn: given an input data set, calculate a minimal statistical model (e.g., sums, raw moments, joint probabilities). * Derive: given an input minimal statistical model, derive the full model (e.g., descriptive statistics, quantiles, correlations, conditional probabilities). NB: It may be, or not be, a problem that a full model was not derived. For instance, when doing parallel calculations, one only wants to derive the full model after all partial calculations have completed. On the other hand, one can also directly provide a full model, that was previously calculated or guessed, and not derive a new one. * Assess: given an input data set, input statistics, and some form of threshold, assess a subset of the data set. * Test: perform at least one statistical test. Therefore, a vtkStatisticsAlgorithm has the following vtkTable ports * 3 input ports: * Data (mandatory) * Parameters to the learn phase (optional) * Input model (optional) * 3 output port (called Output): * Data (annotated

with assessments when the Assess option is ON). * Output model (identical to the the input model when Learn option is OFF). * Meta information about the model and/or the overall fit of the data to the model; is filled only when the Assess option is ON.

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkStatisticsAlgorithm, simply invoke its constructor as follows

```
obj = vtkStatisticsAlgorithm
```

36.97.2 Methods

The class vtkStatisticsAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStatisticsAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStatisticsAlgorithm = obj.NewInstance ()`
- `vtkStatisticsAlgorithm = obj.SafeDownCast (vtkObject o)`
- `obj.SetLearnOptionParameterConnection (vtkAlgorithmOutput params)` - A convenience method for setting learn input parameters (if one is expected or allowed). It is equivalent to calling SetInput(1, params);
- `obj.SetLearnOptionParameters (vtkDataObject params)` - A convenience method for setting the input model (if one is expected or allowed). It is equivalent to calling SetInputConnection(2, model);
- `obj.SetInputModelConnection (vtkAlgorithmOutput model)` - //
- `obj.SetInputModel (vtkDataObject model)` - Set/Get the Learn option.
- `obj.SetLearnOption (bool )` - Set/Get the Learn option.
- `bool = obj.GetLearnOption ()` - Set/Get the Learn option.
- `obj.SetDeriveOption (bool )` - Set/Get the Derive option.
- `bool = obj.GetDeriveOption ()` - Set/Get the Derive option.
- `obj.SetAssessOption (bool )` - Set/Get the Assess option.
- `bool = obj.GetAssessOption ()` - Set/Get the Assess option.
- `obj.SetTestOption (bool )` - Set/Get the Test option.
- `bool = obj.GetTestOption ()` - Set/Get the Test option.
- `obj.SetAssessParameters (vtkStringArray )` - Set/get assessment parameters.
- `vtkStringArray = obj.GetAssessParameters ()` - Set/get assessment parameters.
- `obj.SetAssessNames (vtkStringArray )` - Set/get assessment names.
- `vtkStringArray = obj.GetAssessNames ()` - Set/get assessment names.

- `obj.SetColumnStatus (string namCol, int status)` - Add or remove a column from the current analysis request. Once all the column status values are set, call RequestSelectedColumns() before selecting another set of columns for a different analysis request. The way that columns selections are used varies from algorithm to algorithm.

  Note: the set of selected columns is maintained in vtkStatisticsAlgorithmPrivate::Buffer until RequestSelectedColumns() is called, at which point the set is appended to vtkStatisticsAlgorithmPrivate::Requests. If there are any columns in vtkStatisticsAlgorithmPrivate::Buffer at the time RequestData() is called, RequestSelectedColumns() will be called and the selection added to the list of requests.

- `obj.ResetAllColumnStates ()` - Set the the status of each and every column in the current request to OFF (0).

- `int = obj.RequestSelectedColumns ()` - Use the current column status values to produce a new request for statistics to be produced when RequestData() is called. See SetColumnStatus() for more information.

- `obj.ResetRequests ()` - Empty the list of current requests.

- `vtkIdType = obj.GetNumberOfRequests ()` - Return the number of requests. This does not include any request that is in the column-status buffer but for which RequestSelectedColumns() has not yet been called (even though it is possible this request will be honored when the filter is run – see SetColumnStatus() for more information).

- `vtkIdType = obj.GetNumberOfColumnsForRequest (vtkIdType request)` - Return the number of columns for a given request.

- `string = obj.GetColumnForRequest (vtkIdType r, vtkIdType c)` - Provide the name of the c-th column for the r-th request.

  For the version of this routine that returns an integer, if the request or column does not exist because r or c is out of bounds, this routine returns 0 and the value of columnName is unspecified. Otherwise, it returns 1 and the value of columnName is set.

  For the version of this routine that returns const char*, if the request or column does not exist because r or c is out of bounds, the routine returns NULL. Otherwise it returns the column name. This version is not thread-safe.

- `obj.Aggregate (vtkDataObjectCollection , vtkDataObject )` - Given a collection of models, calculate aggregate model

36.98 vtkStrahlerMetric

36.98.1 Usage

The Strahler metric is a value assigned to each vertex of a tree that characterizes the structural complexity of the sub-tree rooted at that node. The metric originated in the study of river systems, but has been applied to other tree- structured systes, Details of the metric and the rationale for using it in infovis can be found in:

Tree Visualization and Navigation Clues for Information Visualization, I. Herman, M. Delest, and G. Melancon, Computer Graphics Forum, Vol 17(2), Blackwell, 1998.

The input tree is copied to the output, but with a new array added to the output vertex data.

.SECTION Thanks Thanks to David Duke from the University of Leeds for providing this implementation.

To create an instance of class vtkStrahlerMetric, simply invoke its constructor as follows

```
obj = vtkStrahlerMetric
```

36.98.2 Methods

The class vtkStrahlerMetric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStrahlerMetric class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStrahlerMetric = obj.NewInstance ()`
- `vtkStrahlerMetric = obj.SafeDownCast (vtkObject o)`
- `obj.SetMetricArrayName (string )` - Set the name of the array in which the Strahler values will be stored within the output vertex data. Default is "Strahler"
- `obj.SetNormalize (int )` - Set/get setting of normalize flag. If this is set, the Strahler values are scaled into the range [0..1]. Default is for normalization to be OFF.
- `int = obj.GetNormalize ()` - Set/get setting of normalize flag. If this is set, the Strahler values are scaled into the range [0..1]. Default is for normalization to be OFF.
- `obj.NormalizeOn ()` - Set/get setting of normalize flag. If this is set, the Strahler values are scaled into the range [0..1]. Default is for normalization to be OFF.
- `obj.NormalizeOff ()` - Set/get setting of normalize flag. If this is set, the Strahler values are scaled into the range [0..1]. Default is for normalization to be OFF.
- `float = obj.GetMaxStrahler ()` - Get the maximum strahler value for the tree.

36.99 vtkStreamGraph

36.99.1 Usage

vtkStreamGraph iteratively collects information from the input graph and combines it in the output graph. It internally maintains a graph instance that is incrementally updated every time the filter is called.

Each update, vtkMergeGraphs is used to combine this filter's input with the internal graph.

To create an instance of class vtkStreamGraph, simply invoke its constructor as follows

```
obj = vtkStreamGraph
```

36.99.2 Methods

The class vtkStreamGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamGraph = obj.NewInstance ()`
- `vtkStreamGraph = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaxEdges (vtkIdType )` - The maximum number of edges in the combined graph. Default is -1, which specifies that there should be no limit on the number of edges.
- `vtkIdType = obj.GetMaxEdges ()` - The maximum number of edges in the combined graph. Default is -1, which specifies that there should be no limit on the number of edges.

36.100 vtkStringToCategory

36.100.1 Usage

vtkStringToCategory creates an integer array named "category" based on the values in a string array. You may use this filter to create an array that you may use to color points/cells by the values in a string array. Currently there is not support to color by a string array directly. The category values will range from zero to N-1, where N is the number of distinct strings in the string array. Set the string array to process with SetInputArrayToProcess(0,0,0,...). The array may be in the point, cell, or field data of the data object.

To create an instance of class vtkStringToCategory, simply invoke its constructor as follows

```
obj = vtkStringToCategory
```

36.100.2 Methods

The class vtkStringToCategory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStringToCategory class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStringToCategory = obj.NewInstance ()`
- `vtkStringToCategory = obj.SafeDownCast (vtkObject o)`
- `obj.SetCategoryArrayName (string )` - The name to give to the output vtkIntArray of category values.
- `string = obj.GetCategoryArrayName ()` - The name to give to the output vtkIntArray of category values.

36.101 vtkStringToNumeric

36.101.1 Usage

vtkStringToNumeric is a filter for converting a string array into a numeric arrays.

To create an instance of class vtkStringToNumeric, simply invoke its constructor as follows

```
obj = vtkStringToNumeric
```

36.101.2 Methods

The class vtkStringToNumeric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStringToNumeric class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStringToNumeric = obj.NewInstance ()`
- `vtkStringToNumeric = obj.SafeDownCast (vtkObject o)`
- `obj.SetConvertFieldData (bool )` - Whether to detect and convert field data arrays. Default is on.

- `bool = obj.GetConvertFieldData ()` - Whether to detect and convert field data arrays. Default is on.
- `obj.ConvertFieldDataOn ()` - Whether to detect and convert field data arrays. Default is on.
- `obj.ConvertFieldDataOff ()` - Whether to detect and convert field data arrays. Default is on.
- `obj.SetConvertPointData (bool )` - Whether to detect and convert cell data arrays. Default is on.
- `bool = obj.GetConvertPointData ()` - Whether to detect and convert cell data arrays. Default is on.
- `obj.ConvertPointDataOn ()` - Whether to detect and convert cell data arrays. Default is on.
- `obj.ConvertPointDataOff ()` - Whether to detect and convert cell data arrays. Default is on.
- `obj.SetConvertCellData (bool )` - Whether to detect and convert point data arrays. Default is on.
- `bool = obj.GetConvertCellData ()` - Whether to detect and convert point data arrays. Default is on.
- `obj.ConvertCellDataOn ()` - Whether to detect and convert point data arrays. Default is on.
- `obj.ConvertCellDataOff ()` - Whether to detect and convert point data arrays. Default is on.
- `obj.SetConvertVertexData (bool b)` - Whether to detect and convert vertex data arrays. Default is on.
- `bool = obj.GetConvertVertexData ()` - Whether to detect and convert vertex data arrays. Default is on.
- `obj.ConvertVertexDataOn ()` - Whether to detect and convert vertex data arrays. Default is on.
- `obj.ConvertVertexDataOff ()` - Whether to detect and convert vertex data arrays. Default is on.
- `obj.SetConvertEdgeData (bool b)` - Whether to detect and convert edge data arrays. Default is on.
- `bool = obj.GetConvertEdgeData ()` - Whether to detect and convert edge data arrays. Default is on.
- `obj.ConvertEdgeDataOn ()` - Whether to detect and convert edge data arrays. Default is on.
- `obj.ConvertEdgeDataOff ()` - Whether to detect and convert edge data arrays. Default is on.
- `obj.SetConvertRowData (bool b)` - Whether to detect and convert row data arrays. Default is on.
- `bool = obj.GetConvertRowData ()` - Whether to detect and convert row data arrays. Default is on.
- `obj.ConvertRowDataOn ()` - Whether to detect and convert row data arrays. Default is on.
- `obj.ConvertRowDataOff ()` - Whether to detect and convert row data arrays. Default is on.

36.102 vtkStringToTimePoint

36.102.1 Usage

vtkStringToTimePoint is a filter for converting a string array into a datetime, time or date array. The input strings must conform to one of the ISO8601 formats defined in vtkTimePointUtility.

The input array specified by SetInputArrayToProcess(...) indicates the array to process. This array must be of type vtkStringArray.

The output array will be of type vtkTypeUInt64Array.

To create an instance of class vtkStringToTimePoint, simply invoke its constructor as follows

```
obj = vtkStringToTimePoint
```

36.102.2 Methods

The class vtkStringToTimePoint has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStringToTimePoint class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStringToTimePoint = obj.NewInstance ()`
- `vtkStringToTimePoint = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputArrayName (string )` - The name of the output array. If this is not specified, the name will be the same as the input array name with either " [to datetime]", " [to date]", or " [to time]" appended.
- `string = obj.GetOutputArrayName ()` - The name of the output array. If this is not specified, the name will be the same as the input array name with either " [to datetime]", " [to date]", or " [to time]" appended.

36.103 vtkTableToArray

36.103.1 Usage

Converts a vtkTable into a dense matrix. Use AddColumn() to designate one-to-many table columns that will become columns in the output matrix.

To create an instance of class vtkTableToArray, simply invoke its constructor as follows

```
obj = vtkTableToArray
```

36.103.2 Methods

The class vtkTableToArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableToArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableToArray = obj.NewInstance ()`
- `vtkTableToArray = obj.SafeDownCast (vtkObject o)`
- `obj.ClearColumns ()` - Specify the set of input table columns that will be mapped to columns in the output matrix.
- `obj.AddColumn (string name)` - Specify the set of input table columns that will be mapped to columns in the output matrix.

36.104 vtkTableToGraph

36.104.1 Usage

vtkTableToGraph converts a table to a graph using an auxilliary link graph. The link graph specifies how each row in the table should be converted to an edge, or a collection of edges. It also specifies which columns of the table should be considered part of the same domain, and which columns should be hidden.

A second, optional, table may be provided as the vertex table. This vertex table must have one or more domain columns whose values match values in the edge table. The linked column name is specified in the domain array in the link graph. The output graph will only contain vertices corresponding to a row in the vertex table. For heterogenous graphs, you may want to use vtkMergeTables to create a single vertex table.

The link graph contains the following arrays:

(1) The "column" array has the names of the columns to connect in each table row. This array is required.

(2) The optional "domain" array provides user-defined domain names for each column. Matching domains in multiple columns will merge vertices with the same value from those columns. By default, all columns are in the same domain. If a vertex table is supplied, the domain indicates the column in the vertex table that the edge table column associates with. If the user provides a vertex table but no domain names, the output will be an empty graph. Hidden columns do not need valid domain names.

(3) The optional "hidden" array is a bit array specifying whether the column should be hidden. The resulting graph will contain edges representing connections "through" the hidden column, but the vertices for that column will not be present. By default, no columns are hidden. Hiding a column in a particular domain hides all columns in that domain.

The output graph will contain three additional arrays in the vertex data. The "domain" column is a string array containing the domain of each vertex. The "label" column is a string version of the distinct value that, along with the domain, defines that vertex. The "ids" column also contains the distinguishing value, but as a vtkVariant holding the raw value instead of being converted to a string. The "ids" column is set as the vertex pedigree ID attribute.

To create an instance of class vtkTableToGraph, simply invoke its constructor as follows

```
obj = vtkTableToGraph
```

36.104.2 Methods

The class vtkTableToGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableToGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableToGraph = obj.NewInstance ()`
- `vtkTableToGraph = obj.SafeDownCast (vtkObject o)`
- `obj.AddLinkVertex (string column, string domain, int hidden)` - Add a vertex to the link graph. Specify the column name, the domain name for the column, and whether the column is hidden.
- `obj.ClearLinkVertices ()` - Clear the link graph vertices. This also clears all edges.
- `obj.AddLinkEdge (string column1, string column2)` - Add an edge to the link graph. Specify the names of the columns to link.
- `obj.ClearLinkEdges ()` - Clear the link graph edges. The graph vertices will remain.
- `vtkMutableDirectedGraph = obj.GetLinkGraph ()` - The graph describing how to link the columns in the table.

- `obj.SetLinkGraph (vtkMutableDirectedGraph g)` - The graph describing how to link the columns in the table.
- `obj.LinkColumnPath (vtkStringArray column, vtkStringArray domain, vtkBitArray hidden)` - Links the columns in a specific order. This creates a simple path as the link graph.
- `obj.SetDirected (bool )` - Specify the directedness of the output graph.
- `bool = obj.GetDirected ()` - Specify the directedness of the output graph.
- `obj.DirectedOn ()` - Specify the directedness of the output graph.
- `obj.DirectedOff ()` - Specify the directedness of the output graph.
- `long = obj.GetMTime ()` - Get the current modified time.
- `obj.SetVertexTableConnection (vtkAlgorithmOutput in)` - A convenience method for setting the vertex table input. This is mainly for the benefit of the VTK client/server layer, vanilla VTK code should use e.g:

  table_to_graph-¿SetInputConnection(1, vertex_table-¿output());

36.105 vtkTableToSparseArray

36.105.1 Usage

Converts a vtkTable into a sparse array. Use AddCoordinateColumn() to designate one-to-many table columns that contain coordinates for each array value, and SetValueColumn() to designate the table column that contains array values.

Thus, the number of dimensions in the output array will equal the number of calls to AddCoordinate-Column().

The coordinate columns will also be used to populate dimension labels in the output array.

.SECTION Thanks Developed by Timothy M. Shead (tshead@sandia.gov) at Sandia National Laboratories.

To create an instance of class vtkTableToSparseArray, simply invoke its constructor as follows

```
obj = vtkTableToSparseArray
```

36.105.2 Methods

The class vtkTableToSparseArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableToSparseArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableToSparseArray = obj.NewInstance ()`
- `vtkTableToSparseArray = obj.SafeDownCast (vtkObject o)`
- `obj.ClearCoordinateColumns ()` - Specify the set of input table columns that will be mapped to coordinates in the output sparse array.
- `obj.AddCoordinateColumn (string name)` - Specify the set of input table columns that will be mapped to coordinates in the output sparse array.

- `obj.SetValueColumn (string name)` - Specify the input table column that will be mapped to values in the output array.
- `string = obj.GetValueColumn ()` - Specify the input table column that will be mapped to values in the output array.

36.106 vtkTableToTreeFilter

36.106.1 Usage

vtkTableToTreeFilter is a filter for converting a vtkTable data structure into a vtkTree datastructure. Currently, this will convert the table into a star, with each row of the table as a child of a new root node. The columns of the table are passed as node fields of the tree.

To create an instance of class vtkTableToTreeFilter, simply invoke its constructor as follows

```
obj = vtkTableToTreeFilter
```

36.106.2 Methods

The class vtkTableToTreeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableToTreeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableToTreeFilter = obj.NewInstance ()`
- `vtkTableToTreeFilter = obj.SafeDownCast (vtkObject o)`

36.107 vtkThresholdTable

36.107.1 Usage

vtkThresholdTable uses minimum and/or maximum values to threshold table rows based on the values in a particular column. The column to threshold is specified using SetInputArrayToProcess(0, ...).

To create an instance of class vtkThresholdTable, simply invoke its constructor as follows

```
obj = vtkThresholdTable
```

36.107.2 Methods

The class vtkThresholdTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThresholdTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThresholdTable = obj.NewInstance ()`
- `vtkThresholdTable = obj.SafeDownCast (vtkObject o)`

- `obj.SetMode (int )` - The mode of the threshold filter. Options are: ACCEPT_LESS_THAN (0) accepts rows with values ¡ MaxValue; ACCEPT_GREATER_THAN (1) accepts rows with values ¿ MinValue; ACCEPT_BETWEEN (2) accepts rows with values ¿ MinValue and ¡ MaxValue; ACCEPT_OUTSIDE (3) accepts rows with values ¡ MinValue or ¿ MaxValue.
- `int = obj.GetModeMinValue ()` - The mode of the threshold filter. Options are: ACCEPT_LESS_THAN (0) accepts rows with values ¡ MaxValue; ACCEPT_GREATER_THAN (1) accepts rows with values ¿ MinValue; ACCEPT_BETWEEN (2) accepts rows with values ¿ MinValue and ¡ MaxValue; ACCEPT_OUTSIDE (3) accepts rows with values ¡ MinValue or ¿ MaxValue.
- `int = obj.GetModeMaxValue ()` - The mode of the threshold filter. Options are: ACCEPT_LESS_THAN (0) accepts rows with values ¡ MaxValue; ACCEPT_GREATER_THAN (1) accepts rows with values ¿ MinValue; ACCEPT_BETWEEN (2) accepts rows with values ¿ MinValue and ¡ MaxValue; ACCEPT_OUTSIDE (3) accepts rows with values ¡ MinValue or ¿ MaxValue.
- `int = obj.GetMode ()` - The mode of the threshold filter. Options are: ACCEPT_LESS_THAN (0) accepts rows with values ¡ MaxValue; ACCEPT_GREATER_THAN (1) accepts rows with values ¿ MinValue; ACCEPT_BETWEEN (2) accepts rows with values ¿ MinValue and ¡ MaxValue; ACCEPT_OUTSIDE (3) accepts rows with values ¡ MinValue or ¿ MaxValue.
- `obj.SetMinValue (double v)` - The maximum value for the threshold as a double.
- `obj.SetMaxValue (double v)` - Criterion is rows whose scalars are between lower and upper thresholds (inclusive of the end values).
- `obj.ThresholdBetween (double lower, double upper)`

36.108 vtkTimePointToString

36.108.1 Usage

vtkTimePointToString is a filter for converting a timestamp array into string array using one of the formats defined in vtkTimePointUtility.h.

Use SetInputArrayToProcess to indicate the array to process. This array must be an unsigned 64-bit integer array for DATETIME formats, and may be either an unsigned 32-bit or unsigned 64-bit array for DATE and TIME formats.

If the new array name is not specified, the array name will be the old name appended by " [to string]".

To create an instance of class vtkTimePointToString, simply invoke its constructor as follows

```
obj = vtkTimePointToString
```

36.108.2 Methods

The class vtkTimePointToString has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTimePointToString class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTimePointToString = obj.NewInstance ()`
- `vtkTimePointToString = obj.SafeDownCast (vtkObject o)`
- `obj.SetISO8601Format (int )` - The format to use when converting the timestamp to a string.
- `int = obj.GetISO8601Format ()` - The format to use when converting the timestamp to a string.

- `obj.SetOutputArrayName (string )` - The name of the output array. If this is not specified, the name will be the input array name with " [to string]" appended to it.
- `string = obj.GetOutputArrayName ()` - The name of the output array. If this is not specified, the name will be the input array name with " [to string]" appended to it.

36.109 vtkTransferAttributes

36.109.1 Usage

The filter requires both a vtkGraph and vtkTree as input. The tree vertices must be a superset of the graph vertices. A common example is when the graph vertices correspond to the leaves of the tree, but the internal vertices of the tree represent groupings of graph vertices. The algorithm matches the vertices using the array "PedigreeId". The user may alternately set the DirectMapping flag to indicate that the two structures must have directly corresponding offsets (i.e. node i in the graph must correspond to node i in the tree).

.SECTION Thanks

To create an instance of class vtkTransferAttributes, simply invoke its constructor as follows

```
obj = vtkTransferAttributes
```

36.109.2 Methods

The class vtkTransferAttributes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransferAttributes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransferAttributes = obj.NewInstance ()`
- `vtkTransferAttributes = obj.SafeDownCast (vtkObject o)`
- `obj.SetDirectMapping (bool )` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `bool = obj.GetDirectMapping ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `obj.DirectMappingOn ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `obj.DirectMappingOff ()` - If on, uses direct mapping from tree to graph vertices. If off, both the graph and tree must contain PedigreeId arrays which are used to match graph and tree vertices. Default is off.
- `string = obj.GetSourceArrayName ()` - The field name to use for storing the source array.
- `obj.SetSourceArrayName (string )` - The field name to use for storing the source array.
- `string = obj.GetTargetArrayName ()` - The field name to use for storing the source array.
- `obj.SetTargetArrayName (string )` - The field name to use for storing the source array.

- `int = obj.GetSourceFieldType ()` - The source field type for accessing the source array. Valid values are those from enum vtkDataObject::FieldAssociations.
- `obj.SetSourceFieldType (int )` - The source field type for accessing the source array. Valid values are those from enum vtkDataObject::FieldAssociations.
- `int = obj.GetTargetFieldType ()` - The target field type for accessing the target array. Valid values are those from enum vtkDataObject::FieldAssociations.
- `obj.SetTargetFieldType (int )` - The target field type for accessing the target array. Valid values are those from enum vtkDataObject::FieldAssociations.
- `int = obj.FillInputPortInformation (int port, vtkInformation info)` - Set the input type of the algorithm to vtkGraph.

36.110 vtkTreeFieldAggregator

36.110.1 Usage

vtkTreeFieldAggregator may be used to assign sizes to all the vertices in the tree, based on the sizes of the leaves. The size of a vertex will equal the sum of the sizes of the child vertices. If you have a data array with values for all leaves, you may specify that array, and the values will be filled in for interior tree vertices. If you do not yet have an array, you may tell the filter to create a new array, assuming that the size of each leaf vertex is 1. You may optionally set a flag to first take the log of all leaf values before aggregating.

To create an instance of class vtkTreeFieldAggregator, simply invoke its constructor as follows

```
obj = vtkTreeFieldAggregator
```

36.110.2 Methods

The class vtkTreeFieldAggregator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeFieldAggregator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeFieldAggregator = obj.NewInstance ()`
- `vtkTreeFieldAggregator = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetField ()` - The field to aggregate. If this is a string array, the entries are converted to double. TODO: Remove this field and use the ArrayToProcess in vtkAlgorithm.
- `obj.SetField (string )` - The field to aggregate. If this is a string array, the entries are converted to double. TODO: Remove this field and use the ArrayToProcess in vtkAlgorithm.
- `double = obj.GetMinValue ()` - If the value of the vertex is less than MinValue then consider it's value to be minVal.
- `obj.SetMinValue (double )` - If the value of the vertex is less than MinValue then consider it's value to be minVal.
- `obj.SetLeafVertexUnitSize (bool )` - If set, the algorithm will assume a size of 1 for each leaf vertex.
- `bool = obj.GetLeafVertexUnitSize ()` - If set, the algorithm will assume a size of 1 for each leaf vertex.

- `obj.LeafVertexUnitSizeOn ()` - If set, the algorithm will assume a size of 1 for each leaf vertex.
- `obj.LeafVertexUnitSizeOff ()` - If set, the algorithm will assume a size of 1 for each leaf vertex.
- `obj.SetLogScale (bool )` - If set, the leaf values in the tree will be logarithmically scaled (base 10).
- `bool = obj.GetLogScale ()` - If set, the leaf values in the tree will be logarithmically scaled (base 10).
- `obj.LogScaleOn ()` - If set, the leaf values in the tree will be logarithmically scaled (base 10).
- `obj.LogScaleOff ()` - If set, the leaf values in the tree will be logarithmically scaled (base 10).

36.111 vtkTreeLayoutStrategy

36.111.1 Usage

Assigns points to the nodes of a tree in either a standard or radial layout. The standard layout places each level on a horizontal line, while the radial layout places each level on a concentric circle. You may specify the sweep angle of the tree which constrains the tree to be contained within a wedge. Also, you may indicate the log scale of the tree, which diminishes the length of arcs at lower levels of the tree. Values near zero give a large proportion of the space to the tree levels near the root, while values near one give nearly equal proportions of space to all tree levels.

The user may also specify an array to use to indicate the distance from the root, either vertically (for standard layout) or radially (for radial layout). You specify this with SetDistanceArrayName().

To create an instance of class vtkTreeLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkTreeLayoutStrategy
```

36.111.2 Methods

The class vtkTreeLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeLayoutStrategy = obj.NewInstance ()`
- `vtkTreeLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout ()` - Perform the tree layout.
- `obj.SetAngle (double )` - The sweep angle of the tree. For a standard tree layout, this should be between 0 and 180. For a radial tree layout, this can be between 0 and 360.
- `double = obj.GetAngleMinValue ()` - The sweep angle of the tree. For a standard tree layout, this should be between 0 and 180. For a radial tree layout, this can be between 0 and 360.
- `double = obj.GetAngleMaxValue ()` - The sweep angle of the tree. For a standard tree layout, this should be between 0 and 180. For a radial tree layout, this can be between 0 and 360.
- `double = obj.GetAngle ()` - The sweep angle of the tree. For a standard tree layout, this should be between 0 and 180. For a radial tree layout, this can be between 0 and 360.
- `obj.SetRadial (bool )` - If set, the tree is laid out with levels on concentric circles around the root. If unset (default), the tree is laid out with levels on horizontal lines.

- `bool = obj.GetRadial ()` - If set, the tree is laid out with levels on concentric circles around the root. If unset (default), the tree is laid out with levels on horizontal lines.
- `obj.RadialOn ()` - If set, the tree is laid out with levels on concentric circles around the root. If unset (default), the tree is laid out with levels on horizontal lines.
- `obj.RadialOff ()` - If set, the tree is laid out with levels on concentric circles around the root. If unset (default), the tree is laid out with levels on horizontal lines.
- `obj.SetLogSpacingValue (double )` - The spacing of tree levels. Levels near zero give more space to levels near the root, while levels near one (the default) create evenly-spaced levels. Levels above one give more space to levels near the leaves.
- `double = obj.GetLogSpacingValue ()` - The spacing of tree levels. Levels near zero give more space to levels near the root, while levels near one (the default) create evenly-spaced levels. Levels above one give more space to levels near the leaves.
- `obj.SetLeafSpacing (double )` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `double = obj.GetLeafSpacingMinValue ()` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `double = obj.GetLeafSpacingMaxValue ()` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `double = obj.GetLeafSpacing ()` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `obj.SetDistanceArrayName (string )` - Get/Set the array to use to determine the distance from the root.
- `string = obj.GetDistanceArrayName ()` - Get/Set the array to use to determine the distance from the root.

36.112 vtkTreeLevelsFilter

36.112.1 Usage

The filter currently add two arrays to the incoming vtkTree datastructure. 1) "levels" this is the distance from the root of the vertex. Root = 0 and you add 1 for each level down from the root 2) "leaf" this array simply indicates whether the vertex is a leaf or not

.SECTION Thanks Thanks to Brian Wylie from Sandia National Laboratories for creating this class.

To create an instance of class vtkTreeLevelsFilter, simply invoke its constructor as follows

```
obj = vtkTreeLevelsFilter
```

36.112.2 Methods

The class vtkTreeLevelsFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeLevelsFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeLevelsFilter = obj.NewInstance ()`
- `vtkTreeLevelsFilter = obj.SafeDownCast (vtkObject o)`

36.113 vtkTreeMapLayout

36.113.1 Usage

vtkTreeMapLayout assigns rectangular regions to each vertex in the tree, creating a tree map. The data is added as a data array with four components per tuple representing the location and size of the rectangle using the format (Xmin, Xmax, Ymin, Ymax).

This algorithm relies on a helper class to perform the actual layout. This helper class is a subclass of vtkTreeMapLayoutStrategy.

.SECTION Thanks Thanks to Brian Wylie and Ken Moreland from Sandia National Laboratories for help developing this class.

Tree map concept comes from: Shneiderman, B. 1992. Tree visualization with tree-maps: 2-d space-filling approach. ACM Trans. Graph. 11, 1 (Jan. 1992), 92-99.

To create an instance of class vtkTreeMapLayout, simply invoke its constructor as follows

```
obj = vtkTreeMapLayout
```

36.113.2 Methods

The class vtkTreeMapLayout has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeMapLayout class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeMapLayout = obj.NewInstance ()`
- `vtkTreeMapLayout = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetRectanglesFieldName ()` - The field name to use for storing the rectangles for each vertex. The rectangles are stored in a quadruple float array (minX, maxX, minY, maxY).
- `obj.SetRectanglesFieldName (string )` - The field name to use for storing the rectangles for each vertex. The rectangles are stored in a quadruple float array (minX, maxX, minY, maxY).
- `obj.SetSizeArrayName (string name)` - The strategy to use when laying out the tree map.
- `vtkTreeMapLayoutStrategy = obj.GetLayoutStrategy ()` - The strategy to use when laying out the tree map.
- `obj.SetLayoutStrategy (vtkTreeMapLayoutStrategy strategy)` - The strategy to use when laying out the tree map.
- `vtkIdType = obj.FindVertex (float pnt[2], float binfo)` - Returns the vertex id that contains pnt (or -1 if no one contains it)
- `obj.GetBoundingBox (vtkIdType id, float binfo)` - Return the min and max 2D points of the vertex's bounding box
- `long = obj.GetMTime ()` - Get the modification time of the layout algorithm.

36.114 vtkTreeMapLayoutStrategy

36.114.1 Usage

All subclasses of this class perform a tree map layout on a tree. This involves assigning a rectangular region to each vertex in the tree, and placing that information in a data array with four components per tuple representing (Xmin, Xmax, Ymin, Ymax).

Instances of subclasses of this class may be assigned as the layout strategy to vtkTreeMapLayout

.SECTION Thanks Thanks to Brian Wylie and Ken Moreland from Sandia National Laboratories for help developing this class.

To create an instance of class vtkTreeMapLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkTreeMapLayoutStrategy
```

36.114.2 Methods

The class vtkTreeMapLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeMapLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeMapLayoutStrategy = obj.NewInstance ()`
- `vtkTreeMapLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.FindVertex (vtkTree tree, vtkDataArray areaArray, float pnt[2])` - Find the vertex at a certain location, or -1 if none found.

36.115 vtkTreeMapToPolyData

36.115.1 Usage

This algorithm requires that the vtkTreeMapLayout filter has already applied to the data in order to create the quadruple array (min x, max x, min y, max y) of bounds for each vertex of the tree.

To create an instance of class vtkTreeMapToPolyData, simply invoke its constructor as follows

```
obj = vtkTreeMapToPolyData
```

36.115.2 Methods

The class vtkTreeMapToPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeMapToPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeMapToPolyData = obj.NewInstance ()`
- `vtkTreeMapToPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetRectanglesArrayName (string name)` - The field containing the level of each tree node. This can be added using vtkTreeLevelsFilter before this filter. If this is not present, the filter simply calls tree-¿GetLevel(v) for each vertex, which will produce the same result, but may not be as efficient.

- `obj.SetLevelArrayName (string name)` - The spacing along the z-axis between tree map levels.
- `double = obj.GetLevelDeltaZ ()` - The spacing along the z-axis between tree map levels.
- `obj.SetLevelDeltaZ (double )` - The spacing along the z-axis between tree map levels.
- `bool = obj.GetAddNormals ()` - The spacing along the z-axis between tree map levels.
- `obj.SetAddNormals (bool )` - The spacing along the z-axis between tree map levels.
- `int = obj.FillInputPortInformation (int port, vtkInformation info)`

36.116 vtkTreeOrbitLayoutStrategy

36.116.1 Usage

Assigns points to the nodes of a tree to an orbital layout. Each parent is orbited by its children, recursively.
To create an instance of class vtkTreeOrbitLayoutStrategy, simply invoke its constructor as follows

```
obj = vtkTreeOrbitLayoutStrategy
```

36.116.2 Methods

The class vtkTreeOrbitLayoutStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeOrbitLayoutStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeOrbitLayoutStrategy = obj.NewInstance ()`
- `vtkTreeOrbitLayoutStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.Layout ()` - Perform the orbital layout.
- `obj.SetLogSpacingValue (double )` - The spacing of orbital levels. Levels near zero give more space to levels near the root, while levels near one (the default) create evenly-spaced levels. Levels above one give more space to levels near the leaves.
- `double = obj.GetLogSpacingValue ()` - The spacing of orbital levels. Levels near zero give more space to levels near the root, while levels near one (the default) create evenly-spaced levels. Levels above one give more space to levels near the leaves.
- `obj.SetLeafSpacing (double )` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `double = obj.GetLeafSpacingMinValue ()` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `double = obj.GetLeafSpacingMaxValue ()` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `double = obj.GetLeafSpacing ()` - The spacing of leaves. Levels near one evenly space leaves with no gaps between subtrees. Levels near zero creates large gaps between subtrees.
- `obj.SetChildRadiusFactor (double )` - This is a magic number right now. Controls the radius of the child layout, all of this should be fixed at some point with a more logical layout. Defaults to .5 :)

- `double = obj.GetChildRadiusFactor ()` - This is a magic number right now. Controls the radius of the child layout, all of this should be fixed at some point with a more logical layout. Defaults to .5 :)

36.117 vtkTreeRingToPolyData

36.117.1 Usage

This algorithm requires that the vtkTreeRingLayout filter has already been applied to the data in order to create the quadruple array (start angle, end angle, inner radius, outer radius) of bounds for each vertex of the tree.

To create an instance of class vtkTreeRingToPolyData, simply invoke its constructor as follows

```
obj = vtkTreeRingToPolyData
```

36.117.2 Methods

The class vtkTreeRingToPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeRingToPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeRingToPolyData = obj.NewInstance ()`
- `vtkTreeRingToPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetSectorsArrayName (string name)` - Define a shrink percentage for each of the sectors.
- `obj.SetShrinkPercentage (double )` - Define a shrink percentage for each of the sectors.
- `double = obj.GetShrinkPercentage ()` - Define a shrink percentage for each of the sectors.
- `int = obj.FillInputPortInformation (int port, vtkInformation info)`

36.118 vtkTulipReader

36.118.1 Usage

vtkTulipReader reads in files in the Tulip format. Definition of the Tulip file format can be found online at: http://tulip.labri.fr/tlpformat.php An example is the following ¡code¿ (nodes 0 1 2 3 4 5 6 7 8 9) (edge 0 0 1) (edge 1 1 2) (edge 2 2 3) (edge 3 3 4) (edge 4 4 5) (edge 5 5 6) (edge 6 6 7) (edge 7 7 8) (edge 8 8 9) (edge 9 9 0) (edge 10 0 5) (edge 11 2 7) (edge 12 4 9) ¡/code¿ where "nodes" defines all the nodes ids in the graph, and "edge" is a triple of edge id, source vertex id, and target vertex id. The graph is read in as undirected graph. NOTE: This currently only supports reading connectivity information. Display information is discarded.

To create an instance of class vtkTulipReader, simply invoke its constructor as follows

```
obj = vtkTulipReader
```

36.118.2 Methods

The class vtkTulipReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTulipReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTulipReader = obj.NewInstance ()`
- `vtkTulipReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()` - The Tulip file name.
- `obj.SetFileName (string )` - The Tulip file name.

36.119 vtkUnivariateStatisticsAlgorithm

36.119.1 Usage

This class specializes statistics algorithms to the univariate case, where a number of columns of interest can be selected in the input data set. This is done by the means of the following functions:

ResetColumns() - reset the list of columns of interest. Add/RemoveColum(namCol) - try to add/remove column with name namCol to/from the list. SetColumnStatus (namCol, status) - mostly for UI wrapping purposes, try to add/remove (depending on status) namCol from the list of columns of interest. The verb "try" is used in the sense that neither attempting to repeat an existing entry nor to remove a non-existent entry will work.

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkUnivariateStatisticsAlgorithm, simply invoke its constructor as follows

```
obj = vtkUnivariateStatisticsAlgorithm
```

36.119.2 Methods

The class vtkUnivariateStatisticsAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnivariateStatisticsAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnivariateStatisticsAlgorithm = obj.NewInstance ()`
- `vtkUnivariateStatisticsAlgorithm = obj.SafeDownCast (vtkObject o)`
- `obj.AddColumn (string namCol)` - Convenience method to create a request with a single column name namCol in a single call; this is the preferred method to select columns, ensuring selection consistency (a single column per request). Warning: no name checking is performed on namCol; it is the user's responsibility to use valid column names.
- `int = obj.RequestSelectedColumns ()` - Use the current column status values to produce a new request for statistics to be produced when RequestData() is called. Unlike the superclass implementation, this version adds a new request for each selected column instead of a single request containing all the columns.

36.120 vtkVertexDegree

36.120.1 Usage

Adds an attribute array with the degree of each vertex. By default the name of the array will be "VertexDegree", but that can be changed by calling SetOutputArrayName("foo");

To create an instance of class vtkVertexDegree, simply invoke its constructor as follows

```
obj = vtkVertexDegree
```

36.120.2 Methods

The class vtkVertexDegree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVertexDegree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVertexDegree = obj.NewInstance ()`
- `vtkVertexDegree = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutputArrayName (string )` - Set the output array name. If no output array name is set then the name 'VertexDegree' is used.

36.121 vtkXMLTreeReader

36.121.1 Usage

vtkXMLTreeReader parses an XML file and uses the nesting structure of the XML tags to generate a tree. Node attributes are assigned to node arrays, and the special arrays .tagname and .chardata contain the tag type and the text internal to the tag, respectively. The arrays are of type vtkStringArray. There is an array for each attribute type in the XML file, even if it appears in only one tag. If an attribute is missing from a tag, its value is the empty string.

If MaskArrays is on (the default is off), the filter will additionally make bit arrays whose names are prepended with ".valid." which are 1 if the element contains that attribute, and 0 otherwise.

For example, the XML file containing the text:

```
\&lt;node name=''jeff'' age=''26''\&gt;
  this is text in jeff's node
  \&lt;node name=''joe''\&gt;
    \&lt;node name=''al'' initials=''amb'' other=''something''/\&gt;
    \&lt;node name=''dave'' age=''30''/\&gt;
  \&lt;/node\&gt;
  \&lt;node name=''lisa''\&gt;this is text in lisa's node\&lt;/node\&gt;
  \&lt;node name=''darlene'' age=''29''/\&gt;
\&lt;/node\&gt;
```

would be parsed into a tree with the following node IDs and structure:

```
0 (jeff) - children: 1 (joe), 4 (lisa), 5 (darlene)
1 (joe)  - children: 2 (al), 3 (dave)
2 (al)
```

```
3 (dave)
4 (lisa)
5 (darlene)
```

and the node data arrays would be as follows:

```
name      initials  other     age       .tagname  .chardata
-------------------------------------------------------------------------------------------
jeff      (empty)   (empty)   26        node      ''  this is text in jeff's node\\n  \\n  \\n  \\n''
joe       (empty)   (empty)   (empty)   node      ''\\n    \\n    \\n  ''
al        amb       something (empty)   node      (empty)
dave      (empty)   (empty)   30        node      (empty)
lisa      (empty)   (empty)   (empty)   node      ''this is text in lisa's node''
darlene   (empty)   (empty)   29        node      (empty)
```

There would also be the following bit arrays if MaskArrays is on:

```
.valid.name   .valid.initials   .valid.other   .valid.age
-----------------------------------------------------------
1             0                 0              1
1             0                 0              0
1             1                 1              0
1             0                 0              1
1             0                 0              0
1             0                 0              1
```

To create an instance of class vtkXMLTreeReader, simply invoke its constructor as follows

```
obj = vtkXMLTreeReader
```

36.121.2 Methods

The class vtkXMLTreeReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLTreeReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLTreeReader = obj.NewInstance ()`
- `vtkXMLTreeReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()` - If set, reads in the XML file specified.
- `obj.SetFileName (string )` - If set, reads in the XML file specified.
- `string = obj.GetXMLString ()` - If set, and FileName is not set, reads in the XML string.
- `obj.SetXMLString (string )` - If set, and FileName is not set, reads in the XML string.
- `string = obj.GetEdgePedigreeIdArrayName ()` - The name of the edge pedigree ids. Default is "edge id".

- `obj.SetEdgePedigreeIdArrayName (string )` - The name of the edge pedigree ids. Default is "edge id".
- `string = obj.GetVertexPedigreeIdArrayName ()` - The name of the vertex pedigree ids. Default is "vertex id".
- `obj.SetVertexPedigreeIdArrayName (string )` - The name of the vertex pedigree ids. Default is "vertex id".
- `obj.SetGenerateEdgePedigreeIds (bool )` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `bool = obj.GetGenerateEdgePedigreeIds ()` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `obj.GenerateEdgePedigreeIdsOn ()` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `obj.GenerateEdgePedigreeIdsOff ()` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `obj.SetGenerateVertexPedigreeIds (bool )` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `bool = obj.GetGenerateVertexPedigreeIds ()` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `obj.GenerateVertexPedigreeIdsOn ()` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `obj.GenerateVertexPedigreeIdsOff ()` - Set whether to use an property from the XML file as pedigree ids (off), or generate a new array with integer values starting at zero (on). Default is on.
- `bool = obj.GetMaskArrays ()` - If on, makes bit arrays for each attribute with name .valid.attribute_name for each attribute. Default is off.
- `obj.SetMaskArrays (bool )` - If on, makes bit arrays for each attribute with name .valid.attribute_name for each attribute. Default is off.
- `obj.MaskArraysOn ()` - If on, makes bit arrays for each attribute with name .valid.attribute_name for each attribute. Default is off.
- `obj.MaskArraysOff ()` - If on, makes bit arrays for each attribute with name .valid.attribute_name for each attribute. Default is off.
- `bool = obj.GetReadCharData ()` - If on, stores the XML character data (i.e. textual data between tags) into an array named CharDataField, otherwise this field is skipped. Default is off.
- `obj.SetReadCharData (bool )` - If on, stores the XML character data (i.e. textual data between tags) into an array named CharDataField, otherwise this field is skipped. Default is off.
- `obj.ReadCharDataOn ()` - If on, stores the XML character data (i.e. textual data between tags) into an array named CharDataField, otherwise this field is skipped. Default is off.
- `obj.ReadCharDataOff ()` - If on, stores the XML character data (i.e. textual data between tags) into an array named CharDataField, otherwise this field is skipped. Default is off.
- `bool = obj.GetReadTagName ()` - If on, stores the XML tag name data in a field called .tagname otherwise this field is skipped. Default is on.
- `obj.SetReadTagName (bool )` - If on, stores the XML tag name data in a field called .tagname otherwise this field is skipped. Default is on.

- `obj.ReadTagNameOn ()` - If on, stores the XML tag name data in a field called .tagname otherwise this field is skipped. Default is on.
- `obj.ReadTagNameOff ()` - If on, stores the XML tag name data in a field called .tagname otherwise this field is skipped. Default is on.

Chapter 37

Visualization Toolkit IO Classes

37.1 vtkAbstractParticleWriter

37.1.1 Usage

vtkAbstractParticleWriter is an abstract class which is used by vtkTemporalStreamTracer to write particles out during simulations. This class is abstract and provides a TimeStep and FileName. Subclasses of this should provide the necessary IO.

To create an instance of class vtkAbstractParticleWriter, simply invoke its constructor as follows

```
obj = vtkAbstractParticleWriter
```

37.1.2 Methods

The class vtkAbstractParticleWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractParticleWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractParticleWriter = obj.NewInstance ()`
- `vtkAbstractParticleWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetTimeStep (int )` - Set/get the TimeStep that is being written
- `int = obj.GetTimeStep ()` - Set/get the TimeStep that is being written
- `obj.SetTimeValue (double )` - Before writing the current data out, set the TimeValue (optional) The TimeValue is a float/double value that corresonds to the real time of the data, it may not be regular, whereas the TimeSteps are simple increments.
- `double = obj.GetTimeValue ()` - Before writing the current data out, set the TimeValue (optional) The TimeValue is a float/double value that corresonds to the real time of the data, it may not be regular, whereas the TimeSteps are simple increments.
- `obj.SetFileName (string )` - Set/get the FileName that is being written to
- `string = obj.GetFileName ()` - Set/get the FileName that is being written to
- `obj.SetCollectiveIO (int )` - When running in parallel, this writer may be capable of Collective IO operations (HDF5). By default, this is off.

- `int = obj.GetCollectiveIO ()` - When running in parallel, this writer may be capable of Collective IO operations (HDF5). By default, this is off.
- `obj.SetWriteModeToCollective ()` - When running in parallel, this writer may be capable of Collective IO operations (HDF5). By default, this is off.
- `obj.SetWriteModeToIndependent ()` - When running in parallel, this writer may be capable of Collective IO operations (HDF5). By default, this is off.
- `obj.CloseFile ()` - Close the file after a write. This is optional but may protect against data loss in between steps

37.2 vtkArrayReader

37.2.1 Usage

Reads sparse and dense vtkArray data written with vtkArrayWriter.

Outputs: Output port 0: vtkArrayData containing a dense or sparse array.

To create an instance of class vtkArrayReader, simply invoke its constructor as follows

```
obj = vtkArrayReader
```

37.2.2 Methods

The class vtkArrayReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayReader = obj.NewInstance ()`
- `vtkArrayReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()` - Set the filesystem location from which data will be read.
- `obj.SetFileName (string )` - Set the filesystem location from which data will be read.

37.3 vtkArrayWriter

37.3.1 Usage

vtkArrayWriter serializes sparse and dense array data using a text-based format that is human-readable and easily parsed (default option). The WriteBinary array option can be set to true in the Write method, which will serialize the sparse and dense array data using a binary format that is optimized for rapid throughput.

Inputs: Input port 0: (required) vtkArrayData object containing a sparse or dense array.

Output Format: The first line of output will contain the array type (sparse or dense) and the type of values stored in the array (double, integer, string, etc).

The second line of output will contain the array extents along each dimension of the array, followed by the number of non-null values stored in the array.

For sparse arrays, each subsequent line of output will contain the coordinates and value for each non-null value stored in the array.

For dense arrays, each subsequent line of output will contain one value from the array, stored in the same order as that used by vtkArrayCoordinateIterator.

To create an instance of class vtkArrayWriter, simply invoke its constructor as follows

```
obj = vtkArrayWriter
```

37.3.2 Methods

The class vtkArrayWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayWriter = obj.NewInstance ()`
- `vtkArrayWriter = obj.SafeDownCast (vtkObject o)`
- `bool = obj.Write (vtkStdString \&file\_name, bool WriteBinaryfalse)` - Write input port 0 data to a file.

37.4 vtkAVSucdReader

37.4.1 Usage

vtkAVSucdReader creates an unstructured grid dataset. It reads binary or ASCII files stored in UCD format, with optional data stored at the nodes or at the cells of the model. A cell-based fielddata stores the material id. The class can automatically detect the endian-ness of the binary files.

To create an instance of class vtkAVSucdReader, simply invoke its constructor as follows

```
obj = vtkAVSucdReader
```

37.4.2 Methods

The class vtkAVSucdReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAVSucdReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAVSucdReader = obj.NewInstance ()`
- `vtkAVSucdReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of AVS UCD datafile to read
- `string = obj.GetFileName ()` - Specify file name of AVS UCD datafile to read
- `obj.SetBinaryFile (int )` - Is the file to be read written in binary format (as opposed to ascii).
- `int = obj.GetBinaryFile ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.BinaryFileOn ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.BinaryFileOff ()` - Is the file to be read written in binary format (as opposed to ascii).
- `int = obj.GetNumberOfCells ()` - Get the total number of cells.

- `int = obj.GetNumberOfNodes ()` - Get the total number of nodes.
- `int = obj.GetNumberOfNodeFields ()` - Get the number of data fields at the nodes.
- `int = obj.GetNumberOfCellFields ()` - Get the number of data fields at the cell centers.
- `int = obj.GetNumberOfFields ()` - Get the number of data fields for the model. Unused because VTK has no methods for it.
- `int = obj.GetNumberOfNodeComponents ()` - Get the number of data components at the nodes and cells.
- `int = obj.GetNumberOfCellComponents ()` - Get the number of data components at the nodes and cells.
- `obj.SetByteOrderToBigEndian ()` - Set/Get the endian-ness of the binary file.
- `obj.SetByteOrderToLittleEndian ()` - Set/Get the endian-ness of the binary file.
- `string = obj.GetByteOrderAsString ()` - Set/Get the endian-ness of the binary file.
- `obj.SetByteOrder (int )`
- `int = obj.GetByteOrder ()`
- `int = obj.GetNumberOfPointArrays ()` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `int = obj.GetNumberOfCellArrays ()` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `string = obj.GetPointArrayName (int index)` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `string = obj.GetCellArrayName (int index)` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `int = obj.GetPointArrayStatus (string name)` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `int = obj.GetCellArrayStatus (string name)` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `obj.SetPointArrayStatus (string name, int status)` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `obj.SetCellArrayStatus (string name, int status)` - The following methods allow selective reading of solutions fields. by default, ALL data fields are the nodes and cells are read, but this can be modified.
- `obj.DisableAllCellArrays ()`
- `obj.EnableAllCellArrays ()`
- `obj.DisableAllPointArrays ()`
- `obj.EnableAllPointArrays ()`
- `obj.GetCellDataRange (int cellComp, int index, float min, float max)`
- `obj.GetNodeDataRange (int nodeComp, int index, float min, float max)`

37.5 vtkBase64InputStream

37.5.1 Usage

vtkBase64InputStream implements base64 decoding with the vtkInputStream interface.

To create an instance of class vtkBase64InputStream, simply invoke its constructor as follows

```
obj = vtkBase64InputStream
```

37.5.2 Methods

The class vtkBase64InputStream has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBase64InputStream class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBase64InputStream = obj.NewInstance ()`
- `vtkBase64InputStream = obj.SafeDownCast (vtkObject o)`
- `obj.StartReading ()` - Called after the stream position has been set by the caller, but before any Seek or Read calls. The stream position should not be adjusted by the caller until after an EndReading call.
- `int = obj.Seek (long offset)` - Seek to the given offset in the input data. Returns 1 for success, 0 for failure.
- `long = obj.Read (string data, long length)` - Read input data of the given length. Returns amount actually read.
- `obj.EndReading ()` - Called after all desired calls to Seek and Read have been made. After this call, the caller is free to change the position of the stream. Additional reads should not be done until after another call to StartReading.

37.6 vtkBase64OutputStream

37.6.1 Usage

vtkBase64OutputStream implements base64 encoding with the vtkOutputStream interface.

To create an instance of class vtkBase64OutputStream, simply invoke its constructor as follows

```
obj = vtkBase64OutputStream
```

37.6.2 Methods

The class vtkBase64OutputStream has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBase64OutputStream class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBase64OutputStream = obj.NewInstance ()`

- `vtkBase64OutputStream = obj.SafeDownCast (vtkObject o)`
- `int = obj.StartWriting ()` - Called after the stream position has been set by the caller, but before any Write calls. The stream position should not be adjusted by the caller until after an EndWriting call.
- `int = obj.Write (string data, long length)` - Write output data of the given length.
- `int = obj.EndWriting ()` - Called after all desired calls to Write have been made. After this call, the caller is free to change the position of the stream. Additional writes should not be done until after another call to StartWriting.

37.7 vtkBase64Utilities

37.7.1 Usage

vtkBase64Utilities implements base64 encoding and decoding.

To create an instance of class vtkBase64Utilities, simply invoke its constructor as follows

```
obj = vtkBase64Utilities
```

37.7.2 Methods

The class vtkBase64Utilities has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBase64Utilities class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBase64Utilities = obj.NewInstance ()`
- `vtkBase64Utilities = obj.SafeDownCast (vtkObject o)`

37.8 vtkBMPReader

37.8.1 Usage

vtkBMPReader is a source object that reads Windows BMP files. This includes indexed and 24bit bitmaps Usually, all BMPs are converted to 24bit RGB, but BMPs may be output as 8bit images with a LookupTable if the Allow8BitBMP flag is set.

BMPReader creates structured point datasets. The dimension of the dataset depends upon the number of files read. Reading a single file results in a 2D image, while reading more than one file results in a 3D volume.

To read a volume, files must be of the form "FileName.¡number¿" (e.g., foo.bmp.0, foo.bmp.1, ...). You must also specify the image range. This range specifies the beginning and ending files to read (range can be any pair of non-negative numbers).

The default behavior is to read a single file. In this case, the form of the file is simply "FileName" (e.g., foo.bmp).

To create an instance of class vtkBMPReader, simply invoke its constructor as follows

```
obj = vtkBMPReader
```

37.8.2 Methods

The class vtkBMPReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBMPReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBMPReader = obj.NewInstance ()`
- `vtkBMPReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDepth ()` - Returns the depth of the BMP, either 8 or 24.
- `int = obj.CanReadFile (string fname)` - Is the given file a BMP file?
- `string = obj.GetFileExtensions ()` - Return a descriptive name for the file format that might be useful in a GUI.
- `string = obj.GetDescriptiveName ()` - If this flag is set and the BMP reader encounters an 8bit file, the data will be kept as unsigned chars and a lookuptable will be exported
- `obj.SetAllow8BitBMP (int )` - If this flag is set and the BMP reader encounters an 8bit file, the data will be kept as unsigned chars and a lookuptable will be exported
- `int = obj.GetAllow8BitBMP ()` - If this flag is set and the BMP reader encounters an 8bit file, the data will be kept as unsigned chars and a lookuptable will be exported
- `obj.Allow8BitBMPOn ()` - If this flag is set and the BMP reader encounters an 8bit file, the data will be kept as unsigned chars and a lookuptable will be exported
- `obj.Allow8BitBMPOff ()` - If this flag is set and the BMP reader encounters an 8bit file, the data will be kept as unsigned chars and a lookuptable will be exported
- `vtkLookupTable = obj.GetLookupTable ()`

37.9 vtkBMPWriter

37.9.1 Usage

vtkBMPWriter writes BMP files. The data type of the file is unsigned char regardless of the input type.

To create an instance of class vtkBMPWriter, simply invoke its constructor as follows

```
obj = vtkBMPWriter
```

37.9.2 Methods

The class vtkBMPWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBMPWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBMPWriter = obj.NewInstance ()`
- `vtkBMPWriter = obj.SafeDownCast (vtkObject o)`

37.10 vtkBYUReader

37.10.1 Usage

vtkBYUReader is a source object that reads MOVIE.BYU polygon files. These files consist of a geometry file (.g), a scalar file (.s), a displacement or vector file (.d), and a 2D texture coordinate file (.t).

To create an instance of class vtkBYUReader, simply invoke its constructor as follows

```
obj = vtkBYUReader
```

37.10.2 Methods

The class vtkBYUReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBYUReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBYUReader = obj.NewInstance ()`
- `vtkBYUReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetGeometryFileName (string )` - Specify name of geometry FileName.
- `string = obj.GetGeometryFileName ()` - Specify name of geometry FileName.
- `obj.SetFileName (string f)` - Specify name of geometry FileName (alias).
- `string = obj.GetFileName ()` - Specify name of displacement FileName.
- `obj.SetDisplacementFileName (string )` - Specify name of displacement FileName.
- `string = obj.GetDisplacementFileName ()` - Specify name of displacement FileName.
- `obj.SetScalarFileName (string )` - Specify name of scalar FileName.
- `string = obj.GetScalarFileName ()` - Specify name of scalar FileName.
- `obj.SetTextureFileName (string )` - Specify name of texture coordinates FileName.
- `string = obj.GetTextureFileName ()` - Specify name of texture coordinates FileName.
- `obj.SetReadDisplacement (int )` - Turn on/off the reading of the displacement file.
- `int = obj.GetReadDisplacement ()` - Turn on/off the reading of the displacement file.
- `obj.ReadDisplacementOn ()` - Turn on/off the reading of the displacement file.
- `obj.ReadDisplacementOff ()` - Turn on/off the reading of the displacement file.
- `obj.SetReadScalar (int )` - Turn on/off the reading of the scalar file.
- `int = obj.GetReadScalar ()` - Turn on/off the reading of the scalar file.
- `obj.ReadScalarOn ()` - Turn on/off the reading of the scalar file.
- `obj.ReadScalarOff ()` - Turn on/off the reading of the scalar file.
- `obj.SetReadTexture (int )` - Turn on/off the reading of the texture coordinate file. Specify name of geometry FileName.

- `int = obj.GetReadTexture ()` - Turn on/off the reading of the texture coordinate file. Specify name of geometry FileName.
- `obj.ReadTextureOn ()` - Turn on/off the reading of the texture coordinate file. Specify name of geometry FileName.
- `obj.ReadTextureOff ()` - Turn on/off the reading of the texture coordinate file. Specify name of geometry FileName.
- `obj.SetPartNumber (int )` - Set/Get the part number to be read.
- `int = obj.GetPartNumberMinValue ()` - Set/Get the part number to be read.
- `int = obj.GetPartNumberMaxValue ()` - Set/Get the part number to be read.
- `int = obj.GetPartNumber ()` - Set/Get the part number to be read.

37.11 vtkBYUWriter

37.11.1 Usage

vtkBYUWriter writes MOVIE.BYU polygonal files. These files consist of a geometry file (.g), a scalar file (.s), a displacement or vector file (.d), and a 2D texture coordinate file (.t). These files must be specified to the object, the appropriate boolean variables must be true, and data must be available from the input for the files to be written. WARNING: this writer does not currently write triangle strips. Use vtkTriangleFilter to convert strips to triangles.

To create an instance of class vtkBYUWriter, simply invoke its constructor as follows

```
obj = vtkBYUWriter
```

37.11.2 Methods

The class vtkBYUWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBYUWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBYUWriter = obj.NewInstance ()`
- `vtkBYUWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetGeometryFileName (string )` - Specify the name of the geometry file to write.
- `string = obj.GetGeometryFileName ()` - Specify the name of the geometry file to write.
- `obj.SetDisplacementFileName (string )` - Specify the name of the displacement file to write.
- `string = obj.GetDisplacementFileName ()` - Specify the name of the displacement file to write.
- `obj.SetScalarFileName (string )` - Specify the name of the scalar file to write.
- `string = obj.GetScalarFileName ()` - Specify the name of the scalar file to write.
- `obj.SetTextureFileName (string )` - Specify the name of the texture file to write.
- `string = obj.GetTextureFileName ()` - Specify the name of the texture file to write.

- `obj.SetWriteDisplacement (int )` - Turn on/off writing the displacement file.
- `int = obj.GetWriteDisplacement ()` - Turn on/off writing the displacement file.
- `obj.WriteDisplacementOn ()` - Turn on/off writing the displacement file.
- `obj.WriteDisplacementOff ()` - Turn on/off writing the displacement file.
- `obj.SetWriteScalar (int )` - Turn on/off writing the scalar file.
- `int = obj.GetWriteScalar ()` - Turn on/off writing the scalar file.
- `obj.WriteScalarOn ()` - Turn on/off writing the scalar file.
- `obj.WriteScalarOff ()` - Turn on/off writing the scalar file.
- `obj.SetWriteTexture (int )` - Turn on/off writing the texture file.
- `int = obj.GetWriteTexture ()` - Turn on/off writing the texture file.
- `obj.WriteTextureOn ()` - Turn on/off writing the texture file.
- `obj.WriteTextureOff ()` - Turn on/off writing the texture file.

37.12 vtkCGMWriter

37.12.1 Usage

vtkCGMWriter writes CGM (Computer Graphics Metafile) output. CGM is a 2D graphics vector format typically used by large plotters. This writer can handle vertices, lines, polygons, and triangle strips in any combination. Colors are specified either 1) from cell scalars (assumed to be RGB or RGBA color specification), 2) from a specified color; or 3) randomly assigned colors.

Note: During output of the polygonal data, triangle strips are converted to triangles, and polylines to lines. Also, due to limitations in the CGM color model, only 256 colors are available to the color palette.

To create an instance of class vtkCGMWriter, simply invoke its constructor as follows

```
obj = vtkCGMWriter
```

37.12.2 Methods

The class vtkCGMWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCGMWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCGMWriter = obj.NewInstance ()`
- `vtkCGMWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetViewport (vtkViewport )` - Specify a vtkViewport object to be used to transform the vtkPolyData points into 2D coordinates. By default (no vtkViewport specified), the point coordinates are generated by ignoring the z values. If a viewport is defined, then the points are transformed into viewport coordinates.

- `vtkViewport = obj.GetViewport ()` - Specify a vtkViewport object to be used to transform the vtkPolyData points into 2D coordinates. By default (no vtkViewport specified), the point coordinates are generated by ignoring the z values. If a viewport is defined, then the points are transformed into viewport coordinates.

- `obj.SetSort (int )` - Turn on/off the sorting of the cells via depth. If enabled, polygonal cells will be sorted from back to front, i.e., a Painter's algorithm sort.

- `int = obj.GetSort ()` - Turn on/off the sorting of the cells via depth. If enabled, polygonal cells will be sorted from back to front, i.e., a Painter's algorithm sort.

- `obj.SetResolution (int )` - Specify the resolution of the CGM file. This number is used to integerize the maximum coordinate range of the plot file.

- `int = obj.GetResolutionMinValue ()` - Specify the resolution of the CGM file. This number is used to integerize the maximum coordinate range of the plot file.

- `int = obj.GetResolutionMaxValue ()` - Specify the resolution of the CGM file. This number is used to integerize the maximum coordinate range of the plot file.

- `int = obj.GetResolution ()` - Specify the resolution of the CGM file. This number is used to integerize the maximum coordinate range of the plot file.

- `obj.SetColorMode (int )` - Control how output polydata is colored. By default (ColorModeToDefault), if per cell colors are defined (unsigned chars of 1-4 components), then the cells are colored with these values. (If point colors are defined and cell colors are not, you can use vtkPointDataToCellData to convert the point colors to cell colors.) Otherwise, by default, the cells are set to the specified color. If ColorModeToSpecifiedColor is set, then the primitives will all be set to this color. If ColorModeToRandomColors is set, each cell will be randomly assigned a color.

- `int = obj.GetColorMode ()` - Control how output polydata is colored. By default (ColorModeToDefault), if per cell colors are defined (unsigned chars of 1-4 components), then the cells are colored with these values. (If point colors are defined and cell colors are not, you can use vtkPointDataToCellData to convert the point colors to cell colors.) Otherwise, by default, the cells are set to the specified color. If ColorModeToSpecifiedColor is set, then the primitives will all be set to this color. If ColorModeToRandomColors is set, each cell will be randomly assigned a color.

- `obj.SetColorModeToDefault ()` - Control how output polydata is colored. By default (ColorModeToDefault), if per cell colors are defined (unsigned chars of 1-4 components), then the cells are colored with these values. (If point colors are defined and cell colors are not, you can use vtkPointDataToCellData to convert the point colors to cell colors.) Otherwise, by default, the cells are set to the specified color. If ColorModeToSpecifiedColor is set, then the primitives will all be set to this color. If ColorModeToRandomColors is set, each cell will be randomly assigned a color.

- `obj.SetColorModeToSpecifiedColor ()` - Control how output polydata is colored. By default (ColorModeToDefault), if per cell colors are defined (unsigned chars of 1-4 components), then the cells are colored with these values. (If point colors are defined and cell colors are not, you can use vtkPointDataToCellData to convert the point colors to cell colors.) Otherwise, by default, the cells are set to the specified color. If ColorModeToSpecifiedColor is set, then the primitives will all be set to this color. If ColorModeToRandomColors is set, each cell will be randomly assigned a color.

- `obj.SetColorModeToRandomColors ()` - Control how output polydata is colored. By default (ColorModeToDefault), if per cell colors are defined (unsigned chars of 1-4 components), then the cells are colored with these values. (If point colors are defined and cell colors are not, you can use vtkPointDataToCellData to convert the point colors to cell colors.) Otherwise, by default, the cells are set to the specified color. If ColorModeToSpecifiedColor is set, then the primitives will all be set to this color. If ColorModeToRandomColors is set, each cell will be randomly assigned a color.

- `obj.SetSpecifiedColor (float , float , float )` - Set/Get the specified color to color the polydata cells. This color is only used when the color mode is set to ColorModeToSpecifiedColor, or ColorModeToDefault is set and no cell colors are specified. The specified color is specified as RGB values ranging from (0,1). (Note: CGM will map this color to the closest color it supports.)
- `obj.SetSpecifiedColor (float a[3])` - Set/Get the specified color to color the polydata cells. This color is only used when the color mode is set to ColorModeToSpecifiedColor, or ColorModeToDefault is set and no cell colors are specified. The specified color is specified as RGB values ranging from (0,1). (Note: CGM will map this color to the closest color it supports.)
- `float = obj. GetSpecifiedColor ()` - Set/Get the specified color to color the polydata cells. This color is only used when the color mode is set to ColorModeToSpecifiedColor, or ColorModeToDefault is set and no cell colors are specified. The specified color is specified as RGB values ranging from (0,1). (Note: CGM will map this color to the closest color it supports.)

37.13 vtkChacoReader

37.13.1 Usage

vtkChacoReader is an unstructured grid source object that reads Chaco files. The reader DOES NOT respond to piece requests. Chaco is a graph partitioning package developed at Sandia National Laboratories in the early 1990s. (http://www.cs.sandia.gov/ bahendr/chaco.html)

Note that the Chaco "edges" become VTK "cells", and the Chaco "vertices" become VTK "points".

To create an instance of class vtkChacoReader, simply invoke its constructor as follows

```
obj = vtkChacoReader
```

37.13.2 Methods

The class vtkChacoReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkChacoReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkChacoReader = obj.NewInstance ()`
- `vtkChacoReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetBaseName (string )`
- `string = obj.GetBaseName ()`
- `obj.SetGenerateGlobalElementIdArray (int )`
- `int = obj.GetGenerateGlobalElementIdArray ()`
- `obj.GenerateGlobalElementIdArrayOn ()`
- `obj.GenerateGlobalElementIdArrayOff ()`
- `obj.SetGenerateGlobalNodeIdArray (int )`
- `int = obj.GetGenerateGlobalNodeIdArray ()`
- `obj.GenerateGlobalNodeIdArrayOn ()`

- `obj.GenerateGlobalNodeIdArrayOff ()`
- `obj.SetGenerateVertexWeightArrays (int )`
- `int = obj.GetGenerateVertexWeightArrays ()`
- `obj.GenerateVertexWeightArraysOn ()`
- `obj.GenerateVertexWeightArraysOff ()`
- `int = obj.GetNumberOfVertexWeights ()`
- `string = obj.GetVertexWeightArrayName (int weight)`
- `obj.SetGenerateEdgeWeightArrays (int )`
- `int = obj.GetGenerateEdgeWeightArrays ()`
- `obj.GenerateEdgeWeightArraysOn ()`
- `obj.GenerateEdgeWeightArraysOff ()`
- `int = obj.GetNumberOfEdgeWeights ()`
- `string = obj.GetEdgeWeightArrayName (int weight)`
- `int = obj.GetDimensionality ()` - Access to meta data generated by RequestInformation.
- `vtkIdType = obj.GetNumberOfEdges ()` - Access to meta data generated by RequestInformation.
- `vtkIdType = obj.GetNumberOfVertices ()` - Access to meta data generated by RequestInformation.
- `int = obj.GetNumberOfCellWeightArrays ()`
- `int = obj.GetNumberOfPointWeightArrays ()`

37.14 vtkDataCompressor

37.14.1 Usage

vtkDataCompressor provides a universal interface for data compression. Subclasses provide one compression method and one decompression method. The public interface to all compressors remains the same, and is defined by this class.

To create an instance of class vtkDataCompressor, simply invoke its constructor as follows

```
obj = vtkDataCompressor
```

37.14.2 Methods

The class vtkDataCompressor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataCompressor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataCompressor = obj.NewInstance ()`
- `vtkDataCompressor = obj.SafeDownCast (vtkObject o)`

- `long = obj.GetMaximumCompressionSpace (long size)` - Get the maximum space that may be needed to store data of the given uncompressed size after compression. This is the minimum size of the output buffer that can be passed to the four-argument Compress method.

- `long = obj.Compress (string uncompressedData, long uncompressedSize, string compressedData, long co` - Compress the given input data buffer into the given output buffer. The size of the output buffer must be at least as large as the value given by GetMaximumCompressionSpace for the given input size.

- `long = obj.Uncompress (string compressedData, long compressedSize, string uncompressedData, long un` - Uncompress the given input data into the given output buffer. The size of the uncompressed data must be known by the caller. It should be transmitted from the compressor by a means outside of this class.

- `vtkUnsignedCharArray = obj.Compress (string uncompressedData, long uncompressedSize)` - Compress the given data. A vtkUnsignedCharArray containing the compressed data is returned with a reference count of 1.

- `vtkUnsignedCharArray = obj.Uncompress (string compressedData, long compressedSize, long uncompresse` - Uncompress the given data. A vtkUnsignedCharArray containing the compressed data is returned with a reference count of 1. The size of the uncompressed data must be known by the caller. It should be transmitted from the compressor by a means outside of this class.

37.15 vtkDataObjectReader

37.15.1 Usage

vtkDataObjectReader is a source object that reads ASCII or binary field data files in vtk format. Fields are general matrix structures used represent complex data. (See text for format details). The output of this reader is a single vtkDataObject. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkDataObjectReader, simply invoke its constructor as follows

```
obj = vtkDataObjectReader
```

37.15.2 Methods

The class vtkDataObjectReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkDataObjectReader = obj.NewInstance ()`

- `vtkDataObjectReader = obj.SafeDownCast (vtkObject o)`

- `vtkDataObject = obj.GetOutput ()` - Get the output field of this reader.

- `vtkDataObject = obj.GetOutput (int idx)` - Get the output field of this reader.

- `obj.SetOutput (vtkDataObject )` - Get the output field of this reader.

37.16 vtkDataObjectWriter

37.16.1 Usage

vtkDataObjectWriter is a source object that writes ASCII or binary field data files in vtk format. Field data is a general form of data in matrix form.

To create an instance of class vtkDataObjectWriter, simply invoke its constructor as follows

```
obj = vtkDataObjectWriter
```

37.16.2 Methods

The class vtkDataObjectWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectWriter = obj.NewInstance ()`
- `vtkDataObjectWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string filename)` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `string = obj.GetFileName ()` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `obj.SetHeader (string header)` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `string = obj.GetHeader ()` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `obj.SetFileType (int type)` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `int = obj.GetFileType ()` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `obj.SetFileTypeToASCII ()` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `obj.SetFileTypeToBinary ()` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `obj.SetFieldDataName (string fieldname)` - Methods delegated to vtkDataWriter, see vtkDataWriter.
- `string = obj.GetFieldDataName ()` - Methods delegated to vtkDataWriter, see vtkDataWriter.

37.17 vtkDataReader

37.17.1 Usage

vtkDataReader is a helper superclass that reads the vtk data file header, dataset type, and attribute data (point and cell attributes such as scalars, vectors, normals, etc.) from a vtk data file. See text for the format of the various vtk file types.

To create an instance of class vtkDataReader, simply invoke its constructor as follows

```
obj = vtkDataReader
```

37.17.2 Methods

The class vtkDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataReader = obj.NewInstance ()`
- `vtkDataReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of vtk data file to read.
- `string = obj.GetFileName ()` - Specify file name of vtk data file to read.
- `int = obj.IsFileValid (string dstype)` - Is the file a valid vtk file of the passed dataset type ? The dataset type is passed as a lower case string.
- `int = obj.IsFileStructuredPoints ()` - Is the file a valid vtk file of the passed dataset type ? The dataset type is passed as a lower case string.
- `int = obj.IsFilePolyData ()` - Is the file a valid vtk file of the passed dataset type ? The dataset type is passed as a lower case string.
- `int = obj.IsFileStructuredGrid ()` - Is the file a valid vtk file of the passed dataset type ? The dataset type is passed as a lower case string.
- `int = obj.IsFileUnstructuredGrid ()` - Is the file a valid vtk file of the passed dataset type ? The dataset type is passed as a lower case string.
- `int = obj.IsFileRectilinearGrid ()` - Is the file a valid vtk file of the passed dataset type ? The dataset type is passed as a lower case string.
- `obj.SetInputString (string in)` - Specify the InputString for use when reading from a character array. Optionally include the length for binary strings. Note that a copy of the string is made and stored. If this causes exceedingly large memory consumption, consider using InputArray instead.
- `string = obj.GetInputString ()` - Specify the InputString for use when reading from a character array. Optionally include the length for binary strings. Note that a copy of the string is made and stored. If this causes exceedingly large memory consumption, consider using InputArray instead.
- `obj.SetInputString (string in, int len)` - Specify the InputString for use when reading from a character array. Optionally include the length for binary strings. Note that a copy of the string is made and stored. If this causes exceedingly large memory consumption, consider using InputArray instead.
- `int = obj.GetInputStringLength ()` - Specify the InputString for use when reading from a character array. Optionally include the length for binary strings. Note that a copy of the string is made and stored. If this causes exceedingly large memory consumption, consider using InputArray instead.
- `obj.SetBinaryInputString (string , int len)` - Specify the InputString for use when reading from a character array. Optionally include the length for binary strings. Note that a copy of the string is made and stored. If this causes exceedingly large memory consumption, consider using InputArray instead.

- `obj.SetInputArray (vtkCharArray )` - Specify the vtkCharArray to be used when reading from a string. If set, this array has precendence over InputString. Use this instead of InputString to avoid the extra memory copy. It should be noted that if the underlying char* is owned by the user (vtkCharArray::SetArray(array, 1);) and is deleted before the reader, bad things will happen during a pipeline update.
- `vtkCharArray = obj.GetInputArray ()` - Specify the vtkCharArray to be used when reading from a string. If set, this array has precendence over InputString. Use this instead of InputString to avoid the extra memory copy. It should be noted that if the underlying char* is owned by the user (vtkCharArray::SetArray(array, 1);) and is deleted before the reader, bad things will happen during a pipeline update.
- `string = obj.GetHeader ()` - Get the header from the vtk data file.
- `obj.SetReadFromInputString (int )` - Enable reading from an InputString or InputArray instead of the default, a file.
- `int = obj.GetReadFromInputString ()` - Enable reading from an InputString or InputArray instead of the default, a file.
- `obj.ReadFromInputStringOn ()` - Enable reading from an InputString or InputArray instead of the default, a file.
- `obj.ReadFromInputStringOff ()` - Enable reading from an InputString or InputArray instead of the default, a file.
- `int = obj.GetFileType ()` - Get the type of file (ASCII or BINARY). Returned value only valid after file has been read.
- `int = obj.GetNumberOfScalarsInFile ()` - How many attributes of various types are in this file? This requires reading the file, so the filename must be set prior to invoking this operation. (Note: file characteristics are cached, so only a single read is necessary to return file characteristics.)
- `int = obj.GetNumberOfVectorsInFile ()` - How many attributes of various types are in this file? This requires reading the file, so the filename must be set prior to invoking this operation. (Note: file characteristics are cached, so only a single read is necessary to return file characteristics.)
- `int = obj.GetNumberOfTensorsInFile ()` - How many attributes of various types are in this file? This requires reading the file, so the filename must be set prior to invoking this operation. (Note: file characteristics are cached, so only a single read is necessary to return file characteristics.)
- `int = obj.GetNumberOfNormalsInFile ()` - How many attributes of various types are in this file? This requires reading the file, so the filename must be set prior to invoking this operation. (Note: file characteristics are cached, so only a single read is necessary to return file characteristics.)
- `int = obj.GetNumberOfTCoordsInFile ()` - How many attributes of various types are in this file? This requires reading the file, so the filename must be set prior to invoking this operation. (Note: file characteristics are cached, so only a single read is necessary to return file characteristics.)
- `int = obj.GetNumberOfFieldDataInFile ()` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.
- `string = obj.GetScalarsNameInFile (int i)` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.
- `string = obj.GetVectorsNameInFile (int i)` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.

- `string = obj.GetTensorsNameInFile (int i)` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.
- `string = obj.GetNormalsNameInFile (int i)` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.
- `string = obj.GetTCoordsNameInFile (int i)` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.
- `string = obj.GetFieldDataNameInFile (int i)` - What is the name of the ith attribute of a certain type in this file? This requires reading the file, so the filename must be set prior to invoking this operation.
- `obj.SetScalarsName (string )` - Set the name of the scalar data to extract. If not specified, first scalar data encountered is extracted.
- `string = obj.GetScalarsName ()` - Set the name of the scalar data to extract. If not specified, first scalar data encountered is extracted.
- `obj.SetVectorsName (string )` - Set the name of the vector data to extract. If not specified, first vector data encountered is extracted.
- `string = obj.GetVectorsName ()` - Set the name of the vector data to extract. If not specified, first vector data encountered is extracted.
- `obj.SetTensorsName (string )` - Set the name of the tensor data to extract. If not specified, first tensor data encountered is extracted.
- `string = obj.GetTensorsName ()` - Set the name of the tensor data to extract. If not specified, first tensor data encountered is extracted.
- `obj.SetNormalsName (string )` - Set the name of the normal data to extract. If not specified, first normal data encountered is extracted.
- `string = obj.GetNormalsName ()` - Set the name of the normal data to extract. If not specified, first normal data encountered is extracted.
- `obj.SetTCoordsName (string )` - Set the name of the texture coordinate data to extract. If not specified, first texture coordinate data encountered is extracted.
- `string = obj.GetTCoordsName ()` - Set the name of the texture coordinate data to extract. If not specified, first texture coordinate data encountered is extracted.
- `obj.SetLookupTableName (string )` - Set the name of the lookup table data to extract. If not specified, uses lookup table named by scalar. Otherwise, this specification supersedes.
- `string = obj.GetLookupTableName ()` - Set the name of the lookup table data to extract. If not specified, uses lookup table named by scalar. Otherwise, this specification supersedes.
- `obj.SetFieldDataName (string )` - Set the name of the field data to extract. If not specified, uses first field data encountered in file.
- `string = obj.GetFieldDataName ()` - Set the name of the field data to extract. If not specified, uses first field data encountered in file.
- `obj.SetReadAllScalars (int )` - Enable reading all scalars.
- `int = obj.GetReadAllScalars ()` - Enable reading all scalars.

- `obj.ReadAllScalarsOn ()` - Enable reading all scalars.
- `obj.ReadAllScalarsOff ()` - Enable reading all scalars.
- `obj.SetReadAllVectors (int )` - Enable reading all vectors.
- `int = obj.GetReadAllVectors ()` - Enable reading all vectors.
- `obj.ReadAllVectorsOn ()` - Enable reading all vectors.
- `obj.ReadAllVectorsOff ()` - Enable reading all vectors.
- `obj.SetReadAllNormals (int )` - Enable reading all normals.
- `int = obj.GetReadAllNormals ()` - Enable reading all normals.
- `obj.ReadAllNormalsOn ()` - Enable reading all normals.
- `obj.ReadAllNormalsOff ()` - Enable reading all normals.
- `obj.SetReadAllTensors (int )` - Enable reading all tensors.
- `int = obj.GetReadAllTensors ()` - Enable reading all tensors.
- `obj.ReadAllTensorsOn ()` - Enable reading all tensors.
- `obj.ReadAllTensorsOff ()` - Enable reading all tensors.
- `obj.SetReadAllColorScalars (int )` - Enable reading all color scalars.
- `int = obj.GetReadAllColorScalars ()` - Enable reading all color scalars.
- `obj.ReadAllColorScalarsOn ()` - Enable reading all color scalars.
- `obj.ReadAllColorScalarsOff ()` - Enable reading all color scalars.
- `obj.SetReadAllTCoords (int )` - Enable reading all tcoords.
- `int = obj.GetReadAllTCoords ()` - Enable reading all tcoords.
- `obj.ReadAllTCoordsOn ()` - Enable reading all tcoords.
- `obj.ReadAllTCoordsOff ()` - Enable reading all tcoords.
- `obj.SetReadAllFields (int )` - Enable reading all fields.
- `int = obj.GetReadAllFields ()` - Enable reading all fields.
- `obj.ReadAllFieldsOn ()` - Enable reading all fields.
- `obj.ReadAllFieldsOff ()` - Enable reading all fields.
- `int = obj.OpenVTKFile ()` - Open a vtk data file. Returns zero if error.
- `int = obj.ReadHeader ()` - Read the header of a vtk data file. Returns 0 if error.
- `int = obj.ReadCellData (vtkDataSet ds, int numCells)` - Read the cell data of a vtk data file. The number of cells (from the dataset) must match the number of cells defined in cell attributes (unless no geometry was defined).
- `int = obj.ReadPointData (vtkDataSet ds, int numPts)` - Read the point data of a vtk data file. The number of points (from the dataset) must match the number of points defined in point attributes (unless no geometry was defined).
- `int = obj.ReadPoints (vtkPointSet ps, int numPts)` - Read point coordinates. Return 0 if error.

- `int = obj.ReadPoints (vtkGraph g, int numPts)` - Read point coordinates. Return 0 if error.
- `int = obj.ReadVertexData (vtkGraph g, int numVertices)` - Read the vertex data of a vtk data file. The number of vertices (from the graph) must match the number of vertices defined in vertex attributes (unless no geometry was defined).
- `int = obj.ReadEdgeData (vtkGraph g, int numEdges)` - Read the edge data of a vtk data file. The number of edges (from the graph) must match the number of edges defined in edge attributes (unless no geometry was defined).
- `int = obj.ReadRowData (vtkTable t, int numEdges)` - Read the row data of a vtk data file.
- `int = obj.ReadCells (int size, int data)` - Read a bunch of "cells". Return 0 if error.
- `int = obj.ReadCells (int size, int data, int skip1, int read2, int skip3)` - Read a piece of the cells (for streaming compliance)
- `int = obj.ReadCoordinates (vtkRectilinearGrid rg, int axes, int numCoords)` - Read the coordinates for a rectilinear grid. The axes parameter specifies which coordinate axes (0,1,2) is being read.
- `vtkAbstractArray = obj.ReadArray (string dataType, int numTuples, int numComp)` - Helper functions for reading data.
- `vtkFieldData = obj.ReadFieldData ()` - Helper functions for reading data.
- `obj.CloseVTKFile ()` - Close the vtk file.
- `int = obj.ReadMetaData (vtkInformation )`

37.18 vtkDataSetReader

37.18.1 Usage

vtkDataSetReader is a class that provides instance variables and methods to read any type of dataset in Visualization Toolkit (vtk) format. The output type of this class will vary depending upon the type of data file. Convenience methods are provided to keep the data as a particular type. (See text for format description details). The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkDataSetReader, simply invoke its constructor as follows

```
obj = vtkDataSetReader
```

37.18.2 Methods

The class vtkDataSetReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetReader = obj.NewInstance ()`
- `vtkDataSetReader = obj.SafeDownCast (vtkObject o)`
- `vtkDataSet = obj.GetOutput ()` - Get the output of this filter

- `vtkDataSet = obj.GetOutput (int idx)` - Get the output of this filter
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `int = obj.ReadOutputType ()` - This method can be used to find out the type of output expected without needing to read the whole file.

37.19 vtkDataSetWriter

37.19.1 Usage

vtkDataSetWriter is an abstract class for mapper objects that write their data to disk (or into a communications port). The input to this object is a dataset of any type.

To create an instance of class vtkDataSetWriter, simply invoke its constructor as follows

```
obj = vtkDataSetWriter
```

37.19.2 Methods

The class vtkDataSetWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetWriter = obj.NewInstance ()`
- `vtkDataSetWriter = obj.SafeDownCast (vtkObject o)`
- `vtkDataSet = obj.GetInput ()` - Get the input to this writer.
- `vtkDataSet = obj.GetInput (int port)` - Get the input to this writer.

37.20 vtkDataWriter

37.20.1 Usage

vtkDataWriter is a helper class that opens and writes the vtk header and point data (e.g., scalars, vectors, normals, etc.) from a vtk data file. See text for various formats.

To create an instance of class vtkDataWriter, simply invoke its constructor as follows

```
obj = vtkDataWriter
```

37.20.2 Methods

The class vtkDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataWriter = obj.NewInstance ()`
- `vtkDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of vtk polygon data file to write.
- `string = obj.GetFileName ()` - Specify file name of vtk polygon data file to write.
- `obj.SetWriteToOutputString (int )` - Enable writing to an OutputString instead of the default, a file.
- `int = obj.GetWriteToOutputString ()` - Enable writing to an OutputString instead of the default, a file.
- `obj.WriteToOutputStringOn ()` - Enable writing to an OutputString instead of the default, a file.
- `obj.WriteToOutputStringOff ()` - Enable writing to an OutputString instead of the default, a file.
- `int = obj.GetOutputStringLength ()` - When WriteToOutputString in on, then a string is allocated, written to, and can be retrieved with these methods. The string is deleted during the next call to write ...
- `string = obj.GetOutputString ()` - When WriteToOutputString in on, then a string is allocated, written to, and can be retrieved with these methods. The string is deleted during the next call to write ...
- `string = obj.RegisterAndGetOutputString ()` - This convenience method returns the string, sets the IVAR to NULL, so that the user is responsible for deleting the string. I am not sure what the name should be, so it may change in the future.
- `obj.SetHeader (string )` - Specify the header for the vtk data file.
- `string = obj.GetHeader ()` - Specify the header for the vtk data file.
- `obj.SetFileType (int )` - Specify file type (ASCII or BINARY) for vtk data file.
- `int = obj.GetFileTypeMinValue ()` - Specify file type (ASCII or BINARY) for vtk data file.
- `int = obj.GetFileTypeMaxValue ()` - Specify file type (ASCII or BINARY) for vtk data file.
- `int = obj.GetFileType ()` - Specify file type (ASCII or BINARY) for vtk data file.

- `obj.SetFileTypeToASCII ()` - Specify file type (ASCII or BINARY) for vtk data file.
- `obj.SetFileTypeToBinary ()` - Specify file type (ASCII or BINARY) for vtk data file.
- `obj.SetScalarsName (string )` - Give a name to the scalar data. If not specified, uses default name "scalars".
- `string = obj.GetScalarsName ()` - Give a name to the scalar data. If not specified, uses default name "scalars".
- `obj.SetVectorsName (string )` - Give a name to the vector data. If not specified, uses default name "vectors".
- `string = obj.GetVectorsName ()` - Give a name to the vector data. If not specified, uses default name "vectors".
- `obj.SetTensorsName (string )` - Give a name to the tensors data. If not specified, uses default name "tensors".
- `string = obj.GetTensorsName ()` - Give a name to the tensors data. If not specified, uses default name "tensors".
- `obj.SetNormalsName (string )` - Give a name to the normals data. If not specified, uses default name "normals".
- `string = obj.GetNormalsName ()` - Give a name to the normals data. If not specified, uses default name "normals".
- `obj.SetTCoordsName (string )` - Give a name to the texture coordinates data. If not specified, uses default name "textureCoords".
- `string = obj.GetTCoordsName ()` - Give a name to the texture coordinates data. If not specified, uses default name "textureCoords".
- `obj.SetGlobalIdsName (string )` - Give a name to the global ids data. If not specified, uses default name "global_ids".
- `string = obj.GetGlobalIdsName ()` - Give a name to the global ids data. If not specified, uses default name "global_ids".
- `obj.SetPedigreeIdsName (string )` - Give a name to the pedigree ids data. If not specified, uses default name "pedigree_ids".
- `string = obj.GetPedigreeIdsName ()` - Give a name to the pedigree ids data. If not specified, uses default name "pedigree_ids".
- `obj.SetLookupTableName (string )` - Give a name to the lookup table. If not specified, uses default name "lookupTable".
- `string = obj.GetLookupTableName ()` - Give a name to the lookup table. If not specified, uses default name "lookupTable".
- `obj.SetFieldDataName (string )` - Give a name to the field data. If not specified, uses default name "field".
- `string = obj.GetFieldDataName ()` - Give a name to the field data. If not specified, uses default name "field".

37.21 vtkDEMReader

37.21.1 Usage

vtkDEMReader reads digital elevation files and creates image data. Digital elevation files are produced by the ¡A HREF="http://www.usgs.gov"¿US Geological Survey¡/A¿. A complete description of the DEM file is located at the USGS site. The reader reads the entire dem file and create a vtkImageData that contains a single scalar component that is the elevation in meters. The spacing is also expressed in meters. A number of get methods provide access to fields on the header.

To create an instance of class vtkDEMReader, simply invoke its constructor as follows

```
obj = vtkDEMReader
```

37.21.2 Methods

The class vtkDEMReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDEMReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDEMReader = obj.NewInstance ()`
- `vtkDEMReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of Digital Elevation Model (DEM) file
- `string = obj.GetFileName ()` - Specify file name of Digital Elevation Model (DEM) file
- `obj.SetElevationReference (int )` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `int = obj.GetElevationReferenceMinValue ()` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `int = obj.GetElevationReferenceMaxValue ()` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `int = obj.GetElevationReference ()` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `obj.SetElevationReferenceToSeaLevel ()` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `obj.SetElevationReferenceToElevationBounds ()` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `string = obj.GetElevationReferenceAsString (void )` - Specify the elevation origin to use. By default, the elevation origin is equal to ElevationBounds[0]. A more convenient origin is to use sea level (i.e., a value of 0.0).
- `string = obj.GetMapLabel ()` - An ASCII description of the map

- `int = obj.GetDEMLevel ()` - Code 1=DEM-1, 2=DEM_2, ...
- `int = obj.GetElevationPattern ()` - Code 1=regular, 2=random, reserved for future use
- `int = obj.GetGroundSystem ()` - Ground planimetric reference system
- `int = obj.GetGroundZone ()` - Zone in ground planimetric reference system
- `float = obj. GetProjectionParameters ()` - Map Projection parameters. All are zero.
- `int = obj.GetPlaneUnitOfMeasure ()` - Defining unit of measure for ground planimetric coordinates throughout the file. 0 = radians, 1 = feet, 2 = meters, 3 = arc-seconds.
- `int = obj.GetElevationUnitOfMeasure ()` - Defining unit of measure for elevation coordinates throughout the file. 1 = feet, 2 = meters
- `int = obj.GetPolygonSize ()` - Number of sides in the polygon which defines the coverage of the DEM file. Set to 4.
- `float = obj. GetElevationBounds ()` - Minimum and maximum elevation for the DEM. The units in the file are in ElevationUnitOfMeasure. This class converts them to meters.
- `float = obj.GetLocalRotation ()` - Counterclockwise angle (in radians) from the primary axis of the planimetric reference to the primary axis of the DEM local reference system. IGNORED BY THIS IMPLEMENTATION.
- `int = obj.GetAccuracyCode ()` - Accuracy code for elevations. 0=unknown accuracy
- `float = obj. GetSpatialResolution ()` - DEM spatial resolution for x,y,z. Values are expressed in units of resolution. Since elevations are read as integers, this permits fractional elevations.
- `int = obj. GetProfileDimension ()` - The number of rows and columns in the DEM.

37.22 vtkDICOMImageReader

37.22.1 Usage

DICOM (stands for Digital Imaging in COmmunications and Medicine) is a medical image file format widely used to exchange data, provided by various modalities. .SECTION Warnings This reader might eventually handle ACR-NEMA file (predecessor of the DICOM format for medical images). This reader does not handle encapsulated format, only plain raw file are handled. This reader also does not handle multi-frames DICOM datasets. .SECTION Warnings Internally DICOMParser assumes the x,y pixel spacing is stored in 0028,0030 and that z spacing is stored in Slice Thickness (correct only when slice were acquired contiguous): 0018,0050. Which means this is only valid for some rare MR Image Storage

To create an instance of class vtkDICOMImageReader, simply invoke its constructor as follows

```
obj = vtkDICOMImageReader
```

37.22.2 Methods

The class vtkDICOMImageReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDICOMImageReader class.

- `string = obj.GetClassName ()` - Static method for construction.
- `int = obj.IsA (string name)` - Static method for construction.
- `vtkDICOMImageReader = obj.NewInstance ()` - Static method for construction.

- `vtkDICOMImageReader = obj.SafeDownCast (vtkObject o)` - Static method for construction.
- `obj.SetFileName (string fn)` - Set the directory name for the reader to look in for DICOM files. If this method is used, the reader will try to find all the DICOM files in a directory. It will select the subset corresponding to the first series UID it stumbles across and it will try to build an ordered volume from them based on the slice number. The volume building will be upgraded to something more sophisticated in the future.
- `obj.SetDirectoryName (string dn)` - Set the directory name for the reader to look in for DICOM files. If this method is used, the reader will try to find all the DICOM files in a directory. It will select the subset corresponding to the first series UID it stumbles across and it will try to build an ordered volume from them based on the slice number. The volume building will be upgraded to something more sophisticated in the future.
- `string = obj.GetDirectoryName ()` - Returns the directory name.
- `double = obj.GetPixelSpacing ()` - Returns the pixel spacing (in X, Y, Z). Note: if there is only one slice, the Z spacing is set to the slice thickness. If there is more than one slice, it is set to the distance between the first two slices.
- `int = obj.GetWidth ()` - Returns the image width.
- `int = obj.GetHeight ()` - Returns the image height.
- `float = obj.GetImagePositionPatient ()` - Get the (DICOM) x,y,z coordinates of the first pixel in the image (upper left hand corner) of the last image processed by the DICOMParser
- `float = obj.GetImageOrientationPatient ()` - Get the (DICOM) directions cosines. It consist of the components of the first two vectors. The third vector needs to be computed to form an orthonormal basis.
- `int = obj.GetBitsAllocated ()` - Get the number of bits allocated for each pixel in the file.
- `int = obj.GetPixelRepresentation ()` - Get the pixel representation of the last image processed by the DICOMParser. A zero is a unsigned quantity. A one indicates a signed quantity
- `int = obj.GetNumberOfComponents ()` - Get the number of components of the image data for the last image processed.
- `string = obj.GetTransferSyntaxUID ()` - Get the transfer syntax UID for the last image processed.
- `float = obj.GetRescaleSlope ()` - Get the rescale slope for the pixel data.
- `float = obj.GetRescaleOffset ()` - Get the rescale offset for the pixel data.
- `string = obj.GetPatientName ()` - Get the patient name for the last image processed.
- `string = obj.GetStudyUID ()` - Get the study uid for the last image processed.
- `string = obj.GetStudyID ()` - Get the Study ID for the last image processed.
- `float = obj.GetGantryAngle ()` - Get the gantry angle for the last image processed.
- `int = obj.CanReadFile (string fname)`
- `string = obj.GetFileExtensions ()` - Return a descriptive name for the file format that might be useful in a GUI.
- `string = obj.GetDescriptiveName ()`

37.23 vtkEnSight6BinaryReader

37.23.1 Usage

vtkEnSight6BinaryReader is a class to read binary EnSight6 files into vtk. Because the different parts of the EnSight data can be of various data types, this reader produces multiple outputs, one per part in the input file. All variable information is being stored in field data. The descriptions listed in the case file are used as the array names in the field data. For complex vector variables, the description is appended with _r (for the array of real values) and _i (for the array if imaginary values). Complex scalar variables are stored as a single array with 2 components, real and imaginary, listed in that order.

To create an instance of class vtkEnSight6BinaryReader, simply invoke its constructor as follows

```
obj = vtkEnSight6BinaryReader
```

37.23.2 Methods

The class vtkEnSight6BinaryReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEnSight6BinaryReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEnSight6BinaryReader = obj.NewInstance ()`
- `vtkEnSight6BinaryReader = obj.SafeDownCast (vtkObject o)`

37.24 vtkEnSight6Reader

37.24.1 Usage

vtkEnSight6Reader is a class to read EnSight6 files into vtk. Because the different parts of the EnSight data can be of various data types, this reader produces multiple outputs, one per part in the input file. All variable information is being stored in field data. The descriptions listed in the case file are used as the array names in the field data. For complex vector variables, the description is appended with _r (for the array of real values) and _i (for the array if imaginary values). Complex scalar variables are stored as a single array with 2 components, real and imaginary, listed in that order.

To create an instance of class vtkEnSight6Reader, simply invoke its constructor as follows

```
obj = vtkEnSight6Reader
```

37.24.2 Methods

The class vtkEnSight6Reader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEnSight6Reader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEnSight6Reader = obj.NewInstance ()`
- `vtkEnSight6Reader = obj.SafeDownCast (vtkObject o)`

37.25 vtkEnSightGoldBinaryReader

37.25.1 Usage

vtkEnSightGoldBinaryReader is a class to read EnSight Gold files into vtk. Because the different parts of the EnSight data can be of various data types, this reader produces multiple outputs, one per part in the input file. All variable information is being stored in field data. The descriptions listed in the case file are used as the array names in the field data. For complex vector variables, the description is appended with _r (for the array of real values) and _i (for the array if imaginary values). Complex scalar variables are stored as a single array with 2 components, real and imaginary, listed in that order.

To create an instance of class vtkEnSightGoldBinaryReader, simply invoke its constructor as follows

```
obj = vtkEnSightGoldBinaryReader
```

37.25.2 Methods

The class vtkEnSightGoldBinaryReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEnSightGoldBinaryReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEnSightGoldBinaryReader = obj.NewInstance ()`
- `vtkEnSightGoldBinaryReader = obj.SafeDownCast (vtkObject o)`

37.26 vtkEnSightGoldReader

37.26.1 Usage

vtkEnSightGoldReader is a class to read EnSight Gold files into vtk. Because the different parts of the EnSight data can be of various data types, this reader produces multiple outputs, one per part in the input file. All variable information is being stored in field data. The descriptions listed in the case file are used as the array names in the field data. For complex vector variables, the description is appended with _r (for the array of real values) and _i (for the array if imaginary values). Complex scalar variables are stored as a single array with 2 components, real and imaginary, listed in that order.

To create an instance of class vtkEnSightGoldReader, simply invoke its constructor as follows

```
obj = vtkEnSightGoldReader
```

37.26.2 Methods

The class vtkEnSightGoldReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEnSightGoldReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEnSightGoldReader = obj.NewInstance ()`
- `vtkEnSightGoldReader = obj.SafeDownCast (vtkObject o)`

37.27 vtkFacetWriter

37.27.1 Usage

vtkFacetWriter creates an unstructured grid dataset. It reads ASCII files stored in Facet format

The facet format looks like this: FACET FILE ... nparts Part 1 name 0 npoints 0 0 p1x p1y p1z p2x p2y p2z ... 1 Part 1 name ncells npointspercell p1c1 p2c1 p3c1 ... pnc1 materialnum partnum p1c2 p2c2 p3c2 ... pnc2 materialnum partnum ...

To create an instance of class vtkFacetWriter, simply invoke its constructor as follows

```
obj = vtkFacetWriter
```

37.27.2 Methods

The class vtkFacetWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFacetWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFacetWriter = obj.NewInstance ()`
- `vtkFacetWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of Facet datafile to read
- `string = obj.GetFileName ()` - Specify file name of Facet datafile to read
- `obj.Write ()` - Write data

37.28 vtkFLUENTReader

37.28.1 Usage

vtkFLUENTReader creates an unstructured grid dataset. It reads .cas and .dat files stored in FLUENT native format.

.SECTION Thanks Thanks to Brian W. Dotson & Terry E. Jordan (Department of Energy, National Energy Technology Laboratory) & Douglas McCorkle (Iowa State University) who developed this class. Please address all comments to Brian Dotson (brian.dotson@netl.doe.gov) & Terry Jordan (terry.jordan@sa.netl.doe.gov) & Doug McCorkle (mccdo@iastate.edu)

To create an instance of class vtkFLUENTReader, simply invoke its constructor as follows

```
obj = vtkFLUENTReader
```

37.28.2 Methods

The class vtkFLUENTReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFLUENTReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFLUENTReader = obj.NewInstance ()`

- `vtkFLUENTReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the file name of the Fluent case file to read.
- `string = obj.GetFileName ()` - Specify the file name of the Fluent case file to read.
- `int = obj.GetNumberOfCells ()` - Get the total number of cells. The number of cells is only valid after a successful read of the data file is performed. Initial value is 0.
- `int = obj.GetNumberOfCellArrays (void )` - Get the number of cell arrays available in the input.
- `string = obj.GetCellArrayName (int index)` - Get the name of the cell array with the given index in the input.
- `int = obj.GetCellArrayStatus (string name)` - Get/Set whether the cell array with the given name is to be read.
- `obj.SetCellArrayStatus (string name, int status)` - Get/Set whether the cell array with the given name is to be read.
- `obj.DisableAllCellArrays ()` - Turn on/off all cell arrays.
- `obj.EnableAllCellArrays ()` - Turn on/off all cell arrays.
- `obj.SetDataByteOrderToBigEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.
- `obj.SetDataByteOrderToLittleEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.
- `int = obj.GetDataByteOrder ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.
- `obj.SetDataByteOrder (int )` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.

- `string = obj.GetDataByteOrderAsString ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.

37.29 vtkGAMBITReader

37.29.1 Usage

vtkGAMBITReader creates an unstructured grid dataset. It reads ASCII files stored in GAMBIT neutral format, with optional data stored at the nodes or at the cells of the model. A cell-based fielddata stores the material id.

To create an instance of class vtkGAMBITReader, simply invoke its constructor as follows

```
obj = vtkGAMBITReader
```

37.29.2 Methods

The class vtkGAMBITReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGAMBITReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGAMBITReader = obj.NewInstance ()`
- `vtkGAMBITReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the file name of the GAMBIT data file to read.
- `string = obj.GetFileName ()` - Specify the file name of the GAMBIT data file to read.
- `int = obj.GetNumberOfCells ()` - Get the total number of cells. The number of cells is only valid after a successful read of the data file is performed.
- `int = obj.GetNumberOfNodes ()` - Get the total number of nodes. The number of nodes is only valid after a successful read of the data file is performed.
- `int = obj.GetNumberOfNodeFields ()` - Get the number of data components at the nodes and cells.
- `int = obj.GetNumberOfCellFields ()` - Get the number of data components at the nodes and cells.

37.30 vtkGaussianCubeReader

37.30.1 Usage

vtkGaussianCubeReader is a source object that reads ASCII files following the description in http://www.gaussian.com/00000
The FileName must be specified.

.SECTION Thanks Dr. Jean M. Favre who developed and contributed this class.

To create an instance of class vtkGaussianCubeReader, simply invoke its constructor as follows

```
obj = vtkGaussianCubeReader
```

37.30.2 Methods

The class vtkGaussianCubeReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGaussianCubeReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGaussianCubeReader = obj.NewInstance ()`
- `vtkGaussianCubeReader = obj.SafeDownCast (vtkObject o)`
- `vtkTransform = obj.GetTransform ()`
- `obj.SetFileName (string )`
- `string = obj.GetFileName ()`
- `vtkImageData = obj.GetGridOutput ()`

37.31 vtkGenericDataObjectReader

37.31.1 Usage

vtkGenericDataObjectReader is a class that provides instance variables and methods to read any type of data object in Visualization Toolkit (vtk) format. The output type of this class will vary depending upon the type of data file. Convenience methods are provided to return the data as a particular type. (See text for format description details). The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkGenericDataObjectReader, simply invoke its constructor as follows

```
obj = vtkGenericDataObjectReader
```

37.31.2 Methods

The class vtkGenericDataObjectReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericDataObjectReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericDataObjectReader = obj.NewInstance ()`
- `vtkGenericDataObjectReader = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetOutput ()` - Get the output of this filter
- `vtkDataObject = obj.GetOutput (int idx)` - Get the output of this filter
- `vtkGraph = obj.GetGraphOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)

- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkTable = obj.GetTableOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkTree = obj.GetTreeOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as various concrete types. This method is typically used when you know exactly what type of data is being read. Otherwise, use the general GetOutput() method. If the wrong type is used NULL is returned. (You must also set the filename of the object prior to getting the output.)
- `int = obj.ReadOutputType ()` - This method can be used to find out the type of output expected without needing to read the whole file.

37.32 vtkGenericDataObjectWriter

37.32.1 Usage

vtkGenericDataObjectWriter is a concrete class that writes data objects to disk. The input to this object is any subclass of vtkDataObject.

To create an instance of class vtkGenericDataObjectWriter, simply invoke its constructor as follows

```
obj = vtkGenericDataObjectWriter
```

37.32.2 Methods

The class vtkGenericDataObjectWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericDataObjectWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkGenericDataObjectWriter = obj.NewInstance ()`
- `vtkGenericDataObjectWriter = obj.SafeDownCast (vtkObject o)`

37.33 vtkGenericEnSightReader

37.33.1 Usage

The class vtkGenericEnSightReader allows the user to read an EnSight data set without a priori knowledge of what type of EnSight data set it is.

To create an instance of class vtkGenericEnSightReader, simply invoke its constructor as follows

```
obj = vtkGenericEnSightReader
```

37.33.2 Methods

The class vtkGenericEnSightReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericEnSightReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericEnSightReader = obj.NewInstance ()`
- `vtkGenericEnSightReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetCaseFileName (string fileName)` - Set/Get the Case file name.
- `string = obj.GetCaseFileName ()` - Set/Get the Case file name.
- `obj.SetFilePath (string )` - Set/Get the file path.
- `string = obj.GetFilePath ()` - Set/Get the file path.
- `int = obj.GetNumberOfVariables ()` - Get the number of variables listed in the case file.
- `int = obj.GetNumberOfComplexVariables ()` - Get the number of variables listed in the case file.
- `int = obj.GetNumberOfVariables (int type)` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfScalarsPerNode ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfVectorsPerNode ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfTensorsSymmPerNode ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfScalarsPerElement ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfVectorsPerElement ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfTensorsSymmPerElement ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfScalarsPerMeasuredNode ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfVectorsPerMeasuredNode ()` - Get the number of variables of a particular type.

- `int = obj.GetNumberOfComplexScalarsPerNode ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfComplexVectorsPerNode ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfComplexScalarsPerElement ()` - Get the number of variables of a particular type.
- `int = obj.GetNumberOfComplexVectorsPerElement ()` - Get the number of variables of a particular type.
- `string = obj.GetDescription (int n)` - Get the nth description for a non-complex variable.
- `string = obj.GetComplexDescription (int n)` - Get the nth description for a complex variable.
- `string = obj.GetDescription (int n, int type)` - Get the nth description of a particular variable type. Returns NULL if no variable of this type exists in this data set. SCALAR_PER_NODE = 0; VECTOR_PER_NODE = 1; TENSOR_SYMM_PER_NODE = 2; SCALAR_PER_ELEMENT = 3; VECTOR_PER_ELEMENT = 4; TENSOR_SYMM_PER_ELEMENT = 5; SCALAR_PER_MEASURED_NODE = 6; VECTOR_PER_MEASURED_NODE = 7; COMPLEX_SCALAR_PER_NODE = 8; COMPLEX_VECTOR_PER_N 9; COMPLEX_SCALAR_PER_ELEMENT = 10; COMPLEX_VECTOR_PER_ELEMENT = 11
- `int = obj.GetVariableType (int n)` - Get the variable type of variable n.
- `int = obj.GetComplexVariableType (int n)` - Get the variable type of variable n.
- `obj.SetTimeValue (float value)` - Set/Get the time value at which to get the value.
- `float = obj.GetTimeValue ()` - Set/Get the time value at which to get the value.
- `float = obj.GetMinimumTimeValue ()` - Get the minimum or maximum time value for this data set.
- `float = obj.GetMaximumTimeValue ()` - Get the minimum or maximum time value for this data set.
- `vtkDataArrayCollection = obj.GetTimeSets ()` - Get the time values per time set
- `int = obj.DetermineEnSightVersion (int quiet)` - Reads the FORMAT part of the case file to determine whether this is an EnSight6 or EnSightGold data set. Returns an identifier listed in the FileTypes enum or -1 if an error occurred or the file could not be indentified as any EnSight type.
- `obj.ReadAllVariablesOn ()` - Set/get the flag for whether to read all the variables
- `obj.ReadAllVariablesOff ()` - Set/get the flag for whether to read all the variables
- `obj.SetReadAllVariables (int )` - Set/get the flag for whether to read all the variables
- `int = obj.GetReadAllVariables ()` - Set/get the flag for whether to read all the variables
- `vtkDataArraySelection = obj.GetPointDataArraySelection ()` - Get the data array selection tables used to configure which data arrays are loaded by the reader.
- `vtkDataArraySelection = obj.GetCellDataArraySelection ()` - Get the data array selection tables used to configure which data arrays are loaded by the reader.
- `int = obj.GetNumberOfPointArrays ()` - Get the number of point or cell arrays available in the input.
- `int = obj.GetNumberOfCellArrays ()` - Get the number of point or cell arrays available in the input.
- `string = obj.GetPointArrayName (int index)` - Get the name of the point or cell array with the given index in the input.

- `string = obj.GetCellArrayName (int index)` - Get the name of the point or cell array with the given index in the input.
- `int = obj.GetPointArrayStatus (string name)` - Get/Set whether the point or cell array with the given name is to be read.
- `int = obj.GetCellArrayStatus (string name)` - Get/Set whether the point or cell array with the given name is to be read.
- `obj.SetPointArrayStatus (string name, int status)` - Get/Set whether the point or cell array with the given name is to be read.
- `obj.SetCellArrayStatus (string name, int status)` - Get/Set whether the point or cell array with the given name is to be read.
- `obj.SetByteOrderToBigEndian ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetByteOrderToLittleEndian ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetByteOrder (int )` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `int = obj.GetByteOrder ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `string = obj.GetByteOrderAsString ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `string = obj.GetGeometryFileName ()` - Get the Geometry file name. Made public to allow access from apps requiring detailed info about the Data contents
- `obj.SetParticleCoordinatesByIndex (int )` - The MeasuredGeometryFile should list particle coordinates from 0-¿N-1. If a file is loaded where point Ids are listed from 1-N the Id to points reference will be wrong and the data will be generated incorrectly. Setting ParticleCoordinatesByIndex to true will force all Id's to increment from 0-¿N-1 (relative to their order in the file) and regardless of the actual Id of of the point. Warning, if the Points are listed in non sequential order then setting this flag will reorder them.
- `int = obj.GetParticleCoordinatesByIndex ()` - The MeasuredGeometryFile should list particle coordinates from 0-¿N-1. If a file is loaded where point Ids are listed from 1-N the Id to points reference will be wrong and the data will be generated incorrectly. Setting ParticleCoordinatesByIndex to true will force all Id's to increment from 0-¿N-1 (relative to their order in the file) and regardless of the actual Id of of the point. Warning, if the Points are listed in non sequential order then setting this flag will reorder them.
- `obj.ParticleCoordinatesByIndexOn ()` - The MeasuredGeometryFile should list particle coordinates from 0-¿N-1. If a file is loaded where point Ids are listed from 1-N the Id to points reference will be wrong and the data will be generated incorrectly. Setting ParticleCoordinatesByIndex to true will force all Id's to increment from 0-¿N-1 (relative to their order in the file) and regardless of the actual Id of of the point. Warning, if the Points are listed in non sequential order then setting this flag will reorder them.

- `obj.ParticleCoordinatesByIndexOff ()` - The MeasuredGeometryFile should list particle coordinates from 0-¿N-1. If a file is loaded where point Ids are listed from 1-N the Id to points reference will be wrong and the data will be generated incorrectly. Setting ParticleCoordinatesByIndex to true will force all Id's to increment from 0-¿N-1 (relative to their order in the file) and regardless of the actual Id of of the point. Warning, if the Points are listed in non sequential order then setting this flag will reorder them.

37.34 vtkGenericMovieWriter

37.34.1 Usage

vtkGenericMovieWriter is the abstract base class for several movie writers. The input type is a vtkImageData. The Start() method will open and create the file, the Write() method will output a frame to the file (i.e. the contents of the vtkImageData), End() will finalize and close the file.

To create an instance of class vtkGenericMovieWriter, simply invoke its constructor as follows

```
obj = vtkGenericMovieWriter
```

37.34.2 Methods

The class vtkGenericMovieWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericMovieWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericMovieWriter = obj.NewInstance ()`
- `vtkGenericMovieWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData input)` - Set/Get the input object from the image pipeline.
- `vtkImageData = obj.GetInput ()` - Set/Get the input object from the image pipeline.
- `obj.SetFileName (string )` - Specify file name of avi file.
- `string = obj.GetFileName ()` - Specify file name of avi file.
- `obj.Start ()` - These methods start writing an Movie file, write a frame to the file and then end the writing process.
- `obj.Write ()` - These methods start writing an Movie file, write a frame to the file and then end the writing process.
- `obj.End ()` - These methods start writing an Movie file, write a frame to the file and then end the writing process.
- `int = obj.GetError ()` - Was there an error on the last write performed?

37.35 vtkGESignaReader

37.35.1 Usage

vtkGESignaReader is a source object that reads some GE Signa ximg files It does support reading in pixel spacing, slice spacing and it computes an origin for the image in millimeters. It always produces greyscale unsigned short data and it supports reading in rectangular, packed, compressed, and packed&compressed. It does not read in slice orientation, or position right now. To use it you just need to specify a filename or a file prefix and pattern.

To create an instance of class vtkGESignaReader, simply invoke its constructor as follows

```
obj = vtkGESignaReader
```

37.35.2 Methods

The class vtkGESignaReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGESignaReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGESignaReader = obj.NewInstance ()`
- `vtkGESignaReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)` - Is the given file a GESigna file?
- `string = obj.GetFileExtensions ()` - A descriptive name for this format
- `string = obj.GetDescriptiveName ()`

37.36 vtkGlobFileNames

37.36.1 Usage

vtkGlobFileNames is a utility for finding files and directories that match a given wildcard pattern. Allowed wildcards are *, ?, [...], [!...]. The "*" wildcard matches any substring, the "?" matches any single character, the [...] matches any one of the enclosed characters, e.g. [abc] will match one of a, b, or c, while [0-9] will match any digit, and [!...] will match any single character except for the ones within the brackets. Special treatment is given to "/" (or "\" on Windows) because these are path separators. These are never matched by a wildcard, they are only matched with another file separator.

To create an instance of class vtkGlobFileNames, simply invoke its constructor as follows

```
obj = vtkGlobFileNames
```

37.36.2 Methods

The class vtkGlobFileNames has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGlobFileNames class.

- `string = obj.GetClassName ()` - Return the class name as a string.
- `int = obj.IsA (string name)` - Return the class name as a string.

- `vtkGlobFileNames = obj.NewInstance ()` - Return the class name as a string.
- `vtkGlobFileNames = obj.SafeDownCast (vtkObject o)` - Return the class name as a string.
- `obj.Reset ()` - Reset the glob by clearing the list of output filenames.
- `obj.SetDirectory (string )` - Set the directory in which to perform the glob. If this is not set, then the current directory will be used. Also, if you use a glob pattern that contains absolute path (one that starts with "/" or a drive letter) then that absolute path will be used and Directory will be ignored.
- `string = obj.GetDirectory ()` - Set the directory in which to perform the glob. If this is not set, then the current directory will be used. Also, if you use a glob pattern that contains absolute path (one that starts with "/" or a drive letter) then that absolute path will be used and Directory will be ignored.
- `int = obj.AddFileNames (string pattern)` - Search for all files that match the given expression, sort them, and add them to the output. This method can be called repeatedly to add files matching additional patterns. Returns 1 if successful, otherwise returns zero.
- `obj.SetRecurse (int )` - Recurse into subdirectories.
- `obj.RecurseOn ()` - Recurse into subdirectories.
- `obj.RecurseOff ()` - Recurse into subdirectories.
- `int = obj.GetRecurse ()` - Recurse into subdirectories.
- `int = obj.GetNumberOfFileNames ()` - Return the number of files found.
- `string = obj.GetNthFileName (int index)` - Return the file at the given index, the indexing is 0 based.
- `vtkStringArray = obj.GetFileNames ()` - Get an array that contains all the file names.

37.37 vtkGraphReader

37.37.1 Usage

vtkGraphReader is a source object that reads ASCII or binary vtkGraph data files in vtk format. (see text for format details). The output of this reader is a single vtkGraph data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkGraphReader, simply invoke its constructor as follows

```
obj = vtkGraphReader
```

37.37.2 Methods

The class vtkGraphReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphReader = obj.NewInstance ()`
- `vtkGraphReader = obj.SafeDownCast (vtkObject o)`

- `vtkGraph = obj.GetOutput ()` - Get the output of this reader.
- `vtkGraph = obj.GetOutput (int idx)` - Get the output of this reader.
- `obj.SetOutput (vtkGraph output)` - Get the output of this reader.

37.38 vtkGraphWriter

37.38.1 Usage

vtkGraphWriter is a sink object that writes ASCII or binary vtkGraph data files in vtk format. See text for format details.

To create an instance of class vtkGraphWriter, simply invoke its constructor as follows

```
obj = vtkGraphWriter
```

37.38.2 Methods

The class vtkGraphWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphWriter = obj.NewInstance ()`
- `vtkGraphWriter = obj.SafeDownCast (vtkObject o)`
- `vtkGraph = obj.GetInput ()` - Get the input to this writer.
- `vtkGraph = obj.GetInput (int port)` - Get the input to this writer.

37.39 vtkImageReader

37.39.1 Usage

vtkImageReader provides methods needed to read a region from a file. It supports both transforms and masks on the input data, but as a result is more complicated and slower than its parent class vtkImageReader2.

To create an instance of class vtkImageReader, simply invoke its constructor as follows

```
obj = vtkImageReader
```

37.39.2 Methods

The class vtkImageReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageReader = obj.NewInstance ()`
- `vtkImageReader = obj.SafeDownCast (vtkObject o)`

- `obj.SetDataVOI (int , int , int , int , int , int )` - Set/get the data VOI. You can limit the reader to only read a subset of the data.
- `obj.SetDataVOI (int a[6])` - Set/get the data VOI. You can limit the reader to only read a subset of the data.
- `int = obj. GetDataVOI ()` - Set/get the data VOI. You can limit the reader to only read a subset of the data.
- `vtkTypeUInt64 = obj.GetDataMask ()` - Set/Get the Data mask. The data mask is a simply integer whose bits are treated as a mask to the bits read from disk. That is, the data mask is bitwise-and'ed to the numbers read from disk. This ivar is stored as 64 bits, the largest mask you will need. The mask will be truncated to the data size required to be read (using the least significant bits).
- `obj.SetDataMask (vtkTypeUInt64 )` - Set/Get the Data mask. The data mask is a simply integer whose bits are treated as a mask to the bits read from disk. That is, the data mask is bitwise-and'ed to the numbers read from disk. This ivar is stored as 64 bits, the largest mask you will need. The mask will be truncated to the data size required to be read (using the least significant bits).
- `obj.SetTransform (vtkTransform )` - Set/Get transformation matrix to transform the data from slice space into world space. This matrix must be a permutation matrix. To qualify, the sums of the rows must be + or - 1.
- `vtkTransform = obj.GetTransform ()` - Set/Get transformation matrix to transform the data from slice space into world space. This matrix must be a permutation matrix. To qualify, the sums of the rows must be + or - 1.
- `obj.ComputeInverseTransformedExtent (int inExtent[6], int outExtent[6])`
- `int = obj.OpenAndSeekFile (int extent[6], int slice)`
- `obj.SetScalarArrayName (string )` - Set/get the scalar array name for this data set.
- `string = obj.GetScalarArrayName ()` - Set/get the scalar array name for this data set.

37.40 vtkImageReader2

37.40.1 Usage

vtkImageReader2 is the parent class for vtkImageReader. It is a good super class for streaming readers that do not require a mask or transform on the data. vtkImageReader was implemented before vtkImageReader2, vtkImageReader2 is intended to have a simpler interface.

To create an instance of class vtkImageReader2, simply invoke its constructor as follows

```
obj = vtkImageReader2
```

37.40.2 Methods

The class vtkImageReader2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageReader2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageReader2 = obj.NewInstance ()`

- `vtkImageReader2 = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name for the image file. If the data is stored in multiple files, then use SetFileNames or SetFilePrefix instead.
- `string = obj.GetFileName ()` - Specify file name for the image file. If the data is stored in multiple files, then use SetFileNames or SetFilePrefix instead.
- `obj.SetFileNames (vtkStringArray )` - Specify a list of file names. Each file must be a single slice, and each slice must be of the same size. The files must be in the correct order. Use SetFileName when reading a volume (multiple slice), since DataExtent will be modified after a SetFileNames call.
- `vtkStringArray = obj.GetFileNames ()` - Specify a list of file names. Each file must be a single slice, and each slice must be of the same size. The files must be in the correct order. Use SetFileName when reading a volume (multiple slice), since DataExtent will be modified after a SetFileNames call.
- `obj.SetFilePrefix (string )` - Specify file prefix for the image file or files. This can be used in place of SetFileName or SetFileNames if the filenames follow a specific naming pattern, but you must explicitly set the DataExtent so that the reader will know what range of slices to load.
- `string = obj.GetFilePrefix ()` - Specify file prefix for the image file or files. This can be used in place of SetFileName or SetFileNames if the filenames follow a specific naming pattern, but you must explicitly set the DataExtent so that the reader will know what range of slices to load.
- `obj.SetFilePattern (string )` - The sprintf-style format string used to build filename from FilePrefix and slice number.
- `string = obj.GetFilePattern ()` - The sprintf-style format string used to build filename from FilePrefix and slice number.
- `obj.SetDataScalarType (int type)` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToFloat ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToDouble ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToInt ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToUnsignedInt ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToShort ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToUnsignedShort ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToChar ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToSignedChar ()` - Set the data type of pixels in the file. If you want the output scalar type to have a different value, set it after this method is called.
- `obj.SetDataScalarTypeToUnsignedChar ()` - Get the file format. Pixels are this type in the file.
- `int = obj.GetDataScalarType ()` - Get the file format. Pixels are this type in the file.

- `obj.SetNumberOfScalarComponents (int )` - Set/Get the number of scalar components
- `int = obj.GetNumberOfScalarComponents ()` - Set/Get the number of scalar components
- `obj.SetDataExtent (int , int , int , int , int , int )` - Get/Set the extent of the data on disk.
- `obj.SetDataExtent (int  a[6])` - Get/Set the extent of the data on disk.
- `int = obj. GetDataExtent ()` - Get/Set the extent of the data on disk.
- `obj.SetFileDimensionality (int )` - The number of dimensions stored in a file. This defaults to two.
- `int = obj.GetFileDimensionality ()` - Set/Get the spacing of the data in the file.
- `obj.SetDataSpacing (double , double , double )` - Set/Get the spacing of the data in the file.
- `obj.SetDataSpacing (double  a[3])` - Set/Get the spacing of the data in the file.
- `double = obj. GetDataSpacing ()` - Set/Get the spacing of the data in the file.
- `obj.SetDataOrigin (double , double , double )` - Set/Get the origin of the data (location of first pixel in the file).
- `obj.SetDataOrigin (double  a[3])` - Set/Get the origin of the data (location of first pixel in the file).
- `double = obj. GetDataOrigin ()` - Set/Get the origin of the data (location of first pixel in the file).
- `long = obj.GetHeaderSize ()` - Get the size of the header computed by this object.
- `long = obj.GetHeaderSize (long slice)` - Get the size of the header computed by this object.
- `obj.SetHeaderSize (long size)` - If there is a tail on the file, you want to explicitly set the header size.
- `obj.SetDataByteOrderToBigEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `obj.SetDataByteOrderToLittleEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `int = obj.GetDataByteOrder ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.

- `obj.SetDataByteOrder (int )` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `string = obj.GetDataByteOrderAsString ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `obj.SetFileNameSliceOffset (int )` - When reading files which start at an unusual index, this can be added to the slice number when generating the file name (default = 0)
- `int = obj.GetFileNameSliceOffset ()` - When reading files which start at an unusual index, this can be added to the slice number when generating the file name (default = 0)
- `obj.SetFileNameSliceSpacing (int )` - When reading files which have regular, but non contiguous slices (eg filename.1,filename.3,filename.5) a spacing can be specified to skip missing files (default = 1)
- `int = obj.GetFileNameSliceSpacing ()` - When reading files which have regular, but non contiguous slices (eg filename.1,filename.3,filename.5) a spacing can be specified to skip missing files (default = 1)
- `obj.SetSwapBytes (int )` - Set/Get the byte swapping to explicitly swap the bytes of a file.
- `int = obj.GetSwapBytes ()` - Set/Get the byte swapping to explicitly swap the bytes of a file.
- `obj.SwapBytesOn ()` - Set/Get the byte swapping to explicitly swap the bytes of a file.
- `obj.SwapBytesOff ()` - Set/Get the byte swapping to explicitly swap the bytes of a file.
- `int = obj.OpenFile ()`
- `obj.SeekFile (int i, int j, int k)`
- `obj.FileLowerLeftOn ()` - Set/Get whether the data comes from the file starting in the lower left corner or upper left corner.
- `obj.FileLowerLeftOff ()` - Set/Get whether the data comes from the file starting in the lower left corner or upper left corner.
- `int = obj.GetFileLowerLeft ()` - Set/Get whether the data comes from the file starting in the lower left corner or upper left corner.
- `obj.SetFileLowerLeft (int )` - Set/Get whether the data comes from the file starting in the lower left corner or upper left corner.
- `obj.ComputeInternalFileName (int slice)` - Set/Get the internal file name
- `string = obj.GetInternalFileName ()` - Set/Get the internal file name
- `int = obj.CanReadFile (string )` - Get the file extensions for this format. Returns a string with a space separated list of extensions in the format .extension

- `string = obj.GetFileExtensions ()` - Return a descriptive name for the file format that might be useful in a GUI.
- `string = obj.GetDescriptiveName ()` - Return a descriptive name for the file format that might be useful in a GUI.

37.41 vtkImageReader2Collection

37.41.1 Usage

vtkImageReader2Collection is an object that creates and manipulates lists of objects of type vtkImageReader2 and its subclasses.

To create an instance of class vtkImageReader2Collection, simply invoke its constructor as follows

```
obj = vtkImageReader2Collection
```

37.41.2 Methods

The class vtkImageReader2Collection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageReader2Collection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageReader2Collection = obj.NewInstance ()`
- `vtkImageReader2Collection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkImageReader2 )` - Add an image reader to the list.
- `vtkImageReader2 = obj.GetNextItem ()` - Get the next image reader in the list.

37.42 vtkImageReader2Factory

37.42.1 Usage

vtkImageReader2Factory: This class is used to create a vtkImageReader2 object given a path name to a file. It calls CanReadFile on all available readers until one of them returns true. The available reader list comes from three places. In the InitializeReaders function of this class, built-in VTK classes are added to the list, users can call RegisterReader, or users can create a vtkObjectFactory that has CreateObject method that returns a new vtkImageReader2 sub class when given the string "vtkImageReaderObject". This way applications can be extended with new readers via a plugin dll or by calling RegisterReader. Of course all of the readers that are part of the vtk release are made automatically available.

To create an instance of class vtkImageReader2Factory, simply invoke its constructor as follows

```
obj = vtkImageReader2Factory
```

37.42.2 Methods

The class vtkImageReader2Factory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageReader2Factory class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkImageReader2Factory = obj.NewInstance ()`
- `vtkImageReader2Factory = obj.SafeDownCast (vtkObject o)`

37.43 vtkImageWriter

37.43.1 Usage

vtkImageWriter writes images to files with any data type. The data type of the file is the same scalar type as the input. The dimensionality determines whether the data will be written in one or multiple files. This class is used as the superclass of most image writing classes such as vtkBMPWriter etc. It supports streaming.

To create an instance of class vtkImageWriter, simply invoke its constructor as follows

```
obj = vtkImageWriter
```

37.43.2 Methods

The class vtkImageWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageWriter = obj.NewInstance ()`
- `vtkImageWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name for the image file. You should specify either a FileName or a FilePrefix. Use FilePrefix if the data is stored in multiple files.
- `string = obj.GetFileName ()` - Specify file name for the image file. You should specify either a FileName or a FilePrefix. Use FilePrefix if the data is stored in multiple files.
- `obj.SetFilePrefix (string )` - Specify file prefix for the image file(s).You should specify either a FileName or FilePrefix. Use FilePrefix if the data is stored in multiple files.
- `string = obj.GetFilePrefix ()` - Specify file prefix for the image file(s).You should specify either a FileName or FilePrefix. Use FilePrefix if the data is stored in multiple files.
- `obj.SetFilePattern (string )` - The sprintf format used to build filename from FilePrefix and number.
- `string = obj.GetFilePattern ()` - The sprintf format used to build filename from FilePrefix and number.
- `obj.SetFileDimensionality (int )` - What dimension are the files to be written. Usually this is 2, or 3. If it is 2 and the input is a volume then the volume will be written as a series of 2d slices.
- `int = obj.GetFileDimensionality ()` - What dimension are the files to be written. Usually this is 2, or 3. If it is 2 and the input is a volume then the volume will be written as a series of 2d slices.
- `obj.Write ()` - The main interface which triggers the writer to start.
- `obj.DeleteFiles ()`

37.44 vtkInputStream

37.44.1 Usage

vtkInputStream provides a VTK-style interface wrapping around a standard input stream. The access methods are virtual so that subclasses can transparently provide decoding of an encoded stream. Data lengths for Seek and Read calls refer to the length of the input data. The actual length in the stream may differ for subclasses that implement an encoding scheme.

To create an instance of class vtkInputStream, simply invoke its constructor as follows

```
obj = vtkInputStream
```

37.44.2 Methods

The class vtkInputStream has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInputStream class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInputStream = obj.NewInstance ()`
- `vtkInputStream = obj.SafeDownCast (vtkObject o)`
- `obj.StartReading ()` - Called after the stream position has been set by the caller, but before any Seek or Read calls. The stream position should not be adjusted by the caller until after an EndReading call.
- `int = obj.Seek (long offset)` - Seek to the given offset in the input data. Returns 1 for success, 0 for failure.
- `long = obj.Read (string data, long length)` - Read input data of the given length. Returns amount actually read.
- `long = obj.Read (string data, long length)` - Read input data of the given length. Returns amount actually read.
- `obj.EndReading ()` - Called after all desired calls to Seek and Read have been made. After this call, the caller is free to change the position of the stream. Additional reads should not be done until after another call to StartReading.

37.45 vtkIVWriter

37.45.1 Usage

vtkIVWriter is a concrete subclass of vtkWriter that writes OpenInventor 2.0 files.

To create an instance of class vtkIVWriter, simply invoke its constructor as follows

```
obj = vtkIVWriter
```

37.45.2 Methods

The class vtkIVWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIVWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIVWriter = obj.NewInstance ()`
- `vtkIVWriter = obj.SafeDownCast (vtkObject o)`

37.46 vtkJPEGReader

37.46.1 Usage

vtkJPEGReader is a source object that reads JPEG files. It should be able to read most any JPEG file

To create an instance of class vtkJPEGReader, simply invoke its constructor as follows

```
obj = vtkJPEGReader
```

37.46.2 Methods

The class vtkJPEGReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkJPEGReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkJPEGReader = obj.NewInstance ()`
- `vtkJPEGReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)` - Is the given file a JPEG file?
- `string = obj.GetFileExtensions ()` - Return a descriptive name for the file format that might be useful in a GUI.
- `string = obj.GetDescriptiveName ()` - Return a descriptive name for the file format that might be useful in a GUI.

37.47 vtkJPEGWriter

37.47.1 Usage

vtkJPEGWriter writes JPEG files. It supports 1 and 3 component data of unsigned char. It relies on the IJG's libjpeg. Thanks to IJG for supplying a public jpeg IO library.

To create an instance of class vtkJPEGWriter, simply invoke its constructor as follows

```
obj = vtkJPEGWriter
```

37.47.2 Methods

The class vtkJPEGWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkJPEGWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkJPEGWriter = obj.NewInstance ()`
- `vtkJPEGWriter = obj.SafeDownCast (vtkObject o)`
- `obj.Write ()` - The main interface which triggers the writer to start.
- `obj.SetQuality (int )` - Compression quality. 0 = Low quality, 100 = High quality
- `int = obj.GetQualityMinValue ()` - Compression quality. 0 = Low quality, 100 = High quality
- `int = obj.GetQualityMaxValue ()` - Compression quality. 0 = Low quality, 100 = High quality
- `int = obj.GetQuality ()` - Compression quality. 0 = Low quality, 100 = High quality
- `obj.SetProgressive (int )` - Progressive JPEG generation.
- `int = obj.GetProgressive ()` - Progressive JPEG generation.
- `obj.ProgressiveOn ()` - Progressive JPEG generation.
- `obj.ProgressiveOff ()` - Progressive JPEG generation.
- `obj.SetWriteToMemory (int )` - Write the image to memory (a vtkUnsignedCharArray)
- `int = obj.GetWriteToMemory ()` - Write the image to memory (a vtkUnsignedCharArray)
- `obj.WriteToMemoryOn ()` - Write the image to memory (a vtkUnsignedCharArray)
- `obj.WriteToMemoryOff ()` - Write the image to memory (a vtkUnsignedCharArray)
- `obj.SetResult (vtkUnsignedCharArray )` - When writing to memory this is the result, it will be NULL until the data is written the first time
- `vtkUnsignedCharArray = obj.GetResult ()` - When writing to memory this is the result, it will be NULL until the data is written the first time

37.48 vtkMaterialLibrary

37.48.1 Usage

This class provides the Material XMLs. .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkMaterialLibrary, simply invoke its constructor as follows

```
obj = vtkMaterialLibrary
```

37.48.2 Methods

The class vtkMaterialLibrary has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMaterialLibrary class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMaterialLibrary = obj.NewInstance ()`
- `vtkMaterialLibrary = obj.SafeDownCast (vtkObject o)`

37.49 vtkMCubesReader

37.49.1 Usage

vtkMCubesReader is a source object that reads binary marching cubes files. (Marching cubes is an isosurfacing technique that generates many triangles.) The binary format is supported by W. Lorensen's marching cubes program (and the vtkSliceCubes object). The format repeats point coordinates, so this object will merge the points with a vtkLocator object. You can choose to supply the vtkLocator or use the default.

To create an instance of class vtkMCubesReader, simply invoke its constructor as follows

```
obj = vtkMCubesReader
```

37.49.2 Methods

The class vtkMCubesReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMCubesReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMCubesReader = obj.NewInstance ()`
- `vtkMCubesReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of marching cubes file.
- `string = obj.GetFileName ()` - Specify file name of marching cubes file.
- `obj.SetLimitsFileName (string )` - Set / get the file name of the marching cubes limits file.
- `string = obj.GetLimitsFileName ()` - Set / get the file name of the marching cubes limits file.
- `obj.SetHeaderSize (int )` - Specify a header size if one exists. The header is skipped and not used at this time.
- `int = obj.GetHeaderSizeMinValue ()` - Specify a header size if one exists. The header is skipped and not used at this time.
- `int = obj.GetHeaderSizeMaxValue ()` - Specify a header size if one exists. The header is skipped and not used at this time.
- `int = obj.GetHeaderSize ()` - Specify a header size if one exists. The header is skipped and not used at this time.

- `obj.SetFlipNormals (int )` - Specify whether to flip normals in opposite direction. Flipping ONLY changes the direction of the normal vector. Contrast this with flipping in vtkPolyDataNormals which flips both the normal and the cell point order.

- `int = obj.GetFlipNormals ()` - Specify whether to flip normals in opposite direction. Flipping ONLY changes the direction of the normal vector. Contrast this with flipping in vtkPolyDataNormals which flips both the normal and the cell point order.

- `obj.FlipNormalsOn ()` - Specify whether to flip normals in opposite direction. Flipping ONLY changes the direction of the normal vector. Contrast this with flipping in vtkPolyDataNormals which flips both the normal and the cell point order.

- `obj.FlipNormalsOff ()` - Specify whether to flip normals in opposite direction. Flipping ONLY changes the direction of the normal vector. Contrast this with flipping in vtkPolyDataNormals which flips both the normal and the cell point order.

- `obj.SetNormals (int )` - Specify whether to read normals.

- `int = obj.GetNormals ()` - Specify whether to read normals.

- `obj.NormalsOn ()` - Specify whether to read normals.

- `obj.NormalsOff ()` - Specify whether to read normals.

- `obj.SetDataByteOrderToBigEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.

- `obj.SetDataByteOrderToLittleEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.

- `int = obj.GetDataByteOrder ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.

- `obj.SetDataByteOrder (int )` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.

- `string = obj.GetDataByteOrderAsString ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `obj.SetSwapBytes (int )` - Turn on/off byte swapping.
- `int = obj.GetSwapBytes ()` - Turn on/off byte swapping.
- `obj.SwapBytesOn ()` - Turn on/off byte swapping.
- `obj.SwapBytesOff ()` - Turn on/off byte swapping.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Set / get a spatial locator for merging points. By default, an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.
- `long = obj.GetMTime ()` - Return the mtime also considering the locator.

37.50 vtkMCubesWriter

37.50.1 Usage

vtkMCubesWriter is a polydata writer that writes binary marching cubes files. (Marching cubes is an isosurfacing technique that generates many triangles.) The binary format is supported by W. Lorensen's marching cubes program (and the vtkSliceCubes object). Each triangle is represented by three records, with each record consisting of six single precision floating point numbers representing the a triangle vertex coordinate and vertex normal.

To create an instance of class vtkMCubesWriter, simply invoke its constructor as follows

```
obj = vtkMCubesWriter
```

37.50.2 Methods

The class vtkMCubesWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMCubesWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMCubesWriter = obj.NewInstance ()`
- `vtkMCubesWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetLimitsFileName (string )` - Set/get file name of marching cubes limits file.
- `string = obj.GetLimitsFileName ()` - Set/get file name of marching cubes limits file.

37.51 vtkMedicalImageProperties

37.51.1 Usage

vtkMedicalImageProperties is a helper class that can be used by medical image readers and applications to encapsulate medical image/acquisition properties. Later on, this should probably be extended to add any user-defined property.

To create an instance of class vtkMedicalImageProperties, simply invoke its constructor as follows

```
obj = vtkMedicalImageProperties
```

37.51.2 Methods

The class vtkMedicalImageProperties has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMedicalImageProperties class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMedicalImageProperties = obj.NewInstance ()`
- `vtkMedicalImageProperties = obj.SafeDownCast (vtkObject o)`
- `obj.Clear ()` - Convenience method to reset all fields to an emptry string/value
- `obj.SetPatientName (string )` - Patient name For ex: DICOM (0010,0010) = DOE,JOHN
- `string = obj.GetPatientName ()` - Patient name For ex: DICOM (0010,0010) = DOE,JOHN
- `obj.SetPatientID (string )` - Patient ID For ex: DICOM (0010,0020) = 1933197
- `string = obj.GetPatientID ()` - Patient ID For ex: DICOM (0010,0020) = 1933197
- `obj.SetPatientAge (string )` - Patient age Format: nnnD, nnW, nnnM or nnnY (eventually nnD, nnW, nnY) with D (day), M (month), W (week), Y (year) For ex: DICOM (0010,1010) = 031Y
- `string = obj.GetPatientAge ()` - Patient age Format: nnnD, nnW, nnnM or nnnY (eventually nnD, nnW, nnY) with D (day), M (month), W (week), Y (year) For ex: DICOM (0010,1010) = 031Y
- `int = obj.GetPatientAgeYear ()`
- `int = obj.GetPatientAgeMonth ()`
- `int = obj.GetPatientAgeWeek ()`
- `int = obj.GetPatientAgeDay ()`
- `obj.SetPatientSex (string )` - Patient sex For ex: DICOM (0010,0040) = M
- `string = obj.GetPatientSex ()` - Patient sex For ex: DICOM (0010,0040) = M
- `obj.SetPatientBirthDate (string )` - Patient birth date Format: yyyymmdd For ex: DICOM (0010,0030) = 19680427
- `string = obj.GetPatientBirthDate ()` - Patient birth date Format: yyyymmdd For ex: DICOM (0010,0030) = 19680427
- `int = obj.GetPatientBirthDateYear ()`
- `int = obj.GetPatientBirthDateMonth ()`

- `int = obj.GetPatientBirthDateDay ()`
- `obj.SetStudyDate (string )` - Study Date Format: yyyymmdd For ex: DICOM (0008,0020) = 20030617
- `string = obj.GetStudyDate ()` - Study Date Format: yyyymmdd For ex: DICOM (0008,0020) = 20030617
- `obj.SetAcquisitionDate (string )` - Acquisition Date Format: yyyymmdd For ex: DICOM (0008,0022) = 20030617
- `string = obj.GetAcquisitionDate ()` - Acquisition Date Format: yyyymmdd For ex: DICOM (0008,0022) = 20030617
- `int = obj.GetAcquisitionDateYear ()`
- `int = obj.GetAcquisitionDateMonth ()`
- `int = obj.GetAcquisitionDateDay ()`
- `obj.SetStudyTime (string )` - Study Time Format: hhmmss.frac (any trailing component(s) can be ommited) For ex: DICOM (0008,0030) = 162552.0705 or 230012, or 0012
- `string = obj.GetStudyTime ()` - Study Time Format: hhmmss.frac (any trailing component(s) can be ommited) For ex: DICOM (0008,0030) = 162552.0705 or 230012, or 0012
- `obj.SetAcquisitionTime (string )` - Acquisition time Format: hhmmss.frac (any trailing component(s) can be ommited) For ex: DICOM (0008,0032) = 162552.0705 or 230012, or 0012
- `string = obj.GetAcquisitionTime ()` - Acquisition time Format: hhmmss.frac (any trailing component(s) can be ommited) For ex: DICOM (0008,0032) = 162552.0705 or 230012, or 0012
- `obj.SetImageDate (string )` - Image Date aka Content Date Format: yyyymmdd For ex: DICOM (0008,0023) = 20030617
- `string = obj.GetImageDate ()` - Image Date aka Content Date Format: yyyymmdd For ex: DICOM (0008,0023) = 20030617
- `int = obj.GetImageDateYear ()`
- `int = obj.GetImageDateMonth ()`
- `int = obj.GetImageDateDay ()`
- `obj.SetImageTime (string )` - Image Time Format: hhmmss.frac (any trailing component(s) can be ommited) For ex: DICOM (0008,0033) = 162552.0705 or 230012, or 0012
- `string = obj.GetImageTime ()` - Image Time Format: hhmmss.frac (any trailing component(s) can be ommited) For ex: DICOM (0008,0033) = 162552.0705 or 230012, or 0012
- `obj.SetImageNumber (string )` - Image number For ex: DICOM (0020,0013) = 1
- `string = obj.GetImageNumber ()` - Image number For ex: DICOM (0020,0013) = 1
- `obj.SetSeriesNumber (string )` - Series number For ex: DICOM (0020,0011) = 902
- `string = obj.GetSeriesNumber ()` - Series number For ex: DICOM (0020,0011) = 902
- `obj.SetSeriesDescription (string )` - Series Description User provided description of the Series For ex: DICOM (0008,103e) = SCOUT
- `string = obj.GetSeriesDescription ()` - Series Description User provided description of the Series For ex: DICOM (0008,103e) = SCOUT

- `obj.SetStudyID (string )` - Study ID For ex: DICOM (0020,0010) = 37481
- `string = obj.GetStudyID ()` - Study ID For ex: DICOM (0020,0010) = 37481
- `obj.SetStudyDescription (string )` - Study description For ex: DICOM (0008,1030) = BRAIN/C-SP/FACIAL
- `string = obj.GetStudyDescription ()` - Study description For ex: DICOM (0008,1030) = BRAIN/C-SP/FACIAL
- `obj.SetModality (string )` - Modality For ex: DICOM (0008,0060)= CT
- `string = obj.GetModality ()` - Modality For ex: DICOM (0008,0060)= CT
- `obj.SetManufacturer (string )` - Manufacturer For ex: DICOM (0008,0070) = Siemens
- `string = obj.GetManufacturer ()` - Manufacturer For ex: DICOM (0008,0070) = Siemens
- `obj.SetManufacturerModelName (string )` - Manufacturer's Model Name For ex: DICOM (0008,1090) = LightSpeed QX/i
- `string = obj.GetManufacturerModelName ()` - Manufacturer's Model Name For ex: DICOM (0008,1090) = LightSpeed QX/i
- `obj.SetStationName (string )` - Station Name For ex: DICOM (0008,1010) = LSPD_OC8
- `string = obj.GetStationName ()` - Station Name For ex: DICOM (0008,1010) = LSPD_OC8
- `obj.SetInstitutionName (string )` - Institution Name For ex: DICOM (0008,0080) = FooCity Medical Center
- `string = obj.GetInstitutionName ()` - Institution Name For ex: DICOM (0008,0080) = FooCity Medical Center
- `obj.SetConvolutionKernel (string )` - Convolution Kernel (or algorithm used to reconstruct the data) For ex: DICOM (0018,1210) = Bone
- `string = obj.GetConvolutionKernel ()` - Convolution Kernel (or algorithm used to reconstruct the data) For ex: DICOM (0018,1210) = Bone
- `obj.SetSliceThickness (string )` - Slice Thickness (Nominal reconstructed slice thickness, in mm) For ex: DICOM (0018,0050) = 0.273438
- `string = obj.GetSliceThickness ()` - Slice Thickness (Nominal reconstructed slice thickness, in mm) For ex: DICOM (0018,0050) = 0.273438
- `double = obj.GetSliceThicknessAsDouble ()` - Slice Thickness (Nominal reconstructed slice thickness, in mm) For ex: DICOM (0018,0050) = 0.273438
- `obj.SetKVP (string )` - Peak kilo voltage output of the (x-ray) generator used For ex: DICOM (0018,0060) = 120
- `string = obj.GetKVP ()` - Peak kilo voltage output of the (x-ray) generator used For ex: DICOM (0018,0060) = 120
- `obj.SetGantryTilt (string )` - Gantry/Detector tilt (Nominal angle of tilt in degrees of the scanning gantry.) For ex: DICOM (0018,1120) = 15
- `string = obj.GetGantryTilt ()` - Gantry/Detector tilt (Nominal angle of tilt in degrees of the scanning gantry.) For ex: DICOM (0018,1120) = 15

- `double = obj.GetGantryTiltAsDouble ()` - Gantry/Detector tilt (Nominal angle of tilt in degrees of the scanning gantry.) For ex: DICOM (0018,1120) = 15
- `obj.SetEchoTime (string )` - Echo Time (Time in ms between the middle of the excitation pulse and the peak of the echo produced) For ex: DICOM (0018,0081) = 105
- `string = obj.GetEchoTime ()` - Echo Time (Time in ms between the middle of the excitation pulse and the peak of the echo produced) For ex: DICOM (0018,0081) = 105
- `obj.SetEchoTrainLength (string )` - Echo Train Length (Number of lines in k-space acquired per excitation per image) For ex: DICOM (0018,0091) = 35
- `string = obj.GetEchoTrainLength ()` - Echo Train Length (Number of lines in k-space acquired per excitation per image) For ex: DICOM (0018,0091) = 35
- `obj.SetRepetitionTime (string )` - Repetition Time The period of time in msec between the beginning of a pulse sequence and the beginning of the succeeding (essentially identical) pulse sequence. For ex: DICOM (0018,0080) = 2040
- `string = obj.GetRepetitionTime ()` - Repetition Time The period of time in msec between the beginning of a pulse sequence and the beginning of the succeeding (essentially identical) pulse sequence. For ex: DICOM (0018,0080) = 2040
- `obj.SetExposureTime (string )` - Exposure time (time of x-ray exposure in msec) For ex: DICOM (0018,1150) = 5
- `string = obj.GetExposureTime ()` - Exposure time (time of x-ray exposure in msec) For ex: DICOM (0018,1150) = 5
- `obj.SetXRayTubeCurrent (string )` - X-ray tube current (in mA) For ex: DICOM (0018,1151) = 400
- `string = obj.GetXRayTubeCurrent ()` - X-ray tube current (in mA) For ex: DICOM (0018,1151) = 400
- `obj.SetExposure (string )` - Exposure (The exposure expressed in mAs, for example calculated from Exposure Time and X-ray Tube Current) For ex: DICOM (0018,1152) = 114
- `string = obj.GetExposure ()` - Exposure (The exposure expressed in mAs, for example calculated from Exposure Time and X-ray Tube Current) For ex: DICOM (0018,1152) = 114
- `obj.SetDirectionCosine (double , double , double , double , double , double )` - Get the direction cosine (default to 1,0,0,0,1,0)
- `obj.SetDirectionCosine (double  a[6])` - Get the direction cosine (default to 1,0,0,0,1,0)
- `double = obj. GetDirectionCosine ()` - Get the direction cosine (default to 1,0,0,0,1,0)
- `obj.AddUserDefinedValue (string name, string value)`
- `string = obj.GetUserDefinedValue (string name)`
- `int = obj.GetNumberOfUserDefinedValues ()`
- `string = obj.GetUserDefinedNameByIndex (int idx)`
- `string = obj.GetUserDefinedValueByIndex (int idx)`
- `obj.RemoveAllUserDefinedValues ()`

- `int = obj.AddWindowLevelPreset (double w, double l)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `obj.RemoveWindowLevelPreset (double w, double l)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `obj.RemoveAllWindowLevelPresets ()` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `int = obj.GetNumberOfWindowLevelPresets ()` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `int = obj.HasWindowLevelPreset (double w, double l)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `int = obj.GetWindowLevelPresetIndex (double w, double l)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `int = obj.GetNthWindowLevelPreset (int idx, double w, double l)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `double = obj.GetNthWindowLevelPreset (int idx)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `obj.SetNthWindowLevelPresetComment (int idx, string comment)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `string = obj.GetNthWindowLevelPresetComment (int idx)` - Add/Remove/Query the window/level presets that may have been associated to a medical image. Window is also known as 'width', level is also known as 'center'. The same window/level pair can not be added twice. As a convenience, a comment (aka Explanation) can be associated to a preset. For ex:

```
DICOM Window Center (0028,1050) = 00045\000470
DICOM Window Width  (0028,1051) = 0106\03412
DICOM Window Center Width Explanation (0028,1055) = WINDOW1\WINDOW2
```

- `string = obj.GetInstanceUIDFromSliceID (int volumeidx, int sliceid)` - Mapping from a sliceidx within a volumeidx into a DICOM Instance UID Some DICOM reader can populate this structure so that later on from a slice index in a vtkImageData volume we can backtrack and find out which 2d slice it was coming from
- `obj.SetInstanceUIDFromSliceID (int volumeidx, int sliceid, string uid)` - Mapping from a sliceidx within a volumeidx into a DICOM Instance UID Some DICOM reader can populate this structure so that later on from a slice index in a vtkImageData volume we can backtrack and find out which 2d slice it was coming from
- `int = obj.GetOrientationType (int volumeidx)`

- `obj.SetOrientationType (int volumeidx, int orientation)`
- `obj.DeepCopy (vtkMedicalImageProperties p)` - Copy the contents of p to this instance.

37.52 vtkMedicalImageReader2

37.52.1 Usage

vtkMedicalImageReader2 is a parent class for medical image readers. It provides a place to store patient information that may be stored in the image header.

To create an instance of class vtkMedicalImageReader2, simply invoke its constructor as follows

```
obj = vtkMedicalImageReader2
```

37.52.2 Methods

The class vtkMedicalImageReader2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMedicalImageReader2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMedicalImageReader2 = obj.NewInstance ()`
- `vtkMedicalImageReader2 = obj.SafeDownCast (vtkObject o)`
- `vtkMedicalImageProperties = obj.GetMedicalImageProperties ()` - Get the medical image properties object
- `obj.SetPatientName (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `string = obj.GetPatientName ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `obj.SetPatientID (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `string = obj.GetPatientID ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `obj.SetDate (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `string = obj.GetDate ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `obj.SetSeries (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `string = obj.GetSeries ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `obj.SetStudy (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.

- `string = obj.GetStudy ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `obj.SetImageNumber (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `string = obj.GetImageNumber ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `obj.SetModality (string )` - For backward compatibility, propagate calls to the MedicalImageProperties object.
- `string = obj.GetModality ()` - For backward compatibility, propagate calls to the MedicalImageProperties object.

37.53 vtkMetaImageReader

37.53.1 Usage

One of the formats for which a reader is already available in the toolkit is the MetaImage file format. This is a fairly simple yet powerful format consisting of a text header and a binary data section. The following instructions describe how you can write a MetaImage header for the data that you download from the BrainWeb page.

The minimal structure of the MetaImage header is the following:

NDims = 3 DimSize = 181 217 181 ElementType = MET_UCHAR ElementSpacing = 1.0 1.0 1.0 ElementByteOrderMSB = False ElementDataFile = brainweb1.raw

* NDims indicate that this is a 3D image. ITK can handle images of arbitrary dimension. * DimSize indicates the size of the volume in pixels along each direction. * ElementType indicate the primitive type used for pixels. In this case is "unsigned char", implying that the data is digitized in 8 bits / pixel. * ElementSpacing indicates the physical separation between the center of one pixel and the center of the next pixel along each direction in space. The units used are millimeters. * ElementByteOrderMSB indicates is the data is encoded in little or big endian order. You might want to play with this value when moving data between different computer platforms. * ElementDataFile is the name of the file containing the raw binary data of the image. This file must be in the same directory as the header.

MetaImage headers are expected to have extension: ".mha" or ".mhd"

Once you write this header text file, it should be possible to read the image into your ITK based application using the itk::FileIOToImageFilter class.

To create an instance of class vtkMetaImageReader, simply invoke its constructor as follows

```
obj = vtkMetaImageReader
```

37.53.2 Methods

The class vtkMetaImageReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMetaImageReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMetaImageReader = obj.NewInstance ()`
- `vtkMetaImageReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileExtensions ()`

- `string = obj.GetDescriptiveName ()`
- `int = obj.GetWidth ()`
- `int = obj.GetHeight ()`
- `int = obj.GetNumberOfComponents ()`
- `int = obj.GetPixelRepresentation ()`
- `int = obj.GetDataByteOrder (void )`
- `double = obj.GetRescaleSlope ()`
- `double = obj.GetRescaleOffset ()`
- `int = obj.GetBitsAllocated ()`
- `string = obj.GetDistanceUnits ()`
- `string = obj.GetAnatomicalOrientation ()`
- `double = obj.GetGantryAngle ()`
- `string = obj.GetPatientName ()`
- `string = obj.GetPatientID ()`
- `string = obj.GetDate ()`
- `string = obj.GetSeries ()`
- `string = obj.GetImageNumber ()`
- `string = obj.GetModality ()`
- `string = obj.GetStudyID ()`
- `string = obj.GetStudyUID ()`
- `string = obj.GetTransferSyntaxUID ()`
- `int = obj.CanReadFile (string name)` - Test whether the file with the given name can be read by this reader.

37.54 vtkMetaImageWriter

37.54.1 Usage

One of the formats for which a reader is already available in the toolkit is the MetaImage file format. This is a fairly simple yet powerful format consisting of a text header and a binary data section. The following instructions describe how you can write a MetaImage header for the data that you download from the BrainWeb page.

The minimal structure of the MetaImage header is the following:

NDims = 3 DimSize = 181 217 181 ElementType = MET_UCHAR ElementSpacing = 1.0 1.0 1.0 ElementByteOrderMSB = False ElementDataFile = brainweb1.raw

* NDims indicate that this is a 3D image. ITK can handle images of arbitrary dimension. * DimSize indicates the size of the volume in pixels along each direction. * ElementType indicate the primitive type used for pixels. In this case is "unsigned char", implying that the data is digitized in 8 bits / pixel. * ElementSpacing indicates the physical separation between the center of one pixel and the center of the next pixel along each direction in space. The units used are millimeters. * ElementByteOrderMSB indicates is

the data is encoded in little or big endian order. You might want to play with this value when moving data between different computer platforms. * ElementDataFile is the name of the file containing the raw binary data of the image. This file must be in the same directory as the header.

MetaImage headers are expected to have extension: ".mha" or ".mhd"

Once you write this header text file, it should be possible to read the image into your ITK based application using the itk::FileIOToImageFilter class.

To create an instance of class vtkMetaImageWriter, simply invoke its constructor as follows

```
obj = vtkMetaImageWriter
```

37.54.2 Methods

The class vtkMetaImageWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMetaImageWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMetaImageWriter = obj.NewInstance ()`
- `vtkMetaImageWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string fname)` - Specify file name of meta file
- `string = obj.GetFileName ()` - Specify the file name of the raw image data.
- `obj.SetRAWFileName (string fname)` - Specify the file name of the raw image data.
- `string = obj.GetRAWFileName ()` - Specify the file name of the raw image data.
- `obj.SetCompression (bool compress)`
- `bool = obj.GetCompression (void )`
- `obj.Write ()`

37.55 vtkMFIXReader

37.55.1 Usage

vtkMFIXReader creates an unstructured grid dataset. It reads a restart file and a set of sp files. The restart file contains the mesh information. MFIX meshes are either cylindrical or rectilinear, but this reader will convert them to an unstructured grid. The sp files contain transient data for the cells. Each sp file has one or more variables stored inside it.

To create an instance of class vtkMFIXReader, simply invoke its constructor as follows

```
obj = vtkMFIXReader
```

37.55.2 Methods

The class vtkMFIXReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMFIXReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkMFIXReader = obj.NewInstance ()`
- `vtkMFIXReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the file name of the MFIX Restart data file to read.
- `string = obj.GetFileName ()` - Specify the file name of the MFIX Restart data file to read.
- `int = obj.GetNumberOfCells ()` - Get the total number of cells. The number of cells is only valid after a successful read of the data file is performed.
- `int = obj.GetNumberOfPoints ()` - Get the total number of nodes. The number of nodes is only valid after a successful read of the data file is performed.
- `int = obj.GetNumberOfCellFields ()` - Get the number of data components at the nodes and cells.
- `obj.SetTimeStep (int )` - Which TimeStep to read.
- `int = obj.GetTimeStep ()` - Which TimeStep to read.
- `int = obj.GetNumberOfTimeSteps ()` - Returns the number of timesteps.
- `int = obj. GetTimeStepRange ()` - Which TimeStepRange to read
- `obj.SetTimeStepRange (int , int )` - Which TimeStepRange to read
- `obj.SetTimeStepRange (int  a[2])` - Which TimeStepRange to read
- `int = obj.GetNumberOfCellArrays (void )`
- `string = obj.GetCellArrayName (int index)` - Get the name of the cell array with the given index in the input.
- `int = obj.GetCellArrayStatus (string name)` - Get/Set whether the cell array with the given name is to be read.
- `obj.SetCellArrayStatus (string name, int status)` - Get/Set whether the cell array with the given name is to be read.
- `obj.DisableAllCellArrays ()` - Turn on/off all cell arrays.
- `obj.EnableAllCellArrays ()` - Turn on/off all cell arrays.
- `obj.GetCellDataRange (int cellComp, int index, float min, float max)` - Get the range of cell data.

37.56 vtkMINCImageAttributes

37.56.1 Usage

This class provides methods to access all of the information contained in the MINC header. If you read a MINC file into VTK and then write it out again, you can use writer-¿SetImageAttributes(reader-¿GetImageAttributes) to ensure that all of the medical information contained in the file is tranferred from the reader to the writer. If you want to change any of the header information, you must use ShallowCopy to make a copy of the reader's attributes and then modify only the copy.

To create an instance of class vtkMINCImageAttributes, simply invoke its constructor as follows

```
obj = vtkMINCImageAttributes
```

37.56.2 Methods

The class vtkMINCImageAttributes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMINCImageAttributes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMINCImageAttributes = obj.NewInstance ()`
- `vtkMINCImageAttributes = obj.SafeDownCast (vtkObject o)`
- `obj.Reset ()` - Reset all the attributes in preparation for loading new information.
- `obj.SetName (string )` - Get the name of the image, not including the path or the extension. This is only needed for printing the header and there is usually no need to set it.
- `string = obj.GetName ()` - Get the name of the image, not including the path or the extension. This is only needed for printing the header and there is usually no need to set it.
- `obj.SetDataType (int )` - Get the image data type, as stored on disk. This information is useful if the file was converted to floating-point when it was loaded. When writing a file from float or double image data, you can use this method to prescribe the output type.
- `int = obj.GetDataType ()` - Get the image data type, as stored on disk. This information is useful if the file was converted to floating-point when it was loaded. When writing a file from float or double image data, you can use this method to prescribe the output type.
- `obj.AddDimension (string dimension)` - Add the names of up to five dimensions. The ordering of these dimensions will determine the dimension order of the file. If no DimensionNames are set, the writer will set the dimension order of the file to be the same as the dimension order in memory.
- `obj.AddDimension (string dimension, vtkIdType length)` - Add the names of up to five dimensions. The ordering of these dimensions will determine the dimension order of the file. If no DimensionNames are set, the writer will set the dimension order of the file to be the same as the dimension order in memory.
- `vtkStringArray = obj.GetDimensionNames ()` - Get the dimension names. The dimension names are same order as written in the file, starting with the slowest-varying dimension. Use this method to get the array if you need to change "space" dimensions to "frequency" after performing a Fourier transform.
- `vtkIdTypeArray = obj.GetDimensionLengths ()` - Get the lengths of all the dimensions. The dimension lengths are informative, the vtkMINCImageWriter does not look at these values but instead uses the dimension sizes of its input.
- `vtkStringArray = obj.GetVariableNames ()` - Get the names of all the variables.
- `vtkStringArray = obj.GetAttributeNames (string variable)` - List the attribute names for a variable. Set the variable to the empty string to get a list of the global attributes.
- `obj.SetImageMin (vtkDoubleArray imageMin)` - Get the image min and max arrays. These are set by the reader, but they aren't used by the writer except to compute the full real data range of the original file.
- `obj.SetImageMax (vtkDoubleArray imageMax)` - Get the image min and max arrays. These are set by the reader, but they aren't used by the writer except to compute the full real data range of the original file.

- `vtkDoubleArray = obj.GetImageMin ()` - Get the image min and max arrays. These are set by the reader, but they aren't used by the writer except to compute the full real data range of the original file.
- `vtkDoubleArray = obj.GetImageMax ()` - Get the image min and max arrays. These are set by the reader, but they aren't used by the writer except to compute the full real data range of the original file.
- `int = obj.GetNumberOfImageMinMaxDimensions ()` - Get the number of ImageMinMax dimensions.
- `obj.SetNumberOfImageMinMaxDimensions (int )` - Get the number of ImageMinMax dimensions.
- `int = obj.HasAttribute (string variable, string attribute)` - Check to see if a particular attribute exists.
- `obj.SetAttributeValueAsArray (string variable, string attribute, vtkDataArray array)` - Set attribute values for a variable as a vtkDataArray. Set the variable to the empty string to access global attributes.
- `vtkDataArray = obj.GetAttributeValueAsArray (string variable, string attribute)` - Set attribute values for a variable as a vtkDataArray. Set the variable to the empty string to access global attributes.
- `obj.SetAttributeValueAsString (string variable, string attribute, string value)` - Set an attribute value as a string. Set the variable to the empty string to access global attributes. If you specify a variable that does not exist, it will be created.
- `string = obj.GetAttributeValueAsString (string variable, string attribute)` - Set an attribute value as a string. Set the variable to the empty string to access global attributes. If you specify a variable that does not exist, it will be created.
- `obj.SetAttributeValueAsInt (string variable, string attribute, int value)` - Set an attribute value as an int. Set the variable to the empty string to access global attributes. If you specify a variable that does not exist, it will be created.
- `int = obj.GetAttributeValueAsInt (string variable, string attribute)` - Set an attribute value as an int. Set the variable to the empty string to access global attributes. If you specify a variable that does not exist, it will be created.
- `obj.SetAttributeValueAsDouble (string variable, string attribute, double value)` - Set an attribute value as a double. Set the variable to the empty string to access global attributes. If you specify a variable that does not exist, it will be created.
- `double = obj.GetAttributeValueAsDouble (string variable, string attribute)` - Set an attribute value as a double. Set the variable to the empty string to access global attributes. If you specify a variable that does not exist, it will be created.
- `int = obj.ValidateAttribute (string varname, string attname, vtkDataArray array)` - Validate a particular attribute. This involves checking that the attribute is a MINC standard attribute, and checking whether it can be set (as opposed to being set automatically from the image information). The return values is 0 if the attribute is set automatically and therefore should not be copied from here, 1 if this attribute is valid and should be set, and 2 if the attribute is non-standard.
- `obj.ShallowCopy (vtkMINCImageAttributes source)` - Do a shallow copy. This will copy all the attributes from the source. It is much more efficient than a DeepCopy would be, since it only copies pointers to the attribute values instead of copying the arrays themselves. You must use this method to make a copy if you want to modify any MINC attributes from a MINCReader before you pass them to a MINCWriter.

- `obj.FindValidRange (double range[2])` - Find the valid range of the data from the information stored in the attributes.
- `obj.FindImageRange (double range[2])` - Find the image range of the data from the information stored in the attributes.
- `obj.PrintFileHeader ()` - A diagnostic function. Print the header of the file in the same format as ncdump or mincheader.

37.57 vtkMINCImageReader

37.57.1 Usage

MINC is a NetCDF-based medical image file format that was developed at the Montreal Neurological Institute in 1992. This class will read a MINC file into VTK, rearranging the data to match the VTK x, y, and z dimensions, and optionally rescaling real-valued data to VTK_FLOAT if RescaleRealValuesOn() is set. If RescaleRealValues is off, then the data will be stored in its original data type and the GetRescaleSlope(), GetRescaleIntercept() method can be used to retrieve global rescaling parameters. If the original file had a time dimension, the SetTimeStep() method can be used to specify a time step to read. All of the original header information can be accessed though the GetImageAttributes() method.

To create an instance of class vtkMINCImageReader, simply invoke its constructor as follows

```
obj = vtkMINCImageReader
```

37.57.2 Methods

The class vtkMINCImageReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMINCImageReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMINCImageReader = obj.NewInstance ()`
- `vtkMINCImageReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string name)` - Set the file name.
- `string = obj.GetFileExtensions ()` - Get the name of this file format.
- `string = obj.GetDescriptiveName ()` - Test whether the specified file can be read.
- `int = obj.CanReadFile (string name)` - Test whether the specified file can be read.
- `vtkMatrix4x4 = obj.GetDirectionCosines ()` - Get a matrix that describes the orientation of the data. The three columns of the matrix are the direction cosines for the x, y and z dimensions respectively.
- `double = obj.GetRescaleSlope ()` - Get the slope and intercept for rescaling the scalar values to real data values. To convert scalar values to real values, use the equation y = x*RescaleSlope + RescaleIntercept.
- `double = obj.GetRescaleIntercept ()` - Get the slope and intercept for rescaling the scalar values to real data values. To convert scalar values to real values, use the equation y = x*RescaleSlope + RescaleIntercept.

- `obj.SetRescaleRealValues (int )` - Rescale real data values to float. If this is done, the RescaleSlope and RescaleIntercept will be set to 1 and 0 respectively. This is off by default.
- `obj.RescaleRealValuesOn ()` - Rescale real data values to float. If this is done, the RescaleSlope and RescaleIntercept will be set to 1 and 0 respectively. This is off by default.
- `obj.RescaleRealValuesOff ()` - Rescale real data values to float. If this is done, the RescaleSlope and RescaleIntercept will be set to 1 and 0 respectively. This is off by default.
- `int = obj.GetRescaleRealValues ()` - Rescale real data values to float. If this is done, the RescaleSlope and RescaleIntercept will be set to 1 and 0 respectively. This is off by default.
- `double = obj.GetDataRange ()` - Get the scalar range of the output from the information in the file header. This is more efficient that computing the scalar range, but in some cases the MINC file stores an incorrect valid_range and the DataRange will be incorrect.
- `obj.GetDataRange (double range[2])` - Get the scalar range of the output from the information in the file header. This is more efficient that computing the scalar range, but in some cases the MINC file stores an incorrect valid_range and the DataRange will be incorrect.
- `int = obj.GetNumberOfTimeSteps ()` - Get the number of time steps in the file.
- `obj.SetTimeStep (int )` - Set the time step to read.
- `int = obj.GetTimeStep ()` - Set the time step to read.
- `vtkMINCImageAttributes = obj.GetImageAttributes ()` - Get the image attributes, which contain patient information and other useful metadata.

37.58 vtkMINCImageWriter

37.58.1 Usage

MINC is a NetCDF-based medical image file format that was developed at the Montreal Neurological Institute in 1992. The data is written slice-by-slice, and this writer is therefore suitable for streaming MINC data that is larger than the memory size through VTK. This writer can also produce files with up to 4 dimensions, where the fourth dimension is provided by using AddInput() to specify multiple input data sets. If you want to set header information for the file, you must supply a vtkMINCImageAttributes

To create an instance of class vtkMINCImageWriter, simply invoke its constructor as follows

```
obj = vtkMINCImageWriter
```

37.58.2 Methods

The class vtkMINCImageWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMINCImageWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMINCImageWriter = obj.NewInstance ()`
- `vtkMINCImageWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileExtensions ()` - Get the name of this file format.
- `string = obj.GetDescriptiveName ()` - Set the file name.

- `obj.SetFileName (string name)` - Set the file name.

- `obj.Write ()` - Write the data. This will attempt to stream the data slice-by-slice through the pipeline and out to the file, unless the whole extent of the input has already been updated.

- `obj.SetDirectionCosines (vtkMatrix4x4 matrix)` - Set a matrix that describes the orientation of the data. The three columns of this matrix should give the unit-vector directions for the VTK x, y and z dimensions respectively. The writer will use this information to determine how to map the VTK dimensions to the canonical MINC dimensions, and if necessary, the writer will re-order one or more dimensions back-to-front to ensure that no MINC dimension ends up with a direction cosines vector whose dot product with the canonical unit vector for that dimension is negative.

- `vtkMatrix4x4 = obj.GetDirectionCosines ()` - Set a matrix that describes the orientation of the data. The three columns of this matrix should give the unit-vector directions for the VTK x, y and z dimensions respectively. The writer will use this information to determine how to map the VTK dimensions to the canonical MINC dimensions, and if necessary, the writer will re-order one or more dimensions back-to-front to ensure that no MINC dimension ends up with a direction cosines vector whose dot product with the canonical unit vector for that dimension is negative.

- `obj.SetRescaleSlope (double )` - Set the slope and intercept for rescaling the intensities. The default values are zero, which indicates to the reader that no rescaling is to be performed.

- `double = obj.GetRescaleSlope ()` - Set the slope and intercept for rescaling the intensities. The default values are zero, which indicates to the reader that no rescaling is to be performed.

- `obj.SetRescaleIntercept (double )` - Set the slope and intercept for rescaling the intensities. The default values are zero, which indicates to the reader that no rescaling is to be performed.

- `double = obj.GetRescaleIntercept ()` - Set the slope and intercept for rescaling the intensities. The default values are zero, which indicates to the reader that no rescaling is to be performed.

- `obj.SetImageAttributes (vtkMINCImageAttributes attributes)` - Set the image attributes, which contain patient information and other useful metadata.

- `vtkMINCImageAttributes = obj.GetImageAttributes ()` - Set the image attributes, which contain patient information and other useful metadata.

- `obj.SetStrictValidation (int )` - Set whether to validate that all variable attributes that have been set are ones that are listed in the MINC standard.

- `obj.StrictValidationOn ()` - Set whether to validate that all variable attributes that have been set are ones that are listed in the MINC standard.

- `obj.StrictValidationOff ()` - Set whether to validate that all variable attributes that have been set are ones that are listed in the MINC standard.

- `int = obj.GetStrictValidation ()` - Set whether to validate that all variable attributes that have been set are ones that are listed in the MINC standard.

- `obj.SetHistoryAddition (string )` - Set a string value to append to the history of the file. This string should describe, briefly, how the file was processed.

- `string = obj.GetHistoryAddition ()` - Set a string value to append to the history of the file. This string should describe, briefly, how the file was processed.

37.59 vtkMoleculeReaderBase

37.59.1 Usage

vtkMoleculeReaderBase is a source object that reads Molecule files The FileName must be specified .SECTION Thanks Dr. Jean M. Favre who developed and contributed this class

To create an instance of class vtkMoleculeReaderBase, simply invoke its constructor as follows

```
obj = vtkMoleculeReaderBase
```

37.59.2 Methods

The class vtkMoleculeReaderBase has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMoleculeReaderBase class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMoleculeReaderBase = obj.NewInstance ()`
- `vtkMoleculeReaderBase = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )`
- `string = obj.GetFileName ()`
- `obj.SetBScale (double )`
- `double = obj.GetBScale ()`
- `obj.SetHBScale (double )`
- `double = obj.GetHBScale ()`
- `int = obj.GetNumberOfAtoms ()`

37.60 vtkMultiBlockPLOT3DReader

37.60.1 Usage

vtkMultiBlockPLOT3DReader is a reader object that reads PLOT3D formatted files and generates structured grid(s) on output. PLOT3D is a computer graphics program designed to visualize the grids and solutions of computational fluid dynamics. Please see the "PLOT3D User's Manual" available from NASA Ames Research Center, Moffett Field CA.

PLOT3D files consist of a grid file (also known as XYZ file), an optional solution file (also known as a Q file), and an optional function file that contains user created data (currently unsupported). The Q file contains solution information as follows: the four parameters free stream mach number (Fsmach), angle of attack (Alpha), Reynolds number (Re), and total integration time (Time). This information is stored in an array called Properties in the FieldData of each output (tuple 0: fsmach, tuple 1: alpha, tuple 2: re, tuple 3: time). In addition, the solution file contains the flow density (scalar), flow momentum (vector), and flow energy (scalar).

The reader can generate additional scalars and vectors (or "functions") from this information. To use vtkMultiBlockPLOT3DReader, you must specify the particular function number for the scalar and vector you want to visualize. This implementation of the reader provides the following functions. The scalar functions are: -1 - don't read or compute any scalars 100 - density 110 - pressure 120 - temperature 130 -

enthalpy 140 - internal energy 144 - kinetic energy 153 - velocity magnitude 163 - stagnation energy 170 - entropy 184 - swirl.

The vector functions are: -1 - don't read or compute any vectors 200 - velocity 201 - vorticity 202 - momentum 210 - pressure gradient.

(Other functions are described in the PLOT3D spec, but only those listed are implemented here.) Note that by default, this reader creates the density scalar (100) and momentum vector (202) as output. (These are just read in from the solution file.) Please note that the validity of computation is a function of this class's gas constants (R, Gamma) and the equations used. They may not be suitable for your computational domain.

Additionally, you can read other data and associate it as a vtkDataArray into the output's point attribute data. Use the method AddFunction() to list all the functions that you'd like to read. AddFunction() accepts an integer parameter that defines the function number.

To create an instance of class vtkMultiBlockPLOT3DReader, simply invoke its constructor as follows

```
obj = vtkMultiBlockPLOT3DReader
```

37.60.2 Methods

The class vtkMultiBlockPLOT3DReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiBlockPLOT3DReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiBlockPLOT3DReader = obj.NewInstance ()`
- `vtkMultiBlockPLOT3DReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string name)` - Set/Get the PLOT3D geometry filename.
- `string = obj.GetFileName ()` - Set/Get the PLOT3D geometry filename.
- `obj.SetXYZFileName (string )` - Set/Get the PLOT3D geometry filename.
- `string = obj.GetXYZFileName ()` - Set/Get the PLOT3D geometry filename.
- `obj.SetQFileName (string )` - Set/Get the PLOT3D solution filename.
- `string = obj.GetQFileName ()` - Set/Get the PLOT3D solution filename.
- `int = obj.GetNumberOfBlocks ()` - This returns the number of outputs this reader will produce. This number is equal to the number of grids in the current file. This method has to be called before getting any output if the number of outputs will be greater than 1 (the first output is always the same). Note that every time this method is invoked, the header file is opened and part of the header is read.
- `int = obj.GetNumberOfGrids ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.SetBinaryFile (int )` - Is the file to be read written in binary format (as opposed to ascii).
- `int = obj.GetBinaryFile ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.BinaryFileOn ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.BinaryFileOff ()` - Is the file to be read written in binary format (as opposed to ascii).

- `obj.SetMultiGrid (int )` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `int = obj.GetMultiGrid ()` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `obj.MultiGridOn ()` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `obj.MultiGridOff ()` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `obj.SetHasByteCount (int )` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `int = obj.GetHasByteCount ()` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `obj.HasByteCountOn ()` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `obj.HasByteCountOff ()` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `obj.SetIBlanking (int )` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `int = obj.GetIBlanking ()` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `obj.IBlankingOn ()` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `obj.IBlankingOff ()` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `obj.SetTwoDimensionalGeometry (int )` - If only two-dimensional data was written to the file, turn this on.
- `int = obj.GetTwoDimensionalGeometry ()` - If only two-dimensional data was written to the file, turn this on.
- `obj.TwoDimensionalGeometryOn ()` - If only two-dimensional data was written to the file, turn this on.
- `obj.TwoDimensionalGeometryOff ()` - If only two-dimensional data was written to the file, turn this on.
- `obj.SetForceRead (int )` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.

- `int = obj.GetForceRead ()` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `obj.ForceReadOn ()` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `obj.ForceReadOff ()` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `obj.SetByteOrderToBigEndian ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetByteOrderToLittleEndian ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetByteOrder (int )` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `int = obj.GetByteOrder ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `string = obj.GetByteOrderAsString ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetR (double )` - Set/Get the gas constant. Default is 1.0.
- `double = obj.GetR ()` - Set/Get the gas constant. Default is 1.0.
- `obj.SetGamma (double )` - Set/Get the ratio of specific heats. Default is 1.4.
- `double = obj.GetGamma ()` - Set/Get the ratio of specific heats. Default is 1.4.
- `obj.SetUvinf (double )` - Set/Get the x-component of the free-stream velocity. Default is 1.0.
- `double = obj.GetUvinf ()` - Set/Get the x-component of the free-stream velocity. Default is 1.0.
- `obj.SetVvinf (double )` - Set/Get the y-component of the free-stream velocity. Default is 1.0.
- `double = obj.GetVvinf ()` - Set/Get the y-component of the free-stream velocity. Default is 1.0.
- `obj.SetWvinf (double )` - Set/Get the z-component of the free-stream velocity. Default is 1.0.
- `double = obj.GetWvinf ()` - Set/Get the z-component of the free-stream velocity. Default is 1.0.
- `obj.SetScalarFunctionNumber (int num)` - Specify the scalar function to extract. If ==(-1), then no scalar function is extracted.
- `int = obj.GetScalarFunctionNumber ()` - Specify the scalar function to extract. If ==(-1), then no scalar function is extracted.
- `obj.SetVectorFunctionNumber (int num)` - Specify the vector function to extract. If ==(-1), then no vector function is extracted.

- `int = obj.GetVectorFunctionNumber ()` - Specify the vector function to extract. If ==(-1), then no vector function is extracted.
- `obj.AddFunction (int functionNumber)` - Specify additional functions to read. These are placed into the point data as data arrays. Later on they can be used by labeling them as scalars, etc.
- `obj.RemoveFunction (int )` - Specify additional functions to read. These are placed into the point data as data arrays. Later on they can be used by labeling them as scalars, etc.
- `obj.RemoveAllFunctions ()` - Specify additional functions to read. These are placed into the point data as data arrays. Later on they can be used by labeling them as scalars, etc.
- `int = obj.CanReadBinaryFile (string fname)` - Return 1 if the reader can read the given file name. Only meaningful for binary files.

37.61 vtkNetCDFCFReader

37.61.1 Usage

Reads netCDF files that follow the CF convention. Details on this convention can be found at ¡http://cf-pcmdi.llnl.gov/¿.

To create an instance of class vtkNetCDFCFReader, simply invoke its constructor as follows

```
obj = vtkNetCDFCFReader
```

37.61.2 Methods

The class vtkNetCDFCFReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkNetCDFCFReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkNetCDFCFReader = obj.NewInstance ()`
- `vtkNetCDFCFReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetSphericalCoordinates ()` - If on (the default), then 3D data with latitude/longitude dimensions will be read in as curvilinear data shaped like spherical coordinates. If false, then the data will always be read in Cartesian coordinates.
- `obj.SetSphericalCoordinates (int )` - If on (the default), then 3D data with latitude/longitude dimensions will be read in as curvilinear data shaped like spherical coordinates. If false, then the data will always be read in Cartesian coordinates.
- `obj.SphericalCoordinatesOn ()` - If on (the default), then 3D data with latitude/longitude dimensions will be read in as curvilinear data shaped like spherical coordinates. If false, then the data will always be read in Cartesian coordinates.
- `obj.SphericalCoordinatesOff ()` - If on (the default), then 3D data with latitude/longitude dimensions will be read in as curvilinear data shaped like spherical coordinates. If false, then the data will always be read in Cartesian coordinates.

- `double = obj.GetVerticalScale ()` - The scale and bias of the vertical component of spherical coordinates. It is common to write the vertical component with respect to something other than the center of the sphere (for example, the surface). In this case, it might be necessary to scale and/or bias the vertical height. The height will become height*scale + bias. Keep in mind that if the positive attribute of the vertical dimension is down, then the height is negated. By default the scale is 1 and the bias is 0 (that is, no change). The scaling will be adjusted if it results in invalid (negative) vertical values.

- `obj.SetVerticalScale (double )` - The scale and bias of the vertical component of spherical coordinates. It is common to write the vertical component with respect to something other than the center of the sphere (for example, the surface). In this case, it might be necessary to scale and/or bias the vertical height. The height will become height*scale + bias. Keep in mind that if the positive attribute of the vertical dimension is down, then the height is negated. By default the scale is 1 and the bias is 0 (that is, no change). The scaling will be adjusted if it results in invalid (negative) vertical values.

- `double = obj.GetVerticalBias ()` - The scale and bias of the vertical component of spherical coordinates. It is common to write the vertical component with respect to something other than the center of the sphere (for example, the surface). In this case, it might be necessary to scale and/or bias the vertical height. The height will become height*scale + bias. Keep in mind that if the positive attribute of the vertical dimension is down, then the height is negated. By default the scale is 1 and the bias is 0 (that is, no change). The scaling will be adjusted if it results in invalid (negative) vertical values.

- `obj.SetVerticalBias (double )` - The scale and bias of the vertical component of spherical coordinates. It is common to write the vertical component with respect to something other than the center of the sphere (for example, the surface). In this case, it might be necessary to scale and/or bias the vertical height. The height will become height*scale + bias. Keep in mind that if the positive attribute of the vertical dimension is down, then the height is negated. By default the scale is 1 and the bias is 0 (that is, no change). The scaling will be adjusted if it results in invalid (negative) vertical values.

37.62 vtkNetCDFPOPReader

37.62.1 Usage

vtkNetCDFPOPReader is a source object that reads NetCDF files. It should be able to read most any NetCDF file that wants to output rectilinear grid

To create an instance of class vtkNetCDFPOPReader, simply invoke its constructor as follows

```
obj = vtkNetCDFPOPReader
```

37.62.2 Methods

The class vtkNetCDFPOPReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkNetCDFPOPReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkNetCDFPOPReader = obj.NewInstance ()`

- `vtkNetCDFPOPReader = obj.SafeDownCast (vtkObject o)`

- `obj.SetFilename (string )`

- `string = obj.GetFilename ()`

- obj.SetWholeExtent (int , int , int , int , int , int)
- obj.SetWholeExtent (int a[6])
- int = obj. GetWholeExtent ()
- obj.SetSubExtent (int , int , int , int , int , int)
- obj.SetSubExtent (int a[6])
- int = obj. GetSubExtent ()
- obj.SetOrigin (double , double , double)
- obj.SetOrigin (double a[3])
- double = obj. GetOrigin ()
- obj.SetSpacing (double , double , double)
- obj.SetSpacing (double a[3])
- double = obj. GetSpacing ()
- obj.SetStride (int , int , int)
- obj.SetStride (int a[3])
- int = obj. GetStride ()
- obj.SetBlockReadSize (int)
- int = obj.GetBlockReadSize ()
- int = obj.GetNumberOfVariableArrays () - Variable array selection.
- string = obj.GetVariableArrayName (int idx) - Variable array selection.
- int = obj.GetVariableArrayStatus (string name) - Variable array selection.
- obj.SetVariableArrayStatus (string name, int status) - Variable array selection.

37.63 vtkNetCDFReader

37.63.1 Usage

A superclass for reading netCDF files. Subclass add conventions to the reader. This class just outputs data into a multi block data set with a vtkImageData at each block. A block is created for each variable except that variables with matching dimensions will be placed in the same block.

To create an instance of class vtkNetCDFReader, simply invoke its constructor as follows

```
obj = vtkNetCDFReader
```

37.63.2 Methods

The class vtkNetCDFReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkNetCDFReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkNetCDFReader = obj.NewInstance ()`
- `vtkNetCDFReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string filename)`
- `string = obj.GetFileName ()`
- `int = obj.UpdateMetaData ()` - Update the meta data from the current file. Automatically called during the RequestInformation pipeline update stage.
- `int = obj.GetNumberOfVariableArrays ()` - Variable array selection.
- `string = obj.GetVariableArrayName (int idx)` - Variable array selection.
- `int = obj.GetVariableArrayStatus (string name)` - Variable array selection.
- `obj.SetVariableArrayStatus (string name, int status)` - Variable array selection.
- `vtkStringArray = obj.GetVariableDimensions ()` - Returns an array with string encodings for the dimensions used in each of the variables. The indices in the returned array correspond to those used in the GetVariableArrayName method. Two arrays with the same dimensions will have the same encoded string returned by this method.
- `obj.SetDimensions (string dimensions)` - Loads the grid with the given dimensions. The dimensions are encoded in a string that conforms to the same format as returned by GetVariableDimensions and GetAllDimensions. This method is really a convenience method for SetVariableArrayStatus. It turns on all variables that have the given dimensions and turns off all other variables.
- `vtkStringArray = obj.GetAllDimensions ()` - Returns an array with string encodings for the dimension combinations used in the variables. The result is the same as GetVariableDimensions except that each entry in the array is unique (a set of dimensions is only given once even if it occurs for multiple variables) and the order is meaningless.
- `int = obj.GetReplaceFillValueWithNan ()` - If on, any float or double variable read that has a _FillValue attribute will have that fill value replaced with a not-a-number (NaN) value. The advantage of setting these to NaN values is that, if implemented properly by the system and careful math operations are used, they can implicitly be ignored by calculations like finding the range of the values. That said, this option should be used with caution as VTK does not fully support NaN values and therefore odd calculations may occur. By default this is off.
- `obj.SetReplaceFillValueWithNan (int )` - If on, any float or double variable read that has a _FillValue attribute will have that fill value replaced with a not-a-number (NaN) value. The advantage of setting these to NaN values is that, if implemented properly by the system and careful math operations are used, they can implicitly be ignored by calculations like finding the range of the values. That said, this option should be used with caution as VTK does not fully support NaN values and therefore odd calculations may occur. By default this is off.

- `obj.ReplaceFillValueWithNanOn ()` - If on, any float or double variable read that has a _FillValue attribute will have that fill value replaced with a not-a-number (NaN) value. The advantage of setting these to NaN values is that, if implemented properly by the system and careful math operations are used, they can implicitly be ignored by calculations like finding the range of the values. That said, this option should be used with caution as VTK does not fully support NaN values and therefore odd calculations may occur. By default this is off.

- `obj.ReplaceFillValueWithNanOff ()` - If on, any float or double variable read that has a _FillValue attribute will have that fill value replaced with a not-a-number (NaN) value. The advantage of setting these to NaN values is that, if implemented properly by the system and careful math operations are used, they can implicitly be ignored by calculations like finding the range of the values. That said, this option should be used with caution as VTK does not fully support NaN values and therefore odd calculations may occur. By default this is off.

37.64 vtkOBJReader

37.64.1 Usage

vtkOBJReader is a source object that reads Wavefront .obj files. The output of this source object is polygonal data.

To create an instance of class vtkOBJReader, simply invoke its constructor as follows

```
obj = vtkOBJReader
```

37.64.2 Methods

The class vtkOBJReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOBJReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkOBJReader = obj.NewInstance ()`

- `vtkOBJReader = obj.SafeDownCast (vtkObject o)`

- `obj.SetFileName (string )` - Specify file name of Wavefront .obj file.

- `string = obj.GetFileName ()` - Specify file name of Wavefront .obj file.

37.65 vtkOpenFOAMReader

37.65.1 Usage

vtkOpenFOAMReader creates a multiblock dataset. It reads mesh information and time dependent data. The polyMesh folders contain mesh information. The time folders contain transient data for the cells. Each folder can contain any number of data files.

To create an instance of class vtkOpenFOAMReader, simply invoke its constructor as follows

```
obj = vtkOpenFOAMReader
```

37.65.2 Methods

The class vtkOpenFOAMReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenFOAMReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenFOAMReader = obj.NewInstance ()`
- `vtkOpenFOAMReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string )` - Determine if the file can be readed with this reader.
- `obj.SetFileName (string )` - Set/Get the filename.
- `string = obj.GetFileName ()` - Set/Get the filename.
- `int = obj.GetNumberOfCellArrays (void )` - Get/Set whether the cell array with the given name is to be read.
- `int = obj.GetCellArrayStatus (string name)` - Get/Set whether the cell array with the given name is to be read.
- `obj.SetCellArrayStatus (string name, int status)` - Get the name of the cell array with the given index in the input.
- `string = obj.GetCellArrayName (int index)` - Turn on/off all cell arrays.
- `obj.DisableAllCellArrays ()` - Turn on/off all cell arrays.
- `obj.EnableAllCellArrays ()` - Get the number of point arrays available in the input.
- `int = obj.GetNumberOfPointArrays (void )` - Get/Set whether the point array with the given name is to be read.
- `int = obj.GetPointArrayStatus (string name)` - Get/Set whether the point array with the given name is to be read.
- `obj.SetPointArrayStatus (string name, int status)` - Get the name of the point array with the given index in the input.
- `string = obj.GetPointArrayName (int index)` - Turn on/off all point arrays.
- `obj.DisableAllPointArrays ()` - Turn on/off all point arrays.
- `obj.EnableAllPointArrays ()` - Get the number of Lagrangian arrays available in the input.
- `int = obj.GetNumberOfLagrangianArrays (void )` - Get/Set whether the Lagrangian array with the given name is to be read.
- `int = obj.GetLagrangianArrayStatus (string name)` - Get/Set whether the Lagrangian array with the given name is to be read.
- `obj.SetLagrangianArrayStatus (string name, int status)` - Get the name of the Lagrangian array with the given index in the input.
- `string = obj.GetLagrangianArrayName (int index)` - Turn on/off all Lagrangian arrays.
- `obj.DisableAllLagrangianArrays ()` - Turn on/off all Lagrangian arrays.

- `obj.EnableAllLagrangianArrays ()` - Get the number of Patches (inlcuding Internal Mesh) available in the input.
- `int = obj.GetNumberOfPatchArrays (void )` - Get/Set whether the Patch with the given name is to be read.
- `int = obj.GetPatchArrayStatus (string name)` - Get/Set whether the Patch with the given name is to be read.
- `obj.SetPatchArrayStatus (string name, int status)` - Get the name of the Patch with the given index in the input.
- `string = obj.GetPatchArrayName (int index)` - Turn on/off all Patches including the Internal Mesh.
- `obj.DisableAllPatchArrays ()` - Turn on/off all Patches including the Internal Mesh.
- `obj.EnableAllPatchArrays ()` - Set/Get whether to create cell-to-point translated data for cell-type data
- `obj.SetCreateCellToPoint (int )` - Set/Get whether to create cell-to-point translated data for cell-type data
- `int = obj.GetCreateCellToPoint ()` - Set/Get whether to create cell-to-point translated data for cell-type data
- `obj.CreateCellToPointOn ()` - Set/Get whether to create cell-to-point translated data for cell-type data
- `obj.CreateCellToPointOff ()` - Set/Get whether to create cell-to-point translated data for cell-type data
- `obj.SetCacheMesh (int )` - Set/Get whether mesh is to be cached.
- `int = obj.GetCacheMesh ()` - Set/Get whether mesh is to be cached.
- `obj.CacheMeshOn ()` - Set/Get whether mesh is to be cached.
- `obj.CacheMeshOff ()` - Set/Get whether mesh is to be cached.
- `obj.SetDecomposePolyhedra (int )` - Set/Get whether polyhedra are to be decomposed.
- `int = obj.GetDecomposePolyhedra ()` - Set/Get whether polyhedra are to be decomposed.
- `obj.DecomposePolyhedraOn ()` - Set/Get whether polyhedra are to be decomposed.
- `obj.DecomposePolyhedraOff ()` - Set/Get whether polyhedra are to be decomposed.
- `obj.SetPositionsIsIn13Format (int )` - Set/Get whether the lagrangian/positions is in OF 1.3 format
- `int = obj.GetPositionsIsIn13Format ()` - Set/Get whether the lagrangian/positions is in OF 1.3 format
- `obj.PositionsIsIn13FormatOn ()` - Set/Get whether the lagrangian/positions is in OF 1.3 format
- `obj.PositionsIsIn13FormatOff ()` - Set/Get whether the lagrangian/positions is in OF 1.3 format
- `obj.SetListTimeStepsByControlDict (int )` - Determine if time directories are to be listed according to controlDict
- `int = obj.GetListTimeStepsByControlDict ()` - Determine if time directories are to be listed according to controlDict

- `obj.ListTimeStepsByControlDictOn ()` - Determine if time directories are to be listed according to controlDict
- `obj.ListTimeStepsByControlDictOff ()` - Determine if time directories are to be listed according to controlDict
- `obj.SetAddDimensionsToArrayNames (int )` - Add dimensions to array names
- `int = obj.GetAddDimensionsToArrayNames ()` - Add dimensions to array names
- `obj.AddDimensionsToArrayNamesOn ()` - Add dimensions to array names
- `obj.AddDimensionsToArrayNamesOff ()` - Add dimensions to array names
- `obj.SetReadZones (int )` - Set/Get whether zones will be read.
- `int = obj.GetReadZones ()` - Set/Get whether zones will be read.
- `obj.ReadZonesOn ()` - Set/Get whether zones will be read.
- `obj.ReadZonesOff ()` - Set/Get whether zones will be read.
- `obj.SetRefresh ()`
- `obj.SetParent (vtkOpenFOAMReader parent)`
- `bool = obj.SetTimeValue (double )`
- `vtkDoubleArray = obj.GetTimeValues ()`
- `int = obj.MakeMetaDataAtTimeStep (bool )`

37.66 vtkOutputStream

37.66.1 Usage

vtkOutputStream provides a VTK-style interface wrapping around a standard output stream. The access methods are virtual so that subclasses can transparently provide encoding of the output. Data lengths for Write calls refer to the length of the data in memory. The actual length in the stream may differ for subclasses that implement an encoding scheme.

To create an instance of class vtkOutputStream, simply invoke its constructor as follows

```
obj = vtkOutputStream
```

37.66.2 Methods

The class vtkOutputStream has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutputStream class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutputStream = obj.NewInstance ()`
- `vtkOutputStream = obj.SafeDownCast (vtkObject o)`
- `int = obj.StartWriting ()` - Called after the stream position has been set by the caller, but before any Write calls. The stream position should not be adjusted by the caller until after an EndWriting call.

- `int = obj.Write (string data, long length)` - Write output data of the given length.
- `int = obj.Write (string data, long length)` - Write output data of the given length.
- `int = obj.EndWriting ()` - Called after all desired calls to Write have been made. After this call, the caller is free to change the position of the stream. Additional writes should not be done until after another call to StartWriting.

37.67 vtkParticleReader

37.67.1 Usage

vtkParticleReader reads either a binary or a text file of particles. Each particle can have associated with it an optional scalar value. So the format is: x, y, z, scalar (all floats or doubles). The text file can consist of a comma delimited set of values. In most cases vtkParticleReader can automatically determine whether the file is text or binary. The data can be either float or double. Progress updates are provided. With respect to binary files, random access into the file to read pieces is supported.

To create an instance of class vtkParticleReader, simply invoke its constructor as follows

```
obj = vtkParticleReader
```

37.67.2 Methods

The class vtkParticleReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParticleReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParticleReader = obj.NewInstance ()`
- `vtkParticleReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name.
- `string = obj.GetFileName ()` - Specify file name.
- `obj.SetDataByteOrderToBigEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.
- `obj.SetDataByteOrderToLittleEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.

- `int = obj.GetDataByteOrder ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.

- `obj.SetDataByteOrder (int )` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.

- `string = obj.GetDataByteOrderAsString ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian. Not used when reading text files.

- `obj.SetSwapBytes (int )` - Set/Get the byte swapping to explicitly swap the bytes of a file. Not used when reading text files.

- `int = obj.GetSwapBytes ()` - Set/Get the byte swapping to explicitly swap the bytes of a file. Not used when reading text files.

- `obj.SwapBytesOn ()` - Set/Get the byte swapping to explicitly swap the bytes of a file. Not used when reading text files.

- `obj.SwapBytesOff ()` - Set/Get the byte swapping to explicitly swap the bytes of a file. Not used when reading text files.

- `obj.SetHasScalar (int )` - Default: 1. If 1 then each particle has a value associated with it.

- `int = obj.GetHasScalar ()` - Default: 1. If 1 then each particle has a value associated with it.

- `obj.HasScalarOn ()` - Default: 1. If 1 then each particle has a value associated with it.

- `obj.HasScalarOff ()` - Default: 1. If 1 then each particle has a value associated with it.

- `obj.SetFileType (int )` - Get/Set the file type. The options are: - FILE_TYPE_IS_UNKNOWN (default) the class will attempt to determine the file type. If this fails then you should set the file type yourself. - FILE_TYPE_IS_TEXT the file type is text. - FILE_TYPE_IS_BINARY the file type is binary.

- `int = obj.GetFileTypeMinValue ()` - Get/Set the file type. The options are: - FILE_TYPE_IS_UNKNOWN (default) the class will attempt to determine the file type. If this fails then you should set the file type yourself. - FILE_TYPE_IS_TEXT the file type is text. - FILE_TYPE_IS_BINARY the file type is binary.

- `int = obj.GetFileTypeMaxValue ()` - Get/Set the file type. The options are: - FILE_TYPE_IS_UNKNOWN (default) the class will attempt to determine the file type. If this fails then you should set the file type yourself. - FILE_TYPE_IS_TEXT the file type is text. - FILE_TYPE_IS_BINARY the file type is binary.
- `int = obj.GetFileType ()` - Get/Set the file type. The options are: - FILE_TYPE_IS_UNKNOWN (default) the class will attempt to determine the file type. If this fails then you should set the file type yourself. - FILE_TYPE_IS_TEXT the file type is text. - FILE_TYPE_IS_BINARY the file type is binary.
- `obj.SetFileTypeToUnknown ()` - Get/Set the file type. The options are: - FILE_TYPE_IS_UNKNOWN (default) the class will attempt to determine the file type. If this fails then you should set the file type yourself. - FILE_TYPE_IS_TEXT the file type is text. - FILE_TYPE_IS_BINARY the file type is binary.
- `obj.SetFileTypeToText ()` - Get/Set the file type. The options are: - FILE_TYPE_IS_UNKNOWN (default) the class will attempt to determine the file type. If this fails then you should set the file type yourself. - FILE_TYPE_IS_TEXT the file type is text. - FILE_TYPE_IS_BINARY the file type is binary.
- `obj.SetFileTypeToBinary ()` - Get/Set the data type. The options are: - VTK_FLOAT (default) single precision floating point. - VTK_DOUBLE double precision floating point.
- `obj.SetDataType (int )` - Get/Set the data type. The options are: - VTK_FLOAT (default) single precision floating point. - VTK_DOUBLE double precision floating point.
- `int = obj.GetDataTypeMinValue ()` - Get/Set the data type. The options are: - VTK_FLOAT (default) single precision floating point. - VTK_DOUBLE double precision floating point.
- `int = obj.GetDataTypeMaxValue ()` - Get/Set the data type. The options are: - VTK_FLOAT (default) single precision floating point. - VTK_DOUBLE double precision floating point.
- `int = obj.GetDataType ()` - Get/Set the data type. The options are: - VTK_FLOAT (default) single precision floating point. - VTK_DOUBLE double precision floating point.
- `obj.SetDataTypeToFloat ()` - Get/Set the data type. The options are: - VTK_FLOAT (default) single precision floating point. - VTK_DOUBLE double precision floating point.
- `obj.SetDataTypeToDouble ()`

37.68 vtkPDBReader

37.68.1 Usage

vtkPDBReader is a source object that reads Molecule files The FileName must be specified
.SECTION Thanks Dr. Jean M. Favre who developed and contributed this class
To create an instance of class vtkPDBReader, simply invoke its constructor as follows

```
obj = vtkPDBReader
```

37.68.2 Methods

The class vtkPDBReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPDBReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkPDBReader = obj.NewInstance ()`
- `vtkPDBReader = obj.SafeDownCast (vtkObject o)`

37.69 vtkPLOT3DReader

37.69.1 Usage

vtkPLOT3DReader is a reader object that reads PLOT3D formatted files and generates structured grid(s) on output. PLOT3D is a computer graphics program designed to visualize the grids and solutions of computational fluid dynamics. Please see the "PLOT3D User's Manual" available from NASA Ames Research Center, Moffett Field CA.

PLOT3D files consist of a grid file (also known as XYZ file), an optional solution file (also known as a Q file), and an optional function file that contains user created data (currently unsupported). The Q file contains solution information as follows: the four parameters free stream mach number (Fsmach), angle of attack (Alpha), Reynolds number (Re), and total integration time (Time). This information is stored in an array called Properties in the FieldData of each output (tuple 0: fsmach, tuple 1: alpha, tuple 2: re, tuple 3: time). In addition, the solution file contains the flow density (scalar), flow momentum (vector), and flow energy (scalar).

The reader can generate additional scalars and vectors (or "functions") from this information. To use vtkPLOT3DReader, you must specify the particular function number for the scalar and vector you want to visualize. This implementation of the reader provides the following functions. The scalar functions are: -1 - don't read or compute any scalars 100 - density 110 - pressure 120 - temperature 130 - enthalpy 140 - internal energy 144 - kinetic energy 153 - velocity magnitude 163 - stagnation energy 170 - entropy 184 - swirl.

The vector functions are: -1 - don't read or compute any vectors 200 - velocity 201 - vorticity 202 - momentum 210 - pressure gradient.

(Other functions are described in the PLOT3D spec, but only those listed are implemented here.) Note that by default, this reader creates the density scalar (100) and momentum vector (202) as output. (These are just read in from the solution file.) Please note that the validity of computation is a function of this class's gas constants (R, Gamma) and the equations used. They may not be suitable for your computational domain.

Additionally, you can read other data and associate it as a vtkDataArray into the output's point attribute data. Use the method AddFunction() to list all the functions that you'd like to read. AddFunction() accepts an integer parameter that defines the function number.

To create an instance of class vtkPLOT3DReader, simply invoke its constructor as follows

```
obj = vtkPLOT3DReader
```

37.69.2 Methods

The class vtkPLOT3DReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPLOT3DReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPLOT3DReader = obj.NewInstance ()`
- `vtkPLOT3DReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string name)` - Set/Get the PLOT3D geometry filename.

- `string = obj.GetFileName ()` - Set/Get the PLOT3D geometry filename.
- `obj.SetXYZFileName (string )` - Set/Get the PLOT3D geometry filename.
- `string = obj.GetXYZFileName ()` - Set/Get the PLOT3D geometry filename.
- `obj.SetQFileName (string )` - Set/Get the PLOT3D solution filename.
- `string = obj.GetQFileName ()` - Set/Get the PLOT3D solution filename.
- `obj.SetFunctionFileName (string )` - Set/Get the PLOT3D Function Filename (optional)
- `string = obj.GetFunctionFileName ()` - Set/Get the PLOT3D Function Filename (optional)
- `int = obj.GetNumberOfOutputs ()` - This returns the number of outputs this reader will produce. This number is equal to the number of grids in the current file. This method has to be called before getting any output if the number of outputs will be greater than 1 (the first output is always the same). Note that every time this method is invoked, the header file is opened and part of the header is read.
- `int = obj.GetNumberOfGrids ()` - Replace an output.
- `obj.SetOutput (int idx, vtkStructuredGrid output)` - Replace an output.
- `obj.SetBinaryFile (int )` - Is the file to be read written in binary format (as opposed to ascii).
- `int = obj.GetBinaryFile ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.BinaryFileOn ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.BinaryFileOff ()` - Is the file to be read written in binary format (as opposed to ascii).
- `obj.SetMultiGrid (int )` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `int = obj.GetMultiGrid ()` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `obj.MultiGridOn ()` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `obj.MultiGridOff ()` - Does the file to be read contain information about number of grids. In some PLOT3D files, the first value contains the number of grids (even if there is only 1). If reading such a file, set this to true.
- `obj.SetHasByteCount (int )` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `int = obj.GetHasByteCount ()` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `obj.HasByteCountOn ()` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.
- `obj.HasByteCountOff ()` - Were the arrays written with leading and trailing byte counts ? Usually, files written by a fortran program will contain these byte counts whereas the ones written by C/C++ won't.

- `obj.SetIBlanking (int )` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `int = obj.GetIBlanking ()` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `obj.IBlankingOn ()` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `obj.IBlankingOff ()` - Is there iblanking (point visibility) information in the file. If there is iblanking arrays, these will be read and assigned to the PointVisibility array of the output.
- `obj.SetTwoDimensionalGeometry (int )` - If only two-dimensional data was written to the file, turn this on.
- `int = obj.GetTwoDimensionalGeometry ()` - If only two-dimensional data was written to the file, turn this on.
- `obj.TwoDimensionalGeometryOn ()` - If only two-dimensional data was written to the file, turn this on.
- `obj.TwoDimensionalGeometryOff ()` - If only two-dimensional data was written to the file, turn this on.
- `obj.SetForceRead (int )` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `int = obj.GetForceRead ()` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `obj.ForceReadOn ()` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `obj.ForceReadOff ()` - Try to read a binary file even if the file length seems to be inconsistent with the header information. Use this with caution, if the file length is not the same as calculated from the header. either the file is corrupt or the settings are wrong.
- `obj.SetDoNotReduceNumberOfOutputs (int )` - If this is on, the reader will never reduce the number of outputs after reading a file with n grids and producing n outputs. If the file read afterwards contains fewer grids, the extra outputs will be empty. This option can be used by application which rely on the initial number of outputs not shrinking.
- `int = obj.GetDoNotReduceNumberOfOutputs ()` - If this is on, the reader will never reduce the number of outputs after reading a file with n grids and producing n outputs. If the file read afterwards contains fewer grids, the extra outputs will be empty. This option can be used by application which rely on the initial number of outputs not shrinking.
- `obj.DoNotReduceNumberOfOutputsOn ()` - If this is on, the reader will never reduce the number of outputs after reading a file with n grids and producing n outputs. If the file read afterwards contains fewer grids, the extra outputs will be empty. This option can be used by application which rely on the initial number of outputs not shrinking.
- `obj.DoNotReduceNumberOfOutputsOff ()` - If this is on, the reader will never reduce the number of outputs after reading a file with n grids and producing n outputs. If the file read afterwards contains fewer grids, the extra outputs will be empty. This option can be used by application which rely on the initial number of outputs not shrinking.

- `obj.SetByteOrderToBigEndian ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetByteOrderToLittleEndian ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetByteOrder (int )` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `int = obj.GetByteOrder ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `string = obj.GetByteOrderAsString ()` - Set the byte order of the file (remember, more Unix workstations write big endian whereas PCs write little endian). Default is big endian (since most older PLOT3D files were written by workstations).
- `obj.SetR (double )` - Set/Get the gas constant. Default is 1.0.
- `double = obj.GetR ()` - Set/Get the gas constant. Default is 1.0.
- `obj.SetGamma (double )` - Set/Get the ratio of specific heats. Default is 1.4.
- `double = obj.GetGamma ()` - Set/Get the ratio of specific heats. Default is 1.4.
- `obj.SetUvinf (double )` - Set/Get the x-component of the free-stream velocity. Default is 1.0.
- `double = obj.GetUvinf ()` - Set/Get the x-component of the free-stream velocity. Default is 1.0.
- `obj.SetVvinf (double )` - Set/Get the y-component of the free-stream velocity. Default is 1.0.
- `double = obj.GetVvinf ()` - Set/Get the y-component of the free-stream velocity. Default is 1.0.
- `obj.SetWvinf (double )` - Set/Get the z-component of the free-stream velocity. Default is 1.0.
- `double = obj.GetWvinf ()` - Set/Get the z-component of the free-stream velocity. Default is 1.0.
- `obj.SetScalarFunctionNumber (int num)` - Specify the scalar function to extract. If ==(-1), then no scalar function is extracted.
- `int = obj.GetScalarFunctionNumber ()` - Specify the scalar function to extract. If ==(-1), then no scalar function is extracted.
- `obj.SetVectorFunctionNumber (int num)` - Specify the vector function to extract. If ==(-1), then no vector function is extracted.
- `int = obj.GetVectorFunctionNumber ()` - Specify the vector function to extract. If ==(-1), then no vector function is extracted.
- `obj.AddFunction (int functionNumber)` - Specify additional functions to read. These are placed into the point data as data arrays. Later on they can be used by labeling them as scalars, etc.
- `obj.RemoveFunction (int )` - Specify additional functions to read. These are placed into the point data as data arrays. Later on they can be used by labeling them as scalars, etc.
- `obj.RemoveAllFunctions ()` - Specify additional functions to read. These are placed into the point data as data arrays. Later on they can be used by labeling them as scalars, etc.
- `int = obj.CanReadBinaryFile (string fname)` - Return 1 if the reader can read the given file name. Only meaningful for binary files.

37.70 vtkPLYReader

37.70.1 Usage

vtkPLYReader is a source object that reads polygonal data in Stanford University PLY file format (see http://graphics.stanford.edu/data/3Dscanrep). It requires that the elements "vertex" and "face" are defined. The "vertex" element must have the properties "x", "y", and "z". The "face" element must have the property "vertex_indices" defined. Optionally, if the "face" element has the properties "intensity" and/or the triplet "red", "green", and "blue"; these are read and added as scalars to the output data.

To create an instance of class vtkPLYReader, simply invoke its constructor as follows

```
obj = vtkPLYReader
```

37.70.2 Methods

The class vtkPLYReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPLYReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPLYReader = obj.NewInstance ()`
- `vtkPLYReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of stereo lithography file.
- `string = obj.GetFileName ()` - Specify file name of stereo lithography file.

37.71 vtkPLYWriter

37.71.1 Usage

vtkPLYWriter writes polygonal data in Stanford University PLY format (see http://graphics.stanford.edu/data/3Dscanrep/). The data can be written in either binary (little or big endian) or ASCII representation. As for PointData and CellData, vtkPLYWriter cannot handle normals or vectors. It only handles RGB PointData and CellData. You need to set the name of the array (using SetName for the array and SetArrayName for the writer). If the array is not a vtkUnsignedCharArray with 3 components, you need to specify a vtkLookupTable to map the scalars to RGB.

To create an instance of class vtkPLYWriter, simply invoke its constructor as follows

```
obj = vtkPLYWriter
```

37.71.2 Methods

The class vtkPLYWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPLYWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPLYWriter = obj.NewInstance ()`

- `vtkPLYWriter = obj.SafeDownCast (vtkObject o)`

- `obj.SetDataByteOrder (int )` - If the file type is binary, then the user can specify which byte order to use (little versus big endian).

- `int = obj.GetDataByteOrderMinValue ()` - If the file type is binary, then the user can specify which byte order to use (little versus big endian).

- `int = obj.GetDataByteOrderMaxValue ()` - If the file type is binary, then the user can specify which byte order to use (little versus big endian).

- `int = obj.GetDataByteOrder ()` - If the file type is binary, then the user can specify which byte order to use (little versus big endian).

- `obj.SetDataByteOrderToBigEndian ()` - If the file type is binary, then the user can specify which byte order to use (little versus big endian).

- `obj.SetDataByteOrderToLittleEndian ()` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)

- `obj.SetColorMode (int )` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)

- `int = obj.GetColorMode ()` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)

- `obj.SetColorModeToDefault ()` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)

- `obj.SetColorModeToUniformCellColor ()` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)
- `obj.SetColorModeToUniformPointColor ()` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)
- `obj.SetColorModeToUniformColor ()` - These methods enable the user to control how to add color into the PLY output file. The default behavior is as follows. The user provides the name of an array and a component number. If the type of the array is three components, unsigned char, then the data is written as three separate "red", "green" and "blue" properties. If the type is not unsigned char, and a lookup table is provided, then the array/component are mapped through the table to generate three separate "red", "green" and "blue" properties in the PLY file. The user can also set the ColorMode to specify a uniform color for the whole part (on a vertex colors, face colors, or both. (Note: vertex colors or cell colors may be written, depending on where the named array is found. If points and cells have the arrays with the same name, then both colors will be written.)
- `obj.SetColorModeToOff ()` - Specify the array name to use to color the data.
- `obj.SetArrayName (string )` - Specify the array name to use to color the data.
- `string = obj.GetArrayName ()` - Specify the array name to use to color the data.
- `obj.SetComponent (int )` - Specify the array component to use to color the data.
- `int = obj.GetComponentMinValue ()` - Specify the array component to use to color the data.
- `int = obj.GetComponentMaxValue ()` - Specify the array component to use to color the data.
- `int = obj.GetComponent ()` - Specify the array component to use to color the data.
- `obj.SetLookupTable (vtkScalarsToColors )` - A lookup table can be specified in order to convert data arrays to RGBA colors.
- `vtkScalarsToColors = obj.GetLookupTable ()` - A lookup table can be specified in order to convert data arrays to RGBA colors.
- `obj.SetColor (char , char , char )` - Set the color to use when using a uniform color (either point or cells, or both). The color is specified as a triplet of three unsigned chars between (0,255). This only takes effect when the ColorMode is set to uniform point, uniform cell, or uniform color.
- `obj.SetColor (char a[3])` - Set the color to use when using a uniform color (either point or cells, or both). The color is specified as a triplet of three unsigned chars between (0,255). This only takes effect when the ColorMode is set to uniform point, uniform cell, or uniform color.
- `char = obj. GetColor ()` - Set the color to use when using a uniform color (either point or cells, or both). The color is specified as a triplet of three unsigned chars between (0,255). This only takes effect when the ColorMode is set to uniform point, uniform cell, or uniform color.

37.72 vtkPNGReader

37.72.1 Usage

vtkPNGReader is a source object that reads PNG files. It should be able to read most any PNG file
To create an instance of class vtkPNGReader, simply invoke its constructor as follows

```
obj = vtkPNGReader
```

37.72.2 Methods

The class vtkPNGReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPNGReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPNGReader = obj.NewInstance ()`
- `vtkPNGReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)` - Is the given file a PNG file?
- `string = obj.GetFileExtensions ()` - Return a descriptive name for the file format that might be useful in a GUI.
- `string = obj.GetDescriptiveName ()`

37.73 vtkPNGWriter

37.73.1 Usage

vtkPNGWriter writes PNG files. It supports 1 to 4 component data of unsigned char or unsigned short
To create an instance of class vtkPNGWriter, simply invoke its constructor as follows

```
obj = vtkPNGWriter
```

37.73.2 Methods

The class vtkPNGWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPNGWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPNGWriter = obj.NewInstance ()`
- `vtkPNGWriter = obj.SafeDownCast (vtkObject o)`
- `obj.Write ()` - The main interface which triggers the writer to start.
- `obj.SetWriteToMemory (int )` - Write the image to memory (a vtkUnsignedCharArray)
- `int = obj.GetWriteToMemory ()` - Write the image to memory (a vtkUnsignedCharArray)

- `obj.WriteToMemoryOn ()` - Write the image to memory (a vtkUnsignedCharArray)
- `obj.WriteToMemoryOff ()` - Write the image to memory (a vtkUnsignedCharArray)
- `obj.SetResult (vtkUnsignedCharArray )` - When writing to memory this is the result, it will be NULL until the data is written the first time
- `vtkUnsignedCharArray = obj.GetResult ()` - When writing to memory this is the result, it will be NULL until the data is written the first time

37.74 vtkPNMReader

37.74.1 Usage

vtkPNMReader is a source object that reads pnm (portable anymap) files. This includes .pbm (bitmap), .pgm (grayscale), and .ppm (pixmap) files. (Currently this object only reads binary versions of these files.)

PNMReader creates structured point datasets. The dimension of the dataset depends upon the number of files read. Reading a single file results in a 2D image, while reading more than one file results in a 3D volume.

To read a volume, files must be of the form "FileName.¡number¿" (e.g., foo.ppm.0, foo.ppm.1, ...). You must also specify the DataExtent. The fifth and sixth values of the DataExtent specify the beginning and ending files to read.

To create an instance of class vtkPNMReader, simply invoke its constructor as follows

```
obj = vtkPNMReader
```

37.74.2 Methods

The class vtkPNMReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPNMReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPNMReader = obj.NewInstance ()`
- `vtkPNMReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)`
- `string = obj.GetFileExtensions ()` - PNM
- `string = obj.GetDescriptiveName ()`

37.75 vtkPNMWriter

37.75.1 Usage

vtkPNMWriter writes PNM file. The data type of the file is unsigned char regardless of the input type.

To create an instance of class vtkPNMWriter, simply invoke its constructor as follows

```
obj = vtkPNMWriter
```

37.75.2 Methods

The class vtkPNMWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPNMWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPNMWriter = obj.NewInstance ()`
- `vtkPNMWriter = obj.SafeDownCast (vtkObject o)`

37.76 vtkPolyDataReader

37.76.1 Usage

vtkPolyDataReader is a source object that reads ASCII or binary polygonal data files in vtk format (see text for format details). The output of this reader is a single vtkPolyData data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkPolyDataReader, simply invoke its constructor as follows

```
obj = vtkPolyDataReader
```

37.76.2 Methods

The class vtkPolyDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataReader = obj.NewInstance ()`
- `vtkPolyDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetOutput ()` - Get the output of this reader.
- `vtkPolyData = obj.GetOutput (int idx)` - Get the output of this reader.
- `obj.SetOutput (vtkPolyData output)` - Get the output of this reader.

37.77 vtkPolyDataWriter

37.77.1 Usage

vtkPolyDataWriter is a source object that writes ASCII or binary polygonal data files in vtk format. See text for format details.

To create an instance of class vtkPolyDataWriter, simply invoke its constructor as follows

```
obj = vtkPolyDataWriter
```

37.77.2 Methods

The class vtkPolyDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataWriter = obj.NewInstance ()`
- `vtkPolyDataWriter = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetInput ()` - Get the input to this writer.
- `vtkPolyData = obj.GetInput (int port)` - Get the input to this writer.

37.78 vtkPostScriptWriter

37.78.1 Usage

vtkPostScriptWriter writes an image as a PostScript file using some reasonable scalings and centered on the page which is assumed to be about 8.5 by 11 inches. This is based loosely off of the code from pnmtops.c. Right now there aren't any real options.

To create an instance of class vtkPostScriptWriter, simply invoke its constructor as follows

```
obj = vtkPostScriptWriter
```

37.78.2 Methods

The class vtkPostScriptWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPostScriptWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPostScriptWriter = obj.NewInstance ()`
- `vtkPostScriptWriter = obj.SafeDownCast (vtkObject o)`

37.79 vtkRectilinearGridReader

37.79.1 Usage

vtkRectilinearGridReader is a source object that reads ASCII or binary rectilinear grid data files in vtk format (see text for format details). The output of this reader is a single vtkRectilinearGrid data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkRectilinearGridReader, simply invoke its constructor as follows

```
obj = vtkRectilinearGridReader
```

37.79.2 Methods

The class vtkRectilinearGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridReader = obj.NewInstance ()`
- `vtkRectilinearGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkRectilinearGrid = obj.GetOutput ()` - Get and set the output of this reader.
- `vtkRectilinearGrid = obj.GetOutput (int idx)` - Get and set the output of this reader.
- `obj.SetOutput (vtkRectilinearGrid output)` - Get and set the output of this reader.
- `int = obj.ReadMetaData (vtkInformation outInfo)` - Read the meta information from the file. This needs to be public to it can be accessed by vtkDataSetReader.

37.80 vtkRectilinearGridWriter

37.80.1 Usage

vtkRectilinearGridWriter is a source object that writes ASCII or binary rectilinear grid data files in vtk format. See text for format details.

To create an instance of class vtkRectilinearGridWriter, simply invoke its constructor as follows

```
obj = vtkRectilinearGridWriter
```

37.80.2 Methods

The class vtkRectilinearGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridWriter = obj.NewInstance ()`
- `vtkRectilinearGridWriter = obj.SafeDownCast (vtkObject o)`
- `vtkRectilinearGrid = obj.GetInput ()` - Get the input to this writer.
- `vtkRectilinearGrid = obj.GetInput (int port)` - Get the input to this writer.

37.81 vtkRowQuery

37.81.1 Usage

The abstract superclass of query classes that return row-oriented (table) results. A subclass will provide database-specific query parameters and implement the vtkRowQuery API to return query results:

Execute() - Execute the query. No results need to be retrieved at this point, unless you are performing caching.

GetNumberOfFields() - After Execute() is performed, returns the number of fields in the query results.

GetFieldName() - The name of the field at an index.

GetFieldType() - The data type of the field at an index.

NextRow() - Advances the query results by one row, and returns whether there are more rows left in the query.

DataValue() - Extract a single data value from the current row.

.SECTION Thanks Thanks to Andrew Wilson from Sandia National Laboratories for his work on the database classes.

To create an instance of class vtkRowQuery, simply invoke its constructor as follows

```
obj = vtkRowQuery
```

37.81.2 Methods

The class vtkRowQuery has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRowQuery class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRowQuery = obj.NewInstance ()`
- `vtkRowQuery = obj.SafeDownCast (vtkObject o)`
- `bool = obj.Execute ()` - Execute the query. This must be performed before any field name or data access functions are used.
- `int = obj.GetNumberOfFields ()` - The number of fields in the query result.
- `string = obj.GetFieldName (int i)` - Return the name of the specified query field.
- `int = obj.GetFieldType (int i)` - Return the type of the field, using the constants defined in vtkType.h.
- `int = obj.GetFieldIndex (string name)` - Return the index of the specified query field. Uses GetNumberOfFields() and GetFieldName() to match field name.
- `bool = obj.NextRow ()` - Advance row, return false if past end.
- `bool = obj.IsActive ()` - Return true if the query is active (i.e. execution was successful and results are ready to be fetched). Returns false on error or inactive query.
- `bool = obj.HasError ()` - Returns true if an error is set, otherwise false.
- `string = obj.GetLastErrorText ()` - Get the last error text from the query
- `obj.SetCaseSensitiveFieldNames (bool )` - Many databases do not preserve case in field names. This can cause GetFieldIndex to fail if you search for a field named someFieldName when the database actually stores it as SOMEFIELDNAME. This ivar controls whether GetFieldIndex() expects field names to be case-sensitive. The default is OFF, i.e. case is not preserved.

- `bool = obj.GetCaseSensitiveFieldNames ()` - Many databases do not preserve case in field names. This can cause GetFieldIndex to fail if you search for a field named someFieldName when the database actually stores it as SOMEFIELDNAME. This ivar controls whether GetFieldIndex() expects field names to be case-sensitive. The default is OFF, i.e. case is not preserved.
- `obj.CaseSensitiveFieldNamesOn ()` - Many databases do not preserve case in field names. This can cause GetFieldIndex to fail if you search for a field named someFieldName when the database actually stores it as SOMEFIELDNAME. This ivar controls whether GetFieldIndex() expects field names to be case-sensitive. The default is OFF, i.e. case is not preserved.
- `obj.CaseSensitiveFieldNamesOff ()` - Many databases do not preserve case in field names. This can cause GetFieldIndex to fail if you search for a field named someFieldName when the database actually stores it as SOMEFIELDNAME. This ivar controls whether GetFieldIndex() expects field names to be case-sensitive. The default is OFF, i.e. case is not preserved.

37.82 vtkRowQueryToTable

37.82.1 Usage

vtkRowQueryToTable creates a vtkTable with the results of an arbitrary SQL query. To use this filter, you first need an instance of a vtkSQLDatabase subclass. You may use the database class to obtain a vtkRowQuery instance. Set that query on this filter to extract the query as a table.

.SECTION Thanks Thanks to Andrew Wilson from Sandia National Laboratories for his work on the database classes.

To create an instance of class vtkRowQueryToTable, simply invoke its constructor as follows

```
obj = vtkRowQueryToTable
```

37.82.2 Methods

The class vtkRowQueryToTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRowQueryToTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRowQueryToTable = obj.NewInstance ()`
- `vtkRowQueryToTable = obj.SafeDownCast (vtkObject o)`
- `obj.SetQuery (vtkRowQuery query)` - The query to execute.
- `vtkRowQuery = obj.GetQuery ()` - The query to execute.
- `long = obj.GetMTime ()` - Update the modified time based on the query.

37.83 vtkRTXMLPolyDataReader

37.83.1 Usage

vtkRTXMLPolyDataReader reads the VTK XML PolyData file format in real time.

To create an instance of class vtkRTXMLPolyDataReader, simply invoke its constructor as follows

```
obj = vtkRTXMLPolyDataReader
```

37.83.2 Methods

The class vtkRTXMLPolyDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRTXMLPolyDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRTXMLPolyDataReader = obj.NewInstance ()`
- `vtkRTXMLPolyDataReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetLocation (string dataLocation)`
- `string = obj.GetDataLocation ()`
- `obj.UpdateToNextFile ()` - Reader will read in the next available data file The filename is this-¿NextFileName maintained internally
- `int = obj.NewDataAvailable ()` - check if there is new data file available in the given DataLocation
- `obj.ResetReader ()` - ResetReader check the data directory specified in this-¿DataLocation, and reset the Internal data structure specifically: this-¿Internal-¿ProcessedFileList for monitoring the arriving new data files if SetDataLocation(char*) is set by the user, this ResetReader() should also be invoked.
- `string = obj.GetNextFileName ()` - Return the name of the next available data file assume NewDataAvailable() return VTK_OK

37.84 vtkSESAMEReader

37.84.1 Usage

vtkSESAMEReader is a source object that reads SESAME files. Currently supported tables include 301, 304, 502, 503, 504, 505, 602

SESAMEReader creates rectilinear grid datasets. The dimension of the dataset depends upon the number of densities and temperatures in the table. Values at certain temperatures and densities are stored as scalars.

To create an instance of class vtkSESAMEReader, simply invoke its constructor as follows

```
obj = vtkSESAMEReader
```

37.84.2 Methods

The class vtkSESAMEReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSESAMEReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSESAMEReader = obj.NewInstance ()`
- `vtkSESAMEReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string file)` - Set the filename to read

- `string = obj.GetFileName ()` - Get the filename to read
- `int = obj.IsValidFile ()` - Return whether this is a valid file
- `int = obj.GetNumberOfTableIds ()` - Get the number of tables in this file
- `vtkIntArray = obj.GetTableIdsAsArray ()` - Returns the table ids in a data array.
- `obj.SetTable (int tableId)` - Set the table to read in
- `int = obj.GetTable ()` - Get the table to read in
- `int = obj.GetNumberOfTableArrayNames ()` - Get the number of arrays for the table to read
- `int = obj.GetNumberOfTableArrays ()` - Get the names of arrays for the table to read
- `string = obj.GetTableArrayName (int index)` - Get the names of arrays for the table to read
- `obj.SetTableArrayStatus (string name, int flag)` - Set whether to read a table array
- `int = obj.GetTableArrayStatus (string name)` - Set whether to read a table array

37.85 vtkShaderCodeLibrary

37.85.1 Usage

This class provides the hardware shader code. .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkShaderCodeLibrary, simply invoke its constructor as follows

```
obj = vtkShaderCodeLibrary
```

37.85.2 Methods

The class vtkShaderCodeLibrary has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShaderCodeLibrary class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShaderCodeLibrary = obj.NewInstance ()`
- `vtkShaderCodeLibrary = obj.SafeDownCast (vtkObject o)`

37.86 vtkSimplePointsReader

37.86.1 Usage

vtkSimplePointsReader is a source object that reads a list of points from a file. Each point is specified by three floating-point values in ASCII format. There is one point per line of the file. A vertex cell is created for each point in the output. This reader is meant as an example of how to write a reader in VTK.

To create an instance of class vtkSimplePointsReader, simply invoke its constructor as follows

```
obj = vtkSimplePointsReader
```

37.86.2 Methods

The class vtkSimplePointsReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimplePointsReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSimplePointsReader = obj.NewInstance ()`
- `vtkSimplePointsReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Set/Get the name of the file from which to read points.
- `string = obj.GetFileName ()` - Set/Get the name of the file from which to read points.

37.87 vtkSLACParticleReader

37.87.1 Usage

A reader for a data format used by Omega3p, Tau3p, and several other tools used at the Standford Linear Accelerator Center (SLAC). The underlying format uses netCDF to store arrays, but also imposes some conventions to store a list of particles in 3D space.

This reader supports pieces, but in actuality only loads anything in piece 0. All other pieces are empty.

To create an instance of class vtkSLACParticleReader, simply invoke its constructor as follows

```
obj = vtkSLACParticleReader
```

37.87.2 Methods

The class vtkSLACParticleReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSLACParticleReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSLACParticleReader = obj.NewInstance ()`
- `vtkSLACParticleReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetFileName ()`
- `obj.SetFileName (string )`

37.88 vtkSLACReader

37.88.1 Usage

A reader for a data format used by Omega3p, Tau3p, and several other tools used at the Standford Linear Accelerator Center (SLAC). The underlying format uses netCDF to store arrays, but also imposes several conventions to form an unstructured grid of elements.

To create an instance of class vtkSLACReader, simply invoke its constructor as follows

```
obj = vtkSLACReader
```

37.88.2 Methods

The class vtkSLACReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSLACReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSLACReader = obj.NewInstance ()`
- `vtkSLACReader = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetMeshFileName ()`
- `obj.SetMeshFileName (string )`
- `obj.AddModeFileName (string fname)` - There may be one mode file (usually for actual modes) or multiple mode files (which usually actually represent time series). These methods set and clear the list of mode files (which can be a single mode file).
- `obj.RemoveAllModeFileNames ()` - There may be one mode file (usually for actual modes) or multiple mode files (which usually actually represent time series). These methods set and clear the list of mode files (which can be a single mode file).
- `int = obj.GetNumberOfModeFileNames ()` - There may be one mode file (usually for actual modes) or multiple mode files (which usually actually represent time series). These methods set and clear the list of mode files (which can be a single mode file).
- `string = obj.GetModeFileName (int idx)` - There may be one mode file (usually for actual modes) or multiple mode files (which usually actually represent time series). These methods set and clear the list of mode files (which can be a single mode file).
- `int = obj.GetReadInternalVolume ()` - If on, reads the internal volume of the data set. Set to off by default.
- `obj.SetReadInternalVolume (int )` - If on, reads the internal volume of the data set. Set to off by default.
- `obj.ReadInternalVolumeOn ()` - If on, reads the internal volume of the data set. Set to off by default.
- `obj.ReadInternalVolumeOff ()` - If on, reads the internal volume of the data set. Set to off by default.
- `int = obj.GetReadExternalSurface ()` - If on, reads the external surfaces of the data set. Set to on by default.
- `obj.SetReadExternalSurface (int )` - If on, reads the external surfaces of the data set. Set to on by default.
- `obj.ReadExternalSurfaceOn ()` - If on, reads the external surfaces of the data set. Set to on by default.
- `obj.ReadExternalSurfaceOff ()` - If on, reads the external surfaces of the data set. Set to on by default.
- `int = obj.GetReadMidpoints ()` - If on, reads midpoint information for external surfaces and builds quadratic surface triangles. Set to on by default.

- `obj.SetReadMidpoints (int )` - If on, reads midpoint information for external surfaces and builds quadratic surface triangles. Set to on by default.
- `obj.ReadMidpointsOn ()` - If on, reads midpoint information for external surfaces and builds quadratic surface triangles. Set to on by default.
- `obj.ReadMidpointsOff ()` - If on, reads midpoint information for external surfaces and builds quadratic surface triangles. Set to on by default.
- `int = obj.GetNumberOfVariableArrays ()` - Variable array selection.
- `string = obj.GetVariableArrayName (int idx)` - Variable array selection.
- `int = obj.GetVariableArrayStatus (string name)` - Variable array selection.
- `obj.SetVariableArrayStatus (string name, int status)` - Variable array selection.

37.89 vtkSLCReader

37.89.1 Usage

vtkSLCReader reads an SLC file and creates a structured point dataset. The size of the volume and the data spacing is set from the SLC file header.

To create an instance of class vtkSLCReader, simply invoke its constructor as follows

```
obj = vtkSLCReader
```

37.89.2 Methods

The class vtkSLCReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSLCReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSLCReader = obj.NewInstance ()`
- `vtkSLCReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Set/Get the name of the file to read.
- `string = obj.GetFileName ()` - Set/Get the name of the file to read.
- `int = obj.GetError ()` - Was there an error on the last read performed?
- `int = obj.CanReadFile (string fname)` - Is the given file an SLC file?
- `string = obj.GetFileExtensions ()` - SLC
- `string = obj.GetDescriptiveName ()`

37.90 vtkSortFileNames

37.90.1 Usage

vtkSortFileNames will take a list of filenames (e.g. from a file load dialog) and sort them into one or more series. If the input list of filenames contains any directories, these can be removed before sorting using the SkipDirectories flag. This class should be used where information about the series groupings can be determined by the filenames, but it might not be successful in cases where the information about the series groupings is stored in the files themselves (e.g DICOM).

To create an instance of class vtkSortFileNames, simply invoke its constructor as follows

```
obj = vtkSortFileNames
```

37.90.2 Methods

The class vtkSortFileNames has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSortFileNames class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSortFileNames = obj.NewInstance ()`
- `vtkSortFileNames = obj.SafeDownCast (vtkObject o)`
- `obj.SetGrouping (int )` - Sort the file names into groups, according to similarity in filename name and path. Files in different directories, or with different extensions, or which do not fit into the same numbered series will be placed into different groups. This is off by default.
- `int = obj.GetGrouping ()` - Sort the file names into groups, according to similarity in filename name and path. Files in different directories, or with different extensions, or which do not fit into the same numbered series will be placed into different groups. This is off by default.
- `obj.GroupingOn ()` - Sort the file names into groups, according to similarity in filename name and path. Files in different directories, or with different extensions, or which do not fit into the same numbered series will be placed into different groups. This is off by default.
- `obj.GroupingOff ()` - Sort the file names into groups, according to similarity in filename name and path. Files in different directories, or with different extensions, or which do not fit into the same numbered series will be placed into different groups. This is off by default.
- `obj.SetNumericSort (int )` - Sort the files numerically, rather than lexicographically. For filenames that contain numbers, this means the order will be [”file8.dat”, ”file9.dat”, ”file10.dat”] instead of the usual alphabetic sorting order [”file10.dat” ”file8.dat”, ”file9.dat”]. NumericSort is off by default.
- `int = obj.GetNumericSort ()` - Sort the files numerically, rather than lexicographically. For filenames that contain numbers, this means the order will be [”file8.dat”, ”file9.dat”, ”file10.dat”] instead of the usual alphabetic sorting order [”file10.dat” ”file8.dat”, ”file9.dat”]. NumericSort is off by default.
- `obj.NumericSortOn ()` - Sort the files numerically, rather than lexicographically. For filenames that contain numbers, this means the order will be [”file8.dat”, ”file9.dat”, ”file10.dat”] instead of the usual alphabetic sorting order [”file10.dat” ”file8.dat”, ”file9.dat”]. NumericSort is off by default.
- `obj.NumericSortOff ()` - Sort the files numerically, rather than lexicographically. For filenames that contain numbers, this means the order will be [”file8.dat”, ”file9.dat”, ”file10.dat”] instead of the usual alphabetic sorting order [”file10.dat” ”file8.dat”, ”file9.dat”]. NumericSort is off by default.

- `obj.SetIgnoreCase (int )` - Ignore case when sorting. This flag is honored by both the sorting and the grouping. This is off by default.
- `int = obj.GetIgnoreCase ()` - Ignore case when sorting. This flag is honored by both the sorting and the grouping. This is off by default.
- `obj.IgnoreCaseOn ()` - Ignore case when sorting. This flag is honored by both the sorting and the grouping. This is off by default.
- `obj.IgnoreCaseOff ()` - Ignore case when sorting. This flag is honored by both the sorting and the grouping. This is off by default.
- `obj.SetSkipDirectories (int )` - Skip directories. If this flag is set, any input item that is a directory rather than a file will not be included in the output. This is off by default.
- `int = obj.GetSkipDirectories ()` - Skip directories. If this flag is set, any input item that is a directory rather than a file will not be included in the output. This is off by default.
- `obj.SkipDirectoriesOn ()` - Skip directories. If this flag is set, any input item that is a directory rather than a file will not be included in the output. This is off by default.
- `obj.SkipDirectoriesOff ()` - Skip directories. If this flag is set, any input item that is a directory rather than a file will not be included in the output. This is off by default.
- `obj.SetInputFileNames (vtkStringArray input)` - Set a list of file names to group and sort.
- `vtkStringArray = obj.GetInputFileNames ()` - Set a list of file names to group and sort.
- `vtkStringArray = obj.GetFileNames ()` - Get the full list of sorted filenames.
- `int = obj.GetNumberOfGroups ()` - Get the number of groups that the names were split into, if grouping is on. The filenames are automatically split into groups, where the filenames in each group will be identical except for their series numbers. If grouping is not on, this method will return zero.
- `vtkStringArray = obj.GetNthGroup (int i)` - Get the Nth group of file names. This method should only be used if grouping is on. If grouping is off, it will always return null.
- `obj.Update ()` - Update the output filenames from the input filenames. This method is called automatically by GetFileNames() and GetNumberOfGroups() if the input names have changed.

37.91 vtkSQLDatabase

37.91.1 Usage

Abstract base class for all SQL database connection classes. Manages a connection to the database, and is responsible for creating instances of the associated vtkSQLQuery objects associated with this class in order to perform execute queries on the database. To allow connections to a new type of database, create both a subclass of this class and vtkSQLQuery, and implement the required functions:

Open() - open the database connection, if possible. Close() - close the connection. GetQueryInstance() - create and return an instance of the vtkSQLQuery subclass associated with the database type.

The subclass should also provide API to set connection parameters.

This class also provides the function EffectSchema to transform a database schema into a SQL database.

.SECTION Thanks Thanks to Andrew Wilson from Sandia National Laboratories for his work on the database classes and for the SQLite example. Thanks to David Thompson and Philippe Pebay from Sandia National Laboratories for implementing this class.

To create an instance of class vtkSQLDatabase, simply invoke its constructor as follows

```
obj = vtkSQLDatabase
```

37.91.2 Methods

The class vtkSQLDatabase has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLDatabase class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLDatabase = obj.NewInstance ()`
- `vtkSQLDatabase = obj.SafeDownCast (vtkObject o)`
- `bool = obj.Open (string password)` - Open a new connection to the database. You need to set up any database parameters before calling this function. For database connections that do not require a password, pass an empty string. Returns true is the database was opened sucessfully, and false otherwise.
- `obj.Close ()` - Close the connection to the database.
- `bool = obj.IsOpen ()` - Return whether the database has an open connection.
- `vtkSQLQuery = obj.GetQueryInstance ()` - Return an empty query on this database.
- `bool = obj.HasError ()` - Did the last operation generate an error
- `string = obj.GetLastErrorText ()` - Get the last error text from the database I'm using const so that people do NOT use the standard vtkGetStringMacro in their implementation, because 99will not be the correct thing to do...
- `string = obj.GetDatabaseType ()` - Get the type of the database (e.g. mysql, psql,..).
- `vtkStringArray = obj.GetTables ()` - Get the list of tables from the database.
- `vtkStringArray = obj.GetRecord (string table)` - Get the list of fields for a particular table.
- `bool = obj.IsSupported (int )` - Get the URL of the database.
- `vtkStdString = obj.GetURL ()` - Get the URL of the database.
- `vtkStdString = obj.GetTablePreamble (bool )` - Return the SQL string with the syntax to create a column inside a "CREATE TABLE" SQL statement. NB: this method implements the following minimally-portable syntax: ¡column name¿ ¡column type¿ ¡column attributes¿ It must be overwritten for those SQL backends which have a different syntax such as, e.g., MySQL.
- `vtkStdString = obj.GetColumnSpecification (vtkSQLDatabaseSchema schema, int tblHandle, int colHandl` - Return the SQL string with the syntax to create a column inside a "CREATE TABLE" SQL statement. NB: this method implements the following minimally-portable syntax: ¡column name¿ ¡column type¿ ¡column attributes¿ It must be overwritten for those SQL backends which have a different syntax such as, e.g., MySQL.
- `vtkStdString = obj.GetTriggerSpecification (vtkSQLDatabaseSchema schema, int tblHandle, int trgHand` - Return the SQL string with the syntax to create a trigger using a "CREATE TRIGGER" SQL statement. NB1: support is contingent on VTK_FEATURE_TRIGGERS being recognized as a supported feature. Not all backends (e.g., SQLite) support it. NB2: this method implements the following minimally-portable syntax: ¡trigger name¿ BEFORE — AFTER ¡event¿ ON ¡table name¿ FOR EACH ROW ¡trigger action¿ It must be overwritten for those SQL backends which have a different syntax such as, e.g., PostgreSQL.
- `bool = obj.EffectSchema (vtkSQLDatabaseSchema , bool dropIfExistsfalse)` - Effect a database schema.

37.92 vtkSQLDatabaseSchema

37.92.1 Usage

A class to create a SQL database schema

.SECTION Thanks Thanks to Philippe Pebay and David Thompson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkSQLDatabaseSchema, simply invoke its constructor as follows

```
obj = vtkSQLDatabaseSchema
```

37.92.2 Methods

The class vtkSQLDatabaseSchema has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLDatabaseSchema class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLDatabaseSchema = obj.NewInstance ()`
- `vtkSQLDatabaseSchema = obj.SafeDownCast (vtkObject o)`
- `int = obj.AddPreamble (string preName, string preAction, string preBackendVTK\_SQL\_ALLBACKENDS)`
- `int = obj.AddTable (string tblName)` - Add a table to the schema
- `int = obj.AddColumnToTable (int tblHandle, int colType, string colName, int colSize, string colAttr`
- `int = obj.AddColumnToTable (string tblName, int colType, string colName, int colSize, string colAtt`
- `int = obj.AddIndexToTable (int tblHandle, int idxType, string idxName)`
- `int = obj.AddIndexToTable (string tblName, int idxType, string idxName)`
- `int = obj.AddColumnToIndex (int tblHandle, int idxHandle, int colHandle)`
- `int = obj.AddColumnToIndex (string tblName, string idxName, string colName)`
- `int = obj.AddTriggerToTable (int tblHandle, int trgType, string trgName, string trgAction, string t`
- `int = obj.AddTriggerToTable (string tblName, int trgType, string trgName, string trgAction, string` - Given a preamble name, get its handle.
- `int = obj.GetPreambleHandleFromName (string preName)` - Given a preamble name, get its handle.
- `string = obj.GetPreambleNameFromHandle (int preHandle)` - Given a preamble handle, get its name.
- `string = obj.GetPreambleActionFromHandle (int preHandle)` - Given a preamble handle, get its action.
- `string = obj.GetPreambleBackendFromHandle (int preHandle)` - Given a preamble handle, get its backend.
- `int = obj.GetTableHandleFromName (string tblName)` - Given a table name, get its handle.
- `string = obj.GetTableNameFromHandle (int tblHandle)` - Given a table hanlde, get its name.

- `int = obj.GetIndexHandleFromName (string tblName, string idxName)` - Given the names of a table and an index, get the handle of the index in this table.
- `string = obj.GetIndexNameFromHandle (int tblHandle, int idxHandle)` - Given the handles of a table and an index, get the name of the index.
- `int = obj.GetIndexTypeFromHandle (int tblHandle, int idxHandle)` - Given the handles of a table and an index, get the type of the index.
- `string = obj.GetIndexColumnNameFromHandle (int tblHandle, int idxHandle, int cnmHandle)` - Given the handles of a table, an index, and a column name, get the column name.
- `int = obj.GetColumnHandleFromName (string tblName, string colName)` - Given the names of a table and a column, get the handle of the column in this table.
- `string = obj.GetColumnNameFromHandle (int tblHandle, int colHandle)` - Given the handles of a table and a column, get the name of the column.
- `int = obj.GetColumnTypeFromHandle (int tblHandle, int colHandle)` - Given the handles of a table and a column, get the type of the column.
- `int = obj.GetColumnSizeFromHandle (int tblHandle, int colHandle)` - Given the handles of a table and a column, get the size of the column.
- `string = obj.GetColumnAttributesFromHandle (int tblHandle, int colHandle)` - Given the handles of a table and a column, get the attributes of the column.
- `int = obj.GetTriggerHandleFromName (string tblName, string trgName)` - Given the names of a trigger and a table, get the handle of the trigger in this table.
- `string = obj.GetTriggerNameFromHandle (int tblHandle, int trgHandle)` - Given the handles of a table and a trigger, get the name of the trigger.
- `int = obj.GetTriggerTypeFromHandle (int tblHandle, int trgHandle)` - Given the handles of a table and a trigger, get the type of the trigger.
- `string = obj.GetTriggerActionFromHandle (int tblHandle, int trgHandle)` - Given the handles of a table and a trigger, get the action of the trigger.
- `string = obj.GetTriggerBackendFromHandle (int tblHandle, int trgHandle)` - Given the handles of a table and a trigger, get the backend of the trigger.
- `obj.Reset ()` - Reset the schema to its initial, empty state.
- `int = obj.GetNumberOfPreambles ()` - Get the number of preambles.
- `int = obj.GetNumberOfTables ()` - Get the number of tables.
- `int = obj.GetNumberOfColumnsInTable (int tblHandle)` - Get the number of columns in a particular table .
- `int = obj.GetNumberOfIndicesInTable (int tblHandle)` - Get the number of indices in a particular table .
- `int = obj.GetNumberOfColumnNamesInIndex (int tblHandle, int idxHandle)` - Get the number of column names associated to a particular index in a particular table .
- `int = obj.GetNumberOfTriggersInTable (int tblHandle)` - Get the number of trigger in a particular table .
- `obj.SetName (string )` - Set/Get the name of the schema.
- `string = obj.GetName ()` - Set/Get the name of the schema.

37.93 vtkSQLiteDatabase

37.93.1 Usage

SQLite (http://www.sqlite.org) is a public-domain SQL database written in C++. It's small, fast, and can be easily embedded inside other applications. Its databases are stored in files.

This class provides a VTK interface to SQLite. You do not need to download any external libraries: we include a copy of SQLite 3.3.16 in VTK/Utilities/vtksqlite.

If you want to open a database that stays in memory and never gets written to disk, pass in the URL 'sqlite://:memory:'; otherwise, specifiy the file path by passing the URL 'sqlite://¡file_path¿'.

.SECTION Thanks Thanks to Andrew Wilson and Philippe Pebay from Sandia National Laboratories for implementing this class.

To create an instance of class vtkSQLiteDatabase, simply invoke its constructor as follows

```
obj = vtkSQLiteDatabase
```

37.93.2 Methods

The class vtkSQLiteDatabase has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLiteDatabase class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLiteDatabase = obj.NewInstance ()`
- `vtkSQLiteDatabase = obj.SafeDownCast (vtkObject o)`
- `bool = obj.Open (string password)` - Open a new connection to the database. You need to set the filename before calling this function. Returns true if the database was opened successfully; false otherwise. - USE_EXISTING (default) - Fail if the file does not exist. - USE_EXISTING_OR_CREATE - Create a new file if necessary. - CREATE_OR_CLEAR - Create new or clear existing file. - CREATE - Create new, fail if file exists.
- `bool = obj.Open (string password, int mode)` - Open a new connection to the database. You need to set the filename before calling this function. Returns true if the database was opened successfully; false otherwise. - USE_EXISTING (default) - Fail if the file does not exist. - USE_EXISTING_OR_CREATE - Create a new file if necessary. - CREATE_OR_CLEAR - Create new or clear existing file. - CREATE - Create new, fail if file exists.
- `obj.Close ()` - Close the connection to the database.
- `bool = obj.IsOpen ()` - Return whether the database has an open connection
- `vtkSQLQuery = obj.GetQueryInstance ()` - Return an empty query on this database.
- `vtkStringArray = obj.GetTables ()` - Get the list of tables from the database
- `vtkStringArray = obj.GetRecord (string table)` - Get the list of fields for a particular table
- `bool = obj.IsSupported (int feature)` - Return whether a feature is supported by the database.
- `bool = obj.HasError ()` - Did the last operation generate an error
- `string = obj.GetLastErrorText ()` - Get the last error text from the database
- `string = obj.GetDatabaseType ()` - String representing database type (e.g. "sqlite").

- `string = obj.GetDatabaseFileName ()` - String representing the database filename.
- `obj.SetDatabaseFileName (string )` - String representing the database filename.
- `vtkStdString = obj.GetURL ()` - Get the URL of the database.
- `vtkStdString = obj.GetColumnSpecification (vtkSQLDatabaseSchema schema, int tblHandle, int colHandl` - Return the SQL string with the syntax to create a column inside a "CREATE TABLE" SQL statement. NB: this method implements the SQLite-specific syntax: ¡column name¿ ¡column type¿ ¡column attributes¿

37.94 vtkSQLiteQuery

37.94.1 Usage

This is an implementation of vtkSQLQuery for SQLite databases. See the documentation for vtkSQLQuery for information about what the methods do.

.SECTION Bugs

Sometimes Execute() will return false (meaning an error) but GetLastErrorText() winds up null. I am not certain why this is happening.

.SECTION Thanks Thanks to Andrew Wilson from Sandia National Laboratories for implementing this class.

To create an instance of class vtkSQLiteQuery, simply invoke its constructor as follows

```
obj = vtkSQLiteQuery
```

37.94.2 Methods

The class vtkSQLiteQuery has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLiteQuery class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLiteQuery = obj.NewInstance ()`
- `vtkSQLiteQuery = obj.SafeDownCast (vtkObject o)`
- `bool = obj.SetQuery (string query)` - Set the SQL query string. This must be performed before Execute() or BindParameter() can be called.
- `bool = obj.Execute ()` - Execute the query. This must be performed before any field name or data access functions are used.
- `int = obj.GetNumberOfFields ()` - The number of fields in the query result.
- `string = obj.GetFieldName (int i)` - Return the name of the specified query field.
- `int = obj.GetFieldType (int i)` - Return the type of the field, using the constants defined in vtkType.h.
- `bool = obj.NextRow ()` - Advance row, return false if past end.
- `bool = obj.HasError ()` - Return true if there is an error on the current query.
- `bool = obj.BeginTransaction ()` - Begin, abort (roll back), or commit a transaction.

- `bool = obj.RollbackTransaction ()` - Begin, abort (roll back), or commit a transaction.
- `bool = obj.CommitTransaction ()` - Begin, abort (roll back), or commit a transaction.
- `string = obj.GetLastErrorText ()` - Get the last error text from the query
- `bool = obj.BindParameter (int index, int value)` - The following methods bind a parameter value to a placeholder in the SQL string. See the documentation for vtkSQLQuery for further explanation. The driver makes internal copies of string and BLOB parameters so you don't need to worry about keeping them in scope until the query finishes executing.
- `bool = obj.BindParameter (int index, float value)` - The following methods bind a parameter value to a placeholder in the SQL string. See the documentation for vtkSQLQuery for further explanation. The driver makes internal copies of string and BLOB parameters so you don't need to worry about keeping them in scope until the query finishes executing.
- `bool = obj.BindParameter (int index, double value)` - The following methods bind a parameter value to a placeholder in the SQL string. See the documentation for vtkSQLQuery for further explanation. The driver makes internal copies of string and BLOB parameters so you don't need to worry about keeping them in scope until the query finishes executing.
- `bool = obj.BindParameter (int index, string stringValue)` - Bind a string value – string must be null-terminated
- `bool = obj.ClearParameterBindings ()` - Bind a blob value. Not all databases support blobs as a data type. Check vtkSQLDatabase::IsSupported(VTK_SQL_FEATURE_BLOB) to make sure.

37.95 vtkSQLQuery

37.95.1 Usage

The abstract superclass of SQL query classes. Instances of subclasses of vtkSQLQuery are created using the GetQueryInstance() function in vtkSQLDatabase. To implement a query connection for a new database type, subclass both vtkSQLDatabase and vtkSQLQuery, and implement the required functions. For the query class, this involves the following:

Execute() - Execute the query on the database. No results need to be retrieved at this point, unless you are performing caching.

GetNumberOfFields() - After Execute() is performed, returns the number of fields in the query results.

GetFieldName() - The name of the field at an index.

GetFieldType() - The data type of the field at an index.

NextRow() - Advances the query results by one row, and returns whether there are more rows left in the query.

DataValue() - Extract a single data value from the current row.

Begin/Rollback/CommitTransaction() - These methods are optional but recommended if the database supports transactions.

.SECTION Thanks Thanks to Andrew Wilson from Sandia National Laboratories for his work on the database classes.

To create an instance of class vtkSQLQuery, simply invoke its constructor as follows

```
obj = vtkSQLQuery
```

37.95.2 Methods

The class vtkSQLQuery has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSQLQuery class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSQLQuery = obj.NewInstance ()`
- `vtkSQLQuery = obj.SafeDownCast (vtkObject o)`
- `bool = obj.SetQuery (string query)` - The query string to be executed. Since some databases will process the query string as soon as it's set, this method returns a boolean to indicate success or failure.
- `string = obj.GetQuery ()` - The query string to be executed. Since some databases will process the query string as soon as it's set, this method returns a boolean to indicate success or failure.
- `bool = obj.IsActive ()` - Execute the query. This must be performed before any field name or data access functions are used.
- `bool = obj.Execute ()` - Execute the query. This must be performed before any field name or data access functions are used.
- `bool = obj.BeginTransaction ()` - Begin, commit, or roll back a transaction. If the underlying database does not support transactions these calls will do nothing.
- `bool = obj.CommitTransaction ()` - Begin, commit, or roll back a transaction. If the underlying database does not support transactions these calls will do nothing.
- `bool = obj.RollbackTransaction ()` - Return the database associated with the query.
- `vtkSQLDatabase = obj.GetDatabase ()` - Return the database associated with the query.
- `bool = obj.BindParameter (int index, int value)`
- `bool = obj.BindParameter (int index, float value)`
- `bool = obj.BindParameter (int index, double value)`
- `bool = obj.BindParameter (int index, string stringValue)` - Bind a string value – string must be null-terminated
- `bool = obj.ClearParameterBindings ()` - Reset all parameter bindings to NULL.
- `string = obj.EscapeString (string src, bool addSurroundingQuotes)` - Escape a string for inclusion into an SQL query. This method exists to provide a wrappable version of the method that takes and returns vtkStdString objects. You are responsible for calling delete [] on the character array returned by this method. This method simply calls the vtkStdString variant and thus need not be re-implemented by subclasses.

37.96 vtkSTLReader

37.96.1 Usage

vtkSTLReader is a source object that reads ASCII or binary stereo lithography files (.stl files). The FileName must be specified to vtkSTLReader. The object automatically detects whether the file is ASCII or binary.

.stl files are quite inefficient since they duplicate vertex definitions. By setting the Merging boolean you can control whether the point data is merged after reading. Merging is performed by default, however, merging requires a large amount of temporary storage since a 3D hash table must be constructed.

To create an instance of class vtkSTLReader, simply invoke its constructor as follows

```
obj = vtkSTLReader
```

37.96.2 Methods

The class vtkSTLReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSTLReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSTLReader = obj.NewInstance ()`
- `vtkSTLReader = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Overload standard modified time function. If locator is modified, then this object is modified as well.
- `obj.SetFileName (string )` - Specify file name of stereo lithography file.
- `string = obj.GetFileName ()` - Specify file name of stereo lithography file.
- `obj.SetMerging (int )` - Turn on/off merging of points/triangles.
- `int = obj.GetMerging ()` - Turn on/off merging of points/triangles.
- `obj.MergingOn ()` - Turn on/off merging of points/triangles.
- `obj.MergingOff ()` - Turn on/off merging of points/triangles.
- `obj.SetScalarTags (int )` - Turn on/off tagging of solids with scalars.
- `int = obj.GetScalarTags ()` - Turn on/off tagging of solids with scalars.
- `obj.ScalarTagsOn ()` - Turn on/off tagging of solids with scalars.
- `obj.ScalarTagsOff ()` - Turn on/off tagging of solids with scalars.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.

37.97 vtkSTLWriter

37.97.1 Usage

vtkSTLWriter writes stereo lithography (.stl) files in either ASCII or binary form. Stereo lithography files only contain triangles. If polygons with more than 3 vertices are present, only the first 3 vertices are written. Use vtkTriangleFilter to convert polygons to triangles.

To create an instance of class vtkSTLWriter, simply invoke its constructor as follows

```
obj = vtkSTLWriter
```

37.97.2 Methods

The class vtkSTLWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSTLWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSTLWriter = obj.NewInstance ()`
- `vtkSTLWriter = obj.SafeDownCast (vtkObject o)`

37.98 vtkStructuredGridReader

37.98.1 Usage

vtkStructuredGridReader is a source object that reads ASCII or binary structured grid data files in vtk format. (see text for format details). The output of this reader is a single vtkStructuredGrid data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkStructuredGridReader, simply invoke its constructor as follows

```
obj = vtkStructuredGridReader
```

37.98.2 Methods

The class vtkStructuredGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridReader = obj.NewInstance ()`
- `vtkStructuredGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkStructuredGrid = obj.GetOutput ()` - Get the output of this reader.
- `vtkStructuredGrid = obj.GetOutput (int idx)` - Get the output of this reader.
- `obj.SetOutput (vtkStructuredGrid output)` - Get the output of this reader.
- `int = obj.ReadMetaData (vtkInformation outInfo)` - Read the meta information from the file. This needs to be public to it can be accessed by vtkDataSetReader.

37.99 vtkStructuredGridWriter

37.99.1 Usage

vtkStructuredGridWriter is a source object that writes ASCII or binary structured grid data files in vtk format. See text for format details.

To create an instance of class vtkStructuredGridWriter, simply invoke its constructor as follows

```
obj = vtkStructuredGridWriter
```

37.99.2 Methods

The class vtkStructuredGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridWriter = obj.NewInstance ()`
- `vtkStructuredGridWriter = obj.SafeDownCast (vtkObject o)`
- `vtkStructuredGrid = obj.GetInput ()` - Get the input to this writer.
- `vtkStructuredGrid = obj.GetInput (int port)` - Get the input to this writer.

37.100 vtkStructuredPointsReader

37.100.1 Usage

vtkStructuredPointsReader is a source object that reads ASCII or binary structured points data files in vtk format (see text for format details). The output of this reader is a single vtkStructuredPoints data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkStructuredPointsReader, simply invoke its constructor as follows

```
obj = vtkStructuredPointsReader
```

37.100.2 Methods

The class vtkStructuredPointsReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsReader = obj.NewInstance ()`
- `vtkStructuredPointsReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutput (vtkStructuredPoints output)` - Set/Get the output of this reader.
- `vtkStructuredPoints = obj.GetOutput (int idx)` - Set/Get the output of this reader.
- `vtkStructuredPoints = obj.GetOutput ()` - Set/Get the output of this reader.
- `int = obj.ReadMetaData (vtkInformation outInfo)` - Read the meta information from the file. This needs to be public to it can be accessed by vtkDataSetReader.

37.101 vtkStructuredPointsWriter

37.101.1 Usage

vtkStructuredPointsWriter is a source object that writes ASCII or binary structured points data in vtk file format. See text for format details.

To create an instance of class vtkStructuredPointsWriter, simply invoke its constructor as follows

```
obj = vtkStructuredPointsWriter
```

37.101.2 Methods

The class vtkStructuredPointsWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsWriter = obj.NewInstance ()`
- `vtkStructuredPointsWriter = obj.SafeDownCast (vtkObject o)`
- `vtkImageData = obj.GetInput ()` - Get the input to this writer.
- `vtkImageData = obj.GetInput (int port)` - Get the input to this writer.

37.102 vtkTableReader

37.102.1 Usage

vtkTableReader is a source object that reads ASCII or binary vtkTable data files in vtk format. (see text for format details). The output of this reader is a single vtkTable data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkTableReader, simply invoke its constructor as follows

```
obj = vtkTableReader
```

37.102.2 Methods

The class vtkTableReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableReader = obj.NewInstance ()`
- `vtkTableReader = obj.SafeDownCast (vtkObject o)`
- `vtkTable = obj.GetOutput ()` - Get the output of this reader.
- `vtkTable = obj.GetOutput (int idx)` - Get the output of this reader.
- `obj.SetOutput (vtkTable output)` - Get the output of this reader.

37.103 vtkTableWriter

37.103.1 Usage

vtkTableWriter is a sink object that writes ASCII or binary vtkTable data files in vtk format. See text for format details.

To create an instance of class vtkTableWriter, simply invoke its constructor as follows

```
obj = vtkTableWriter
```

37.103.2 Methods

The class vtkTableWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableWriter = obj.NewInstance ()`
- `vtkTableWriter = obj.SafeDownCast (vtkObject o)`
- `vtkTable = obj.GetInput ()` - Get the input to this writer.
- `vtkTable = obj.GetInput (int port)` - Get the input to this writer.

37.104 vtkTecplotReader

37.104.1 Usage

vtkTecplotReader parses an ASCII Tecplot file to get a vtkMultiBlockDataSet object made up of several vtkDataSet objects, of which each is of type either vtkStructuredGrid or vtkUnstructuredGrid. Each vtkDataSet object maintains the geometry, topology, and some associated attributes describing physical properties.

Tecplot treats 3D coordinates (only one or two coordinates might be explicitly specified in a file) as varaibles too, whose names (e.g., 'X' / 'x' / 'I', 'Y' / 'y' / 'J', 'Z' / 'z' / 'K') are provided in the variables list (the 'VARIABLES' section). These names are then followed in the list by those of other traditional variables or attributes (node- based and / or cell-based data with the mode specified via token 'VAR LOCATION', to be extracted to create vtkPointData and / or vtkCellData). Each zone described afterwards (in the 'ZONE's section) provides the specific values of the aforementioned variables (including 3D coordinates), in the same order as indicated by the variable-names list, through either POINT-packing (i.e., tuple-based storage) or BLOCK-packing (component-based storage). In particular, the first / description line of each zone tells the type of all the constituent cells as the connectivity / topology information. In other words, the entire dataset is made up of multiple zones (blocks), of which each maintains a set of cells of the same type ('BRICK', 'TRIANGLE', 'QUADRILATERAL', 'TETRAHEDRON', and 'POINT' in Tecplot terms). In addition, the description line of each zone specifies the zone name, dimensionality information (size of each dimension for a structured zone), number of nodes, and number of cells. Information about the file format is available at http://download.tecplot.com/360/dataformat.pdf.

To create an instance of class vtkTecplotReader, simply invoke its constructor as follows

```
obj = vtkTecplotReader
```

37.104.2 Methods

The class vtkTecplotReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTecplotReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTecplotReader = obj.NewInstance ()`
- `vtkTecplotReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfVariables ()` - Get the number of all variables (including 3D coordinates).
- `obj.SetFileName (string fileName)` - Specify a Tecplot ASCII file for data loading.
- `string = obj.GetDataTitle ()` - Get the Tecplot data title.
- `int = obj.GetNumberOfBlocks ()` - Get the number of blocks (i.e., zones in Tecplot terms).
- `string = obj.GetBlockName (int blockIdx)` - Get the name of a block specified by a zero-based index. NULL is returned for an invalid block index.
- `int = obj.GetNumberOfDataAttributes ()` - Get the number of standard data attributes (node-based and cell-based), excluding 3D coordinates.
- `string = obj.GetDataAttributeName (int attrIndx)` - Get the name of a zero-based data attribute (not 3D coordinates). NULL is returned for an invalid attribute index.
- `int = obj.IsDataAttributeCellBased (string attrName)` - Get the type (0 for node-based and 1 for cell-based) of a specified data attribute (not 3D coordinates). -1 is returned for an invalid attribute name.
- `int = obj.IsDataAttributeCellBased (int attrIndx)` - Get the type (0 for node-based and 1 for cell-based) of a specified data attribute (not 3D coordinates). -1 is returned for an invalid attribute index.
- `int = obj.GetNumberOfDataArrays ()` - Get the number of all data attributes (point data and cell data).
- `string = obj.GetDataArrayName (int arrayIdx)` - Get the name of a data array specified by the zero-based index (arrayIdx).
- `int = obj.GetDataArrayStatus (string arayName)` - Get the status of a specific data array (0: un-selected; 1: selected).
- `obj.SetDataArrayStatus (string arayName, int bChecked)` - Set the status of a specific data array (0: de-select; 1: select) specified by the name.

37.105 vtkTIFFReader

37.105.1 Usage

vtkTIFFReader is a source object that reads TIFF files. It should be able to read almost any TIFF file
To create an instance of class vtkTIFFReader, simply invoke its constructor as follows

```
obj = vtkTIFFReader
```

37.105.2 Methods

The class vtkTIFFReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTIFFReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTIFFReader = obj.NewInstance ()`
- `vtkTIFFReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string fname)` - Is the given file name a tiff file file?
- `string = obj.GetFileExtensions ()` - Return a descriptive name for the file format that might be useful in a GUI.
- `string = obj.GetDescriptiveName ()` - Auxilary methods used by the reader internally.
- `obj.InitializeColors ()` - Auxilary methods used by the reader internally.
- `obj.SetOrientationType (int orientationType)` - Set orientation type ORIENTATION_TOPLEFT 1 (row 0 top, col 0 lhs) ORIENTATION_TOPRIGHT 2 (row 0 top, col 0 rhs) ORIENTATION_BOTRIGHT 3 (row 0 bottom, col 0 rhs) ORIENTATION_BOTLEFT 4 (row 0 bottom, col 0 lhs) ORIENTATION_LEFTTOP 5 (row 0 lhs, col 0 top) ORIENTATION_RIGHTTOP 6 (row 0 rhs, col 0 top) ORIENTATION_RIGHTBOT 7 (row 0 rhs, col 0 bottom) ORIENTATION_LEFTBOT 8 (row 0 lhs, col 0 bottom) User need to explicitely include vtk_tiff.h header to have access to those #define
- `int = obj.GetOrientationType ()` - Set orientation type ORIENTATION_TOPLEFT 1 (row 0 top, col 0 lhs) ORIENTATION_TOPRIGHT 2 (row 0 top, col 0 rhs) ORIENTATION_BOTRIGHT 3 (row 0 bottom, col 0 rhs) ORIENTATION_BOTLEFT 4 (row 0 bottom, col 0 lhs) ORIENTATION_LEFTTOP 5 (row 0 lhs, col 0 top) ORIENTATION_RIGHTTOP 6 (row 0 rhs, col 0 top) ORIENTATION_RIGHTBOT 7 (row 0 rhs, col 0 bottom) ORIENTATION_LEFTBOT 8 (row 0 lhs, col 0 bottom) User need to explicitely include vtk_tiff.h header to have access to those #define
- `bool = obj.GetOrientationTypeSpecifiedFlag ()` - Get method to check if orientation type is specified
- `obj.SetOriginSpecifiedFlag (bool )` - Set/get methods to see if manual Origin/Spacing have been set.
- `bool = obj.GetOriginSpecifiedFlag ()` - Set/get methods to see if manual Origin/Spacing have been set.
- `obj.OriginSpecifiedFlagOn ()` - Set/get methods to see if manual Origin/Spacing have been set.
- `obj.OriginSpecifiedFlagOff ()` - Set/get methods to see if manual Origin/Spacing have been set.
- `obj.SetSpacingSpecifiedFlag (bool )` -
- `bool = obj.GetSpacingSpecifiedFlag ()` -
- `obj.SpacingSpecifiedFlagOn ()` -
- `obj.SpacingSpecifiedFlagOff ()` -

37.106 vtkTIFFWriter

37.106.1 Usage

vtkTIFFWriter writes image data as a TIFF data file. Data can be written uncompressed or compressed. Several forms of compression are supported including packed bits, JPEG, deflation, and LZW. (Note: LZW compression is currently under patent in the US and is disabled until the patent expires. However, the mechanism for supporting this compression is available for those with a valid license or to whom the patent does not apply.)

To create an instance of class vtkTIFFWriter, simply invoke its constructor as follows

```
obj = vtkTIFFWriter
```

37.106.2 Methods

The class vtkTIFFWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTIFFWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTIFFWriter = obj.NewInstance ()`
- `vtkTIFFWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetCompression (int )` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `int = obj.GetCompressionMinValue ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `int = obj.GetCompressionMaxValue ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `int = obj.GetCompression ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `obj.SetCompressionToNoCompression ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `obj.SetCompressionToPackBits ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `obj.SetCompressionToJPEG ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `obj.SetCompressionToDeflate ()` - Set compression type. Sinze LZW compression is patented outside US, the additional work steps have to be taken in order to use that compression.
- `obj.SetCompressionToLZW ()`

37.107 vtkTreeReader

37.107.1 Usage

vtkTreeReader is a source object that reads ASCII or binary vtkTree data files in vtk format. (see text for format details). The output of this reader is a single vtkTree data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkTreeReader, simply invoke its constructor as follows

```
obj = vtkTreeReader
```

37.107.2 Methods

The class vtkTreeReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeReader = obj.NewInstance ()`
- `vtkTreeReader = obj.SafeDownCast (vtkObject o)`
- `vtkTree = obj.GetOutput ()` - Get the output of this reader.
- `vtkTree = obj.GetOutput (int idx)` - Get the output of this reader.
- `obj.SetOutput (vtkTree output)` - Get the output of this reader.

37.108 vtkTreeWriter

37.108.1 Usage

vtkTreeWriter is a sink object that writes ASCII or binary vtkTree data files in vtk format. See text for format details.

To create an instance of class vtkTreeWriter, simply invoke its constructor as follows

```
obj = vtkTreeWriter
```

37.108.2 Methods

The class vtkTreeWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeWriter = obj.NewInstance ()`
- `vtkTreeWriter = obj.SafeDownCast (vtkObject o)`
- `vtkTree = obj.GetInput ()` - Get the input to this writer.
- `vtkTree = obj.GetInput (int port)` - Get the input to this writer.

37.109 vtkUGFacetReader

37.109.1 Usage

vtkUGFacetReader is a source object that reads Unigraphics facet files. Unigraphics is a solid modeling system; facet files are the polygonal plot files it uses to create 3D plots.

To create an instance of class vtkUGFacetReader, simply invoke its constructor as follows

```
obj = vtkUGFacetReader
```

37.109.2 Methods

The class vtkUGFacetReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUGFacetReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUGFacetReader = obj.NewInstance ()`
- `vtkUGFacetReader = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Overload standard modified time function. If locator is modified, then this object is modified as well.
- `obj.SetFileName (string )` - Specify Unigraphics file name.
- `string = obj.GetFileName ()` - Specify Unigraphics file name.
- `int = obj.GetNumberOfParts ()` - Special methods for interrogating the data file.
- `short = obj.GetPartColorIndex (int partId)` - Retrieve color index for the parts in the file.
- `obj.SetPartNumber (int )` - Specify the desired part to extract. The part number must range between [0,NumberOfParts-1]. If the value is =(-1), then all parts will be extracted. If the value is ¡(-1), then no parts will be extracted but the part colors will be updated.
- `int = obj.GetPartNumber ()` - Specify the desired part to extract. The part number must range between [0,NumberOfParts-1]. If the value is =(-1), then all parts will be extracted. If the value is ¡(-1), then no parts will be extracted but the part colors will be updated.
- `obj.SetMerging (int )` - Turn on/off merging of points/triangles.
- `int = obj.GetMerging ()` - Turn on/off merging of points/triangles.
- `obj.MergingOn ()` - Turn on/off merging of points/triangles.
- `obj.MergingOff ()` - Turn on/off merging of points/triangles.
- `obj.SetLocator (vtkIncrementalPointLocator locator)` - Specify a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `vtkIncrementalPointLocator = obj.GetLocator ()` - Specify a spatial locator for merging points. By default an instance of vtkMergePoints is used.
- `obj.CreateDefaultLocator ()` - Create default locator. Used to create one when none is specified.

37.110 vtkUnstructuredGridReader

37.110.1 Usage

vtkUnstructuredGridReader is a source object that reads ASCII or binary unstructured grid data files in vtk format. (see text for format details). The output of this reader is a single vtkUnstructuredGrid data object. The superclass of this class, vtkDataReader, provides many methods for controlling the reading of the data file, see vtkDataReader for more information.

To create an instance of class vtkUnstructuredGridReader, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridReader
```

37.110.2 Methods

The class vtkUnstructuredGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridReader = obj.NewInstance ()`
- `vtkUnstructuredGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkUnstructuredGrid = obj.GetOutput ()` - Get the output of this reader.
- `vtkUnstructuredGrid = obj.GetOutput (int idx)` - Get the output of this reader.
- `obj.SetOutput (vtkUnstructuredGrid output)` - Get the output of this reader.

37.111 vtkUnstructuredGridWriter

37.111.1 Usage

vtkUnstructuredGridWriter is a source object that writes ASCII or binary unstructured grid data files in vtk format. See text for format details.

To create an instance of class vtkUnstructuredGridWriter, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridWriter
```

37.111.2 Methods

The class vtkUnstructuredGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridWriter = obj.NewInstance ()`
- `vtkUnstructuredGridWriter = obj.SafeDownCast (vtkObject o)`
- `vtkUnstructuredGrid = obj.GetInput ()` - Get the input to this writer.
- `vtkUnstructuredGrid = obj.GetInput (int port)` - Get the input to this writer.

37.112 vtkVolume16Reader

37.112.1 Usage

vtkVolume16Reader is a source object that reads 16 bit image files.

Volume16Reader creates structured point datasets. The dimension of the dataset depends upon the number of files read. Reading a single file results in a 2D image, while reading more than one file results in a 3D volume.

File names are created using FilePattern and FilePrefix as follows: sprintf (filename, FilePattern, FilePrefix, number); where number is in the range ImageRange[0] to ImageRange[1]. If ImageRange[1] ¡= ImageRange[0], then slice number ImageRange[0] is read. Thus to read an image set ImageRange[0] = ImageRange[1] = slice number. The default behavior is to read a single file (i.e., image slice 1).

The DataMask instance variable is used to read data files with imbedded connectivity or segmentation information. For example, some data has the high order bit set to indicate connected surface. The DataMask allows you to select this data. Other important ivars include HeaderSize, which allows you to skip over initial info, and SwapBytes, which turns on/off byte swapping.

The Transform instance variable specifies a permutation transformation to map slice space into world space. vtkImageReader has replaced the functionality of this class and should be used instead.

To create an instance of class vtkVolume16Reader, simply invoke its constructor as follows

```
obj = vtkVolume16Reader
```

37.112.2 Methods

The class vtkVolume16Reader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolume16Reader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolume16Reader = obj.NewInstance ()`
- `vtkVolume16Reader = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataDimensions (int , int )` - Specify the dimensions for the data.
- `obj.SetDataDimensions (int  a[2])` - Specify the dimensions for the data.
- `int = obj. GetDataDimensions ()` - Specify the dimensions for the data.
- `obj.SetDataMask (short )` - Specify a mask used to eliminate data in the data file (e.g., connectivity bits).
- `short = obj.GetDataMask ()` - Specify a mask used to eliminate data in the data file (e.g., connectivity bits).
- `obj.SetHeaderSize (int )` - Specify the number of bytes to seek over at start of image.
- `int = obj.GetHeaderSize ()` - Specify the number of bytes to seek over at start of image.
- `obj.SetDataByteOrderToBigEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.

- `obj.SetDataByteOrderToLittleEndian ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `int = obj.GetDataByteOrder ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `obj.SetDataByteOrder (int )` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `string = obj.GetDataByteOrderAsString ()` - These methods should be used instead of the SwapBytes methods. They indicate the byte ordering of the file you are trying to read in. These methods will then either swap or not swap the bytes depending on the byte ordering of the machine it is being run on. For example, reading in a BigEndian file on a BigEndian machine will result in no swapping. Trying to read the same file on a LittleEndian machine will result in swapping. As a quick note most UNIX machines are BigEndian while PC's and VAX tend to be LittleEndian. So if the file you are reading in was generated on a VAX or PC, SetDataByteOrderToLittleEndian otherwise SetDataByteOrderToBigEndian.
- `obj.SetSwapBytes (int )` - Turn on/off byte swapping.
- `int = obj.GetSwapBytes ()` - Turn on/off byte swapping.
- `obj.SwapBytesOn ()` - Turn on/off byte swapping.
- `obj.SwapBytesOff ()` - Turn on/off byte swapping.
- `obj.SetTransform (vtkTransform )` - Set/Get transformation matrix to transform the data from slice space into world space. This matrix must be a permutation matrix. To qualify, the sums of the rows must be + or - 1.
- `vtkTransform = obj.GetTransform ()` - Set/Get transformation matrix to transform the data from slice space into world space. This matrix must be a permutation matrix. To qualify, the sums of the rows must be + or - 1.
- `vtkImageData = obj.GetImage (int ImageNumber)` - Other objects make use of these methods

37.113 vtkVolumeReader

37.113.1 Usage

vtkVolumeReader is a source object that reads image files.

VolumeReader creates structured point datasets. The dimension of the dataset depends upon the number of files read. Reading a single file results in a 2D image, while reading more than one file results in a 3D volume.

File names are created using FilePattern and FilePrefix as follows: sprintf (filename, FilePattern, FilePrefix, number); where number is in the range ImageRange[0] to ImageRange[1]. If ImageRange[1] ¡= ImageRange[0], then slice number ImageRange[0] is read. Thus to read an image set ImageRange[0] = ImageRange[1] = slice number. The default behavior is to read a single file (i.e., image slice 1).

The DataMask instance variable is used to read data files with imbedded connectivity or segmentation information. For example, some data has the high order bit set to indicate connected surface. The DataMask allows you to select this data. Other important ivars include HeaderSize, which allows you to skip over initial info, and SwapBytes, which turns on/off byte swapping. Consider using vtkImageReader as a replacement.

To create an instance of class vtkVolumeReader, simply invoke its constructor as follows

```
obj = vtkVolumeReader
```

37.113.2 Methods

The class vtkVolumeReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeReader = obj.NewInstance ()`
- `vtkVolumeReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilePrefix (string )` - Specify file prefix for the image file(s).
- `string = obj.GetFilePrefix ()` - Specify file prefix for the image file(s).
- `obj.SetFilePattern (string )` - The sprintf format used to build filename from FilePrefix and number.
- `string = obj.GetFilePattern ()` - The sprintf format used to build filename from FilePrefix and number.
- `obj.SetImageRange (int , int )` - Set the range of files to read.
- `obj.SetImageRange (int  a[2])` - Set the range of files to read.
- `int = obj. GetImageRange ()` - Set the range of files to read.
- `obj.SetDataSpacing (double , double , double )` - Specify the spacing for the data.
- `obj.SetDataSpacing (double  a[3])` - Specify the spacing for the data.
- `double = obj. GetDataSpacing ()` - Specify the spacing for the data.
- `obj.SetDataOrigin (double , double , double )` - Specify the origin for the data.
- `obj.SetDataOrigin (double  a[3])` - Specify the origin for the data.
- `double = obj. GetDataOrigin ()` - Specify the origin for the data.
- `vtkImageData = obj.GetImage (int ImageNumber)` - Other objects make use of this method.

37.114 vtkWriter

37.114.1 Usage

vtkWriter is an abstract class for mapper objects that write their data to disk (or into a communications port). All writers respond to Write() method. This method insures that there is input and input is up to date.

To create an instance of class vtkWriter, simply invoke its constructor as follows

```
obj = vtkWriter
```

37.114.2 Methods

The class vtkWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWriter = obj.NewInstance ()`
- `vtkWriter = obj.SafeDownCast (vtkObject o)`
- `int = obj.Write ()` - Write data to output. Method executes subclasses WriteData() method, as well as StartMethod() and EndMethod() methods. Returns 1 on success and 0 on failure.
- `obj.EncodeString (string resname, string name, bool doublePercent)` - Encode the string so that the reader will not have problems. The resulting string is up to three times the size of the input string. doublePercent indicates whether to output a double 'escaped characters so the string may be used as a printf format string.
- `obj.SetInput (vtkDataObject input)` - Set/get the input to this writer.
- `obj.SetInput (int index, vtkDataObject input)` - Set/get the input to this writer.

37.115 vtkXMLCompositeDataReader

37.115.1 Usage

vtkXMLCompositeDataReader reads the VTK XML multi-group data file format. XML multi-group data files are meta-files that point to a list of serial VTK XML files. When reading in parallel, it will distribute sub-blocks among processor. If the number of sub-blocks is less than the number of processors, some processors will not have any sub-blocks for that group. If the number of sub-blocks is larger than the number of processors, each processor will possibly have more than 1 sub-block.

To create an instance of class vtkXMLCompositeDataReader, simply invoke its constructor as follows

```
obj = vtkXMLCompositeDataReader
```

37.115.2 Methods

The class vtkXMLCompositeDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLCompositeDataReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkXMLCompositeDataReader = obj.NewInstance ()`
- `vtkXMLCompositeDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkCompositeDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkCompositeDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.

37.116 vtkXMLCompositeDataWriter

37.116.1 Usage

vtkXMLCompositeDataWriter writes (serially) the VTK XML multi-group, multi-block hierarchical and hierarchical box files. XML multi-group data files are meta-files that point to a list of serial VTK XML files.

To create an instance of class vtkXMLCompositeDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLCompositeDataWriter
```

37.116.2 Methods

The class vtkXMLCompositeDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLCompositeDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLCompositeDataWriter = obj.NewInstance ()`
- `vtkXMLCompositeDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.
- `int = obj.GetGhostLevel ()` - Get/Set the number of ghost levels to be written.
- `obj.SetGhostLevel (int )` - Get/Set the number of ghost levels to be written.
- `int = obj.GetWriteMetaFile ()` - Get/Set whether this instance will write the meta-file.
- `obj.SetWriteMetaFile (int flag)` - Get/Set whether this instance will write the meta-file.

37.117 vtkXMLDataParser

37.117.1 Usage

vtkXMLDataParser provides a subclass of vtkXMLParser that constructs a representation of an XML data format's file using vtkXMLDataElement to represent each XML element. This representation is then used by vtkXMLReader and its subclasses to traverse the structure of the file and extract data.

To create an instance of class vtkXMLDataParser, simply invoke its constructor as follows

```
obj = vtkXMLDataParser
```

37.117.2 Methods

The class vtkXMLDataParser has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLDataParser class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLDataParser = obj.NewInstance ()`
- `vtkXMLDataParser = obj.SafeDownCast (vtkObject o)`
- `vtkXMLDataElement = obj.GetRootElement ()` - Get the root element from the XML document.
- `obj.SetCompressor (vtkDataCompressor )` - Get/Set the compressor used to decompress binary and appended data after reading from the file.
- `vtkDataCompressor = obj.GetCompressor ()` - Get/Set the compressor used to decompress binary and appended data after reading from the file.
- `long = obj.GetWordTypeSize (int wordType)` - Get the size of a word of the given type.
- `int = obj.Parse ()` - Parse the XML input and check that the file is safe to read. Returns 1 for okay, 0 for error.
- `int = obj.GetAbort ()` - Get/Set flag to abort reading of data. This may be set by a progress event observer.
- `obj.SetAbort (int )` - Get/Set flag to abort reading of data. This may be set by a progress event observer.
- `float = obj.GetProgress ()` - Get/Set progress of reading data. This may be checked by a progress event observer.
- `obj.SetProgress (float )` - Get/Set progress of reading data. This may be checked by a progress event observer.
- `obj.SetAttributesEncoding (int )` - Get/Set the character encoding that will be used to set the attributes's encoding type of each vtkXMLDataElement created by this parser (i.e., the data element attributes will use that encoding internally). If set to VTK_ENCODING_NONE (default), the attribute encoding type will not be changed and will default to the vtkXMLDataElement default encoding type (see vtkXMLDataElement::AttributeEncoding).
- `int = obj.GetAttributesEncodingMinValue ()` - Get/Set the character encoding that will be used to set the attributes's encoding type of each vtkXMLDataElement created by this parser (i.e., the data element attributes will use that encoding internally). If set to VTK_ENCODING_NONE (default), the attribute encoding type will not be changed and will default to the vtkXMLDataElement default encoding type (see vtkXMLDataElement::AttributeEncoding).
- `int = obj.GetAttributesEncodingMaxValue ()` - Get/Set the character encoding that will be used to set the attributes's encoding type of each vtkXMLDataElement created by this parser (i.e., the data element attributes will use that encoding internally). If set to VTK_ENCODING_NONE (default), the attribute encoding type will not be changed and will default to the vtkXMLDataElement default encoding type (see vtkXMLDataElement::AttributeEncoding).

- `int = obj.GetAttributesEncoding ()` - Get/Set the character encoding that will be used to set the attributes's encoding type of each vtkXMLDataElement created by this parser (i.e., the data element attributes will use that encoding internally). If set to VTK_ENCODING_NONE (default), the attribute encoding type will not be changed and will default to the vtkXMLDataElement default encoding type (see vtkXMLDataElement::AttributeEncoding).

- `obj.CharacterDataHandler (string data, int length)` - If you need the text inside XMLElements, turn IgnoreCharacterData off. This method will then be called when the file is parsed, and the text will be stored in each XMLDataElement. VTK XML Readers store the information elsewhere, so the default is to ignore it.

37.118 vtkXMLDataReader

37.118.1 Usage

vtkXMLDataReader provides functionality common to all VTK XML file readers. Concrete subclasses call upon this functionality when needed.

To create an instance of class vtkXMLDataReader, simply invoke its constructor as follows

```
obj = vtkXMLDataReader
```

37.118.2 Methods

The class vtkXMLDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLDataReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkXMLDataReader = obj.NewInstance ()`

- `vtkXMLDataReader = obj.SafeDownCast (vtkObject o)`

- `vtkIdType = obj.GetNumberOfPoints ()` - Get the number of points in the output.

- `vtkIdType = obj.GetNumberOfCells ()` - Get the number of cells in the output.

- `obj.CopyOutputInformation (vtkInformation outInfo, int port)`

37.119 vtkXMLDataSetWriter

37.119.1 Usage

vtkXMLDataSetWriter is a wrapper around the VTK XML file format writers. Given an input vtkDataSet, the correct writer is automatically selected based on the type of input.

To create an instance of class vtkXMLDataSetWriter, simply invoke its constructor as follows

```
obj = vtkXMLDataSetWriter
```

37.119.2 Methods

The class vtkXMLDataSetWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLDataSetWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLDataSetWriter = obj.NewInstance ()`
- `vtkXMLDataSetWriter = obj.SafeDownCast (vtkObject o)`

37.120 vtkXMLFileReadTester

37.120.1 Usage

vtkXMLFileReadTester reads the smallest part of a file necessary to determine whether it is a VTK XML file. If so, it extracts the file type and version number.

To create an instance of class vtkXMLFileReadTester, simply invoke its constructor as follows

```
obj = vtkXMLFileReadTester
```

37.120.2 Methods

The class vtkXMLFileReadTester has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLFileReadTester class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLFileReadTester = obj.NewInstance ()`
- `vtkXMLFileReadTester = obj.SafeDownCast (vtkObject o)`
- `int = obj.TestReadFile ()` - Try to read the file given by FileName. Returns 1 if the file is a VTK XML file, and 0 otherwise.
- `obj.SetFileName (string )` - Get/Set the name of the file tested by TestReadFile().
- `string = obj.GetFileName ()` - Get/Set the name of the file tested by TestReadFile().
- `string = obj.GetFileDataType ()` - Get the data type of the XML file tested. If the file could not be read, returns NULL.
- `string = obj.GetFileVersion ()` - Get the file version of the XML file tested. If the file could not be read, returns NULL.

37.121 vtkXMLHierarchicalBoxDataReader

37.121.1 Usage

vtkXMLHierarchicalBoxDataReader reads the VTK XML hierarchical data file format. XML hierarchical data files are meta-files that point to a list of serial VTK XML files. When reading in parallel, it will distribute sub-blocks among processor. If the number of sub-blocks is less than the number of processors, some processors will not have any sub-blocks for that level. If the number of sub-blocks is larger than the number of processors, each processor will possibly have more than 1 sub-block.

To create an instance of class vtkXMLHierarchicalBoxDataReader, simply invoke its constructor as follows

```
obj = vtkXMLHierarchicalBoxDataReader
```

37.121.2 Methods

The class vtkXMLHierarchicalBoxDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLHierarchicalBoxDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLHierarchicalBoxDataReader = obj.NewInstance ()`
- `vtkXMLHierarchicalBoxDataReader = obj.SafeDownCast (vtkObject o)`

37.122 vtkXMLHierarchicalBoxDataWriter

37.122.1 Usage

vtkXMLHierarchicalBoxDataWriter is a vtkXMLCompositeDataWriter subclass to handle vtkHierarchicalBoxDataSet.

To create an instance of class vtkXMLHierarchicalBoxDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLHierarchicalBoxDataWriter
```

37.122.2 Methods

The class vtkXMLHierarchicalBoxDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLHierarchicalBoxDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLHierarchicalBoxDataWriter = obj.NewInstance ()`
- `vtkXMLHierarchicalBoxDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()`

37.123 vtkXMLHierarchicalDataReader

37.123.1 Usage

vtkXMLHierarchicalDataReader reads the VTK XML hierarchical data file format. XML hierarchical data files are meta-files that point to a list of serial VTK XML files. When reading in parallel, it will distribute sub-blocks among processor. If the number of sub-blocks is less than the number of processors, some processors will not have any sub-blocks for that level. If the number of sub-blocks is larger than the number of processors, each processor will possibly have more than 1 sub-block.

To create an instance of class vtkXMLHierarchicalDataReader, simply invoke its constructor as follows

```
obj = vtkXMLHierarchicalDataReader
```

37.123.2 Methods

The class vtkXMLHierarchicalDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLHierarchicalDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLHierarchicalDataReader = obj.NewInstance ()`
- `vtkXMLHierarchicalDataReader = obj.SafeDownCast (vtkObject o)`

37.124 vtkXMLHyperOctreeReader

37.124.1 Usage

vtkXMLHyperOctreeReader reads the VTK XML HyperOctree file format. One rectilinear grid file can be read to produce one output. Streaming is supported. The standard extension for this reader's file format is "vto". This reader is also used to read a single piece of the parallel file format.

To create an instance of class vtkXMLHyperOctreeReader, simply invoke its constructor as follows

```
obj = vtkXMLHyperOctreeReader
```

37.124.2 Methods

The class vtkXMLHyperOctreeReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLHyperOctreeReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLHyperOctreeReader = obj.NewInstance ()`
- `vtkXMLHyperOctreeReader = obj.SafeDownCast (vtkObject o)`
- `vtkHyperOctree = obj.GetOutput ()` - Get the reader's output.
- `vtkHyperOctree = obj.GetOutput (int idx)` - Get the reader's output.

37.125 vtkXMLHyperOctreeWriter

37.125.1 Usage

vtkXMLHyperOctreeWriter writes the VTK XML HyperOctree file format. One HyperOctree input can be written into one file in any number of streamed pieces. The standard extension for this writer's file format is "vto". This writer is also used to write a single piece of the parallel file format.

To create an instance of class vtkXMLHyperOctreeWriter, simply invoke its constructor as follows

```
obj = vtkXMLHyperOctreeWriter
```

37.125.2 Methods

The class vtkXMLHyperOctreeWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLHyperOctreeWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLHyperOctreeWriter = obj.NewInstance ()`
- `vtkXMLHyperOctreeWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.126 vtkXMLImageDataReader

37.126.1 Usage

vtkXMLImageDataReader reads the VTK XML ImageData file format. One image data file can be read to produce one output. Streaming is supported. The standard extension for this reader's file format is "vti". This reader is also used to read a single piece of the parallel file format.

To create an instance of class vtkXMLImageDataReader, simply invoke its constructor as follows

```
obj = vtkXMLImageDataReader
```

37.126.2 Methods

The class vtkXMLImageDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLImageDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLImageDataReader = obj.NewInstance ()`
- `vtkXMLImageDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkImageData = obj.GetOutput ()` - Get the reader's output.
- `vtkImageData = obj.GetOutput (int idx)` - Get the reader's output.
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)` - For the specified port, copy the information this reader sets up in SetupOutputInformation to outInfo

37.127 vtkXMLImageDataWriter

37.127.1 Usage

vtkXMLImageDataWriter writes the VTK XML ImageData file format. One image data input can be written into one file in any number of streamed pieces. The standard extension for this writer's file format is "vti". This writer is also used to write a single piece of the parallel file format.

To create an instance of class vtkXMLImageDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLImageDataWriter
```

37.127.2 Methods

The class vtkXMLImageDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLImageDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLImageDataWriter = obj.NewInstance ()`
- `vtkXMLImageDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.128 vtkXMLMaterial

37.128.1 Usage

vtkXMLMaterial encapsulates VTK Material description. It keeps a pointer to vtkXMLDataElement that defines the material and provides access to Shaders/Properties defined in it. .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkXMLMaterial, simply invoke its constructor as follows

```
obj = vtkXMLMaterial
```

37.128.2 Methods

The class vtkXMLMaterial has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLMaterial class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLMaterial = obj.NewInstance ()`
- `vtkXMLMaterial = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfProperties ()` - Get number of elements of type Property.
- `int = obj.GetNumberOfTextures ()` - Get number of elements of type Texture.
- `int = obj.GetNumberOfVertexShaders ()` - Get number of Vertex shaders.

- `int = obj.GetNumberOfFragmentShaders ()` - Get number of fragment shaders.
- `vtkXMLDataElement = obj.GetProperty (int id)` - Get the ith vtkXMLDataElement of type ¡Property /¿.
- `vtkXMLDataElement = obj.GetTexture (int id)` - Get the ith vtkXMLDataElement of type ¡Texture /¿.
- `vtkXMLShader = obj.GetVertexShader (int id)` - Get the ith vtkXMLDataElement of type ¡VertexShader /¿.
- `vtkXMLShader = obj.GetFragmentShader (int id)` - Get the ith vtkXMLDataElement of type ¡FragmentShader /¿.
- `vtkXMLDataElement = obj.GetRootElement ()` - Get/Set the XML root element that describes this material.
- `obj.SetRootElement (vtkXMLDataElement )` - Get/Set the XML root element that describes this material.
- `int = obj.GetShaderLanguage ()` - Get the Language used by the shaders in this Material. The Language of a vtkXMLMaterial is based on the Language of it's shaders.
- `int = obj.GetShaderStyle ()` - Get the style the shaders.

37.129 vtkXMLMaterialParser

37.129.1 Usage

vtkXMLMaterialParser parses a VTK Material file and provides that file's description of a number of vertex and fragment shaders along with data values specified for data members of vtkProperty. This material is to be applied to an actor through it's vtkProperty and augments VTK's concept of a vtkProperty to include explicitly include vertex and fragment shaders and parameter settings for those shaders. This effectively makes reflectance models and other shaders a material property. If no shaders are specified VTK should default to standard rendering.

.SECTION Design vtkXMLMaterialParser provides access to 3 distinct types of first-level vtkXMLDataElements that describe a VTK material. These elements are as follows:

vtkProperty - describe values for vtkProperty data members

vtkVertexShader - a vertex shader and enough information to install it into the hardware rendering pipeline including values for specific shader parameters and structures.

vtkFragmentShader - a fragment shader and enough information to install it into the hardware rendering pipeline including values for specific shader parameters and structures.

The design of the material file closely follows that of vtk's xml descriptions of it's data sets. This allows use of the very handy vtkXMLDataElement which provides easy access to an xml element's attribute values. Inlined data is currently not handled.

Ideally this class would be a Facade to a DOM parser, but VTK only provides access to expat, a SAX parser. Other vtk classes that parse xml files are tuned to read vtkDataSets and don't provide the functionality to handle generic xml data. As such they are of little use here.

This class may be extended for better data handling or may become a Facade to a DOM parser should on become part of the VTK code base. .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkXMLMaterialParser, simply invoke its constructor as follows

```
obj = vtkXMLMaterialParser
```

37.129.2 Methods

The class vtkXMLMaterialParser has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLMaterialParser class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLMaterialParser = obj.NewInstance ()`
- `vtkXMLMaterialParser = obj.SafeDownCast (vtkObject o)`
- `vtkXMLMaterial = obj.GetMaterial ()` - Set/Get the vtkXMLMaterial representation of the parsed material.
- `obj.SetMaterial (vtkXMLMaterial )` - Set/Get the vtkXMLMaterial representation of the parsed material.
- `int = obj.Parse ()` - Overridden to initialize the internal structures before the parsing begins.
- `int = obj.Parse (string inputString)` - Overridden to initialize the internal structures before the parsing begins.
- `int = obj.Parse (string inputString, int length)` - Overridden to initialize the internal structures before the parsing begins.
- `int = obj.InitializeParser ()` - Overridden to clean up internal structures before the chunk-parsing begins.

37.130 vtkXMLMaterialReader

37.130.1 Usage

vtkXMLMaterialReader provides access to three types of vtkXMLDataElement found in XML Material Files. This class sorts them by type and integer id from 0-N for N elements of a specific type starting with the first instance found.

.SECTION Design This class is basically a Facade for vtkXMLMaterialParser. Currently functionality is to only provide access to vtkXMLDataElements but further extensions may return higher level data structures.

Having both an vtkXMLMaterialParser and a vtkXMLMaterialReader is consistent with VTK's design for handling xml file and provides for future flexibility, that is better data handlers and interfacing with a DOM xml parser.

vtkProperty - defines values for some or all data members of vtkProperty

vtkVertexShader - defines vertex shaders

vtkFragmentShader - defines fragment shaders .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkXMLMaterialReader, simply invoke its constructor as follows

```
obj = vtkXMLMaterialReader
```

37.130.2 Methods

The class vtkXMLMaterialReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLMaterialReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLMaterialReader = obj.NewInstance ()`
- `vtkXMLMaterialReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Set and get file name.
- `string = obj.GetFileName ()` - Set and get file name.
- `obj.ReadMaterial ()` - Read the material file refered to in FileName. If the Reader hasn't changed since the last ReadMaterial(), it does not read the file again.
- `vtkXMLMaterial = obj.GetMaterial ()` - Get the Material representation read by the reader.

37.131 vtkXMLMultiBlockDataReader

37.131.1 Usage

vtkXMLMultiBlockDataReader reads the VTK XML multi-block data file format. XML multi-block data files are meta-files that point to a list of serial VTK XML files. When reading in parallel, it will distribute sub-blocks among processor. If the number of sub-blocks is less than the number of processors, some processors will not have any sub-blocks for that block. If the number of sub-blocks is larger than the number of processors, each processor will possibly have more than 1 sub-block.

To create an instance of class vtkXMLMultiBlockDataReader, simply invoke its constructor as follows

```
obj = vtkXMLMultiBlockDataReader
```

37.131.2 Methods

The class vtkXMLMultiBlockDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLMultiBlockDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLMultiBlockDataReader = obj.NewInstance ()`
- `vtkXMLMultiBlockDataReader = obj.SafeDownCast (vtkObject o)`

37.132 vtkXMLMultiBlockDataWriter

37.132.1 Usage

vtkXMLMultiBlockDataWriter is a vtkXMLCompositeDataWriter subclass to handle vtkMultiBlockDataSet.

To create an instance of class vtkXMLMultiBlockDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLMultiBlockDataWriter
```

37.132.2 Methods

The class vtkXMLMultiBlockDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLMultiBlockDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLMultiBlockDataWriter = obj.NewInstance ()`
- `vtkXMLMultiBlockDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()`

37.133 vtkXMLMultiGroupDataReader

37.133.1 Usage

vtkXMLMultiGroupDataReader is a legacy reader that reads multi group files into multiblock datasets.

To create an instance of class vtkXMLMultiGroupDataReader, simply invoke its constructor as follows

```
obj = vtkXMLMultiGroupDataReader
```

37.133.2 Methods

The class vtkXMLMultiGroupDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLMultiGroupDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLMultiGroupDataReader = obj.NewInstance ()`
- `vtkXMLMultiGroupDataReader = obj.SafeDownCast (vtkObject o)`

37.134 vtkXMLParser

37.134.1 Usage

vtkXMLParser reads a stream and parses XML element tags and corresponding attributes. Each element begin tag and its attributes are sent to the StartElement method. Each element end tag is sent to the EndElement method. Subclasses should replace these methods to actually use the tags. .SECTION ToDo: Add commands for parsing in Tcl.

To create an instance of class vtkXMLParser, simply invoke its constructor as follows

```
obj = vtkXMLParser
```

37.134.2 Methods

The class vtkXMLParser has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLParser class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLParser = obj.NewInstance ()`
- `vtkXMLParser = obj.SafeDownCast (vtkObject o)`
- `long = obj.TellG ()` - Used by subclasses and their supporting classes. These methods wrap around the tellg and seekg methods of the input stream to work-around stream bugs on various platforms.
- `obj.SeekG (long position)` - Used by subclasses and their supporting classes. These methods wrap around the tellg and seekg methods of the input stream to work-around stream bugs on various platforms.
- `int = obj.Parse ()` - Parse the XML input.
- `int = obj.Parse (string inputString)` - Parse the XML message. If length is specified, parse only the first "length" characters
- `int = obj.Parse (string inputString, int length)` - Parse the XML message. If length is specified, parse only the first "length" characters
- `int = obj.InitializeParser ()` - When parsing fragments of XML or streaming XML, use the following three methods. InitializeParser method initialize parser but does not perform any actual parsing. ParseChunk parses framgent of XML. This has to match to what was already parsed. CleanupParser finishes parsing. If there were errors, CleanupParser will report them.
- `int = obj.ParseChunk (string inputString, int length)` - When parsing fragments of XML or streaming XML, use the following three methods. InitializeParser method initialize parser but does not perform any actual parsing. ParseChunk parses framgent of XML. This has to match to what was already parsed. CleanupParser finishes parsing. If there were errors, CleanupParser will report them.
- `int = obj.CleanupParser ()` - When parsing fragments of XML or streaming XML, use the following three methods. InitializeParser method initialize parser but does not perform any actual parsing. ParseChunk parses framgent of XML. This has to match to what was already parsed. CleanupParser finishes parsing. If there were errors, CleanupParser will report them.
- `obj.SetFileName (string )` - Set and get file name.
- `string = obj.GetFileName ()` - Set and get file name.
- `obj.SetIgnoreCharacterData (int )` - If this is off (the default), CharacterDataHandler will be called to process text within XML Elements. If this is on, the text will be ignored.
- `int = obj.GetIgnoreCharacterData ()` - If this is off (the default), CharacterDataHandler will be called to process text within XML Elements. If this is on, the text will be ignored.
- `obj.SetEncoding (string )` - Set and get the encoding the parser should expect (NULL defaults to Expat's own default encoder, i.e UTF-8). This should be set before parsing (i.e. a call to Parse()) or even initializing the parser (i.e. a call to InitializeParser())
- `string = obj.GetEncoding ()` - Set and get the encoding the parser should expect (NULL defaults to Expat's own default encoder, i.e UTF-8). This should be set before parsing (i.e. a call to Parse()) or even initializing the parser (i.e. a call to InitializeParser())

37.135 vtkXMLPDataReader

37.135.1 Usage

vtkXMLPDataReader provides functionality common to all PVTK XML file readers. Concrete subclasses call upon this functionality when needed.

To create an instance of class vtkXMLPDataReader, simply invoke its constructor as follows

```
obj = vtkXMLPDataReader
```

37.135.2 Methods

The class vtkXMLPDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPDataReader = obj.NewInstance ()`
- `vtkXMLPDataReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfPieces ()` - Get the number of pieces from the summary file being read.
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)`

37.136 vtkXMLPDataSetWriter

37.136.1 Usage

vtkXMLPDataSetWriter is a wrapper around the PVTK XML file format writers. Given an input vtkDataSet, the correct writer is automatically selected based on the type of input.

To create an instance of class vtkXMLPDataSetWriter, simply invoke its constructor as follows

```
obj = vtkXMLPDataSetWriter
```

37.136.2 Methods

The class vtkXMLPDataSetWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPDataSetWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPDataSetWriter = obj.NewInstance ()`
- `vtkXMLPDataSetWriter = obj.SafeDownCast (vtkObject o)`

37.137 vtkXMLPDataWriter

37.137.1 Usage

vtkXMLPDataWriter is the superclass for all XML parallel data set writers. It provides functionality needed for writing parallel formats, such as the selection of which writer writes the summary file and what range of pieces are assigned to each serial writer.

To create an instance of class vtkXMLPDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPDataWriter
```

37.137.2 Methods

The class vtkXMLPDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPDataWriter = obj.NewInstance ()`
- `vtkXMLPDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPieces (int )` - Get/Set the number of pieces that are being written in parallel.
- `int = obj.GetNumberOfPieces ()` - Get/Set the number of pieces that are being written in parallel.
- `obj.SetStartPiece (int )` - Get/Set the range of pieces assigned to this writer.
- `int = obj.GetStartPiece ()` - Get/Set the range of pieces assigned to this writer.
- `obj.SetEndPiece (int )` - Get/Set the range of pieces assigned to this writer.
- `int = obj.GetEndPiece ()` - Get/Set the range of pieces assigned to this writer.
- `obj.SetGhostLevel (int )` - Get/Set the ghost level used for this writer's piece.
- `int = obj.GetGhostLevel ()` - Get/Set the ghost level used for this writer's piece.
- `obj.SetWriteSummaryFile (int flag)` - Get/Set whether this instance of the writer should write the summary file that refers to all of the pieces' individual files. Default is yes only for piece 0 writer.
- `int = obj.GetWriteSummaryFile ()` - Get/Set whether this instance of the writer should write the summary file that refers to all of the pieces' individual files. Default is yes only for piece 0 writer.
- `obj.WriteSummaryFileOn ()` - Get/Set whether this instance of the writer should write the summary file that refers to all of the pieces' individual files. Default is yes only for piece 0 writer.
- `obj.WriteSummaryFileOff ()` - Get/Set whether this instance of the writer should write the summary file that refers to all of the pieces' individual files. Default is yes only for piece 0 writer.

37.138 vtkXMLPImageDataReader

37.138.1 Usage

vtkXMLPImageDataReader reads the PVTK XML ImageData file format. This reads the parallel format's summary file and then uses vtkXMLImageDataReader to read data from the individual ImageData piece files. Streaming is supported. The standard extension for this reader's file format is "pvti".

To create an instance of class vtkXMLPImageDataReader, simply invoke its constructor as follows

```
obj = vtkXMLPImageDataReader
```

37.138.2 Methods

The class vtkXMLPImageDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPImageDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPImageDataReader = obj.NewInstance ()`
- `vtkXMLPImageDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkImageData = obj.GetOutput ()` - Get the reader's output.
- `vtkImageData = obj.GetOutput (int idx)` - Get the reader's output.
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)`

37.139 vtkXMLPImageDataWriter

37.139.1 Usage

vtkXMLPImageDataWriter writes the PVTK XML ImageData file format. One image data input can be written into a parallel file format with any number of pieces spread across files. The standard extension for this writer's file format is "pvti". This writer uses vtkXMLImageDataWriter to write the individual piece files.

To create an instance of class vtkXMLPImageDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPImageDataWriter
```

37.139.2 Methods

The class vtkXMLPImageDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPImageDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPImageDataWriter = obj.NewInstance ()`
- `vtkXMLPImageDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.140 vtkXMLPolyDataReader

37.140.1 Usage

vtkXMLPolyDataReader reads the VTK XML PolyData file format. One polygonal data file can be read to produce one output. Streaming is supported. The standard extension for this reader's file format is "vtp". This reader is also used to read a single piece of the parallel file format.

To create an instance of class vtkXMLPolyDataReader, simply invoke its constructor as follows

```
obj = vtkXMLPolyDataReader
```

37.140.2 Methods

The class vtkXMLPolyDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPolyDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPolyDataReader = obj.NewInstance ()`
- `vtkXMLPolyDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetOutput ()` - Get the reader's output.
- `vtkPolyData = obj.GetOutput (int idx)` - Get the reader's output.
- `vtkIdType = obj.GetNumberOfVerts ()` - Get the number of verts/lines/strips/polys in the output.
- `vtkIdType = obj.GetNumberOfLines ()` - Get the number of verts/lines/strips/polys in the output.
- `vtkIdType = obj.GetNumberOfStrips ()` - Get the number of verts/lines/strips/polys in the output.
- `vtkIdType = obj.GetNumberOfPolys ()` - Get the number of verts/lines/strips/polys in the output.

37.141 vtkXMLPolyDataWriter

37.141.1 Usage

vtkXMLPolyDataWriter writes the VTK XML PolyData file format. One polygonal data input can be written into one file in any number of streamed pieces (if supported by the rest of the pipeline). The standard extension for this writer's file format is "vtp". This writer is also used to write a single piece of the parallel file format.

To create an instance of class vtkXMLPolyDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPolyDataWriter
```

37.141.2 Methods

The class vtkXMLPolyDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPolyDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPolyDataWriter = obj.NewInstance ()`
- `vtkXMLPolyDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.142 vtkXMLPPolyDataReader

37.142.1 Usage

vtkXMLPPolyDataReader reads the PVTK XML PolyData file format. This reads the parallel format's summary file and then uses vtkXMLPolyDataReader to read data from the individual PolyData piece files. Streaming is supported. The standard extension for this reader's file format is "pvtp".

To create an instance of class vtkXMLPPolyDataReader, simply invoke its constructor as follows

```
obj = vtkXMLPPolyDataReader
```

37.142.2 Methods

The class vtkXMLPPolyDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPPolyDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPPolyDataReader = obj.NewInstance ()`
- `vtkXMLPPolyDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetOutput ()` - Get the reader's output.
- `vtkPolyData = obj.GetOutput (int idx)` - Get the reader's output.

37.143 vtkXMLPPolyDataWriter

37.143.1 Usage

vtkXMLPPolyDataWriter writes the PVTK XML PolyData file format. One poly data input can be written into a parallel file format with any number of pieces spread across files. The standard extension for this writer's file format is "pvtp". This writer uses vtkXMLPolyDataWriter to write the individual piece files.

To create an instance of class vtkXMLPPolyDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPPolyDataWriter
```

37.143.2 Methods

The class vtkXMLPPolyDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPPolyDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPPolyDataWriter = obj.NewInstance ()`
- `vtkXMLPPolyDataWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.144 vtkXMLPRectilinearGridReader

37.144.1 Usage

vtkXMLPRectilinearGridReader reads the PVTK XML RectilinearGrid file format. This reads the parallel format's summary file and then uses vtkXMLRectilinearGridReader to read data from the individual RectilinearGrid piece files. Streaming is supported. The standard extension for this reader's file format is "pvtr".

To create an instance of class vtkXMLPRectilinearGridReader, simply invoke its constructor as follows

```
obj = vtkXMLPRectilinearGridReader
```

37.144.2 Methods

The class vtkXMLPRectilinearGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPRectilinearGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPRectilinearGridReader = obj.NewInstance ()`
- `vtkXMLPRectilinearGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkRectilinearGrid = obj.GetOutput ()` - Get the reader's output.
- `vtkRectilinearGrid = obj.GetOutput (int idx)` - Get the reader's output.

37.145 vtkXMLPRectilinearGridWriter

37.145.1 Usage

vtkXMLPRectilinearGridWriter writes the PVTK XML RectilinearGrid file format. One rectilinear grid input can be written into a parallel file format with any number of pieces spread across files. The standard extension for this writer's file format is "pvtr". This writer uses vtkXMLRectilinearGridWriter to write the individual piece files.

To create an instance of class vtkXMLPRectilinearGridWriter, simply invoke its constructor as follows

```
obj = vtkXMLPRectilinearGridWriter
```

37.145.2 Methods

The class vtkXMLPRectilinearGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPRectilinearGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPRectilinearGridWriter = obj.NewInstance ()`
- `vtkXMLPRectilinearGridWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.146 vtkXMLPStructuredDataReader

37.146.1 Usage

vtkXMLPStructuredDataReader provides functionality common to all parallel structured data format readers.

To create an instance of class vtkXMLPStructuredDataReader, simply invoke its constructor as follows

```
obj = vtkXMLPStructuredDataReader
```

37.146.2 Methods

The class vtkXMLPStructuredDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPStructuredDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPStructuredDataReader = obj.NewInstance ()`
- `vtkXMLPStructuredDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkExtentTranslator = obj.GetExtentTranslator ()` - Get an extent translator that will create pieces matching the input file's piece breakdown. This can be used further down the pipeline to prevent reading from outside this process's piece. The translator is only valid after an UpdateInformation has been called.
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)`

37.147 vtkXMLPStructuredDataWriter

37.147.1 Usage

vtkXMLPStructuredDataWriter provides PVTK XML writing functionality that is common among all the parallel structured data formats.

To create an instance of class vtkXMLPStructuredDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPStructuredDataWriter
```

37.147.2 Methods

The class vtkXMLPStructuredDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPStructuredDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPStructuredDataWriter = obj.NewInstance ()`
- `vtkXMLPStructuredDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetExtentTranslator (vtkExtentTranslator )` - Get/Set the extent translator used for creating pieces.
- `vtkExtentTranslator = obj.GetExtentTranslator ()` - Get/Set the extent translator used for creating pieces.

37.148 vtkXMLPStructuredGridReader

37.148.1 Usage

vtkXMLPStructuredGridReader reads the PVTK XML StructuredGrid file format. This reads the parallel format's summary file and then uses vtkXMLStructuredGridReader to read data from the individual StructuredGrid piece files. Streaming is supported. The standard extension for this reader's file format is "pvts".

To create an instance of class vtkXMLPStructuredGridReader, simply invoke its constructor as follows

```
obj = vtkXMLPStructuredGridReader
```

37.148.2 Methods

The class vtkXMLPStructuredGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPStructuredGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPStructuredGridReader = obj.NewInstance ()`
- `vtkXMLPStructuredGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkStructuredGrid = obj.GetOutput ()` - Get the reader's output.
- `vtkStructuredGrid = obj.GetOutput (int idx)` - Needed for ParaView

37.149 vtkXMLPStructuredGridWriter

37.149.1 Usage

vtkXMLPStructuredGridWriter writes the PVTK XML StructuredGrid file format. One structured grid input can be written into a parallel file format with any number of pieces spread across files. The standard extension for this writer's file format is "pvts". This writer uses vtkXMLStructuredGridWriter to write the individual piece files.

To create an instance of class vtkXMLPStructuredGridWriter, simply invoke its constructor as follows

```
obj = vtkXMLPStructuredGridWriter
```

37.149.2 Methods

The class vtkXMLPStructuredGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPStructuredGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPStructuredGridWriter = obj.NewInstance ()`
- `vtkXMLPStructuredGridWriter = obj.SafeDownCast (vtkObject o)`

37.150 vtkXMLPUnstructuredDataReader

37.150.1 Usage

vtkXMLPUnstructuredDataReader provides functionality common to all parallel unstructured data format readers.

To create an instance of class vtkXMLPUnstructuredDataReader, simply invoke its constructor as follows

```
obj = vtkXMLPUnstructuredDataReader
```

37.150.2 Methods

The class vtkXMLPUnstructuredDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPUnstructuredDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPUnstructuredDataReader = obj.NewInstance ()`
- `vtkXMLPUnstructuredDataReader = obj.SafeDownCast (vtkObject o)`
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)`

37.151 vtkXMLPUnstructuredDataWriter

37.151.1 Usage

vtkXMLPUnstructuredDataWriter provides PVTK XML writing functionality that is common among all the parallel unstructured data formats.

To create an instance of class vtkXMLPUnstructuredDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPUnstructuredDataWriter
```

37.151.2 Methods

The class vtkXMLPUnstructuredDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPUnstructuredDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPUnstructuredDataWriter = obj.NewInstance ()`
- `vtkXMLPUnstructuredDataWriter = obj.SafeDownCast (vtkObject o)`

37.152 vtkXMLPUnstructuredGridReader

37.152.1 Usage

vtkXMLPUnstructuredGridReader reads the PVTK XML UnstructuredGrid file format. This reads the parallel format's summary file and then uses vtkXMLUnstructuredGridReader to read data from the individual UnstructuredGrid piece files. Streaming is supported. The standard extension for this reader's file format is "pvtu".

To create an instance of class vtkXMLPUnstructuredGridReader, simply invoke its constructor as follows

```
obj = vtkXMLPUnstructuredGridReader
```

37.152.2 Methods

The class vtkXMLPUnstructuredGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPUnstructuredGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPUnstructuredGridReader = obj.NewInstance ()`
- `vtkXMLPUnstructuredGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkUnstructuredGrid = obj.GetOutput ()` - Get the reader's output.
- `vtkUnstructuredGrid = obj.GetOutput (int idx)` - Get the reader's output.

37.153 vtkXMLPUnstructuredGridWriter

37.153.1 Usage

vtkXMLPUnstructuredGridWriter writes the PVTK XML UnstructuredGrid file format. One unstructured grid input can be written into a parallel file format with any number of pieces spread across files. The standard extension for this writer's file format is "pvtu". This writer uses vtkXMLUnstructuredGridWriter to write the individual piece files.

To create an instance of class vtkXMLPUnstructuredGridWriter, simply invoke its constructor as follows

```
obj = vtkXMLPUnstructuredGridWriter
```

37.153.2 Methods

The class vtkXMLPUnstructuredGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPUnstructuredGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPUnstructuredGridWriter = obj.NewInstance ()`
- `vtkXMLPUnstructuredGridWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.154 vtkXMLReader

37.154.1 Usage

vtkXMLReader uses vtkXMLDataParser to parse a VTK XML input file. Concrete subclasses then traverse the parsed file structure and extract data.

To create an instance of class vtkXMLReader, simply invoke its constructor as follows

```
obj = vtkXMLReader
```

37.154.2 Methods

The class vtkXMLReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLReader = obj.NewInstance ()`
- `vtkXMLReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Get/Set the name of the input file.
- `string = obj.GetFileName ()` - Get/Set the name of the input file.
- `int = obj.CanReadFile (string name)` - Test whether the file with the given name can be read by this reader.
- `vtkDataSet = obj.GetOutputAsDataSet ()` - Get the output as a vtkDataSet pointer.
- `vtkDataSet = obj.GetOutputAsDataSet (int index)` - Get the output as a vtkDataSet pointer.
- `vtkDataArraySelection = obj.GetPointDataArraySelection ()` - Get the data array selection tables used to configure which data arrays are loaded by the reader.
- `vtkDataArraySelection = obj.GetCellDataArraySelection ()` - Get the data array selection tables used to configure which data arrays are loaded by the reader.
- `int = obj.GetNumberOfPointArrays ()` - Get the number of point or cell arrays available in the input.
- `int = obj.GetNumberOfCellArrays ()` - Get the number of point or cell arrays available in the input.
- `string = obj.GetPointArrayName (int index)` - Get the name of the point or cell array with the given index in the input.
- `string = obj.GetCellArrayName (int index)` - Get the name of the point or cell array with the given index in the input.
- `int = obj.GetPointArrayStatus (string name)` - Get/Set whether the point or cell array with the given name is to be read.
- `int = obj.GetCellArrayStatus (string name)` - Get/Set whether the point or cell array with the given name is to be read.
- `obj.SetPointArrayStatus (string name, int status)` - Get/Set whether the point or cell array with the given name is to be read.

- `obj.SetCellArrayStatus (string name, int status)` - Get/Set whether the point or cell array with the given name is to be read.
- `obj.CopyOutputInformation (vtkInformation , int )` - Which TimeStep to read.
- `obj.SetTimeStep (int )` - Which TimeStep to read.
- `int = obj.GetTimeStep ()` - Which TimeStep to read.
- `int = obj.GetNumberOfTimeSteps ()`
- `int = obj. GetTimeStepRange ()` - Which TimeStepRange to read
- `obj.SetTimeStepRange (int , int )` - Which TimeStepRange to read
- `obj.SetTimeStepRange (int  a[2])` - Which TimeStepRange to read

37.155 vtkXMLRectilinearGridReader

37.155.1 Usage

vtkXMLRectilinearGridReader reads the VTK XML RectilinearGrid file format. One rectilinear grid file can be read to produce one output. Streaming is supported. The standard extension for this reader's file format is "vtr". This reader is also used to read a single piece of the parallel file format.

To create an instance of class vtkXMLRectilinearGridReader, simply invoke its constructor as follows

```
obj = vtkXMLRectilinearGridReader
```

37.155.2 Methods

The class vtkXMLRectilinearGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLRectilinearGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLRectilinearGridReader = obj.NewInstance ()`
- `vtkXMLRectilinearGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkRectilinearGrid = obj.GetOutput ()` - Get the reader's output.
- `vtkRectilinearGrid = obj.GetOutput (int idx)` - Get the reader's output.

37.156 vtkXMLRectilinearGridWriter

37.156.1 Usage

vtkXMLRectilinearGridWriter writes the VTK XML RectilinearGrid file format. One rectilinear grid input can be written into one file in any number of streamed pieces. The standard extension for this writer's file format is "vtr". This writer is also used to write a single piece of the parallel file format.

To create an instance of class vtkXMLRectilinearGridWriter, simply invoke its constructor as follows

```
obj = vtkXMLRectilinearGridWriter
```

37.156.2 Methods

The class vtkXMLRectilinearGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLRectilinearGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLRectilinearGridWriter = obj.NewInstance ()`
- `vtkXMLRectilinearGridWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.157 vtkXMLShader

37.157.1 Usage

vtkXMLShader encapsulates the XML description for a Shader. It provides convenient access to various attributes/properties of a shader. .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkXMLShader, simply invoke its constructor as follows

```
obj = vtkXMLShader
```

37.157.2 Methods

The class vtkXMLShader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLShader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLShader = obj.NewInstance ()`
- `vtkXMLShader = obj.SafeDownCast (vtkObject o)`
- `vtkXMLDataElement = obj.GetRootElement ()` - Get/Set the XML root element that describes this shader.
- `obj.SetRootElement (vtkXMLDataElement )` - Get/Set the XML root element that describes this shader.
- `int = obj.GetLanguage ()` - Returns the shader's language as defined in the XML description.
- `int = obj.GetScope ()` - Returns the type of the shader as defined in the XML description.
- `int = obj.GetLocation ()` - Returns the location of the shader as defined in the XML description.
- `int = obj.GetStyle ()` - Returns the style of the shader as optionaly defined in the XML description. If not present, default style is 1. "style=2" means it is a shader without a main(). In style 2, the "main" function for the vertex shader part is void propFuncVS(void), the main function for the fragment shader part is void propFuncFS(). This is useful when combining a shader at the actor level and a shader defines at the renderer level, like the depth peeling pass.

- `string = obj.GetName ()` - Get the name of the Shader.
- `string = obj.GetEntry ()` - Get the entry point to the shader code as defined in the XML.
- `string = obj.GetCode ()` - Get the shader code.

37.158 vtkXMLStructuredDataReader

37.158.1 Usage

vtkXMLStructuredDataReader provides functionality common to all structured data format readers.

To create an instance of class vtkXMLStructuredDataReader, simply invoke its constructor as follows

```
obj = vtkXMLStructuredDataReader
```

37.158.2 Methods

The class vtkXMLStructuredDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLStructuredDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLStructuredDataReader = obj.NewInstance ()`
- `vtkXMLStructuredDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetNumberOfPoints ()` - Get the number of points in the output.
- `vtkIdType = obj.GetNumberOfCells ()` - Get the number of cells in the output.
- `obj.SetWholeSlices (int )` - Get/Set whether the reader gets a whole slice from disk when only a rectangle inside it is needed. This mode reads more data than necessary, but prevents many short reads from interacting poorly with the compression and encoding schemes.
- `int = obj.GetWholeSlices ()` - Get/Set whether the reader gets a whole slice from disk when only a rectangle inside it is needed. This mode reads more data than necessary, but prevents many short reads from interacting poorly with the compression and encoding schemes.
- `obj.WholeSlicesOn ()` - Get/Set whether the reader gets a whole slice from disk when only a rectangle inside it is needed. This mode reads more data than necessary, but prevents many short reads from interacting poorly with the compression and encoding schemes.
- `obj.WholeSlicesOff ()` - Get/Set whether the reader gets a whole slice from disk when only a rectangle inside it is needed. This mode reads more data than necessary, but prevents many short reads from interacting poorly with the compression and encoding schemes.
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)` - For the specified port, copy the information this reader sets up in SetupOutputInformation to outInfo

37.159 vtkXMLStructuredDataWriter

37.159.1 Usage

vtkXMLStructuredDataWriter provides VTK XML writing functionality that is common among all the structured data formats.

To create an instance of class vtkXMLStructuredDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLStructuredDataWriter
```

37.159.2 Methods

The class vtkXMLStructuredDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLStructuredDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLStructuredDataWriter = obj.NewInstance ()`
- `vtkXMLStructuredDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPieces (int )` - Get/Set the number of pieces used to stream the image through the pipeline while writing to the file.
- `int = obj.GetNumberOfPieces ()` - Get/Set the number of pieces used to stream the image through the pipeline while writing to the file.
- `obj.SetWriteExtent (int , int , int , int , int , int )` - Get/Set the extent of the input that should be treated as the WholeExtent in the output file. The default is the WholeExtent of the input.
- `obj.SetWriteExtent (int  a[6])` - Get/Set the extent of the input that should be treated as the WholeExtent in the output file. The default is the WholeExtent of the input.
- `int = obj. GetWriteExtent ()` - Get/Set the extent of the input that should be treated as the WholeExtent in the output file. The default is the WholeExtent of the input.
- `obj.SetExtentTranslator (vtkExtentTranslator )` - Get/Set the extent translator used for streaming.
- `vtkExtentTranslator = obj.GetExtentTranslator ()` - Get/Set the extent translator used for streaming.

37.160 vtkXMLStructuredGridReader

37.160.1 Usage

vtkXMLStructuredGridReader reads the VTK XML StructuredGrid file format. One structured grid file can be read to produce one output. Streaming is supported. The standard extension for this reader's file format is "vts". This reader is also used to read a single piece of the parallel file format.

To create an instance of class vtkXMLStructuredGridReader, simply invoke its constructor as follows

```
obj = vtkXMLStructuredGridReader
```

37.160.2 Methods

The class vtkXMLStructuredGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLStructuredGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLStructuredGridReader = obj.NewInstance ()`
- `vtkXMLStructuredGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkStructuredGrid = obj.GetOutput ()` - Get the reader's output.
- `vtkStructuredGrid = obj.GetOutput (int idx)` - Get the reader's output.

37.161 vtkXMLStructuredGridWriter

37.161.1 Usage

vtkXMLStructuredGridWriter writes the VTK XML StructuredGrid file format. One structured grid input can be written into one file in any number of streamed pieces. The standard extension for this writer's file format is "vts". This writer is also used to write a single piece of the parallel file format.

To create an instance of class vtkXMLStructuredGridWriter, simply invoke its constructor as follows

```
obj = vtkXMLStructuredGridWriter
```

37.161.2 Methods

The class vtkXMLStructuredGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLStructuredGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLStructuredGridWriter = obj.NewInstance ()`
- `vtkXMLStructuredGridWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.162 vtkXMLUnstructuredDataReader

37.162.1 Usage

vtkXMLUnstructuredDataReader provides functionality common to all unstructured data format readers.

To create an instance of class vtkXMLUnstructuredDataReader, simply invoke its constructor as follows

```
obj = vtkXMLUnstructuredDataReader
```

37.162.2 Methods

The class vtkXMLUnstructuredDataReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLUnstructuredDataReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLUnstructuredDataReader = obj.NewInstance ()`
- `vtkXMLUnstructuredDataReader = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetNumberOfPoints ()` - Get the number of points in the output.
- `vtkIdType = obj.GetNumberOfCells ()` - Get the number of cells in the output.
- `obj.SetupUpdateExtent (int piece, int numberOfPieces, int ghostLevel)` - Setup the reader as if the given update extent were requested by its output. This can be used after an UpdateInformation to validate GetNumberOfPoints() and GetNumberOfCells() without actually reading data.
- `obj.CopyOutputInformation (vtkInformation outInfo, int port)`

37.163 vtkXMLUnstructuredDataWriter

37.163.1 Usage

vtkXMLUnstructuredDataWriter provides VTK XML writing functionality that is common among all the unstructured data formats.

To create an instance of class vtkXMLUnstructuredDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLUnstructuredDataWriter
```

37.163.2 Methods

The class vtkXMLUnstructuredDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLUnstructuredDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLUnstructuredDataWriter = obj.NewInstance ()`
- `vtkXMLUnstructuredDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPieces (int )` - Get/Set the number of pieces used to stream the image through the pipeline while writing to the file.
- `int = obj.GetNumberOfPieces ()` - Get/Set the number of pieces used to stream the image through the pipeline while writing to the file.
- `obj.SetWritePiece (int )` - Get/Set the piece to write to the file. If this is negative or equal to the NumberOfPieces, all pieces will be written.
- `int = obj.GetWritePiece ()` - Get/Set the piece to write to the file. If this is negative or equal to the NumberOfPieces, all pieces will be written.

- `obj.SetGhostLevel (int )` - Get/Set the ghost level used to pad each piece.
- `int = obj.GetGhostLevel ()` - Get/Set the ghost level used to pad each piece.

37.164 vtkXMLUnstructuredGridReader

37.164.1 Usage

vtkXMLUnstructuredGridReader reads the VTK XML UnstructuredGrid file format. One unstructured grid file can be read to produce one output. Streaming is supported. The standard extension for this reader's file format is "vtu". This reader is also used to read a single piece of the parallel file format.

To create an instance of class vtkXMLUnstructuredGridReader, simply invoke its constructor as follows

```
obj = vtkXMLUnstructuredGridReader
```

37.164.2 Methods

The class vtkXMLUnstructuredGridReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLUnstructuredGridReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLUnstructuredGridReader = obj.NewInstance ()`
- `vtkXMLUnstructuredGridReader = obj.SafeDownCast (vtkObject o)`
- `vtkUnstructuredGrid = obj.GetOutput ()` - Get the reader's output.
- `vtkUnstructuredGrid = obj.GetOutput (int idx)` - Get the reader's output.

37.165 vtkXMLUnstructuredGridWriter

37.165.1 Usage

vtkXMLUnstructuredGridWriter writes the VTK XML UnstructuredGrid file format. One unstructured grid input can be written into one file in any number of streamed pieces (if supported by the rest of the pipeline). The standard extension for this writer's file format is "vtu". This writer is also used to write a single piece of the parallel file format.

To create an instance of class vtkXMLUnstructuredGridWriter, simply invoke its constructor as follows

```
obj = vtkXMLUnstructuredGridWriter
```

37.165.2 Methods

The class vtkXMLUnstructuredGridWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLUnstructuredGridWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLUnstructuredGridWriter = obj.NewInstance ()`

- `vtkXMLUnstructuredGridWriter = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

37.166 vtkXMLUtilities

37.166.1 Usage

vtkXMLUtilities provides XML-related convenience functions.

To create an instance of class vtkXMLUtilities, simply invoke its constructor as follows

```
obj = vtkXMLUtilities
```

37.166.2 Methods

The class vtkXMLUtilities has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLUtilities class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLUtilities = obj.NewInstance ()`
- `vtkXMLUtilities = obj.SafeDownCast (vtkObject o)`

37.167 vtkXMLWriter

37.167.1 Usage

vtkXMLWriter provides methods implementing most of the functionality needed to write VTK XML file formats. Concrete subclasses provide actual writer implementations calling upon this functionality.

To create an instance of class vtkXMLWriter, simply invoke its constructor as follows

```
obj = vtkXMLWriter
```

37.167.2 Methods

The class vtkXMLWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLWriter = obj.NewInstance ()`
- `vtkXMLWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetByteOrder (int )` - Get/Set the byte order of data written to the file. The default is the machine's hardware byte order.
- `int = obj.GetByteOrder ()` - Get/Set the byte order of data written to the file. The default is the machine's hardware byte order.

- `obj.SetByteOrderToBigEndian ()` - Get/Set the byte order of data written to the file. The default is the machine's hardware byte order.
- `obj.SetByteOrderToLittleEndian ()` - Get/Set the byte order of data written to the file. The default is the machine's hardware byte order.
- `obj.SetIdType (int )` - Get/Set the size of the vtkIdType values stored in the file. The default is the real size of vtkIdType.
- `int = obj.GetIdType ()` - Get/Set the size of the vtkIdType values stored in the file. The default is the real size of vtkIdType.
- `obj.SetIdTypeToInt32 ()` - Get/Set the size of the vtkIdType values stored in the file. The default is the real size of vtkIdType.
- `obj.SetIdTypeToInt64 ()` - Get/Set the size of the vtkIdType values stored in the file. The default is the real size of vtkIdType.
- `obj.SetFileName (string )` - Get/Set the name of the output file.
- `string = obj.GetFileName ()` - Get/Set the name of the output file.
- `obj.SetCompressor (vtkDataCompressor )` - Get/Set the compressor used to compress binary and appended data before writing to the file. Default is a vtkZLibDataCompressor.
- `vtkDataCompressor = obj.GetCompressor ()` - Get/Set the compressor used to compress binary and appended data before writing to the file. Default is a vtkZLibDataCompressor.
- `obj.SetCompressorType (int compressorType)` - Convenience functions to set the compressor to certain known types.
- `obj.SetCompressorTypeToNone ()` - Convenience functions to set the compressor to certain known types.
- `obj.SetCompressorTypeToZLib ()` - Get/Set the block size used in compression. When reading, this controls the granularity of how much extra information must be read when only part of the data are requested. The value should be a multiple of the largest scalar data type.
- `obj.SetBlockSize (int blockSize)` - Get/Set the block size used in compression. When reading, this controls the granularity of how much extra information must be read when only part of the data are requested. The value should be a multiple of the largest scalar data type.
- `int = obj.GetBlockSize ()` - Get/Set the block size used in compression. When reading, this controls the granularity of how much extra information must be read when only part of the data are requested. The value should be a multiple of the largest scalar data type.
- `obj.SetDataMode (int )` - Get/Set the data mode used for the file's data. The options are vtkXMLWriter::Ascii, vtkXMLWriter::Binary, and vtkXMLWriter::Appended.
- `int = obj.GetDataMode ()` - Get/Set the data mode used for the file's data. The options are vtkXMLWriter::Ascii, vtkXMLWriter::Binary, and vtkXMLWriter::Appended.
- `obj.SetDataModeToAscii ()` - Get/Set the data mode used for the file's data. The options are vtkXMLWriter::Ascii, vtkXMLWriter::Binary, and vtkXMLWriter::Appended.
- `obj.SetDataModeToBinary ()` - Get/Set the data mode used for the file's data. The options are vtkXMLWriter::Ascii, vtkXMLWriter::Binary, and vtkXMLWriter::Appended.
- `obj.SetDataModeToAppended ()` - Get/Set the data mode used for the file's data. The options are vtkXMLWriter::Ascii, vtkXMLWriter::Binary, and vtkXMLWriter::Appended.

- `obj.SetEncodeAppendedData (int )` - Get/Set whether the appended data section is base64 encoded. If encoded, reading and writing will be slower, but the file will be fully valid XML and text-only. If not encoded, the XML specification will be violated, but reading and writing will be fast. The default is to do the encoding.

- `int = obj.GetEncodeAppendedData ()` - Get/Set whether the appended data section is base64 encoded. If encoded, reading and writing will be slower, but the file will be fully valid XML and text-only. If not encoded, the XML specification will be violated, but reading and writing will be fast. The default is to do the encoding.

- `obj.EncodeAppendedDataOn ()` - Get/Set whether the appended data section is base64 encoded. If encoded, reading and writing will be slower, but the file will be fully valid XML and text-only. If not encoded, the XML specification will be violated, but reading and writing will be fast. The default is to do the encoding.

- `obj.EncodeAppendedDataOff ()` - Get/Set whether the appended data section is base64 encoded. If encoded, reading and writing will be slower, but the file will be fully valid XML and text-only. If not encoded, the XML specification will be violated, but reading and writing will be fast. The default is to do the encoding.

- `obj.SetInput (vtkDataObject )` - Set/Get an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline

- `obj.SetInput (int , vtkDataObject )` - Set/Get an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline

- `vtkDataObject = obj.GetInput (int port)` - Set/Get an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline

- `vtkDataObject = obj.GetInput ()` - Set/Get an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline

- `string = obj.GetDefaultFileExtension ()` - Get the default file extension for files written by this writer.

- `int = obj.Write ()` - Invoke the writer. Returns 1 for success, 0 for failure.

- `obj.SetTimeStep (int )` - Which TimeStep to write.

- `int = obj.GetTimeStep ()` - Which TimeStep to write.

- `int = obj. GetTimeStepRange ()` - Which TimeStepRange to write.

- `obj.SetTimeStepRange (int , int )` - Which TimeStepRange to write.

- `obj.SetTimeStepRange (int  a[2])` - Which TimeStepRange to write.

- `int = obj.GetNumberOfTimeSteps ()` - Set the number of time steps

- `obj.SetNumberOfTimeSteps (int )` - Set the number of time steps

- `obj.Start ()` - API to interface an outside the VTK pipeline control

- `obj.Stop ()` - API to interface an outside the VTK pipeline control

- `obj.WriteNextTime (double time)` - API to interface an outside the VTK pipeline control

37.168 vtkXYZMolReader

37.168.1 Usage

vtkXYZMolReader is a source object that reads Molecule files The FileName must be specified
.SECTION Thanks Dr. Jean M. Favre who developed and contributed this class
To create an instance of class vtkXYZMolReader, simply invoke its constructor as follows

```
obj = vtkXYZMolReader
```

37.168.2 Methods

The class vtkXYZMolReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXYZMolReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXYZMolReader = obj.NewInstance ()`
- `vtkXYZMolReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string name)` - Test whether the file with the given name can be read by this reader.
- `obj.SetTimeStep (int )` - Set the current time step. It should be greater than 0 and smaller than MaxTimeStep.
- `int = obj.GetTimeStep ()` - Set the current time step. It should be greater than 0 and smaller than MaxTimeStep.
- `int = obj.GetMaxTimeStep ()` - Get the maximum time step.

37.169 vtkZLibDataCompressor

37.169.1 Usage

vtkZLibDataCompressor provides a concrete vtkDataCompressor class using zlib for compressing and uncompressing data.
To create an instance of class vtkZLibDataCompressor, simply invoke its constructor as follows

```
obj = vtkZLibDataCompressor
```

37.169.2 Methods

The class vtkZLibDataCompressor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkZLibDataCompressor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkZLibDataCompressor = obj.NewInstance ()`
- `vtkZLibDataCompressor = obj.SafeDownCast (vtkObject o)`

- `long = obj.GetMaximumCompressionSpace (long size)` - Get the maximum space that may be needed to store data of the given uncompressed size after compression. This is the minimum size of the output buffer that can be passed to the four-argument Compress method.
- `obj.SetCompressionLevel (int )` - Get/Set the compression level.
- `int = obj.GetCompressionLevelMinValue ()` - Get/Set the compression level.
- `int = obj.GetCompressionLevelMaxValue ()` - Get/Set the compression level.
- `int = obj.GetCompressionLevel ()` - Get/Set the compression level.

Chapter 38

Visualization Toolkit Parallel Classes

38.1 vtkBranchExtentTranslator

38.1.1 Usage

vtkBranchExtentTranslator is like extent translator, but it uses an alternative source as a whole extent. The whole extent passed is assumed to be a subextent of the original source. we simply take the intersection of the split extent and the whole extdent passed in. We are attempting to make branching pipelines request consistent extents with the same piece requests.

To create an instance of class vtkBranchExtentTranslator, simply invoke its constructor as follows

```
obj = vtkBranchExtentTranslator
```

38.1.2 Methods

The class vtkBranchExtentTranslator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBranchExtentTranslator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBranchExtentTranslator = obj.NewInstance ()`
- `vtkBranchExtentTranslator = obj.SafeDownCast (vtkObject o)`
- `obj.SetOriginalSource (vtkImageData )` - This is the original upstream image source.
- `vtkImageData = obj.GetOriginalSource ()` - This is the original upstream image source.
- `int = obj.PieceToExtent ()` - Generates the extent from the pieces.
- `obj.SetAssignedPiece (int )` - This unstructured extent/piece is store here for the users convenience. It is not used internally. The intent was to let an "assignment" be made when the translator/first source is created. The translator/assignment can be used for any new filter that uses the original source as output. Branches will then have the same assignment.
- `int = obj.GetAssignedPiece ()` - This unstructured extent/piece is store here for the users convenience. It is not used internally. The intent was to let an "assignment" be made when the translator/first source is created. The translator/assignment can be used for any new filter that uses the original source as output. Branches will then have the same assignment.

- `obj.SetAssignedNumberOfPieces (int )` - This unstructured extent/piece is store here for the users convenience. It is not used internally. The intent was to let an "assignment" be made when the translator/first source is created. The translator/assignment can be used for any new filter that uses the original source as output. Branches will then have the same assignment.
- `int = obj.GetAssignedNumberOfPieces ()` - This unstructured extent/piece is store here for the users convenience. It is not used internally. The intent was to let an "assignment" be made when the translator/first source is created. The translator/assignment can be used for any new filter that uses the original source as output. Branches will then have the same assignment.

38.2 vtkCachingInterpolatedVelocityField

38.2.1 Usage

vtkCachingInterpolatedVelocityField acts as a continuous velocity field by performing cell interpolation on the underlying vtkDataSet. This is a concrete sub-class of vtkFunctionSet with NumberOfIndependentVariables = 4 (x,y,z,t) and NumberOfFunctions = 3 (u,v,w). Normally, every time an evaluation is performed, the cell which contains the point (x,y,z) has to be found by calling FindCell. This is a computationally expensive operation. In certain cases, the cell search can be avoided or shortened by providing a guess for the cell id. For example, in streamline integration, the next evaluation is usually in the same or a neighbour cell. For this reason, vtkCachingInterpolatedVelocityField stores the last cell id. If caching is turned on, it uses this id as the starting point.

To create an instance of class vtkCachingInterpolatedVelocityField, simply invoke its constructor as follows

```
obj = vtkCachingInterpolatedVelocityField
```

38.2.2 Methods

The class vtkCachingInterpolatedVelocityField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCachingInterpolatedVelocityField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCachingInterpolatedVelocityField = obj.NewInstance ()`
- `vtkCachingInterpolatedVelocityField = obj.SafeDownCast (vtkObject o)`
- `int = obj.FunctionValues (double x, double f)` - Evaluate the velocity field, f=u,v,w, at x, y, z. returns 1 if valid, 0 if test failed
- `int = obj.InsideTest (double x)` - Evaluate the velocity field, f=u,v,w, at x, y, z. returns 1 if valid, 0 if test failed
- `obj.SetDataSet (int I, vtkDataSet dataset, bool staticdataset, vtkAbstractCellLocator locator)` - Add a dataset used by the interpolation function evaluation.
- `string = obj.GetVectorsSelection ()` - If you want to work with an arbitrary vector array, then set its name here. By default this in NULL and the filter will use the active vector array.
- `obj.SelectVectors (string fieldName)` - Return the cell id cached from last evaluation.
- `obj.SetLastCellInfo (vtkIdType c, int datasetindex)` - Return the cell id cached from last evaluation.

- `obj.ClearLastCellInfo ()` - Set the last cell id to -1 so that the next search does not start from the previous cell
- `int = obj.GetLastWeights (double w)` - Returns the interpolation weights/pcoords cached from last evaluation if the cached cell is valid (returns 1). Otherwise, it does not change w and returns 0.
- `int = obj.GetLastLocalCoordinates (double pcoords[3])` - Returns the interpolation weights/pcoords cached from last evaluation if the cached cell is valid (returns 1). Otherwise, it does not change w and returns 0.
- `int = obj.GetCellCacheHit ()` - Caching statistics.
- `int = obj.GetDataSetCacheHit ()` - Caching statistics.
- `int = obj.GetCacheMiss ()` - Caching statistics.

38.3 vtkCollectGraph

38.3.1 Usage

This filter has code to collect a graph from across processes onto vertex 0. Collection can be turned on or off using the "PassThrough" flag.

To create an instance of class vtkCollectGraph, simply invoke its constructor as follows

```
obj = vtkCollectGraph
```

38.3.2 Methods

The class vtkCollectGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollectGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollectGraph = obj.NewInstance ()`
- `vtkCollectGraph = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetSocketController (vtkSocketController )` - When this filter is being used in client-server mode, this is the controller used to communicate between client and server. Client should not set the other controller.
- `vtkSocketController = obj.GetSocketController ()` - When this filter is being used in client-server mode, this is the controller used to communicate between client and server. Client should not set the other controller.
- `obj.SetPassThrough (int )` - To collect or just copy input to output. Off (collect) by default.
- `int = obj.GetPassThrough ()` - To collect or just copy input to output. Off (collect) by default.
- `obj.PassThroughOn ()` - To collect or just copy input to output. Off (collect) by default.

- `obj.PassThroughOff ()` - To collect or just copy input to output. Off (collect) by default.
- `obj.SetOutputType (int )` - Directedness flag, used to signal whether the output graph is directed or undirected. DIRECTED_OUTPUT expects that this filter is generating a directed graph. UNDIRECTED_OUTPUT expects that this filter is generating an undirected graph. DIRECTED_OUTPUT and UNDIRECTED_OUTPUT flags should only be set on the client filter. Server filters should be set to USE_INPUT_TYPE since they have valid input and the directedness is determined from the input type.
- `int = obj.GetOutputType ()` - Directedness flag, used to signal whether the output graph is directed or undirected. DIRECTED_OUTPUT expects that this filter is generating a directed graph. UNDIRECTED_OUTPUT expects that this filter is generating an undirected graph. DIRECTED_OUTPUT and UNDIRECTED_OUTPUT flags should only be set on the client filter. Server filters should be set to USE_INPUT_TYPE since they have valid input and the directedness is determined from the input type.

38.4 vtkCollectPolyData

38.4.1 Usage

This filter has code to collect polydat from across processes onto node 0. Collection can be turned on or off using the "PassThrough" flag.

To create an instance of class vtkCollectPolyData, simply invoke its constructor as follows

```
obj = vtkCollectPolyData
```

38.4.2 Methods

The class vtkCollectPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollectPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollectPolyData = obj.NewInstance ()`
- `vtkCollectPolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetSocketController (vtkSocketController )` - When this filter is being used in client-server mode, this is the controller used to communicate between client and server. Client should not set the other controller.
- `vtkSocketController = obj.GetSocketController ()` - When this filter is being used in client-server mode, this is the controller used to communicate between client and server. Client should not set the other controller.
- `obj.SetPassThrough (int )` - To collect or just copy input to output. Off (collect) by default.
- `int = obj.GetPassThrough ()` - To collect or just copy input to output. Off (collect) by default.

- `obj.PassThroughOn ()` - To collect or just copy input to output. Off (collect) by default.
- `obj.PassThroughOff ()` - To collect or just copy input to output. Off (collect) by default.

38.5 vtkCollectTable

38.5.1 Usage

This filter has code to collect a table from across processes onto node 0. Collection can be turned on or off using the "PassThrough" flag.

To create an instance of class vtkCollectTable, simply invoke its constructor as follows

```
obj = vtkCollectTable
```

38.5.2 Methods

The class vtkCollectTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollectTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollectTable = obj.NewInstance ()`
- `vtkCollectTable = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetSocketController (vtkSocketController )` - When this filter is being used in client-server mode, this is the controller used to communicate between client and server. Client should not set the other controller.
- `vtkSocketController = obj.GetSocketController ()` - When this filter is being used in client-server mode, this is the controller used to communicate between client and server. Client should not set the other controller.
- `obj.SetPassThrough (int )` - To collect or just copy input to output. Off (collect) by default.
- `int = obj.GetPassThrough ()` - To collect or just copy input to output. Off (collect) by default.
- `obj.PassThroughOn ()` - To collect or just copy input to output. Off (collect) by default.
- `obj.PassThroughOff ()` - To collect or just copy input to output. Off (collect) by default.

38.6 vtkCommunicator

38.6.1 Usage

This is an abstact class which contains functionality for sending and receiving inter-process messages. It contains methods for marshaling an object into a string (currently used by the MPI communicator but not the shared memory communicator).

To create an instance of class vtkCommunicator, simply invoke its constructor as follows

```
obj = vtkCommunicator
```

38.6.2 Methods

The class vtkCommunicator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCommunicator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCommunicator = obj.NewInstance ()`
- `vtkCommunicator = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfProcesses (int num)` - Set the number of processes you will be using. This defaults to the maximum number available. If you set this to a value higher than the default, you will get an error.
- `int = obj.GetNumberOfProcesses ()` - Set the number of processes you will be using. This defaults to the maximum number available. If you set this to a value higher than the default, you will get an error.
- `int = obj.GetLocalProcessId ()` - Tells you which process [0, NumProcess) you are in.
- `int = obj.Send (vtkDataObject data, int remoteHandle, int tag)` - This method sends a data object to a destination. Tag eliminates ambiguity and is used to match sends to receives.
- `int = obj.Send (vtkDataArray data, int remoteHandle, int tag)` - This method sends a data array to a destination. Tag eliminates ambiguity and is used to match sends to receives.
- `int = obj.Send (int data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Send (int data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Send (long data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Send (string data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Send (string data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Send (float data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Send (double data, vtkIdType length, int remoteHandle, int tag)` - Convenience methods for sending data arrays.
- `int = obj.Receive (vtkDataObject data, int remoteHandle, int tag)` - This method receives a data object from a corresponding send. It blocks until the receive is finished.
- `vtkDataObject = obj.ReceiveDataObject (int remoteHandle, int tag)` - The caller does not have to know the data type before this call is made. It returns the newly created object.
- `int = obj.Receive (vtkDataArray data, int remoteHandle, int tag)` - This method receives a data array from a corresponding send. It blocks until the receive is finished.

- `int = obj.Receive (int data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `int = obj.Receive (int data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `int = obj.Receive (long data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `int = obj.Receive (string data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `int = obj.Receive (string data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `int = obj.Receive (float data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `int = obj.Receive (double data, vtkIdType maxlength, int remoteHandle, int tag)` - Convenience methods for receiving data arrays.
- `vtkIdType = obj.GetCount ()` - Returns the number of words received by the most recent Receive(). Note that this is not the number of bytes received, but the number of items of the data-type received by the most recent Receive() eg. if Receive(int*,..) was used, then this returns the number of ints received; if Receive(double*,..) was used, then this returns the number of doubles received etc. The return value is valid only after a successful Receive().
- `obj.Barrier ()` - Will block the processes until all other processes reach the Barrier function.
- `int = obj.Broadcast (int data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (long data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (string data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (string data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (float data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (double data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (vtkDataObject data, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (vtkDataArray data, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.

- `int = obj.Gather (int sendBuffer, int recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (long sendBuffer, long recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (string sendBuffer, string recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (string sendBuffer, string recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (float sendBuffer, float recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (double sendBuffer, double recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int destProcessId)` - Gather collects arrays in the process with id ɖestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Scatter (int sendBuffer, int recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id şrcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first ļength values, process 1 receives the second ļength values, and so on. Scatter is the inverse operation of Gather.
- `int = obj.Scatter (long sendBuffer, long recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id şrcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first ļength values, process 1 receives the second ļength values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (string sendBuffer, string recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (string sendBuffer, string recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (float sendBuffer, float recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (double sendBuffer, double recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.AllGather (int sendBuffer, int recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (long sendBuffer, long recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (string sendBuffer, string recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (string sendBuffer, string recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (float sendBuffer, float recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (double sendBuffer, double recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (vtkDataArray sendBuffer, vtkDataArray recvBuffer)` - Same as gather except that the result ends up on all processes.

- `int = obj.Reduce (int sendBuffer, int recvBuffer, vtkIdType length, int operation, int destProcessI` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.

- `int = obj.Reduce (long sendBuffer, long recvBuffer, vtkIdType length, int operation, int destProces` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.

- `int = obj.Reduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation, int destPr` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.

- `int = obj.Reduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation, int destPr`
  - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (float sendBuffer, float recvBuffer, vtkIdType length, int operation, int destProc`
  - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (double sendBuffer, double recvBuffer, vtkIdType length, int operation, int destPr`
  - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int operation, int destProcessI`
  - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.AllReduce (int sendBuffer, int recvBuffer, vtkIdType length, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (long sendBuffer, long recvBuffer, vtkIdType length, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (float sendBuffer, float recvBuffer, vtkIdType length, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (double sendBuffer, double recvBuffer, vtkIdType length, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int operation)`
  - Same as Reduce except that the result is placed in all of the processes.

38.7 vtkCompositer

38.7.1 Usage

vtkCompositer operates in multiple processes. Each compositer has a render window. They use vtkMultiProcessControllers to communicate the color and depth buffer to process 0's render window. It will not handle transparency well.

To create an instance of class vtkCompositer, simply invoke its constructor as follows

```
obj = vtkCompositer
```

38.7.2 Methods

The class vtkCompositer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkCompositer = obj.NewInstance ()`
- `vtkCompositer = obj.SafeDownCast (vtkObject o)`
- `obj.CompositeBuffer (vtkDataArray pBuf, vtkFloatArray zBuf, vtkDataArray pTmp, vtkFloatArray zTmp)` - This method gets called on every process. The final image gets put into pBuf and zBuf.
- `obj.SetController (vtkMultiProcessController )` - Access to the controller.
- `vtkMultiProcessController = obj.GetController ()` - Access to the controller.
- `obj.SetNumberOfProcesses (int )` - A hack to get a sub world until I can get communicators working.
- `int = obj.GetNumberOfProcesses ()` - A hack to get a sub world until I can get communicators working.

38.8 vtkCompositeRenderManager

38.8.1 Usage

vtkCompositeRenderManager is a subclass of vtkParallelRenderManager that uses compositing to do parallel rendering. This class has replaced vtkCompositeManager.

To create an instance of class vtkCompositeRenderManager, simply invoke its constructor as follows

```
obj = vtkCompositeRenderManager
```

38.8.2 Methods

The class vtkCompositeRenderManager has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeRenderManager class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeRenderManager = obj.NewInstance ()`
- `vtkCompositeRenderManager = obj.SafeDownCast (vtkObject o)`
- `obj.SetCompositer (vtkCompositer c)` - Set/Get the composite algorithm.
- `vtkCompositer = obj.GetCompositer ()` - Set/Get the composite algorithm.
- `double = obj.GetImageProcessingTime ()` - Get rendering metrics.

38.9 vtkCompressCompositer

38.9.1 Usage

vtkCompressCompositer operates in multiple processes. Each compositer has a render window. They use vtkMultiProcessController to communicate the color and depth buffer to process 0's render window. It will not handle transparency. Compositing is run length encoding of background pixels.

SECTION See Also vtkCompositeManager.

To create an instance of class vtkCompressCompositer, simply invoke its constructor as follows

```
obj = vtkCompressCompositer
```

38.9.2 Methods

The class vtkCompressCompositer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompressCompositer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompressCompositer = obj.NewInstance ()`
- `vtkCompressCompositer = obj.SafeDownCast (vtkObject o)`
- `obj.CompositeBuffer (vtkDataArray pBuf, vtkFloatArray zBuf, vtkDataArray pTmp, vtkFloatArray zTmp)`

38.10 vtkCutMaterial

38.10.1 Usage

vtkCutMaterial computes a cut plane based on an up vector, center of the bounding box and the location of the maximum variable value. These computed values are available so that they can be used to set the camera for the best view of the plane.

To create an instance of class vtkCutMaterial, simply invoke its constructor as follows

```
obj = vtkCutMaterial
```

38.10.2 Methods

The class vtkCutMaterial has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCutMaterial class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCutMaterial = obj.NewInstance ()`
- `vtkCutMaterial = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaterialArrayName (string )` - Cell array that contains the material values.
- `string = obj.GetMaterialArrayName ()` - Cell array that contains the material values.
- `obj.SetMaterial (int )` - Material to probe.
- `int = obj.GetMaterial ()` - Material to probe.
- `obj.SetArrayName (string )` - For now, we just use the cell values. The array name to cut.
- `string = obj.GetArrayName ()` - For now, we just use the cell values. The array name to cut.
- `obj.SetUpVector (double , double , double )` - The last piece of information that specifies the plane.
- `obj.SetUpVector (double  a[3])` - The last piece of information that specifies the plane.
- `double = obj. GetUpVector ()` - The last piece of information that specifies the plane.

- `double = obj. GetMaximumPoint ()` - Accesses to the values computed during the execute method. They could be used to get a good camera view for the resulting plane.
- `double = obj. GetCenterPoint ()` - Accesses to the values computed during the execute method. They could be used to get a good camera view for the resulting plane.
- `double = obj. GetNormal ()` - Accesses to the values computed during the execute method. They could be used to get a good camera view for the resulting plane.

38.11 vtkDistributedDataFilter

38.11.1 Usage

This filter redistributes data among processors in a parallel application into spatially contiguous vtkUnstructuredGrids. The execution model anticipated is that all processes read in part of a large vtkDataSet. Each process sets the input of filter to be that DataSet. When executed, this filter builds in parallel a k-d tree, decomposing the space occupied by the distributed DataSet into spatial regions. It assigns each spatial region to a processor. The data is then redistributed and the output is a single vtkUnstructuredGrid containing the cells in the process' assigned regions.

This filter is sometimes called "D3" for "distributed data decomposition".

Enhancement: You can set the k-d tree decomposition, rather than have D3 compute it. This allows you to divide a dataset using the decomposition computed for another dataset. Obtain a description of the k-d tree cuts this way:

vtkBSPCuts *cuts = D3Object1-¿GetCuts()

And set it this way:

D3Object2-¿SetCuts(cuts)

It is desirable to have a field array of global node IDs for two reasons:

1. When merging together sub grids that were distributed across processors, global node IDs can be used to remove duplicate points and significantly reduce the size of the resulting output grid. If no such array is available, D3 will use a tolerance to merge points, which is much slower.

2. If ghost cells have been requested, D3 requires a global node ID array in order to request and transfer ghost cells in parallel among the processors. If there is no global node ID array, D3 will in parallel create a global node ID array, and the time to do this can be significant.

If you know the name of a global node ID array in the input dataset, set that name with this method. If you leave it unset, D3 will search the input data set for certain common names of global node ID arrays. If none is found, and ghost cells have been requested, D3 will create a temporary global node ID array before aquiring ghost cells. It is also desirable to have global element IDs. However, if they don't exist D3 can create them relatively quickly. Set the name of the global element ID array if you have it. If it is not set, D3 will search for it using common names. If still not found, D3 will create a temporary array of global element IDs.

To create an instance of class vtkDistributedDataFilter, simply invoke its constructor as follows

```
obj = vtkDistributedDataFilter
```

38.11.2 Methods

The class vtkDistributedDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistributedDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDistributedDataFilter = obj.NewInstance ()`

- `vtkDistributedDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController c)` - Set/Get the communicator object
- `vtkMultiProcessController = obj.GetController ()` - Set/Get the communicator object
- `vtkPKdTree = obj.GetKdtree ()`
- `obj.RetainKdtreeOn ()`
- `obj.RetainKdtreeOff ()`
- `int = obj.GetRetainKdtree ()`
- `obj.SetRetainKdtree (int )`
- `obj.IncludeAllIntersectingCellsOn ()`
- `obj.IncludeAllIntersectingCellsOff ()`
- `int = obj.GetIncludeAllIntersectingCells ()`
- `obj.SetIncludeAllIntersectingCells (int )`
- `obj.ClipCellsOn ()`
- `obj.ClipCellsOff ()`
- `int = obj.GetClipCells ()`
- `obj.SetClipCells (int )`
- `obj.SetBoundaryMode (int mode)` - Handling of ClipCells and IncludeAllIntersectingCells.
- `obj.SetBoundaryModeToAssignToOneRegion ()` - Handling of ClipCells and IncludeAllIntersecting-Cells.
- `obj.SetBoundaryModeToAssignToAllIntersectingRegions ()` - Handling of ClipCells and IncludeAllIntersectingCells.
- `obj.SetBoundaryModeToSplitBoundaryCells ()` - Handling of ClipCells and IncludeAllIntersecting-Cells.
- `int = obj.GetBoundaryMode ()` - Handling of ClipCells and IncludeAllIntersectingCells.
- `obj.UseMinimalMemoryOn ()`
- `obj.UseMinimalMemoryOff ()`
- `int = obj.GetUseMinimalMemory ()`
- `obj.SetUseMinimalMemory (int )`
- `obj.TimingOn ()`
- `obj.TimingOff ()`
- `obj.SetTiming (int )`
- `int = obj.GetTiming ()`

- `vtkBSPCuts = obj.GetCuts ()` - You can set the k-d tree decomposition, rather than have D3 compute it. This allows you to divide a dataset using the decomposition computed for another dataset. Obtain a description of the k-d tree cuts this way:

  vtkBSPCuts *cuts = D3Object1-¿GetCuts()

  And set it this way:

  D3Object2-¿SetCuts(cuts)

- `obj.SetCuts (vtkBSPCuts cuts)` - You can set the k-d tree decomposition, rather than have D3 compute it. This allows you to divide a dataset using the decomposition computed for another dataset. Obtain a description of the k-d tree cuts this way:

  vtkBSPCuts *cuts = D3Object1-¿GetCuts()

  And set it this way:

  D3Object2-¿SetCuts(cuts)

38.12 vtkDistributedStreamTracer

38.12.1 Usage

This filter integrates streamlines on a distributed dataset. It is essentially a serial algorithm: only one process is active at one time and it is not more efficient than a single process integration. It is useful when the data is too large to be on one process and has to be kept distributed.

To create an instance of class vtkDistributedStreamTracer, simply invoke its constructor as follows

```
obj = vtkDistributedStreamTracer
```

38.12.2 Methods

The class vtkDistributedStreamTracer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistributedStreamTracer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDistributedStreamTracer = obj.NewInstance ()`
- `vtkDistributedStreamTracer = obj.SafeDownCast (vtkObject o)`

38.13 vtkDummyCommunicator

38.13.1 Usage

This is a dummy communicator, which can be used by applications that always require a controller but are also compiled on systems without threads or MPI. Because there is always only one process, no real communication takes place.

To create an instance of class vtkDummyCommunicator, simply invoke its constructor as follows

```
obj = vtkDummyCommunicator
```

38.13.2 Methods

The class vtkDummyCommunicator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDummyCommunicator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDummyCommunicator = obj.NewInstance ()`
- `vtkDummyCommunicator = obj.SafeDownCast (vtkObject o)`

38.14 vtkDummyController

38.14.1 Usage

This is a dummy controller which can be used by applications which always require a controller but are also compile on systems without threads or mpi.

To create an instance of class vtkDummyController, simply invoke its constructor as follows

```
obj = vtkDummyController
```

38.14.2 Methods

The class vtkDummyController has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDummyController class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDummyController = obj.NewInstance ()`
- `vtkDummyController = obj.SafeDownCast (vtkObject o)`
- `obj.Finalize ()` - This method is for setting up the processes.
- `obj.Finalize (int )` - This method always returns 0.
- `int = obj.GetLocalProcessId ()` - Directly calls the single method.
- `obj.SingleMethodExecute ()` - Directly calls the single method.
- `obj.MultipleMethodExecute ()` - Directly calls multiple method 0.
- `obj.CreateOutputWindow ()` - If you don't need any special functionality from the controller, you can swap out the dummy communicator for another one.
- `vtkCommunicator = obj.GetCommunicator ()` - If you don't need any special functionality from the controller, you can swap out the dummy communicator for another one.
- `vtkCommunicator = obj.GetRMICommunicator ()` - If you don't need any special functionality from the controller, you can swap out the dummy communicator for another one.
- `obj.SetCommunicator (vtkCommunicator )` - If you don't need any special functionality from the controller, you can swap out the dummy communicator for another one.
- `obj.SetRMICommunicator (vtkCommunicator )` - If you don't need any special functionality from the controller, you can swap out the dummy communicator for another one.

38.15 vtkDuplicatePolyData

38.15.1 Usage

This filter collects poly data and duplicates it on every node. Converts data parallel so every node has a complete copy of the data. The filter is used at the end of a pipeline for driving a tiled display.

To create an instance of class vtkDuplicatePolyData, simply invoke its constructor as follows

```
obj = vtkDuplicatePolyData
```

38.15.2 Methods

The class vtkDuplicatePolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDuplicatePolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDuplicatePolyData = obj.NewInstance ()`
- `vtkDuplicatePolyData = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.InitializeSchedule (int numProcs)`
- `obj.SetSynchronous (int )` - This flag causes sends and receives to be matched. When this flag is off, two sends occur then two receives. I want to see if it makes a difference in performance. The flag is on by default.
- `int = obj.GetSynchronous ()` - This flag causes sends and receives to be matched. When this flag is off, two sends occur then two receives. I want to see if it makes a difference in performance. The flag is on by default.
- `obj.SynchronousOn ()` - This flag causes sends and receives to be matched. When this flag is off, two sends occur then two receives. I want to see if it makes a difference in performance. The flag is on by default.
- `obj.SynchronousOff ()` - This flag causes sends and receives to be matched. When this flag is off, two sends occur then two receives. I want to see if it makes a difference in performance. The flag is on by default.
- `vtkSocketController = obj.GetSocketController ()` - This duplicate filter works in client server mode when this controller is set. We have a client flag to diferentiate the client and server because the socket controller is odd: Proth processes think their id is 0.
- `obj.SetSocketController (vtkSocketController controller)` - This duplicate filter works in client server mode when this controller is set. We have a client flag to diferentiate the client and server because the socket controller is odd: Proth processes think their id is 0.
- `obj.SetClientFlag (int )` - This duplicate filter works in client server mode when this controller is set. We have a client flag to diferentiate the client and server because the socket controller is odd: Proth processes think their id is 0.

- `int = obj.GetClientFlag ()` - This duplicate filter works in client server mode when this controller is set. We have a client flag to diferentiate the client and server because the socket controller is odd: Proth processes think their id is 0.
- `long = obj.GetMemorySize ()` - This returns to size of the output (on this process). This method is not really used. It is needed to have the same API as vtkCollectPolyData.

38.16 vtkEnSightWriter

38.16.1 Usage

vtkEnSightWriter is a source object that writes binary unstructured grid data files in EnSight format. See EnSight Manual for format details

To create an instance of class vtkEnSightWriter, simply invoke its constructor as follows

```
obj = vtkEnSightWriter
```

38.16.2 Methods

The class vtkEnSightWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEnSightWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEnSightWriter = obj.NewInstance ()`
- `vtkEnSightWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetProcessNumber (int )`
- `int = obj.GetProcessNumber ()`
- `obj.SetPath (string )` - Specify path of EnSight data files to write.
- `string = obj.GetPath ()` - Specify path of EnSight data files to write.
- `obj.SetBaseName (string )` - Specify base name of EnSight data files to write.
- `string = obj.GetBaseName ()` - Specify base name of EnSight data files to write.
- `obj.SetFileName (string )` - Specify the path and base name of the output files.
- `string = obj.GetFileName ()` - Specify the path and base name of the output files.
- `obj.SetTimeStep (int )`
- `int = obj.GetTimeStep ()`
- `obj.SetGhostLevel (int )`
- `int = obj.GetGhostLevel ()`
- `obj.SetTransientGeometry (bool )`
- `bool = obj.GetTransientGeometry ()`
- `obj.SetNumberOfBlocks (int )`

- `int = obj.GetNumberOfBlocks ()`
- `obj.SetBlockIDs (int val)`
- `obj.SetInput (vtkUnstructuredGrid input)` - Specify the input data or filter.
- `vtkUnstructuredGrid = obj.GetInput ()` - Specify the input data or filter.
- `obj.WriteCaseFile (int TotalTimeSteps)`
- `obj.WriteSOSCaseFile (int NumProcs)`
- `obj.SetModelMetadata (vtkModelMetadata model)`
- `vtkModelMetadata = obj.GetModelMetadata ()`

38.17 vtkExodusIIWriter

38.17.1 Usage

This is a vtkWriter that writes it's vtkUnstructuredGrid input out to an Exodus II file. Go to http://endo.sandia.gov/SEACAS for more information about the Exodus II format.

Exodus files contain much information that is not captured in a vtkUnstructuredGrid, such as time steps, information lines, node sets, and side sets. This information can be stored in a vtkModelMetadata object.

The vtkExodusReader and vtkPExodusReader can create a vtkModelMetadata object and embed it in a vtkUnstructuredGrid in a series of field arrays. This writer searches for these field arrays and will use the metadata contained in them when creating the new Exodus II file.

You can also explicitly give the vtkExodusIIWriter a vtkModelMetadata object to use when writing the file.

In the absence of the information provided by vtkModelMetadata, if this writer is not part of a parallel application, we will use reasonable defaults for all the values in the output Exodus file. If you don't provide a block ID element array, we'll create a block for each cell type that appears in the unstructured grid.

However if this writer is part of a parallel application (hence writing out a distributed Exodus file), then we need at the very least a list of all the block IDs that appear in the file. And we need the element array of block IDs for the input unstructured grid.

In the absense of a vtkModelMetadata object, you can also provide time step information which we will include in the output Exodus file.

.SECTION Caveats If the input floating point field arrays and point locations are all floats or all doubles, this class will operate more efficiently. Mixing floats and doubles will slow you down, because Exodus II requires that we write only floats or only doubles.

We use the terms "point" and "node" interchangeably. Also, we use the terms "element" and "cell" interchangeably.

To create an instance of class vtkExodusIIWriter, simply invoke its constructor as follows

```
obj = vtkExodusIIWriter
```

38.17.2 Methods

The class vtkExodusIIWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExodusIIWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExodusIIWriter = obj.NewInstance ()`

- `vtkExodusIIWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetModelMetadata (vtkModelMetadata )`
- `vtkModelMetadata = obj.GetModelMetadata ()`
- `obj.SetFileName (string )`
- `string = obj.GetFileName ()`
- `obj.SetStoreDoubles (int )`
- `int = obj.GetStoreDoubles ()`
- `obj.SetGhostLevel (int )`
- `int = obj.GetGhostLevel ()`
- `obj.SetWriteOutBlockIdArray (int )`
- `int = obj.GetWriteOutBlockIdArray ()`
- `obj.WriteOutBlockIdArrayOn ()`
- `obj.WriteOutBlockIdArrayOff ()`
- `obj.SetWriteOutGlobalNodeIdArray (int )`
- `int = obj.GetWriteOutGlobalNodeIdArray ()`
- `obj.WriteOutGlobalNodeIdArrayOn ()`
- `obj.WriteOutGlobalNodeIdArrayOff ()`
- `obj.SetWriteOutGlobalElementIdArray (int )`
- `int = obj.GetWriteOutGlobalElementIdArray ()`
- `obj.WriteOutGlobalElementIdArrayOn ()`
- `obj.WriteOutGlobalElementIdArrayOff ()`
- `obj.SetWriteAllTimeSteps (int )`
- `int = obj.GetWriteAllTimeSteps ()`
- `obj.WriteAllTimeStepsOn ()`
- `obj.WriteAllTimeStepsOff ()`
- `obj.SetBlockIdArrayName (string )`
- `string = obj.GetBlockIdArrayName ()`

38.18 vtkExtractCTHPart

38.18.1 Usage

vtkExtractCTHPart is a filter that is specialized for creating visualization of a CTH simulation. First it converts the cell data to point data. It contours the selected volume fraction at a value of 0.5. The user has the option of clipping the part with a plane. Clipped surfaces of the part are generated.

To create an instance of class vtkExtractCTHPart, simply invoke its constructor as follows

```
obj = vtkExtractCTHPart
```

38.18.2 Methods

The class vtkExtractCTHPart has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractCTHPart class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractCTHPart = obj.NewInstance ()`
- `vtkExtractCTHPart = obj.SafeDownCast (vtkObject o)`
- `obj.RemoveDoubleVolumeArrayNames ()` - Names of cell volume fraction arrays to extract.
- `obj.RemoveFloatVolumeArrayNames ()` - Names of cell volume fraction arrays to extract.
- `obj.RemoveUnsignedCharVolumeArrayNames ()` - Names of cell volume fraction arrays to extract.
- `int = obj.GetNumberOfVolumeArrayNames ()` - Names of cell volume fraction arrays to extract.
- `string = obj.GetVolumeArrayName (int idx)` - Names of cell volume fraction arrays to extract.
- `obj.RemoveAllVolumeArrayNames ()` - Names of cell volume fraction arrays to extract. for backwards compatibility
- `obj.AddDoubleVolumeArrayName (string arrayName)`
- `obj.AddFloatVolumeArrayName (string arrayName)`
- `obj.AddUnsignedCharVolumeArrayName (string arrayName)`
- `obj.AddVolumeArrayName (string arrayName)`
- `obj.SetClipPlane (vtkPlane clipPlane)` - Set, get or maninpulate the implicit clipping plane.
- `vtkPlane = obj.GetClipPlane ()` - Set, get or maninpulate the implicit clipping plane.
- `long = obj.GetMTime ()` - Look at clip plane to compute MTime.
- `obj.SetController (vtkMultiProcessController controller)` - Set the controller used to coordinate parallel processing.
- `vtkMultiProcessController = obj.GetController ()` - Return the controller used to coordinate parallel processing. By default, it is the global controller.
- `obj.SetVolumeFractionSurfaceValue (double )` - Set and get the volume fraction surface value. This value should be between 0 and 1
- `double = obj.GetVolumeFractionSurfaceValueMinValue ()` - Set and get the volume fraction surface value. This value should be between 0 and 1
- `double = obj.GetVolumeFractionSurfaceValueMaxValue ()` - Set and get the volume fraction surface value. This value should be between 0 and 1
- `double = obj.GetVolumeFractionSurfaceValue ()` - Set and get the volume fraction surface value. This value should be between 0 and 1

38.19 vtkExtractPiece

38.19.1 Usage

vtkExtractPiece returns the appropriate piece of each sub-dataset in the vtkCompositeDataSet. This filter can handle sub-datasets of type vtkImageData, vtkPolyData, vtkRectilinearGrid, vtkStructuredGrid, and vtkUnstructuredGrid; it does not handle sub-grids of type vtkCompositeDataSet.

To create an instance of class vtkExtractPiece, simply invoke its constructor as follows

```
obj = vtkExtractPiece
```

38.19.2 Methods

The class vtkExtractPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractPiece = obj.NewInstance ()`
- `vtkExtractPiece = obj.SafeDownCast (vtkObject o)`

38.20 vtkExtractUserDefinedPiece

38.20.1 Usage

Provided a function that determines which cells are zero-level cells ("the piece"), this class outputs the piece with the requested number of ghost levels. The only difference between this class and the class it is derived from is that the zero-level cells are specified by a function you provide, instead of determined by dividing up the cells based on cell Id.

To create an instance of class vtkExtractUserDefinedPiece, simply invoke its constructor as follows

```
obj = vtkExtractUserDefinedPiece
```

38.20.2 Methods

The class vtkExtractUserDefinedPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtractUserDefinedPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtractUserDefinedPiece = obj.NewInstance ()`
- `vtkExtractUserDefinedPiece = obj.SafeDownCast (vtkObject o)`

38.21 vtkImageRenderManager

38.21.1 Usage

vtkImageRenderManager is a subclass of vtkParallelRenderManager that uses RGBA compositing (blending) to do parallel rendering. This is the exact opposite of vtkCompositeRenderManager. It actually does nothing special. It relies on the rendering pipeline to be initialized with a vtkCompositeRGBAPass. Compositing makes sense only for renderers in layer 0.

To create an instance of class vtkImageRenderManager, simply invoke its constructor as follows

```
obj = vtkImageRenderManager
```

38.21.2 Methods

The class vtkImageRenderManager has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageRenderManager class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageRenderManager = obj.NewInstance ()`
- `vtkImageRenderManager = obj.SafeDownCast (vtkObject o)`

38.22 vtkMemoryLimitImageDataStreamer

38.22.1 Usage

To satisfy a request, this filter calls update on its input many times with smaller update extents. All processing up stream streams smaller pieces.

To create an instance of class vtkMemoryLimitImageDataStreamer, simply invoke its constructor as follows

```
obj = vtkMemoryLimitImageDataStreamer
```

38.22.2 Methods

The class vtkMemoryLimitImageDataStreamer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMemoryLimitImageDataStreamer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMemoryLimitImageDataStreamer = obj.NewInstance ()`
- `vtkMemoryLimitImageDataStreamer = obj.SafeDownCast (vtkObject o)`
- `obj.SetMemoryLimit (long )` - Set / Get the memory limit in kilobytes.
- `long = obj.GetMemoryLimit ()` - Set / Get the memory limit in kilobytes.

38.23 vtkMPIImageReader

38.23.1 Usage

vtkMPIImageReader provides the mechanism to read a brick of bytes (or shorts, or ints, or floats, or doubles, ...) from a file or series of files. You can use it to read raw image data from files. You may also be able to subclass this to read simple file formats.

What distinguishes this class from vtkImageReader and vtkImageReader2 is that it performs synchronized parallel I/O using the MPIIO layer. This can make a huge difference in file read times, especially when reading in parallel from a parallel file system.

Dispite the name of this class, vtkMPIImageReader will work even if MPI is not available. If MPI is not available or MPIIO is not available or the given Controller is not a vtkMPIController (or NULL), then this class will silently work exactly like its superclass. The point is that you can safely use this class in applications that may or may not be compiled with MPI (or may or may not actually be run with MPI).

To create an instance of class vtkMPIImageReader, simply invoke its constructor as follows

```
obj = vtkMPIImageReader
```

38.23.2 Methods

The class vtkMPIImageReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMPIImageReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMPIImageReader = obj.NewInstance ()`
- `vtkMPIImageReader = obj.SafeDownCast (vtkObject o)`
- `vtkMultiProcessController = obj.GetController ()` - Get/set the multi process controller to use for coordinated reads. By default, set to the global controller.
- `obj.SetController (vtkMultiProcessController )` - Get/set the multi process controller to use for coordinated reads. By default, set to the global controller.

38.24 vtkMultiProcessController

38.24.1 Usage

vtkMultiProcessController is used to control multiple processes in a distributed computing environment. It has methods for executing single/multiple method(s) on multiple processors, triggering registered callbacks (Remote Methods) (AddRMI(), TriggerRMI()) and communication. Please note that the communication is done using the communicator which is accessible to the user. Therefore it is possible to get the communicator with GetCommunicator() and use it to send and receive data. This is the encouraged communication method. The internal (RMI) communications are done using a second internal communicator (called RMI-Communicator).

To create an instance of class vtkMultiProcessController, simply invoke its constructor as follows

```
obj = vtkMultiProcessController
```

38.24.2 Methods

The class vtkMultiProcessController has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiProcessController class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiProcessController = obj.NewInstance ()`
- `vtkMultiProcessController = obj.SafeDownCast (vtkObject o)`
- `obj.Finalize ()` - This method is for cleaning up. If a subclass needs to clean up process communication (i.e. MPI) it would over ride this method.
- `obj.Finalize (int finalizedExternally)` - This method is for cleaning up. If a subclass needs to clean up process communication (i.e. MPI) it would over ride this method. Provided for finalization outside vtk.
- `obj.SetNumberOfProcesses (int num)` - Set the number of processes you will be using. This defaults to the maximum number available. If you set this to a value higher than the default, you will get an error.
- `int = obj.GetNumberOfProcesses ()` - Set the number of processes you will be using. This defaults to the maximum number available. If you set this to a value higher than the default, you will get an error.
- `obj.SingleMethodExecute ()` - Execute the SingleMethod (as define by SetSingleMethod) using this-¿NumberOfProcesses processes. This will only return when all the processes finish executing their methods.
- `obj.MultipleMethodExecute ()` - Execute the MultipleMethods (as define by calling SetMultipleMethod for each of the required this-¿NumberOfProcesses methods) using this-¿NumberOfProcesses processes.
- `int = obj.GetLocalProcessId ()` - Tells you which process [0, NumProcess) you are in.
- `obj.CreateOutputWindow ()` - This method can be used to tell the controller to create a special output window in which all messages are preceded by the process id.
- `vtkMultiProcessController = obj.CreateSubController (vtkProcessGroup group)` - Creates a new controller with the processes specified by the given group. The new controller will already be initialized for you. You are responsible for deleting the controller once you are done. It is invalid to pass this method a group with a different communicator than is used by this controller. This operation is collective accross all processes defined in the group. It is undefined what will happen if the group is not the same on all processes. This method must be called by all processes in the controller regardless of whether they are in the group. NULL is returned on all process not in the group.
- `vtkMultiProcessController = obj.PartitionController (int localColor, int localKey)` - Partitions this controller based on a coloring. That is, each process passes in a color. All processes with the same color are grouped into the same partition. The processes are ordered by their self-assigned key. Lower keys have lower process ids. Ties are broken by the current process ids. (For example, if all the keys are 0, then the resulting processes will be ordered in the same way.) This method returns a new controller to each process that represents the local partition. This is basically the same operation as MPI_Comm_split.
- `obj.TriggerBreakRMIs ()` - A conveniance method. Called on process 0 to break "ProcessRMIs" loop on all other processes.

- `obj.TriggerRMI (int remoteProcessId, string arg, int tag)` - Convenience method when there is no argument.

- `obj.TriggerRMI (int remoteProcessId, int tag)` - This is a convenicence method to trigger an RMI call on all the "children" of the current node. The children of the current node can be determined by drawing a binary tree starting at node 0 and then assigned nodes ids incrementally in a breadth-first fashion from left to right. This is designed to be used when trigger an RMI call on all satellites from the root node.

- `obj.TriggerRMIOnAllChildren (string arg, int tag)` - This is a convenicence method to trigger an RMI call on all the "children" of the current node. The children of the current node can be determined by drawing a binary tree starting at node 0 and then assigned nodes ids incrementally in a breadth-first fashion from left to right. This is designed to be used when trigger an RMI call on all satellites from the root node.

- `obj.TriggerRMIOnAllChildren (int tag)` - Calling this method gives control to the controller to start processing RMIs. Possible return values are: RMI_NO_ERROR, RMI_TAG_ERROR : rmi tag could not be received, RMI_ARG_ERROR : rmi arg could not be received. If reportErrors is false, no vtkErrorMacro is called. ProcessRMIs() calls ProcessRMIs(int) with reportErrors = 0. If dont_loop is 1, this call just process one RMI message and exits.

- `int = obj.ProcessRMIs (int reportErrors, int dont\_loop)` - Calling this method gives control to the controller to start processing RMIs. Possible return values are: RMI_NO_ERROR, RMI_TAG_ERROR : rmi tag could not be received, RMI_ARG_ERROR : rmi arg could not be received. If reportErrors is false, no vtkErrorMacro is called. ProcessRMIs() calls ProcessRMIs(int) with reportErrors = 0. If dont_loop is 1, this call just process one RMI message and exits.

- `int = obj.ProcessRMIs ()` - Calling this method gives control to the controller to start processing RMIs. Possible return values are: RMI_NO_ERROR, RMI_TAG_ERROR : rmi tag could not be received, RMI_ARG_ERROR : rmi arg could not be received. If reportErrors is false, no vtkErrorMacro is called. ProcessRMIs() calls ProcessRMIs(int) with reportErrors = 0. If dont_loop is 1, this call just process one RMI message and exits.

- `obj.SetBreakFlag (int )` - Setting this flag to 1 will cause the ProcessRMIs loop to return. This also causes vtkUpStreamPorts to return from their WaitForUpdate loops.

- `int = obj.GetBreakFlag ()` - Setting this flag to 1 will cause the ProcessRMIs loop to return. This also causes vtkUpStreamPorts to return from their WaitForUpdate loops.

- `vtkCommunicator = obj.GetCommunicator ()` - Returns the communicator associated with this controller. A default communicator is created in constructor.

- `obj.Barrier ()` - This method can be used to synchronize processes.

- `int = obj.Send (int data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (int data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (long data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (string data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (string data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (float data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (double data, vtkIdType length, int remoteProcessId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (vtkDataObject data, int remoteId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Send (vtkDataArray data, int remoteId, int tag)` - This method sends data to another process. Tag eliminates ambiguity when multiple sends or receives exist in the same process. It is recommended to use custom tag number over 100. vtkMultiProcessController has reserved tags between 1 and 4. vtkCommunicator has reserved tags between 10 and 16.

- `int = obj.Receive (int data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (int data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (long data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (string data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (string data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (float data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (double data, vtkIdType maxlength, int remoteProcessId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (vtkDataObject data, int remoteId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `int = obj.Receive (vtkDataArray data, int remoteId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `vtkDataObject = obj.ReceiveDataObject (int remoteId, int tag)` - This method receives data from a corresponding send. It blocks until the receive is finished. It calls methods in "data" to communicate the sending data. In the overrloads that take in a maxlength argument, this length is the maximum length of the message to receive. If the maxlength is less than the length of the message sent by the sender, an error will be flagged. Once a message is received, use the GetCount() method to determine the actual size of the data received.

- `vtkIdType = obj.GetCount ()` - Returns the number of words received by the most recent Receive(). Note that this is not the number of bytes received, but the number of items of the data-type received by the most recent Receive() eg. if Receive(int*,..) was used, then this returns the number of ints received; if Receive(double*,..) was used, then this returns the number of doubles received etc. The return value is valid only after a successful Receive().

- `int = obj.Broadcast (int data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id srcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.

- `int = obj.Broadcast (long data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id srcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.

- `int = obj.Broadcast (string data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (string data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (float data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (double data, vtkIdType length, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (vtkDataObject data, int srcProcessId)` - Broadcast sends the array in the process with id şrcProcessId to all of the other processes. All processes must call these method with the same arguments in order for it to complete.
- `int = obj.Broadcast (vtkDataArray data, int srcProcessId)` - Gather collects arrays in the process with id ḑestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (int sendBuffer, int recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ḑestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (long sendBuffer, long recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ḑestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (string sendBuffer, string recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ḑestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (string sendBuffer, string recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ḑestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The ļength argument (which must be the same on all processes) is the length of the sendBuffers. The ŗecvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.
- `int = obj.Gather (float sendBuffer, float recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id ḑestProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the

messages and stores them in rank order. The length argument (which must be the same on all processes) is the length of the sendBuffers. The recvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.

- `int = obj.Gather (double sendBuffer, double recvBuffer, vtkIdType length, int destProcessId)` - Gather collects arrays in the process with id destProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The length argument (which must be the same on all processes) is the length of the sendBuffers. The recvBuffer (on te destination process) must be of length length*numProcesses. Gather is the inverse operation of Scatter.

- `int = obj.Gather (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int destProcessId)` - GatherV is the vector variant of Gather. It extends the functionality of Gather by allowing a varying count of data from each process. GatherV collects arrays in the process with id destProcessId. Each process (including the destination) sends the contents of its send buffer to the destination process. The destination process receives the messages and stores them in rank order. The sendLength argument defines how much the local process sends to destProcessId and recvLengths is an array containing the amount destProcessId receives from each process, in rank order.

- `int = obj.Scatter (int sendBuffer, int recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (long sendBuffer, long recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (string sendBuffer, string recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (string sendBuffer, string recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (float sendBuffer, float recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (double sendBuffer, double recvBuffer, vtkIdType length, int srcProcessId)` - Scatter takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer. Process 0 receives the first length values, process 1 receives the second length values, and so on. Scatter is the inverse operation of Gather.

- `int = obj.Scatter (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int srcProcessId)` - ScatterV is the vector variant of Scatter. It extends the functionality of Scatter by allowing a varying count of data to each process. ScatterV takes an array in the process with id srcProcessId and distributes it. Each process (including the source) receives a portion of the send buffer defined by the sendLengths and offsets arrays.

- `int = obj.AllGather (int sendBuffer, int recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.

- `int = obj.AllGather (long sendBuffer, long recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.
- `int = obj.AllGather (string sendBuffer, string recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.
- `int = obj.AllGather (string sendBuffer, string recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.
- `int = obj.AllGather (float sendBuffer, float recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.
- `int = obj.AllGather (double sendBuffer, double recvBuffer, vtkIdType length)` - Same as gather except that the result ends up on all processes.
- `int = obj.AllGather (vtkDataArray sendBuffer, vtkDataArray recvBuffer)` - Same as GatherV except that the result is placed in all processes.
- `int = obj.Reduce (int sendBuffer, int recvBuffer, vtkIdType length, int operation, int destProcessI` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (long sendBuffer, long recvBuffer, vtkIdType length, int operation, int destProces` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation, int destPr` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation, int destPr` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (float sendBuffer, float recvBuffer, vtkIdType length, int operation, int destProc` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (double sendBuffer, double recvBuffer, vtkIdType length, int operation, int destPr` - Reduce an array to the given destination process. This version of Reduce takes an identifier defined in the vtkCommunicator::StandardOperations enum to define the operation.
- `int = obj.Reduce (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int operation, int destProcessI` - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (int sendBuffer, int recvBuffer, vtkIdType length, int operation)` - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (long sendBuffer, long recvBuffer, vtkIdType length, int operation)` - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation)` - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (string sendBuffer, string recvBuffer, vtkIdType length, int operation)` - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (float sendBuffer, float recvBuffer, vtkIdType length, int operation)` - Same as Reduce except that the result is placed in all of the processes.

- `int = obj.AllReduce (double sendBuffer, double recvBuffer, vtkIdType length, int operation)` - Same as Reduce except that the result is placed in all of the processes.
- `int = obj.AllReduce (vtkDataArray sendBuffer, vtkDataArray recvBuffer, int operation)`

38.25 vtkParallelFactory

38.25.1 Usage

To create an instance of class vtkParallelFactory, simply invoke its constructor as follows

```
obj = vtkParallelFactory
```

38.25.2 Methods

The class vtkParallelFactory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelFactory class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelFactory = obj.NewInstance ()`
- `vtkParallelFactory = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetVTKSourceVersion ()`
- `string = obj.GetDescription ()`

38.26 vtkParallelRenderManager

38.26.1 Usage

vtkParallelRenderManager operates in multiple processes. It provides proper renderers and render windows for performing the parallel rendering correctly. It can also attach itself to render windows and propagate rendering events and camera views.

.SECTION Note: Many parallel rendering schemes do not correctly handle transparency. Unless otherwise documented, assume a sub class does not.

.SECTION ToDo: Synchronization/barrier primitives.

Query ranges of scalar values of objects in addition to the boundry in three-space

To create an instance of class vtkParallelRenderManager, simply invoke its constructor as follows

```
obj = vtkParallelRenderManager
```

38.26.2 Methods

The class vtkParallelRenderManager has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelRenderManager class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkParallelRenderManager = obj.NewInstance ()`
- `vtkParallelRenderManager = obj.SafeDownCast (vtkObject o)`
- `vtkRenderWindow = obj.MakeRenderWindow ()` - Builds a vtkRenderWindow compatible with this render manager. The user program is responsible for registering the render window with the SetRenderWindow method and calling Delete. It is not advisable to use a parallel render manager with a render window that was not built with this method.
- `vtkRenderer = obj.MakeRenderer ()` - Builds a vtkRenderer compatible with this render manager. (Should we also register it?) The user program is responsible for calling Delete. It is not advisable to use a parallel render manager with a renderer that was not built with this method.
- `vtkRenderWindow = obj.GetRenderWindow ()` - Set/Get the RenderWindow to use for compositing. We add a start and end observer to the window.
- `obj.SetRenderWindow (vtkRenderWindow renWin)` - Set/Get the RenderWindow to use for compositing. We add a start and end observer to the window.
- `vtkMultiProcessController = obj.GetController ()` - Set/Get the vtkMultiProcessController which will handle communications for the parallel rendering.
- `obj.SetController (vtkMultiProcessController controller)` - Set/Get the vtkMultiProcessController which will handle communications for the parallel rendering.
- `obj.InitializePieces ()` - This method sets the piece and number of pieces for each actor with a polydata mapper.
- `obj.InitializeOffScreen ()` - Make all rendering windows not viewable set as off screen rendering. To make all renderwindows on screen rendering again, call OffScreenRenderingOff on all the render windows. This class assumes the window on root node is the only one viewable. Subclasses should change this as necessary.
- `obj.StartInteractor ()` - Initializes the RMIs and then, if on root node, starts the interactor on the attached render window. Otherwise, starts processing RMIs. When the interactor returns, it breaks the RMI listening on all other processors.
- `obj.StartServices ()` - If on node other than root, starts serving RMI requests for parallel renders.
- `obj.StopServices ()` - If on root node, stops the RMI processing on all service nodes.
- `obj.StartRender ()` - Callbacks that initialize and finish rendering and other tasks.
- `obj.EndRender ()` - Callbacks that initialize and finish rendering and other tasks.
- `obj.SatelliteStartRender ()` - Callbacks that initialize and finish rendering and other tasks.
- `obj.SatelliteEndRender ()` - Callbacks that initialize and finish rendering and other tasks.
- `obj.RenderRMI ()` - Callbacks that initialize and finish rendering and other tasks.
- `obj.ResetCamera (vtkRenderer ren)` - Callbacks that initialize and finish rendering and other tasks.
- `obj.ResetCameraClippingRange (vtkRenderer ren)` - Callbacks that initialize and finish rendering and other tasks.
- `obj.ComputeVisiblePropBoundsRMI (int renderId)` - Callbacks that initialize and finish rendering and other tasks.
- `obj.InitializeRMIs ()`

- `obj.ResetAllCameras ()` - Resets the camera of each renderer contained in the RenderWindow. Should only be called in the "root" process, and all remote processes must be processing RMIs for this method to complete.
- `obj.ComputeVisiblePropBounds (vtkRenderer ren, double bounds[6])` - Calculates the bounds by gathering information from all processes.
- `obj.SetParallelRendering (int )` - Turns on/off parallel rendering. When on (the default) the object responds to render events of the attached window, propagates the render event to other processors, and otherwise enables the parallel rendering process.
- `int = obj.GetParallelRendering ()` - Turns on/off parallel rendering. When on (the default) the object responds to render events of the attached window, propagates the render event to other processors, and otherwise enables the parallel rendering process.
- `obj.ParallelRenderingOn ()` - Turns on/off parallel rendering. When on (the default) the object responds to render events of the attached window, propagates the render event to other processors, and otherwise enables the parallel rendering process.
- `obj.ParallelRenderingOff ()` - Turns on/off parallel rendering. When on (the default) the object responds to render events of the attached window, propagates the render event to other processors, and otherwise enables the parallel rendering process.
- `obj.SetRenderEventPropagation (int )` - Turns on/off render event propagation. When on (the default) and ParallelRendering is on, process 0 will send an RMI call to all remote processes to perform a synchronized render. When off, render must be manually called on each process.
- `int = obj.GetRenderEventPropagation ()` - Turns on/off render event propagation. When on (the default) and ParallelRendering is on, process 0 will send an RMI call to all remote processes to perform a synchronized render. When off, render must be manually called on each process.
- `obj.RenderEventPropagationOn ()` - Turns on/off render event propagation. When on (the default) and ParallelRendering is on, process 0 will send an RMI call to all remote processes to perform a synchronized render. When off, render must be manually called on each process.
- `obj.RenderEventPropagationOff ()` - Turns on/off render event propagation. When on (the default) and ParallelRendering is on, process 0 will send an RMI call to all remote processes to perform a synchronized render. When off, render must be manually called on each process.
- `obj.SetUseCompositing (int )` - This is used for tiled display rendering. When data has been duplicated on all processes, then we do not need to compositing. Cameras and renders are still propagated though.
- `int = obj.GetUseCompositing ()` - This is used for tiled display rendering. When data has been duplicated on all processes, then we do not need to compositing. Cameras and renders are still propagated though.
- `obj.UseCompositingOn ()` - This is used for tiled display rendering. When data has been duplicated on all processes, then we do not need to compositing. Cameras and renders are still propagated though.
- `obj.UseCompositingOff ()` - This is used for tiled display rendering. When data has been duplicated on all processes, then we do not need to compositing. Cameras and renders are still propagated though.
- `obj.SetImageReductionFactor (double factor)` - Set/Get the reduction factor (for sort-last based parallel renderers). The size of rendered image is divided by the reduction factor and then is blown up to the size of the current vtkRenderWindow. Setting higher reduction factors enables shorter image transfer times (which is often the bottleneck) but will greatly reduce image quality. A reduction factor of 2 or greater should only be used for intermediate images in interactive applications. A reduction factor of 1 (or less) will result in no change in image quality. A parallel render manager may ignore

the image reduction factor if it will result in little or no performance enhancements (eg. it does not do image space manipulations).

- `double = obj.GetImageReductionFactor ()` - Set/Get the reduction factor (for sort-last based parallel renderers). The size of rendered image is divided by the reduction factor and then is blown up to the size of the current vtkRenderWindow. Setting higher reduction factors enables shorter image transfer times (which is often the bottleneck) but will greatly reduce image quality. A reduction factor of 2 or greater should only be used for intermediate images in interactive applications. A reduction factor of 1 (or less) will result in no change in image quality. A parallel render manager may ignore the image reduction factor if it will result in little or no performance enhancements (eg. it does not do image space manipulations).
- `obj.SetMaxImageReductionFactor (double )`
- `double = obj.GetMaxImageReductionFactor ()`
- `obj.SetImageReductionFactorForUpdateRate (double DesiredUpdateRate)` - Sets the ReductionFactor based on the given desired update rate and the rendering metrics taken from the last time UpdateServerInfo was called. Note that if AutoReductionFactor is on, this function is called with the desired update rate of the render window automatically.
- `obj.SetAutoImageReductionFactor (int )` - If on, the ReductionFactor is automatically adjusted to best meet the the DesiredUpdateRate in the current RenderWindow based on metrics from the last render.
- `int = obj.GetAutoImageReductionFactor ()` - If on, the ReductionFactor is automatically adjusted to best meet the the DesiredUpdateRate in the current RenderWindow based on metrics from the last render.
- `obj.AutoImageReductionFactorOn ()` - If on, the ReductionFactor is automatically adjusted to best meet the the DesiredUpdateRate in the current RenderWindow based on metrics from the last render.
- `obj.AutoImageReductionFactorOff ()` - If on, the ReductionFactor is automatically adjusted to best meet the the DesiredUpdateRate in the current RenderWindow based on metrics from the last render.
- `double = obj.GetRenderTime ()` - Get rendering metrics.
- `double = obj.GetImageProcessingTime ()` - Get rendering metrics.
- `int = obj.GetSyncRenderWindowRenderers ()` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.
- `obj.SetSyncRenderWindowRenderers (int )` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.
- `obj.SyncRenderWindowRenderersOn ()` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.

- `obj.SyncRenderWindowRenderersOff ()` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.

- `obj.AddRenderer (vtkRenderer )` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.

- `obj.RemoveRenderer (vtkRenderer )` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.

- `obj.RemoveAllRenderers ()` - By default, the state of all renderers in the root's render window is propagated to the rest of the processes. In order for this to work, all render windows must have the same renderers in the same order. If this is not the case, you can turn off the SyncRenderWindowRenderers. When this flag is off, the list of renderers held by this parallel render manager (initially empty) is synced. You can modify the list of renderers with the AddRenderer, RemoveRenderer, and RemoveAllRenderers methods.

- `obj.SetWriteBackImages (int )` - If on (the default), the result of any image space manipulations are written back to the render window frame buffer. If off, the image stored in the frame buffer may not be correct. Either way, the correct frame buffer images may be read with vtkParallelRenderManager::GetPixelData. Turning WriteBackImages off may result in a speedup if the render window is not visible to the user and images are read back for further processing or transit.

- `int = obj.GetWriteBackImages ()` - If on (the default), the result of any image space manipulations are written back to the render window frame buffer. If off, the image stored in the frame buffer may not be correct. Either way, the correct frame buffer images may be read with vtkParallelRenderManager::GetPixelData. Turning WriteBackImages off may result in a speedup if the render window is not visible to the user and images are read back for further processing or transit.

- `obj.WriteBackImagesOn ()` - If on (the default), the result of any image space manipulations are written back to the render window frame buffer. If off, the image stored in the frame buffer may not be correct. Either way, the correct frame buffer images may be read with vtkParallelRenderManager::GetPixelData. Turning WriteBackImages off may result in a speedup if the render window is not visible to the user and images are read back for further processing or transit.

- `obj.WriteBackImagesOff ()` - If on (the default), the result of any image space manipulations are written back to the render window frame buffer. If off, the image stored in the frame buffer may not be correct. Either way, the correct frame buffer images may be read with vtkParallelRenderManager::GetPixelData. Turning WriteBackImages off may result in a speedup if the render window is not visible to the user and images are read back for further processing or transit.

- `obj.SetMagnifyImages (int )` - If on (the default), when the ImageReductionFactor is greater than 1 and WriteBackImages is on, the image will be magnified to fill the entire render window.

- `int = obj.GetMagnifyImages ()` - If on (the default), when the ImageReductionFactor is greater than 1 and WriteBackImages is on, the image will be magnified to fill the entire render window.

- `obj.MagnifyImagesOn ()` - If on (the default), when the ImageReductionFactor is greater than 1 and WriteBackImages is on, the image will be magnified to fill the entire render window.
- `obj.MagnifyImagesOff ()` - If on (the default), when the ImageReductionFactor is greater than 1 and WriteBackImages is on, the image will be magnified to fill the entire render window.
- `obj.SetMagnifyImageMethod (int method)` - Sets the method used to magnify images. Nearest simply replicates each pixel enough times to fill the image. Linear performs linear interpolation between the pixels.
- `int = obj.GetMagnifyImageMethod ()` - Sets the method used to magnify images. Nearest simply replicates each pixel enough times to fill the image. Linear performs linear interpolation between the pixels.
- `obj.SetMagnifyImageMethodToNearest ()` - Sets the method used to magnify images. Nearest simply replicates each pixel enough times to fill the image. Linear performs linear interpolation between the pixels.
- `obj.SetMagnifyImageMethodToLinear ()` - Convenience functions for magnifying images.
- `obj.MagnifyImage (vtkUnsignedCharArray fullImage, int fullImageSize[2], vtkUnsignedCharArray reduce` - Convenience functions for magnifying images.
- `obj.GetPixelData (vtkUnsignedCharArray data)` - The most appropriate way to retrieve full size image data after a render. Will work regardless of whether WriteBackImages or MagnifyImage is on or off. The data returned may be a shallow copy of an internal array. Therefore, the data may be invalid after the next render or if the ParallelRenderManager is destroyed.
- `obj.GetPixelData (int x1, int y1, int x2, int y2, vtkUnsignedCharArray data)` - The most appropriate way to retrieve full size image data after a render. Will work regardless of whether WriteBackImages or MagnifyImage is on or off. The data returned may be a shallow copy of an internal array. Therefore, the data may be invalid after the next render or if the ParallelRenderManager is destroyed.
- `obj.GetReducedPixelData (vtkUnsignedCharArray data)` - The most appropriate way to retrieve reduced size image data after a render. Will work regardless of whether WriteBackImages or MagnifyImage is on or off. The data returned may be a shallow copy of an internal array. Therefore, the data may be invalid after the next render or if the ParallelRenderManager is destroyed.
- `obj.GetReducedPixelData (int x1, int y1, int x2, int y2, vtkUnsignedCharArray data)` - The most appropriate way to retrieve reduced size image data after a render. Will work regardless of whether WriteBackImages or MagnifyImage is on or off. The data returned may be a shallow copy of an internal array. Therefore, the data may be invalid after the next render or if the ParallelRenderManager is destroyed.
- `int = obj. GetFullImageSize ()` - Returns the full image size calculated at the last render.
- `int = obj. GetReducedImageSize ()` - Returns the reduced image size calculated at the last render.
- `obj.TileWindows (int xsize, int ysize, int nColumns)` - Given the x and y size of the render windows, reposition them in a tile of n columns.
- `obj.SetUseRGBA (int )` - Get/Set if all Images must use RGBA instead of RGB. By default, this flag is on.
- `int = obj.GetUseRGBA ()` - Get/Set if all Images must use RGBA instead of RGB. By default, this flag is on.
- `obj.SetForceRenderWindowSize (int )` - If ForceRenderWindowSize is set to true, the render manager will use the RenderWindowSize ivar instead of getting the size from the render window.

- `int = obj.GetForceRenderWindowSize ()` - If ForceRenderWindowSize is set to true, the render manager will use the RenderWindowSize ivar instead of getting the size from the render window.
- `obj.SetForcedRenderWindowSize (int , int )` - If ForceRenderWindowSize is set to true, the render manager will use the Size ivar instead of getting the size from the render window.
- `obj.SetForcedRenderWindowSize (int a[2])` - If ForceRenderWindowSize is set to true, the render manager will use the Size ivar instead of getting the size from the render window.
- `int = obj. GetForcedRenderWindowSize ()` - If ForceRenderWindowSize is set to true, the render manager will use the Size ivar instead of getting the size from the render window.
- `obj.StartService ()` - @deprecated Replaced by vtkParallelRenderManager::StartServices() as of VTK 5.0.
- `obj.SetUseBackBuffer (int )`
- `int = obj.GetUseBackBuffer ()`
- `obj.UseBackBufferOn ()`
- `obj.UseBackBufferOff ()`
- `obj.SetSynchronizeTileProperties (int )` - When set the render manager will synchronize the TileViewport and TileScale properties. This may not be desirable in cases where there's some other mechanism to set the tile dimensions eg. Tile displays.
- `int = obj.GetSynchronizeTileProperties ()` - When set the render manager will synchronize the TileViewport and TileScale properties. This may not be desirable in cases where there's some other mechanism to set the tile dimensions eg. Tile displays.
- `obj.SynchronizeTilePropertiesOn ()` - When set the render manager will synchronize the TileViewport and TileScale properties. This may not be desirable in cases where there's some other mechanism to set the tile dimensions eg. Tile displays.
- `obj.SynchronizeTilePropertiesOff ()` - When set the render manager will synchronize the TileViewport and TileScale properties. This may not be desirable in cases where there's some other mechanism to set the tile dimensions eg. Tile displays.
- `obj.GenericStartRenderCallback ()` - INTERNAL METHODS (DON NOT USE). There are internal methods made public so that they can be called from callback functions.
- `obj.GenericEndRenderCallback ()` - INTERNAL METHODS (DON NOT USE). There are internal methods made public so that they can be called from callback functions.

38.27 vtkPassThroughFilter

38.27.1 Usage

This filter shallow copies it's input to it's output. It is normally used by PVSources with multiple outputs as the VTK filter in the dummy connection objects at each output.

To create an instance of class vtkPassThroughFilter, simply invoke its constructor as follows

```
obj = vtkPassThroughFilter
```

38.27.2 Methods

The class vtkPassThroughFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPassThroughFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPassThroughFilter = obj.NewInstance ()`
- `vtkPassThroughFilter = obj.SafeDownCast (vtkObject o)`

38.28 vtkPCellDataToPointData

38.28.1 Usage

Like it super class, this filter averages the cell data around a point to get new point data. This subclass requests a layer of ghost cells to make the results invariant to pieces. There is a "PieceInvariant" flag that lets the user change the behavior of the filter to that of its superclass.

To create an instance of class vtkPCellDataToPointData, simply invoke its constructor as follows

```
obj = vtkPCellDataToPointData
```

38.28.2 Methods

The class vtkPCellDataToPointData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPCellDataToPointData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPCellDataToPointData = obj.NewInstance ()`
- `vtkPCellDataToPointData = obj.SafeDownCast (vtkObject o)`
- `obj.SetPieceInvariant (int )` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.
- `int = obj.GetPieceInvariant ()` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.
- `obj.PieceInvariantOn ()` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.
- `obj.PieceInvariantOff ()` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.

38.29 vtkPChacoReader

38.29.1 Usage

vtkPChacoReader is a unstructured grid source object that reads Chaco files. The file is read by process 0 and converted into a vtkUnstructuredGrid. The vtkDistributedDataFilter is invoked to divide the grid among the processes.

To create an instance of class vtkPChacoReader, simply invoke its constructor as follows

```
obj = vtkPChacoReader
```

38.29.2 Methods

The class vtkPChacoReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPChacoReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPChacoReader = obj.NewInstance ()`
- `vtkPChacoReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController c)`
- `vtkMultiProcessController = obj.GetController ()`

38.30 vtkPCosmoHaloFinder

38.30.1 Usage

vtkPCosmoHaloFinder is a filter object that operates on the unstructured grid of all particles and assigns each particle a halo id.

To create an instance of class vtkPCosmoHaloFinder, simply invoke its constructor as follows

```
obj = vtkPCosmoHaloFinder
```

38.30.2 Methods

The class vtkPCosmoHaloFinder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPCosmoHaloFinder class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPCosmoHaloFinder = obj.NewInstance ()`
- `vtkPCosmoHaloFinder = obj.SafeDownCast (vtkObject o)`
- `vtkMultiProcessController = obj.GetController ()` - Set the communicator object for interprocess communication
- `obj.SetController (vtkMultiProcessController )` - Set the communicator object for interprocess communication

- `obj.SetNP (int )` - Specify the number of seeded particles in one dimension (total = np$\hat{3}$)
- `int = obj.GetNP ()` - Specify the number of seeded particles in one dimension (total = np$\hat{3}$)
- `obj.SetRL (float )` - Specify the physical box dimensions size (rL) (default 91)
- `float = obj.GetRL ()` - Specify the physical box dimensions size (rL) (default 91)
- `obj.SetOverlap (float )` - Specify the ghost cell spacing (edge boundary of box) (default 5)
- `float = obj.GetOverlap ()` - Specify the ghost cell spacing (edge boundary of box) (default 5)
- `obj.SetPMin (int )` - Specify the minimum number of particles for a halo (pmin)
- `int = obj.GetPMin ()` - Specify the minimum number of particles for a halo (pmin)
- `obj.SetBB (float )` - Specify the linking length (bb)
- `float = obj.GetBB ()` - Specify the linking length (bb)
- `obj.SetParticleMass (float )` - Specify the particle mass
- `float = obj.GetParticleMass ()` - Specify the particle mass
- `obj.SetCopyHaloDataToParticles (int )` - Copy the halo information to the original particles (Default on)
- `int = obj.GetCopyHaloDataToParticles ()` - Copy the halo information to the original particles (Default on)

38.31 vtkPCosmoReader

38.31.1 Usage

vtkPCosmoReader creates a vtkUnstructuredGrid from a binary cosmology file. The file contains fields for: x_position, x_velocity (float) y_position, y_velocity (float) z-position, z_velocity (float) mass (float) identification tag (integer)

If the file contains particle information x,y,z is the location of the particle in simulation space with a velocity vector and a mass which will be the same for all particles.

To create an instance of class vtkPCosmoReader, simply invoke its constructor as follows

```
obj = vtkPCosmoReader
```

38.31.2 Methods

The class vtkPCosmoReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPCosmoReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPCosmoReader = obj.NewInstance ()`
- `vtkPCosmoReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the name of the cosmology particle binary file to read
- `string = obj.GetFileName ()` - Specify the name of the cosmology particle binary file to read

- `obj.SetRL (float )` - Specify the physical box dimensions size (rL) (default 91)
- `float = obj.GetRL ()` - Specify the physical box dimensions size (rL) (default 91)
- `obj.SetOverlap (float )` - Specify the ghost cell spacing (edge boundary of box) (default 5)
- `float = obj.GetOverlap ()` - Specify the ghost cell spacing (edge boundary of box) (default 5)
- `obj.SetReadMode (int )` - Set the read mode (0 = one-to-one, 1 = default, round-robin)
- `int = obj.GetReadMode ()` - Set the read mode (0 = one-to-one, 1 = default, round-robin)
- `obj.SetCosmoFormat (int )` - Set the filetype to Gadget or Cosmo read mode (0 = Gadget, 1 = default, Cosmo)
- `int = obj.GetCosmoFormat ()` - Set the filetype to Gadget or Cosmo read mode (0 = Gadget, 1 = default, Cosmo)
- `vtkMultiProcessController = obj.GetController ()` - Set the communicator object for interprocess communication
- `obj.SetController (vtkMultiProcessController )` - Set the communicator object for interprocess communication

38.32 vtkPDataSetReader

38.32.1 Usage

vtkPDataSetReader will read a piece of a file, it takes as input a metadata file that lists all of the files in a data set.

To create an instance of class vtkPDataSetReader, simply invoke its constructor as follows

```
obj = vtkPDataSetReader
```

38.32.2 Methods

The class vtkPDataSetReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPDataSetReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPDataSetReader = obj.NewInstance ()`
- `vtkPDataSetReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - This file to open and read.
- `string = obj.GetFileName ()` - This file to open and read.
- `int = obj.GetDataType ()` - This is set when UpdateInformation is called. It shows the type of the output.
- `int = obj.CanReadFile (string filename)` - Called to determine if the file can be read by the reader.

38.33 vtkPDataSetWriter

38.33.1 Usage

vtkPDataSetWriter will write a piece of a file, and will also create a metadata file that lists all of the files in a data set.

To create an instance of class vtkPDataSetWriter, simply invoke its constructor as follows

```
obj = vtkPDataSetWriter
```

38.33.2 Methods

The class vtkPDataSetWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPDataSetWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPDataSetWriter = obj.NewInstance ()`
- `vtkPDataSetWriter = obj.SafeDownCast (vtkObject o)`
- `int = obj.Write ()` - Write the pvtk file and cooresponding vtk files.
- `obj.SetNumberOfPieces (int num)` - This is how many pieces the whole data set will be divided into.
- `int = obj.GetNumberOfPieces ()` - This is how many pieces the whole data set will be divided into.
- `obj.SetGhostLevel (int )` - Extra ghost cells will be written out to each piece file if this value is larger than 0.
- `int = obj.GetGhostLevel ()` - Extra ghost cells will be written out to each piece file if this value is larger than 0.
- `obj.SetStartPiece (int )` - This is the range of pieces that that this writer is responsible for writing. All pieces must be written by some process. The process that writes piece 0 also writes the pvtk file that lists all the piece file names.
- `int = obj.GetStartPiece ()` - This is the range of pieces that that this writer is responsible for writing. All pieces must be written by some process. The process that writes piece 0 also writes the pvtk file that lists all the piece file names.
- `obj.SetEndPiece (int )` - This is the range of pieces that that this writer is responsible for writing. All pieces must be written by some process. The process that writes piece 0 also writes the pvtk file that lists all the piece file names.
- `int = obj.GetEndPiece ()` - This is the range of pieces that that this writer is responsible for writing. All pieces must be written by some process. The process that writes piece 0 also writes the pvtk file that lists all the piece file names.
- `obj.SetFilePattern (string )` - This file pattern uses the file name and piece number to contruct a file name for the piece file.
- `string = obj.GetFilePattern ()` - This file pattern uses the file name and piece number to contruct a file name for the piece file.

- `obj.SetUseRelativeFileNames (int )` - This flag determines whether to use absolute paths for the piece files. By default the pieces are put in the main directory, and the piece file names in the meta data pvtk file are relative to this directory. This should make moving the whole lot to another directory, an easier task.

- `int = obj.GetUseRelativeFileNames ()` - This flag determines whether to use absolute paths for the piece files. By default the pieces are put in the main directory, and the piece file names in the meta data pvtk file are relative to this directory. This should make moving the whole lot to another directory, an easier task.

- `obj.UseRelativeFileNamesOn ()` - This flag determines whether to use absolute paths for the piece files. By default the pieces are put in the main directory, and the piece file names in the meta data pvtk file are relative to this directory. This should make moving the whole lot to another directory, an easier task.

- `obj.UseRelativeFileNamesOff ()` - This flag determines whether to use absolute paths for the piece files. By default the pieces are put in the main directory, and the piece file names in the meta data pvtk file are relative to this directory. This should make moving the whole lot to another directory, an easier task.

38.34 vtkPExtractArraysOverTime

38.34.1 Usage

vtkPExtractArraysOverTime is a parallelized version of vtkExtractArraysOverTime. vtkExtractArraysOverTime extract point or cell data given a selection. For every cell or point extracted, vtkExtractArraysOverTime create a vtkTable that is placed in an appropriately named block in an output multi-block dataset. For global-id based selections or location based selections, it's possible that over time the cell/point moves across processes. This filter ensures that such extractions spread across processes are combined correctly into a single vtkTable. This filter produces a valid output on the root node alone, all other nodes, simply have empty multi-block dataset with number of blocks matching the root (to ensure that all processes have the same structure).

To create an instance of class vtkPExtractArraysOverTime, simply invoke its constructor as follows

```
obj = vtkPExtractArraysOverTime
```

38.34.2 Methods

The class vtkPExtractArraysOverTime has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPExtractArraysOverTime class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkPExtractArraysOverTime = obj.NewInstance ()`

- `vtkPExtractArraysOverTime = obj.SafeDownCast (vtkObject o)`

- `obj.SetController (vtkMultiProcessController )` - Set and get the controller.

- `vtkMultiProcessController = obj.GetController ()` - Set and get the controller.

38.35 vtkPieceRequestFilter

38.35.1 Usage

Sends the piece and number of pieces to upstream filters; passes the input to the output unmodified.

To create an instance of class vtkPieceRequestFilter, simply invoke its constructor as follows

```
obj = vtkPieceRequestFilter
```

38.35.2 Methods

The class vtkPieceRequestFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPieceRequestFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPieceRequestFilter = obj.NewInstance ()`
- `vtkPieceRequestFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPieces (int )` - The total number of pieces.
- `int = obj.GetNumberOfPiecesMinValue ()` - The total number of pieces.
- `int = obj.GetNumberOfPiecesMaxValue ()` - The total number of pieces.
- `int = obj.GetNumberOfPieces ()` - The total number of pieces.
- `obj.SetPiece (int )` - The piece to extract.
- `int = obj.GetPieceMinValue ()` - The piece to extract.
- `int = obj.GetPieceMaxValue ()` - The piece to extract.
- `int = obj.GetPiece ()` - The piece to extract.
- `vtkDataObject = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm.

38.36 vtkPieceScalars

38.36.1 Usage

vtkPieceScalars is meant to display which piece is being requested as scalar values. It is usefull for visualizing the partitioning for streaming or distributed pipelines.

To create an instance of class vtkPieceScalars, simply invoke its constructor as follows

```
obj = vtkPieceScalars
```

38.36.2 Methods

The class vtkPieceScalars has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPieceScalars class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPieceScalars = obj.NewInstance ()`
- `vtkPieceScalars = obj.SafeDownCast (vtkObject o)`
- `obj.SetScalarModeToCellData ()` - Option to centerate cell scalars of points scalars. Default is point scalars.
- `obj.SetScalarModeToPointData ()` - Option to centerate cell scalars of points scalars. Default is point scalars.
- `int = obj.GetScalarMode ()`
- `obj.SetRandomMode (int )`
- `int = obj.GetRandomMode ()`
- `obj.RandomModeOn ()`
- `obj.RandomModeOff ()`

38.37 vtkPImageWriter

38.37.1 Usage

vtkPImageWriter writes images to files with any data type. The data type of the file is the same scalar type as the input. The dimensionality determines whether the data will be written in one or multiple files. This class is used as the superclass of most image writing classes such as vtkBMPWriter etc. It supports streaming.

To create an instance of class vtkPImageWriter, simply invoke its constructor as follows

```
obj = vtkPImageWriter
```

38.37.2 Methods

The class vtkPImageWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPImageWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPImageWriter = obj.NewInstance ()`
- `vtkPImageWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetMemoryLimit (long )` - Set / Get the memory limit in kilobytes. The writer will stream to attempt to keep the pipeline size within this limit
- `long = obj.GetMemoryLimit ()` - Set / Get the memory limit in kilobytes. The writer will stream to attempt to keep the pipeline size within this limit

38.38 vtkPKdTree

38.38.1 Usage

Build, in parallel, a k-d tree decomposition of one or more vtkDataSets distributed across processors. We assume each process has read in one portion of a large distributed data set. When done, each process has access to the k-d tree structure, can obtain information about which process contains data for each spatial region, and can depth sort the spatial regions.

This class can also assign spatial regions to processors, based on one of several region assignment schemes. By default a contiguous, convex region is assigned to each process. Several queries return information about how many and what cells I have that lie in a region assigned to another process.

To create an instance of class vtkPKdTree, simply invoke its constructor as follows

```
obj = vtkPKdTree
```

38.38.2 Methods

The class vtkPKdTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPKdTree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPKdTree = obj.NewInstance ()`
- `vtkPKdTree = obj.SafeDownCast (vtkObject o)`
- `obj.BuildLocator ()` - Build the spatial decomposition. Call this explicitly after changing any parameters affecting the build of the tree. It must be called by all processes in the parallel application, or it will hang.
- `vtkIdType = obj.GetTotalNumberOfCells ()` - Create tables of counts of cells per process per region. These tables can be accessed with queries like "HasData", "GetProcessCellCountForRegion", and so on. You must have called BuildLocator() beforehand. This method must be called by all processes or it will hang. Returns 1 on error, 0 when no error.
- `int = obj.CreateProcessCellCountData ()` - Create tables of counts of cells per process per region. These tables can be accessed with queries like "HasData", "GetProcessCellCountForRegion", and so on. You must have called BuildLocator() beforehand. This method must be called by all processes or it will hang. Returns 1 on error, 0 when no error.
- `int = obj.CreateGlobalDataArrayBounds ()` - A convenience function which compiles the global bounds of the data arrays across processes. These bounds can be accessed with "GetCellArrayGlobalRange" and "GetPointArrayGlobalRange". This method must be called by all processes or it will hang. Returns 1 on error, 0 when no error.
- `obj.SetController (vtkMultiProcessController c)` - Set/Get the communicator object
- `vtkMultiProcessController = obj.GetController ()` - Set/Get the communicator object
- `int = obj.GetRegionAssignment ()` - The PKdTree class can assign spatial regions to processors after building the k-d tree, using one of several partitioning criteria. These functions Set/Get whether this assignment is computed. The default is "Off", no assignment is computed. If "On", and no assignment scheme is specified, contiguous assignment will be computed. Specifying an assignment scheme (with AssignRegions*()) automatically turns on RegionAssignment.

- `int = obj.AssignRegions (int map, int numRegions)` - Assign spatial regions to processes via a user defined map. The user-supplied map is indexed by region ID, and provides a process ID for each region.
- `int = obj.AssignRegionsRoundRobin ()` - Let the PKdTree class assign a process to each region in a round robin fashion. If the k-d tree has not yet been built, the regions will be assigned after BuildLocator executes.
- `int = obj.AssignRegionsContiguous ()` - Let the PKdTree class assign a process to each region by assigning contiguous sets of spatial regions to each process. The set of regions assigned to each process will always have a union that is a convex space (a box). If the k-d tree has not yet been built, the regions will be assigned after BuildLocator executes.
- `int = obj.GetRegionAssignmentList (int procId, vtkIntArray list)` - Writes the list of region IDs assigned to the specified process. Regions IDs start at 0 and increase by 1 from there. Returns the number of regions in the list.
- `obj.GetAllProcessesBorderingOnPoint (float x, float y, float z, vtkIntArray list)` - The k-d tree spatial regions have been assigned to processes. Given a point on the boundary of one of the regions, this method creates a list of all processes whose region boundaries include that point. This may be required when looking for processes that have cells adjacent to the cells of a given process.
- `int = obj.GetProcessAssignedToRegion (int regionId)` - Returns the ID of the process assigned to the region.
- `int = obj.HasData (int processId, int regionId)` - Returns 1 if the process has data for the given region, 0 otherwise.
- `int = obj.GetProcessCellCountForRegion (int processId, int regionId)` - Returns the number of cells the specified process has in the specified region.
- `int = obj.GetTotalProcessesInRegion (int regionId)` - Returns the total number of processes that have data falling within this spatial region.
- `int = obj.GetProcessListForRegion (int regionId, vtkIntArray processes)` - Adds the list of processes having data for the given region to the supplied list, returns the number of processes added.
- `int = obj.GetProcessesCellCountForRegion (int regionId, int count, int len)` - Writes the number of cells each process has for the region to the supplied list of length len. Returns the number of cell counts written. The order of the cell counts corresponds to the order of process IDs in the process list returned by GetProcessListForRegion.
- `int = obj.GetTotalRegionsForProcess (int processId)` - Returns the total number of spatial regions that a given process has data for.
- `int = obj.GetRegionListForProcess (int processId, vtkIntArray regions)` - Adds the region IDs for which this process has data to the supplied vtkIntArray. Retruns the number of regions.
- `int = obj.GetRegionsCellCountForProcess (int ProcessId, int count, int len)` - Writes to the supplied integer array the number of cells this process has for each region. Returns the number of cell counts written. The order of the cell counts corresponds to the order of region IDs in the region list returned by GetRegionListForProcess.
- `vtkIdType = obj.GetCellListsForProcessRegions (int ProcessId, int set, vtkIdList inRegionCells, vtk` - After regions have been assigned to processes, I may want to know which cells I have that are in the regions assigned to a particular process.

  This method takes a process ID and two vtkIdLists. It writes to the first list the IDs of the cells contained in the process' regions. (That is, their cell centroid is contained in the region.) To the

second list it write the IDs of the cells which intersect the process' regions but whose cell centroid lies elsewhere.

The total number of cell IDs written to both lists is returned. Either list pointer passed in can be NULL, and it will be ignored. If there are multiple data sets, you must specify which data set you wish cell IDs for.

The caller should delete these two lists when done. This method uses the cell lists created in vtkKdTree::CreateCellLists(). If the cell lists for the process' regions do not exist, this method will first build the cell lists for all regions by calling CreateCellLists(). You must remember to DeleteCellLists() when done with all calls to this method, as cell lists can require a great deal of memory.

- `vtkIdType = obj.GetCellListsForProcessRegions (int ProcessId, vtkDataSet set, vtkIdList inRegionCel`
  - After regions have been assigned to processes, I may want to know which cells I have that are in the regions assigned to a particular process.

  This method takes a process ID and two vtkIdLists. It writes to the first list the IDs of the cells contained in the process' regions. (That is, their cell centroid is contained in the region.) To the second list it write the IDs of the cells which intersect the process' regions but whose cell centroid lies elsewhere.

  The total number of cell IDs written to both lists is returned. Either list pointer passed in can be NULL, and it will be ignored. If there are multiple data sets, you must specify which data set you wish cell IDs for.

  The caller should delete these two lists when done. This method uses the cell lists created in vtkKdTree::CreateCellLists(). If the cell lists for the process' regions do not exist, this method will first build the cell lists for all regions by calling CreateCellLists(). You must remember to DeleteCellLists() when done with all calls to this method, as cell lists can require a great deal of memory.

- `vtkIdType = obj.GetCellListsForProcessRegions (int ProcessId, vtkIdList inRegionCells, vtkIdList or`
  - After regions have been assigned to processes, I may want to know which cells I have that are in the regions assigned to a particular process.

  This method takes a process ID and two vtkIdLists. It writes to the first list the IDs of the cells contained in the process' regions. (That is, their cell centroid is contained in the region.) To the second list it write the IDs of the cells which intersect the process' regions but whose cell centroid lies elsewhere.

  The total number of cell IDs written to both lists is returned. Either list pointer passed in can be NULL, and it will be ignored. If there are multiple data sets, you must specify which data set you wish cell IDs for.

  The caller should delete these two lists when done. This method uses the cell lists created in vtkKdTree::CreateCellLists(). If the cell lists for the process' regions do not exist, this method will first build the cell lists for all regions by calling CreateCellLists(). You must remember to DeleteCellLists() when done with all calls to this method, as cell lists can require a great deal of memory.

- `int = obj.DepthOrderAllProcesses (double directionOfProjection, vtkIntArray orderedList)`
  - DO NOT CALL. Deprecated in VTK 5.2. Use ViewOrderAllProcessesInDirection or ViewOrderAllProcessesFromPosition.

- `int = obj.ViewOrderAllProcessesInDirection (double directionOfProjection[3], vtkIntArray orderedLis`
  - Return a list of all processes in order from front to back given a vector direction of projection. Use this to do visibility sorts in parallel projection mode. 'orderedList' will be resized to the number of processes. The return value is the number of processes.

- `int = obj.ViewOrderAllProcessesFromPosition (double cameraPosition[3], vtkIntArray orderedList)`
  - Return a list of all processes in order from front to back given a camera position. Use this to do visibility sorts in perspective projection mode. 'orderedList' will be resized to the number of processes. The return value is the number of processes.

- `int = obj.GetCellArrayGlobalRange (string name, float range[2])`
- `int = obj.GetPointArrayGlobalRange (string name, float range[2])`
- `int = obj.GetCellArrayGlobalRange (string name, double range[2])`
- `int = obj.GetPointArrayGlobalRange (string name, double range[2])`
- `int = obj.GetCellArrayGlobalRange (int arrayIndex, double range[2])`
- `int = obj.GetPointArrayGlobalRange (int arrayIndex, double range[2])`
- `int = obj.GetCellArrayGlobalRange (int arrayIndex, float range[2])`
- `int = obj.GetPointArrayGlobalRange (int arrayIndex, float range[2])`

38.39 vtkPLinearExtrusionFilter

38.39.1 Usage

vtkPLinearExtrusionFilter is a parallel version of vtkLinearExtrusionFilter.

To create an instance of class vtkPLinearExtrusionFilter, simply invoke its constructor as follows

```
obj = vtkPLinearExtrusionFilter
```

38.39.2 Methods

The class vtkPLinearExtrusionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPLinearExtrusionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPLinearExtrusionFilter = obj.NewInstance ()`
- `vtkPLinearExtrusionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetPieceInvariant (int )`
- `int = obj.GetPieceInvariant ()`
- `obj.PieceInvariantOn ()`
- `obj.PieceInvariantOff ()`

38.40 vtkPNrrdReader

38.40.1 Usage

vtkPNrrdReader is a subclass of vtkMPIImageReader that will read Nrrd format header information of the image before reading the data. This means that the reader will automatically set information like file dimensions.

.SECTION Bugs

There are several limitations on what type of nrrd files we can read. This reader only supports nrrd files in raw format. Other encodings like ascii and hex will result in errors. When reading in detached headers, this only supports reading one file that is detached.

To create an instance of class vtkPNrrdReader, simply invoke its constructor as follows

```
obj = vtkPNrrdReader
```

38.40.2 Methods

The class vtkPNrrdReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPNrrdReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPNrrdReader = obj.NewInstance ()`
- `vtkPNrrdReader = obj.SafeDownCast (vtkObject o)`
- `int = obj.CanReadFile (string filename)`

38.41 vtkPOpenFOAMReader

38.41.1 Usage

vtkPOpenFOAMReader creates a multiblock dataset. It reads parallel-decomposed mesh information and time dependent data. The polyMesh folders contain mesh information. The time folders contain transient data for the cells. Each folder can contain any number of data files.

To create an instance of class vtkPOpenFOAMReader, simply invoke its constructor as follows

```
obj = vtkPOpenFOAMReader
```

38.41.2 Methods

The class vtkPOpenFOAMReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPOpenFOAMReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPOpenFOAMReader = obj.NewInstance ()`
- `vtkPOpenFOAMReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetCaseType (int t)` - Set and get case type. 0 = decomposed case, 1 = reconstructed case.
- `obj.SetController (vtkMultiProcessController )` - Set and get the controller.
- `vtkMultiProcessController = obj.GetController ()` - Set and get the controller.

38.42 vtkPOPReader

38.42.1 Usage

vtkPOPReader Just converts from images to a structured grid for now.

To create an instance of class vtkPOPReader, simply invoke its constructor as follows

```
obj = vtkPOPReader
```

38.42.2 Methods

The class vtkPOPReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPOPReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPOPReader = obj.NewInstance ()`
- `vtkPOPReader = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetDimensions ()` - This is the longitude and latitude dimensions of the structured grid.
- `string = obj.GetGridFileName ()` - This file contains the latitude and longitude of the grid. It must be double with no header.
- `string = obj.GetUFlowFileName ()` - These files contains the u and v components of the flow.
- `string = obj.GetVFlowFileName ()` - These files contains the u and v components of the flow.
- `obj.SetFileName (string )` - This file contains information about all the files.
- `string = obj.GetFileName ()` - This file contains information about all the files.
- `obj.SetRadius (double )` - Radius of the earth.
- `double = obj.GetRadius ()` - Radius of the earth.
- `obj.SetClipExtent (int , int , int , int , int , int )` - Because the data can be so large, here is an option to clip while reading.
- `obj.SetClipExtent (int  a[6])` - Because the data can be so large, here is an option to clip while reading.
- `int = obj. GetClipExtent ()` - Because the data can be so large, here is an option to clip while reading.
- `obj.SetNumberOfGhostLevels (int )` - Set the number of ghost levels to include in the data
- `int = obj.GetNumberOfGhostLevels ()` - Set the number of ghost levels to include in the data

38.43 vtkPOutlineCornerFilter

38.43.1 Usage

vtkPOutlineCornerFilter works like vtkOutlineCornerFilter, but it looks for data partitions in other processes. It assumes the filter is operated in a data parallel pipeline.

To create an instance of class vtkPOutlineCornerFilter, simply invoke its constructor as follows

```
obj = vtkPOutlineCornerFilter
```

38.43.2 Methods

The class vtkPOutlineCornerFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPOutlineCornerFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPOutlineCornerFilter = obj.NewInstance ()`
- `vtkPOutlineCornerFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetCornerFactor (double )` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactorMinValue ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactorMaxValue ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `double = obj.GetCornerFactor ()` - Set/Get the factor that controls the relative size of the corners to the length of the corresponding bounds
- `obj.SetController (vtkMultiProcessController )` - Set and get the controller.
- `vtkMultiProcessController = obj.GetController ()` - Set and get the controller.

38.44 vtkPOutlineFilter

38.44.1 Usage

vtkPOutlineFilter works like vtkOutlineFilter, but it looks for data partitions in other processes. It assumes the filter is operated in a data parallel pipeline.

To create an instance of class vtkPOutlineFilter, simply invoke its constructor as follows

```
obj = vtkPOutlineFilter
```

38.44.2 Methods

The class vtkPOutlineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPOutlineFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPOutlineFilter = obj.NewInstance ()`
- `vtkPOutlineFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Set and get the controller.
- `vtkMultiProcessController = obj.GetController ()` - Set and get the controller.

38.45 vtkPPolyDataNormals

38.45.1 Usage

To create an instance of class vtkPPolyDataNormals, simply invoke its constructor as follows

```
obj = vtkPPolyDataNormals
```

38.45.2 Methods

The class vtkPPolyDataNormals has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPPolyDataNormals class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPPolyDataNormals = obj.NewInstance ()`
- `vtkPPolyDataNormals = obj.SafeDownCast (vtkObject o)`
- `obj.SetPieceInvariant (int )` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.
- `int = obj.GetPieceInvariant ()` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.
- `obj.PieceInvariantOn ()` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.
- `obj.PieceInvariantOff ()` - To get piece invariance, this filter has to request an extra ghost level. By default piece invariance is on.

38.46 vtkPProbeFilter

38.46.1 Usage

To create an instance of class vtkPProbeFilter, simply invoke its constructor as follows

```
obj = vtkPProbeFilter
```

38.46.2 Methods

The class vtkPProbeFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPProbeFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPProbeFilter = obj.NewInstance ()`
- `vtkPProbeFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Set and get the controller.
- `vtkMultiProcessController = obj.GetController ()` - Set and get the controller.

38.47 vtkPReflectionFilter

38.47.1 Usage

vtkPReflectionFilter is a parallel version of vtkReflectionFilter which takes into consideration the full dataset bounds for performing the reflection.

To create an instance of class vtkPReflectionFilter, simply invoke its constructor as follows

```
obj = vtkPReflectionFilter
```

38.47.2 Methods

The class vtkPReflectionFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPReflectionFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPReflectionFilter = obj.NewInstance ()`
- `vtkPReflectionFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the parallel controller.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the parallel controller.

38.48 vtkProcess

38.48.1 Usage

vtkProcess is an abstract class representing a process that can be launched by a vtkMultiProcessController. Concrete classes just have to implement Execute() method and make sure it set the proper value in ReturnValue.

.SECTION Example class MyProcess: public vtkProcess ... vtkMultiProcessController *c; MyProcess *p=new MyProcess::New(); p-¿SetArgs(argc,argv); // some parameters specific to the process p-¿SetX(10.0); // ... c-¿SetSingleProcess(p); c-¿SingleMethodExecute(); int returnValue=p-¿GetReturnValue();

To create an instance of class vtkProcess, simply invoke its constructor as follows

```
obj = vtkProcess
```

38.48.2 Methods

The class vtkProcess has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProcess class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProcess = obj.NewInstance ()`
- `vtkProcess = obj.SafeDownCast (vtkObject o)`
- `obj.Execute ()`

- `vtkMultiProcessController = obj.GetController ()` - Give access to the controller that launched the process. Initial value is NULL.
- `obj.SetController (vtkMultiProcessController aController)` - This method should not be called directly but set by the controller itself.
- `int = obj.GetReturnValue ()` - Value set at the end of a call to Execute.

38.49 vtkProcessGroup

38.49.1 Usage

This class is used for creating groups of processes. A vtkProcessGroup is initialized by passing the controller or communicator on which the group is based off of. You can then use the group to subset and reorder the the processes. Eventually, you can pass the group object to the CreateSubController method of vtkMultiProcessController to create a controller for the defined group of processes. You must use the same controller (or attached communicator) from which this group was initialized with.

To create an instance of class vtkProcessGroup, simply invoke its constructor as follows

```
obj = vtkProcessGroup
```

38.49.2 Methods

The class vtkProcessGroup has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProcessGroup class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProcessGroup = obj.NewInstance ()`
- `vtkProcessGroup = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkMultiProcessController controller)` - Initialize the group to the given controller or communicator. The group will be set to contain all of the processes in the controller/communicator in the same order.
- `obj.Initialize (vtkCommunicator communicator)` - Initialize the group to the given controller or communicator. The group will be set to contain all of the processes in the controller/communicator in the same order.
- `vtkCommunicator = obj.GetCommunicator ()` - Get the communicator on which this group is based on.
- `obj.SetCommunicator (vtkCommunicator communicator)` - Set the communicator. This has the same effect as Initialize except that the contents of the group will not be modified (although they may be truncated if the new communicator is smaller than the current group). Note that this can lead to an invalid group if there are values in the group that are not valid in the new communicator.
- `int = obj.GetNumberOfProcessIds ()` - Returns the size of this group (the number of processes defined in it).
- `int = obj.GetProcessId (int pos)` - Get the process id for the local process (as defined by the group's communicator). Returns -1 if the local process is not in the group.

- `int = obj.GetLocalProcessId ()` - Get the process id for the local process (as defined by the group's communicator). Returns -1 if the local process is not in the group.
- `int = obj.FindProcessId (int processId)` - Given a process id in the communicator, this method returns its location in the group or -1 if it is not in the group. For example, if this group contains 6, 2, 8, 1, then FindProcessId(2) will return 1 and FindProcessId(3) will return -1.
- `int = obj.AddProcessId (int processId)` - Add a process id to the end of the group (if it is not already in the group). Returns the location where the id was stored.
- `int = obj.RemoveProcessId (int processId)` - Remove the given process id from the group (assuming it is in the group). All ids to the "right" of the removed id are shifted over. Returns 1 if the process id was removed, 0 if the process id was not in the group in the first place.
- `obj.RemoveAllProcessIds ()` - Removes all the processes ids from the group, leaving the group empty.
- `obj.Copy (vtkProcessGroup group)` - Copies the given group's communicator and process ids.

38.50 vtkProcessIdScalars

38.50.1 Usage

vtkProcessIdScalars is meant to display which processor owns which cells and points. It is useful for visualizing the partitioning for streaming or distributed pipelines.

To create an instance of class vtkProcessIdScalars, simply invoke its constructor as follows

```
obj = vtkProcessIdScalars
```

38.50.2 Methods

The class vtkProcessIdScalars has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProcessIdScalars class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProcessIdScalars = obj.NewInstance ()`
- `vtkProcessIdScalars = obj.SafeDownCast (vtkObject o)`
- `obj.SetScalarModeToCellData ()` - Option to centerate cell scalars of points scalars. Default is point scalars.
- `obj.SetScalarModeToPointData ()` - Option to centerate cell scalars of points scalars. Default is point scalars.
- `int = obj.GetScalarMode ()`
- `obj.SetRandomMode (int )`
- `int = obj.GetRandomMode ()`
- `obj.RandomModeOn ()`
- `obj.RandomModeOff ()`

- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.

- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.

38.51 vtkPSLACReader

38.51.1 Usage

Extends the vtkSLACReader to read in partitioned pieces. Due to the nature of the data layout, this reader only works in a data parallel mode where each process in a parallel job simultaneously attempts to read the piece corresponding to the local process id.

To create an instance of class vtkPSLACReader, simply invoke its constructor as follows

```
obj = vtkPSLACReader
```

38.51.2 Methods

The class vtkPSLACReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPSLACReader class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkPSLACReader = obj.NewInstance ()`

- `vtkPSLACReader = obj.SafeDownCast (vtkObject o)`

- `vtkMultiProcessController = obj.GetController ()` - The controller used to communicate partition data. The number of pieces requested must agree with the number of processes, the piece requested must agree with the local process id, and all process must invoke ProcessRequests of this filter simultaneously.

- `obj.SetController (vtkMultiProcessController )` - The controller used to communicate partition data. The number of pieces requested must agree with the number of processes, the piece requested must agree with the local process id, and all process must invoke ProcessRequests of this filter simultaneously.

38.52 vtkPStreamTracer

38.52.1 Usage

This class implements some necessary functionality used by distributed and parallel streamline generators. Note that all processes must have access to the WHOLE seed source, i.e. the source must be identical on all processes.

To create an instance of class vtkPStreamTracer, simply invoke its constructor as follows

```
obj = vtkPStreamTracer
```

38.52.2 Methods

The class vtkPStreamTracer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPStreamTracer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPStreamTracer = obj.NewInstance ()`
- `vtkPStreamTracer = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController controller)` - Set/Get the controller use in compositing (set to the global controller by default) If not using the default, this must be called before any other methods.
- `vtkMultiProcessController = obj.GetController ()` - Set/Get the controller use in compositing (set to the global controller by default) If not using the default, this must be called before any other methods.

38.53 vtkPTableToStructuredGrid

38.53.1 Usage

vtkPTableToStructuredGrid is vtkTableToStructuredGrid specialization which handles distribution of the input table. For starters, this assumes that the input table is only available on the root node.

To create an instance of class vtkPTableToStructuredGrid, simply invoke its constructor as follows

```
obj = vtkPTableToStructuredGrid
```

38.53.2 Methods

The class vtkPTableToStructuredGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPTableToStructuredGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPTableToStructuredGrid = obj.NewInstance ()`
- `vtkPTableToStructuredGrid = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Get/Set the controller.
- `vtkMultiProcessController = obj.GetController ()` - Get/Set the controller.

38.54 vtkRectilinearGridOutlineFilter

38.54.1 Usage

vtkRectilinearGridOutlineFilter works in parallel. There is no reason. to use this filter if you are not breaking the processing into pieces. With one piece you can simply use vtkOutlineFilter. This filter ignores internal edges when the extent is not the whole extent.

To create an instance of class vtkRectilinearGridOutlineFilter, simply invoke its constructor as follows

```
obj = vtkRectilinearGridOutlineFilter
```

38.54.2 Methods

The class vtkRectilinearGridOutlineFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridOutlineFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridOutlineFilter = obj.NewInstance ()`
- `vtkRectilinearGridOutlineFilter = obj.SafeDownCast (vtkObject o)`

38.55 vtkSocketCommunicator

38.55.1 Usage

This is a concrete implementation of vtkCommunicator which supports interprocess communication using BSD style sockets. It supports byte swapping for the communication of machines with different endianness.

To create an instance of class vtkSocketCommunicator, simply invoke its constructor as follows

```
obj = vtkSocketCommunicator
```

38.55.2 Methods

The class vtkSocketCommunicator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSocketCommunicator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSocketCommunicator = obj.NewInstance ()`
- `vtkSocketCommunicator = obj.SafeDownCast (vtkObject o)`
- `int = obj.WaitForConnection (int port)` - Wait for connection on a given port. These methods return 1 on success, 0 on error.
- `int = obj.WaitForConnection (vtkServerSocket socket, long msec)` - Wait for connection on a given port. These methods return 1 on success, 0 on error.
- `obj.CloseConnection ()` - Close a connection.
- `int = obj.ConnectTo (string hostName, int port)` - Open a connection to host.
- `int = obj.GetSwapBytesInReceivedData ()` - Returns 1 if bytes must be swapped in received ints, floats, etc
- `int = obj.GetIsConnected ()` - Is the communicator connected?.
- `obj.SetNumberOfProcesses (int num)` - Set the number of processes you will be using.
- `obj.Barrier ()` - This class foolishly breaks the conventions of the superclass, so this overload fixes the method.

- `obj.SetPerformHandshake (int )` - Set or get the PerformHandshake ivar. If it is on, the communicator will try to perform a handshake when connected. It is on by default.
- `int = obj.GetPerformHandshakeMinValue ()` - Set or get the PerformHandshake ivar. If it is on, the communicator will try to perform a handshake when connected. It is on by default.
- `int = obj.GetPerformHandshakeMaxValue ()` - Set or get the PerformHandshake ivar. If it is on, the communicator will try to perform a handshake when connected. It is on by default.
- `obj.PerformHandshakeOn ()` - Set or get the PerformHandshake ivar. If it is on, the communicator will try to perform a handshake when connected. It is on by default.
- `obj.PerformHandshakeOff ()` - Set or get the PerformHandshake ivar. If it is on, the communicator will try to perform a handshake when connected. It is on by default.
- `int = obj.GetPerformHandshake ()` - Set or get the PerformHandshake ivar. If it is on, the communicator will try to perform a handshake when connected. It is on by default.
- `int = obj.LogToFile (string name)` - Log messages to the given file. The file is truncated unless the second argument is non-zero (default is to truncate). If the file name is empty or NULL, logging is disabled. Returns 0 if the file failed to open, and 1 otherwise.
- `int = obj.LogToFile (string name, int append)` - Log messages to the given file. The file is truncated unless the second argument is non-zero (default is to truncate). If the file name is empty or NULL, logging is disabled. Returns 0 if the file failed to open, and 1 otherwise.
- `obj.SetReportErrors (int )` - If ReportErrors if false, all vtkErrorMacros are suppressed.
- `int = obj.GetReportErrors ()` - If ReportErrors if false, all vtkErrorMacros are suppressed.
- `vtkClientSocket = obj.GetSocket ()` - Get/Set the actual socket used for communication.
- `obj.SetSocket (vtkClientSocket )` - Get/Set the actual socket used for communication.
- `int = obj.Handshake ()` - Performs handshake. This uses vtkClientSocket::ConnectingSide to decide whether to perform ServerSideHandshake or ClientSideHandshake.
- `int = obj.ServerSideHandshake ()` - Performs ServerSide handshake. One should preferably use Handshake() which calls ServerSideHandshake or ClientSideHandshake as required.
- `int = obj.ClientSideHandshake ()` - Performs ClientSide handshake. One should preferably use Handshake() which calls ServerSideHandshake or ClientSideHandshake as required.
- `int = obj.GetIsServer ()` - Returns true if this side of the socket is the server. The result is invalid if the socket is not connected.

38.56 vtkSocketController

38.56.1 Usage

This is a concrete implementation of vtkMultiProcessController. It supports one-to-one communication using sockets. Note that process 0 will always correspond to self and process 1 to the remote process. This class is best used with ports.

To create an instance of class vtkSocketController, simply invoke its constructor as follows

```
obj = vtkSocketController
```

38.56.2 Methods

The class vtkSocketController has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSocketController class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSocketController = obj.NewInstance ()`
- `vtkSocketController = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Does not apply to sockets. Does nothing.
- `obj.Finalize ()` - Does not apply to sockets. Does nothing.
- `obj.Finalize (int )` - Does not apply to sockets. Does nothing.
- `obj.SingleMethodExecute ()` - Does not apply to sockets. Does nothing.
- `obj.MultipleMethodExecute ()` - Does not apply to sockets. Does nothing.
- `obj.CreateOutputWindow ()` - Does not apply to sockets. Does nothing.
- `int = obj.WaitForConnection (int port)` - Wait for connection on a given port, forwarded to the communicator
- `obj.CloseConnection ()` - Close a connection, forwarded to the communicator
- `int = obj.ConnectTo (string hostName, int port)` - Open a connection to a give machine, forwarded to the communicator
- `int = obj.GetSwapBytesInReceivedData ()`
- `obj.SetCommunicator (vtkSocketCommunicator comm)` - Set the communicator used in normal and rmi communications.
- `vtkMultiProcessController = obj.CreateCompliantController ()` - FOOLISH MORTALS! Thou hast forsaken the sacred laws of ad-hoc polymorphism when thou broke a critical assumption of the superclass (namely, each process has thine own id). The time frame to fix thy error has passed. Too much code has come to rely on this abhorrent behavior. Instead, we offer this gift: a method for creating an equivalent communicator with correct process id semantics. The calling code is responsible for deleting this controller.

38.57 vtkSubCommunicator

38.57.1 Usage

This class provides an implementation for communicating on process groups. In general, you should never use this class directly. Instead, use the vtkMultiProcessController::CreateSubController method.

.SECTION BUGS

Because all communication is delegated to the original communicator, any error will report process ids with respect to the original communicator, not this communicator that was actually used.

To create an instance of class vtkSubCommunicator, simply invoke its constructor as follows

```
obj = vtkSubCommunicator
```

38.57.2 Methods

The class vtkSubCommunicator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSubCommunicator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSubCommunicator = obj.NewInstance ()`
- `vtkSubCommunicator = obj.SafeDownCast (vtkObject o)`
- `vtkProcessGroup = obj.GetGroup ()` - Set/get the group on which communication will happen.
- `obj.SetGroup (vtkProcessGroup group)` - Set/get the group on which communication will happen.

38.58 vtkSubGroup

38.58.1 Usage

This class provides scalable broadcast, reduce, etc. using only a vtkMultiProcessController. It does not require MPI. Users are vtkPKdTree and vtkDistributedDataFilter.

.SECTION Note This class will be deprecated soon. Instead of using this class, use the collective and subgrouping operations now built into vtkMultiProcessController. The only reason this class is not deprecated already is because vtkPKdTree relies heavily on this class in ways that are not easy to work around. Since vtkPKdTree is due for a major overhaul anyway, we are leaving things the way they are for now.

To create an instance of class vtkSubGroup, simply invoke its constructor as follows

```
obj = vtkSubGroup
```

38.58.2 Methods

The class vtkSubGroup has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSubGroup class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSubGroup = obj.NewInstance ()`
- `vtkSubGroup = obj.SafeDownCast (vtkObject o)`
- `int = obj.Initialize (int p0, int p1, int me, int tag, vtkCommunicator c)`
- `int = obj.Gather (int data, int to, int length, int root)`
- `int = obj.Gather (string data, string to, int length, int root)`
- `int = obj.Gather (float data, float to, int length, int root)`
- `int = obj.Broadcast (float data, int length, int root)`
- `int = obj.Broadcast (double data, int length, int root)`
- `int = obj.Broadcast (int data, int length, int root)`

- `int = obj.Broadcast (string data, int length, int root)`
- `int = obj.ReduceSum (int data, int to, int length, int root)`
- `int = obj.ReduceMax (float data, float to, int length, int root)`
- `int = obj.ReduceMax (double data, double to, int length, int root)`
- `int = obj.ReduceMax (int data, int to, int length, int root)`
- `int = obj.ReduceMin (float data, float to, int length, int root)`
- `int = obj.ReduceMin (double data, double to, int length, int root)`
- `int = obj.ReduceMin (int data, int to, int length, int root)`
- `obj.setGatherPattern (int root, int length)`
- `int = obj.getLocalRank (int processID)`
- `int = obj.Barrier ()`
- `obj.PrintSubGroup () const`

38.59 vtkTemporalFractal

38.59.1 Usage

vtkTemporalFractal is a collection of uniform grids. All have the same dimensions. Each block has a different origin and spacing. It uses mandelbrot to create cell data. I scale the fractal array to look like a volme fraction. I may also add block id and level as extra cell arrays. This source produces a vtkHierarchicalBoxDataSet when GenerateRectilinearGrids is off, otherwise produces a vtkMultiBlockDataSet.

To create an instance of class vtkTemporalFractal, simply invoke its constructor as follows

```
obj = vtkTemporalFractal
```

38.59.2 Methods

The class vtkTemporalFractal has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalFractal class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalFractal = obj.NewInstance ()`
- `vtkTemporalFractal = obj.SafeDownCast (vtkObject o)`
- `obj.SetFractalValue (float )` - Essentially the iso surface value. The fractal array is scaled to map this value to 0.5 for use as a volume fraction.
- `float = obj.GetFractalValue ()` - Essentially the iso surface value. The fractal array is scaled to map this value to 0.5 for use as a volume fraction.
- `obj.SetMaximumLevel (int )` - Any blocks touching a predefined line will be subdivided to this level. Other blocks are subdivided so that neighboring blocks only differ by one level.

- `int = obj.GetMaximumLevel ()` - Any blocks touching a predefined line will be subdivided to this level. Other blocks are subdivided so that neighboring blocks only differ by one level.
- `obj.SetDimensions (int )` - XYZ dimensions of cells.
- `int = obj.GetDimensions ()` - XYZ dimensions of cells.
- `obj.SetGhostLevels (int )` - For testing ghost levels.
- `int = obj.GetGhostLevels ()` - For testing ghost levels.
- `obj.GhostLevelsOn ()` - For testing ghost levels.
- `obj.GhostLevelsOff ()` - For testing ghost levels.
- `obj.SetGenerateRectilinearGrids (int )` - Generate either rectilinear grids either uniform grids. Default is false.
- `int = obj.GetGenerateRectilinearGrids ()` - Generate either rectilinear grids either uniform grids. Default is false.
- `obj.GenerateRectilinearGridsOn ()` - Generate either rectilinear grids either uniform grids. Default is false.
- `obj.GenerateRectilinearGridsOff ()` - Generate either rectilinear grids either uniform grids. Default is false.
- `obj.SetDiscreteTimeSteps (int )` - Limit this source to discrete integer time steps Default is off (continuous)
- `int = obj.GetDiscreteTimeSteps ()` - Limit this source to discrete integer time steps Default is off (continuous)
- `obj.DiscreteTimeStepsOn ()` - Limit this source to discrete integer time steps Default is off (continuous)
- `obj.DiscreteTimeStepsOff ()` - Limit this source to discrete integer time steps Default is off (continuous)
- `obj.SetTwoDimensional (int )` - Make a 2D data set to test.
- `int = obj.GetTwoDimensional ()` - Make a 2D data set to test.
- `obj.TwoDimensionalOn ()` - Make a 2D data set to test.
- `obj.TwoDimensionalOff ()` - Make a 2D data set to test.
- `obj.SetAsymetric (int )` - Test the case when the blocks do not have the same sizes. Adds 2 to the x extent of the far x blocks (level 1).
- `int = obj.GetAsymetric ()` - Test the case when the blocks do not have the same sizes. Adds 2 to the x extent of the far x blocks (level 1).
- `obj.SetAdaptiveSubdivision (int )` - Make the division adaptive or not, defaults to Adaptive
- `int = obj.GetAdaptiveSubdivision ()` - Make the division adaptive or not, defaults to Adaptive
- `obj.AdaptiveSubdivisionOn ()` - Make the division adaptive or not, defaults to Adaptive
- `obj.AdaptiveSubdivisionOff ()` - Make the division adaptive or not, defaults to Adaptive

38.60 vtkTemporalInterpolatedVelocityField

38.60.1 Usage

vtkTemporalInterpolatedVelocityField is a general purpose helper for the temporal particle tracing code (vtkTemporalStreamTracer)

It maintains two copies of vtkCachingInterpolatedVelocityField internally and uses them to obtain velocity values at time T0 and T1.

In fact the class does quite a bit more than this because when the geometry of the datasets is the same at T0 and T1, we can re-use cached cell Ids and weights used in the cell interpolation routines. Additionally, the same weights can be used when interpolating (point) scalar values and computing vorticity etc.

To create an instance of class vtkTemporalInterpolatedVelocityField, simply invoke its constructor as follows

```
obj = vtkTemporalInterpolatedVelocityField
```

38.60.2 Methods

The class vtkTemporalInterpolatedVelocityField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalInterpolatedVelocityField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalInterpolatedVelocityField = obj.NewInstance ()`
- `vtkTemporalInterpolatedVelocityField = obj.SafeDownCast (vtkObject o)`
- `int = obj.FunctionValues (double x, double u)` - Evaluate the velocity field, f, at (x, y, z, t). For now, t is ignored.
- `int = obj.FunctionValuesAtT (int T, double x, double u)` - Evaluate the velocity field, f, at (x, y, z, t). For now, t is ignored.
- `obj.SelectVectors (string fieldName)` - In order to use this class, two sets of data must be supplied, corresponding to times T1 and T2. Data is added via this function.
- `obj.SetDataSetAtTime (int I, int N, double T, vtkDataSet dataset, bool staticdataset)` - In order to use this class, two sets of data must be supplied, corresponding to times T1 and T2. Data is added via this function.
- `obj.ClearCache ()` - Set the last cell id to -1 so that the next search does not start from the previous cell
- `int = obj.TestPoint (double x)` - A utility function which evaluates the point at T1, T2 to see if it is inside the data at both times or only one.
- `int = obj.QuickTestPoint (double x)` - A utility function which evaluates the point at T1, T2 to see if it is inside the data at both times or only one.
- `double = obj. GetLastGoodVelocity ()` - If an interpolation was successful, we can retrieve the last computed value from here. Initial value is (0.0,0.0,0.0)
- `double = obj.GetCurrentWeight ()` - Get the most recent weight between 0-¿1 from T1-¿T2. Initial value is 0.
- `bool = obj.InterpolatePoint (vtkPointData outPD1, vtkPointData outPD2, vtkIdType outIndex)`

- `bool = obj.InterpolatePoint (int T, vtkPointData outPD1, vtkIdType outIndex)`
- `obj.ShowCacheResults ()`
- `bool = obj.IsStatic (int datasetIndex)`
- `obj.AdvanceOneTimeStep ()`

38.61 vtkTemporalStreamTracer

38.61.1 Usage

vtkTemporalStreamTracer is a filter that integrates a vector field to generate

To create an instance of class vtkTemporalStreamTracer, simply invoke its constructor as follows

```
obj = vtkTemporalStreamTracer
```

38.61.2 Methods

The class vtkTemporalStreamTracer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalStreamTracer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalStreamTracer = obj.NewInstance ()`
- `vtkTemporalStreamTracer = obj.SafeDownCast (vtkObject o)`
- `obj.SetTimeStep (int )` - Set/Get the TimeStep. This is the primary means of advancing the particles. The TimeStep should be animated and this will drive the pipeline forcing timesteps to be fetched from upstream.
- `int = obj.GetTimeStep ()` - Set/Get the TimeStep. This is the primary means of advancing the particles. The TimeStep should be animated and this will drive the pipeline forcing timesteps to be fetched from upstream.
- `obj.SetIgnorePipelineTime (int )` - To get around problems with the Paraview Animation controls we can just animate the time step and ignore the TIME_ requests
- `int = obj.GetIgnorePipelineTime ()` - To get around problems with the Paraview Animation controls we can just animate the time step and ignore the TIME_ requests
- `obj.IgnorePipelineTimeOn ()` - To get around problems with the Paraview Animation controls we can just animate the time step and ignore the TIME_ requests
- `obj.IgnorePipelineTimeOff ()` - To get around problems with the Paraview Animation controls we can just animate the time step and ignore the TIME_ requests
- `obj.SetTimeStepResolution (double )` - If the data source does not have the correct time values present on each time step - setting this value to non unity can be used to adjust the time step size from 1s pre step to 1x_TimeStepResolution : Not functional in this version. Broke it @todo, put back time scaling
- `double = obj.GetTimeStepResolution ()` - If the data source does not have the correct time values present on each time step - setting this value to non unity can be used to adjust the time step size from 1s pre step to 1x_TimeStepResolution : Not functional in this version. Broke it @todo, put back time scaling

- `obj.SetForceReinjectionEveryNSteps (int )` - When animating particles, it is nice to inject new ones every Nth step to produce a continuous flow. Setting ForceReinjectionEveryNSteps to a non zero value will cause the particle source to reinject particles every Nth step even if it is otherwise unchanged. Note that if the particle source is also animated, this flag will be redundant as the particles will be reinjected whenever the source changes anyway

- `int = obj.GetForceReinjectionEveryNSteps ()` - When animating particles, it is nice to inject new ones every Nth step to produce a continuous flow. Setting ForceReinjectionEveryNSteps to a non zero value will cause the particle source to reinject particles every Nth step even if it is otherwise unchanged. Note that if the particle source is also animated, this flag will be redundant as the particles will be reinjected whenever the source changes anyway

- `obj.SetTerminationTime (double )` - Setting TerminationTime to a positive value will cause particles to terminate when the time is reached. Use a vlue of zero to diable termination. The units of time should be consistent with the primary time variable.

- `double = obj.GetTerminationTime ()` - Setting TerminationTime to a positive value will cause particles to terminate when the time is reached. Use a vlue of zero to diable termination. The units of time should be consistent with the primary time variable.

- `obj.SetTerminationTimeUnit (int )` - The units of TerminationTime may be actual 'Time' units as described by the data, or just TimeSteps of iteration.

- `int = obj.GetTerminationTimeUnit ()` - The units of TerminationTime may be actual 'Time' units as described by the data, or just TimeSteps of iteration.

- `obj.SetTerminationTimeUnitToTimeUnit ()` - The units of TerminationTime may be actual 'Time' units as described by the data, or just TimeSteps of iteration.

- `obj.SetTerminationTimeUnitToStepUnit ()` - The units of TerminationTime may be actual 'Time' units as described by the data, or just TimeSteps of iteration.

- `obj.SetStaticSeeds (int )` - if StaticSeeds is set and the mesh is static, then every time particles are injected we can re-use the same injection information. We classify particles according to processor just once before start. If StaticSeeds is set and a moving seed source is specified the motion will be ignored and results will not be as expected.

- `int = obj.GetStaticSeeds ()` - if StaticSeeds is set and the mesh is static, then every time particles are injected we can re-use the same injection information. We classify particles according to processor just once before start. If StaticSeeds is set and a moving seed source is specified the motion will be ignored and results will not be as expected.

- `obj.StaticSeedsOn ()` - if StaticSeeds is set and the mesh is static, then every time particles are injected we can re-use the same injection information. We classify particles according to processor just once before start. If StaticSeeds is set and a moving seed source is specified the motion will be ignored and results will not be as expected.

- `obj.StaticSeedsOff ()` - if StaticSeeds is set and the mesh is static, then every time particles are injected we can re-use the same injection information. We classify particles according to processor just once before start. If StaticSeeds is set and a moving seed source is specified the motion will be ignored and results will not be as expected.

- `obj.SetStaticMesh (int )` - if StaticMesh is set, many optimizations for cell caching can be assumed. if StaticMesh is not set, the algorithm will attempt to find out if optimizations can be used, but setting it to true will force all optimizations. Do not Set StaticMesh to true if a dynamic mesh is being used as this will invalidate all results.

- `int = obj.GetStaticMesh ()` - if StaticMesh is set, many optimizations for cell caching can be assumed. if StaticMesh is not set, the algorithm will attempt to find out if optimizations can be used, but setting it to true will force all optimizations. Do not Set StaticMesh to true if a dynamic mesh is being used as this will invalidate all results.
- `obj.StaticMeshOn ()` - if StaticMesh is set, many optimizations for cell caching can be assumed. if StaticMesh is not set, the algorithm will attempt to find out if optimizations can be used, but setting it to true will force all optimizations. Do not Set StaticMesh to true if a dynamic mesh is being used as this will invalidate all results.
- `obj.StaticMeshOff ()` - if StaticMesh is set, many optimizations for cell caching can be assumed. if StaticMesh is not set, the algorithm will attempt to find out if optimizations can be used, but setting it to true will force all optimizations. Do not Set StaticMesh to true if a dynamic mesh is being used as this will invalidate all results.
- `obj.SetController (vtkMultiProcessController controller)` - Set/Get the controller used when sending particles between processes The controller must be an instance of vtkMPIController. If VTK was compiled without VTK_USE_MPI on, then the Controller is simply ignored.
- `vtkMultiProcessController = obj.GetController ()` - Set/Get the controller used when sending particles between processes The controller must be an instance of vtkMPIController. If VTK was compiled without VTK_USE_MPI on, then the Controller is simply ignored.
- `obj.SetParticleWriter (vtkAbstractParticleWriter pw)` - Set/Get the Writer associated with this Particle Tracer Ideally a parallel IO capable vtkH5PartWriter should be used which will collect particles from all parallel processes and write them to a single HDF5 file.
- `vtkAbstractParticleWriter = obj.GetParticleWriter ()` - Set/Get the Writer associated with this Particle Tracer Ideally a parallel IO capable vtkH5PartWriter should be used which will collect particles from all parallel processes and write them to a single HDF5 file.
- `obj.SetParticleFileName (string )` - Set/Get the filename to be used with the particle writer when dumping particles to disk
- `string = obj.GetParticleFileName ()` - Set/Get the filename to be used with the particle writer when dumping particles to disk
- `obj.SetEnableParticleWriting (int )` - Set/Get the filename to be used with the particle writer when dumping particles to disk
- `int = obj.GetEnableParticleWriting ()` - Set/Get the filename to be used with the particle writer when dumping particles to disk
- `obj.EnableParticleWritingOn ()` - Set/Get the filename to be used with the particle writer when dumping particles to disk
- `obj.EnableParticleWritingOff ()` - Set/Get the filename to be used with the particle writer when dumping particles to disk
- `obj.AddSourceConnection (vtkAlgorithmOutput input)` - Provide support for multiple see sources
- `obj.RemoveAllSources ()` - Provide support for multiple see sources

38.62 vtkTransmitImageDataPiece

38.62.1 Usage

This filter updates the appropriate piece by requesting the piece from process 0. Process 0 always updates all of the data. It is important that Execute get called on all processes, otherwise the filter will deadlock.

To create an instance of class vtkTransmitImageDataPiece, simply invoke its constructor as follows

```
obj = vtkTransmitImageDataPiece
```

38.62.2 Methods

The class vtkTransmitImageDataPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransmitImageDataPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransmitImageDataPiece = obj.NewInstance ()`
- `vtkTransmitImageDataPiece = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetCreateGhostCells (int )` - Turn on/off creating ghost cells (on by default).
- `int = obj.GetCreateGhostCells ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOn ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOff ()` - Turn on/off creating ghost cells (on by default).

38.63 vtkTransmitPolyDataPiece

38.63.1 Usage

This filter updates the appropriate piece by requesting the piece from process 0. Process 0 always updates all of the data. It is important that Execute get called on all processes, otherwise the filter will deadlock.

To create an instance of class vtkTransmitPolyDataPiece, simply invoke its constructor as follows

```
obj = vtkTransmitPolyDataPiece
```

38.63.2 Methods

The class vtkTransmitPolyDataPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransmitPolyDataPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransmitPolyDataPiece = obj.NewInstance ()`
- `vtkTransmitPolyDataPiece = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.

- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetCreateGhostCells (int )` - Turn on/off creating ghost cells (on by default).
- `int = obj.GetCreateGhostCells ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOn ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOff ()` - Turn on/off creating ghost cells (on by default).

38.64 vtkTransmitRectilinearGridPiece

38.64.1 Usage

This filter updates the appropriate piece by requesting the piece from process 0. Process 0 always updates all of the data. It is important that Execute get called on all processes, otherwise the filter will deadlock.

To create an instance of class vtkTransmitRectilinearGridPiece, simply invoke its constructor as follows

```
obj = vtkTransmitRectilinearGridPiece
```

38.64.2 Methods

The class vtkTransmitRectilinearGridPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransmitRectilinearGridPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransmitRectilinearGridPiece = obj.NewInstance ()`
- `vtkTransmitRectilinearGridPiece = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetCreateGhostCells (int )` - Turn on/off creating ghost cells (on by default).
- `int = obj.GetCreateGhostCells ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOn ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOff ()` - Turn on/off creating ghost cells (on by default).

38.65 vtkTransmitStructuredGridPiece

38.65.1 Usage

This filter updates the appropriate piece by requesting the piece from process 0. Process 0 always updates all of the data. It is important that Execute get called on all processes, otherwise the filter will deadlock.

To create an instance of class vtkTransmitStructuredGridPiece, simply invoke its constructor as follows

```
obj = vtkTransmitStructuredGridPiece
```

38.65.2 Methods

The class vtkTransmitStructuredGridPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransmitStructuredGridPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransmitStructuredGridPiece = obj.NewInstance ()`
- `vtkTransmitStructuredGridPiece = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetCreateGhostCells (int )` - Turn on/off creating ghost cells (on by default).
- `int = obj.GetCreateGhostCells ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOn ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOff ()` - Turn on/off creating ghost cells (on by default).

38.66 vtkTransmitUnstructuredGridPiece

38.66.1 Usage

This filter updates the appropriate piece by requesting the piece from process 0. Process 0 always updates all of the data. It is important that Execute get called on all processes, otherwise the filter will deadlock.

To create an instance of class vtkTransmitUnstructuredGridPiece, simply invoke its constructor as follows

```
obj = vtkTransmitUnstructuredGridPiece
```

38.66.2 Methods

The class vtkTransmitUnstructuredGridPiece has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransmitUnstructuredGridPiece class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransmitUnstructuredGridPiece = obj.NewInstance ()`
- `vtkTransmitUnstructuredGridPiece = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `vtkMultiProcessController = obj.GetController ()` - By defualt this filter uses the global controller, but this method can be used to set another instead.
- `obj.SetCreateGhostCells (int )` - Turn on/off creating ghost cells (on by default).

- `int = obj.GetCreateGhostCells ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOn ()` - Turn on/off creating ghost cells (on by default).
- `obj.CreateGhostCellsOff ()` - Turn on/off creating ghost cells (on by default).

38.67 vtkTreeCompositer

38.67.1 Usage

vtkTreeCompositer operates in multiple processes. Each compositer has a render window. They use a vtkMultiProcessController to communicate the color and depth buffer to process 0's render window. It will not handle transparency well.

To create an instance of class vtkTreeCompositer, simply invoke its constructor as follows

```
obj = vtkTreeCompositer
```

38.67.2 Methods

The class vtkTreeCompositer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeCompositer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeCompositer = obj.NewInstance ()`
- `vtkTreeCompositer = obj.SafeDownCast (vtkObject o)`
- `obj.CompositeBuffer (vtkDataArray pBuf, vtkFloatArray zBuf, vtkDataArray pTmp, vtkFloatArray zTmp)`

38.68 vtkVPICReader

38.68.1 Usage

vtkDataReader is a helper superclass that reads the vtk data file header, dataset type, and attribute data (point and cell attributes such as scalars, vectors, normals, etc.) from a vtk data file. See text for the format of the various vtk file types.

To create an instance of class vtkVPICReader, simply invoke its constructor as follows

```
obj = vtkVPICReader
```

38.68.2 Methods

The class vtkVPICReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVPICReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVPICReader = obj.NewInstance ()`

- `vtkVPICReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify file name of VPIC data file to read.
- `string = obj.GetFileName ()` - Specify file name of VPIC data file to read.
- `obj.SetStride (int , int , int )` - Set the stride in each dimension
- `obj.SetStride (int  a[3])` - Set the stride in each dimension
- `int = obj. GetStride ()` - Set the stride in each dimension
- `obj.SetXExtent (int , int )` - Set the simulation file decomposition in each dimension
- `obj.SetXExtent (int  a[2])` - Set the simulation file decomposition in each dimension
- `obj.SetYExtent (int , int )` - Set the simulation file decomposition in each dimension
- `obj.SetYExtent (int  a[2])` - Set the simulation file decomposition in each dimension
- `obj.SetZExtent (int , int )` - Set the simulation file decomposition in each dimension
- `obj.SetZExtent (int  a[2])` - Set the simulation file decomposition in each dimension
- `int = obj. GetXLayout ()`
- `int = obj. GetYLayout ()`
- `int = obj. GetZLayout ()`
- `vtkImageData = obj.GetOutput ()` - Get the reader's output
- `vtkImageData = obj.GetOutput (int index)` - Get the reader's output
- `int = obj.GetNumberOfPointArrays ()` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `string = obj.GetPointArrayName (int index)` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `int = obj.GetPointArrayStatus (string name)` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `obj.SetPointArrayStatus (string name, int status)` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `obj.DisableAllPointArrays ()` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `obj.EnableAllPointArrays ()` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.

38.69 vtkWindBladeReader

38.69.1 Usage

vtkWindBladeReader is a source object that reads WindBlade files which are block binary files with tags before and after each block giving the number of bytes within the block. The number of data variables dumped varies. The data is 3D rectilinear with irregular spacing on the Z dimension.

To create an instance of class vtkWindBladeReader, simply invoke its constructor as follows

```
obj = vtkWindBladeReader
```

38.69.2 Methods

The class vtkWindBladeReader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWindBladeReader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWindBladeReader = obj.NewInstance ()`
- `vtkWindBladeReader = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilename (string )`
- `string = obj.GetFilename ()`
- `obj.SetWholeExtent (int , int , int , int , int , int )`
- `obj.SetWholeExtent (int  a[6])`
- `int = obj. GetWholeExtent ()`
- `obj.SetSubExtent (int , int , int , int , int , int )`
- `obj.SetSubExtent (int  a[6])`
- `int = obj. GetSubExtent ()`
- `vtkStructuredGrid = obj.GetFieldOutput ()` - Get the reader's output
- `vtkUnstructuredGrid = obj.GetBladeOutput ()` - Get the reader's output
- `int = obj.GetNumberOfPointArrays ()` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `string = obj.GetPointArrayName (int index)` - The following methods allow selective reading of solutions fields. By default, ALL data fields on the nodes are read, but this can be modified.
- `int = obj.GetPointArrayStatus (string name)`
- `obj.SetPointArrayStatus (string name, int status)`
- `obj.DisableAllPointArrays ()`
- `obj.EnableAllPointArrays ()`

38.70 vtkXMLPHierarchicalBoxDataWriter

38.70.1 Usage

vtkXMLPCompositeDataWriter writes (in parallel or serially) the VTK XML multi-group, multi-block hierarchical and hierarchical box files. XML multi-group data files are meta-files that point to a list of serial VTK XML files.

To create an instance of class vtkXMLPHierarchicalBoxDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPHierarchicalBoxDataWriter
```

38.70.2 Methods

The class vtkXMLPHierarchicalBoxDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPHierarchicalBoxDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPHierarchicalBoxDataWriter = obj.NewInstance ()`
- `vtkXMLPHierarchicalBoxDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Controller used to communicate data type of blocks. By default, the global controller is used. If you want another controller to be used, set it with this. If no controller is set, only the local blocks will be written to the meta-file.
- `vtkMultiProcessController = obj.GetController ()` - Controller used to communicate data type of blocks. By default, the global controller is used. If you want another controller to be used, set it with this. If no controller is set, only the local blocks will be written to the meta-file.
- `obj.SetWriteMetaFile (int flag)` - Set whether this instance will write the meta-file. WriteMetaFile is set to flag only on process 0 and all other processes have WriteMetaFile set to 0 by default.

38.71 vtkXMLPMultiBlockDataWriter

38.71.1 Usage

vtkXMLPCompositeDataWriter writes (in parallel or serially) the VTK XML multi-group, multi-block hierarchical and hierarchical box files. XML multi-group data files are meta-files that point to a list of serial VTK XML files.

To create an instance of class vtkXMLPMultiBlockDataWriter, simply invoke its constructor as follows

```
obj = vtkXMLPMultiBlockDataWriter
```

38.71.2 Methods

The class vtkXMLPMultiBlockDataWriter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLPMultiBlockDataWriter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLPMultiBlockDataWriter = obj.NewInstance ()`
- `vtkXMLPMultiBlockDataWriter = obj.SafeDownCast (vtkObject o)`
- `obj.SetController (vtkMultiProcessController )` - Controller used to communicate data type of blocks. By default, the global controller is used. If you want another controller to be used, set it with this. If no controller is set, only the local blocks will be written to the meta-file.
- `vtkMultiProcessController = obj.GetController ()` - Controller used to communicate data type of blocks. By default, the global controller is used. If you want another controller to be used, set it with this. If no controller is set, only the local blocks will be written to the meta-file.
- `obj.SetWriteMetaFile (int flag)` - Set whether this instance will write the meta-file. WriteMetaFile is set to flag only on process 0 and all other processes have WriteMetaFile set to 0 by default.

Chapter 39

Visualization Toolkit Rendering Classes

39.1 vtkAbstractMapper3D

39.1.1 Usage

vtkAbstractMapper3D is an abstract class to specify interface between 3D data and graphics primitives or software rendering techniques. Subclasses of vtkAbstractMapper3D can be used for rendering geometry or rendering volumetric data.

This class also defines an API to support hardware clipping planes (at most six planes can be defined). It also provides geometric data about the input data it maps, such as the bounding box and center.

To create an instance of class vtkAbstractMapper3D, simply invoke its constructor as follows

```
obj = vtkAbstractMapper3D
```

39.1.2 Methods

The class vtkAbstractMapper3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractMapper3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractMapper3D = obj.NewInstance ()`
- `vtkAbstractMapper3D = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetBounds ()` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax). Update this-¿Bounds as a side effect.
- `obj.GetBounds (double bounds[6])` - Get the bounds for this mapper as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `double = obj.GetCenter ()` - Return the Center of this mapper's data.
- `obj.GetCenter (double center[3])` - Return the diagonal length of this mappers bounding box.
- `double = obj.GetLength ()` - Return the diagonal length of this mappers bounding box.
- `int = obj.IsARayCastMapper ()` - Is this a "render into image" mapper? A subclass would return 1 if the mapper produces an image by rendering into a software image buffer.
- `int = obj.IsARenderIntoImageMapper ()`

39.2 vtkAbstractPicker

39.2.1 Usage

vtkAbstractPicker is an abstract superclass that defines a minimal API for its concrete subclasses. The minimum functionality of a picker is to return the x-y-z global coordinate position of a pick (the pick itself is defined in display coordinates).

The API to this class is to invoke the Pick() method with a selection point (in display coordinates - pixels) and a renderer. Then get the resulting pick position in global coordinates with the GetPickPosition() method.

vtkPicker fires events during the picking process. These events are StartPickEvent, PickEvent, and EndPickEvent which are invoked prior to picking, when something is picked, and after all picking candidates have been tested. Note that during the pick process the PickEvent of vtkProp (and its subclasses such as vtkActor) is fired prior to the PickEvent of vtkPicker.

To create an instance of class vtkAbstractPicker, simply invoke its constructor as follows

```
obj = vtkAbstractPicker
```

39.2.2 Methods

The class vtkAbstractPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractPicker = obj.NewInstance ()`
- `vtkAbstractPicker = obj.SafeDownCast (vtkObject o)`
- `vtkRenderer = obj.GetRenderer ()` - Get the renderer in which pick event occurred.
- `double = obj. GetSelectionPoint ()` - Get the selection point in screen (pixel) coordinates. The third value is related to z-buffer depth. (Normally should be =0.)
- `double = obj. GetPickPosition ()` - Return position in global coordinates of pick point.
- `int = obj.Pick (double selectionX, double selectionY, double selectionZ, vtkRenderer renderer)` - Perform pick operation with selection point provided. Normally the first two values for the selection point are x-y pixel coordinate, and the third value is =0. Return non-zero if something was successfully picked.
- `int = obj.Pick (double selectionPt[3], vtkRenderer ren)` - provided. Normally the first two values for the selection point are x-y pixel coordinate, and the third value is =0. Return non-zero if something was successfully picked.
- `obj.SetPickFromList (int )` - Use these methods to control whether to limit the picking to this list (rather than renderer's actors). Make sure that the pick list contains actors that referred to by the picker's renderer.
- `int = obj.GetPickFromList ()` - Use these methods to control whether to limit the picking to this list (rather than renderer's actors). Make sure that the pick list contains actors that referred to by the picker's renderer.
- `obj.PickFromListOn ()` - Use these methods to control whether to limit the picking to this list (rather than renderer's actors). Make sure that the pick list contains actors that referred to by the picker's renderer.

- `obj.PickFromListOff ()` - Use these methods to control whether to limit the picking to this list (rather than renderer's actors). Make sure that the pick list contains actors that referred to by the picker's renderer.
- `obj.InitializePickList ()` - Initialize list of actors in pick list.
- `obj.AddPickList (vtkProp )` - Add an actor to the pick list.
- `obj.DeletePickList (vtkProp )` - Delete an actor from the pick list.
- `vtkPropCollection = obj.GetPickList ()`

39.3 vtkAbstractPropPicker

39.3.1 Usage

vtkAbstractPropPicker is an abstract superclass for pickers that can pick an instance of vtkProp. Some pickers, like vtkWorldPointPicker (not a subclass of this class), cannot identify the prop that is picked. Subclasses of vtkAbstractPropPicker return a prop in the form of a vtkAssemblyPath when a pick is invoked. Note that an vtkAssemblyPath contain a list of vtkAssemblyNodes, each of which in turn contains a reference to a vtkProp and a 4x4 transformation matrix. The path fully describes the entire pick path, so you can pick assemblies or portions of assemblies, or just grab the tail end of the vtkAssemblyPath (which is the picked prop).

To create an instance of class vtkAbstractPropPicker, simply invoke its constructor as follows

```
obj = vtkAbstractPropPicker
```

39.3.2 Methods

The class vtkAbstractPropPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractPropPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractPropPicker = obj.NewInstance ()`
- `vtkAbstractPropPicker = obj.SafeDownCast (vtkObject o)`
- `obj.SetPath (vtkAssemblyPath )` - Return the vtkAssemblyPath that has been picked. The assembly path lists all the vtkProps that form an assembly. If no assembly is present, then the assembly path will have one node (which is the picked prop). The set method is used internally to set the path. (Note: the structure of an assembly path is a collection of vtkAssemblyNode, each node pointing to a vtkProp and (possibly) a transformation matrix.)
- `vtkAssemblyPath = obj.GetPath ()` - Return the vtkAssemblyPath that has been picked. The assembly path lists all the vtkProps that form an assembly. If no assembly is present, then the assembly path will have one node (which is the picked prop). The set method is used internally to set the path. (Note: the structure of an assembly path is a collection of vtkAssemblyNode, each node pointing to a vtkProp and (possibly) a transformation matrix.)
- `vtkProp = obj.GetViewProp ()` - Return the vtkProp that has been picked. If NULL, nothing was picked. If anything at all was picked, this method will return something.
- `vtkProp3D = obj.GetProp3D ()` - Return the vtkProp that has been picked. If NULL, no vtkProp3D was picked.

- `vtkActor = obj.GetActor ()` - Return the vtkActor that has been picked. If NULL, no actor was picked.
- `vtkActor2D = obj.GetActor2D ()` - Return the vtkActor2D that has been picked. If NULL, no actor2D was picked.
- `vtkVolume = obj.GetVolume ()` - Return the vtkVolume that has been picked. If NULL, no volume was picked.
- `vtkAssembly = obj.GetAssembly ()` - Return the vtkAssembly that has been picked. If NULL, no assembly was picked. (Note: the returned assembly is the first node in the assembly path. If the path is one node long, then the assembly and the prop are the same, assuming that the first node is a vtkAssembly.)
- `vtkPropAssembly = obj.GetPropAssembly ()` - Return the vtkPropAssembly that has been picked. If NULL, no prop assembly was picked. (Note: the returned prop assembly is the first node in the assembly path. If the path is one node long, then the prop assembly and the prop are the same, assuming that the first node is a vtkPropAssembly.)
- `vtkProp = obj.GetProp ()` - @deprecated Replaced by vtkAbstractPicker::GetViewProp() as of VTK 5.0.

39.4 vtkAbstractVolumeMapper

39.4.1 Usage

vtkAbstractVolumeMapper is the abstract definition of a volume mapper. Specific subclasses deal with different specific types of data input

To create an instance of class vtkAbstractVolumeMapper, simply invoke its constructor as follows

```
obj = vtkAbstractVolumeMapper
```

39.4.2 Methods

The class vtkAbstractVolumeMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractVolumeMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractVolumeMapper = obj.NewInstance ()`
- `vtkAbstractVolumeMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet )` - Set/Get the input data
- `vtkDataSet = obj.GetDataSetInput ()` - Set/Get the input data
- `vtkDataObject = obj.GetDataObjectInput ()` - Set/Get the input data
- `double = obj.GetBounds ()` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.GetBounds (double bounds[6])` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).

- `obj.SetScalarMode (int )` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `int = obj.GetScalarMode ()` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `obj.SetScalarModeToDefault ()` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `obj.SetScalarModeToUsePointData ()` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `obj.SetScalarModeToUseCellData ()` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `obj.SetScalarModeToUsePointFieldData ()` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `obj.SetScalarModeToUseCellFieldData ()` - Control how the mapper works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the mapper will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the mapper to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectScalarArray.

- `obj.SelectScalarArray (int arrayNum)` - When ScalarMode is set to UsePointFieldData or UseCellFieldData, you can specify which scalar array to use during rendering. The transfer function in the vtkVolumeProperty (attached to the calling vtkVolume) will decide how to convert vectors to colors.
- `obj.SelectScalarArray (string arrayName)` - When ScalarMode is set to UsePointFieldData or UseCellFieldData, you can specify which scalar array to use during rendering. The transfer function in the vtkVolumeProperty (attached to the calling vtkVolume) will decide how to convert vectors to colors.
- `string = obj.GetArrayName ()` - Get the array name or number and component to use for rendering.
- `int = obj.GetArrayId ()` - Get the array name or number and component to use for rendering.
- `int = obj.GetArrayAccessMode ()` - Return the method for obtaining scalar data.
- `string = obj.GetScalarModeAsString ()` - Return the method for obtaining scalar data.

39.5 vtkActor

39.5.1 Usage

vtkActor is used to represent an entity in a rendering scene. It inherits functions related to the actors position, and orientation from vtkProp. The actor also has scaling and maintains a reference to the defining geometry (i.e., the mapper), rendering properties, and possibly a texture map. vtkActor combines these instance variables into one 4x4 transformation matrix as follows: [x y z 1] = [x y z 1] Translate(-origin) Scale(scale) Rot(y) Rot(x) Rot (z) Trans(origin) Trans(position)

To create an instance of class vtkActor, simply invoke its constructor as follows

```
obj = vtkActor
```

39.5.2 Methods

The class vtkActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkActor = obj.NewInstance ()`
- `vtkActor = obj.SafeDownCast (vtkObject o)`
- `obj.GetActors (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.Render (vtkRenderer , vtkMapper )` - Shallow copy of an actor. Overloads the virtual vtkProp method.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an actor. Overloads the virtual vtkProp method.

- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

- `obj.SetProperty (vtkProperty lut)` - Set/Get the property object that controls this actors surface properties. This should be an instance of a vtkProperty object. Every actor must have a property associated with it. If one isn't specified, then one will be generated automatically. Multiple actors can share one property object.

- `vtkProperty = obj.GetProperty ()` - Set/Get the property object that controls this actors surface properties. This should be an instance of a vtkProperty object. Every actor must have a property associated with it. If one isn't specified, then one will be generated automatically. Multiple actors can share one property object.

- `vtkProperty = obj.MakeProperty ()` - Create a new property suitable for use with this type of Actor. For example, a vtkMesaActor should create a vtkMesaProperty in this function. The default is to just call vtkProperty::New.

- `obj.SetBackfaceProperty (vtkProperty lut)` - Set/Get the property object that controls this actors backface surface properties. This should be an instance of a vtkProperty object. If one isn't specified, then the front face properties will be used. Multiple actors can share one property object.

- `vtkProperty = obj.GetBackfaceProperty ()` - Set/Get the property object that controls this actors backface surface properties. This should be an instance of a vtkProperty object. If one isn't specified, then the front face properties will be used. Multiple actors can share one property object.

- `obj.SetTexture (vtkTexture )` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. An actor does not need to have an associated texture map and multiple actors can share one texture.

- `vtkTexture = obj.GetTexture ()` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. An actor does not need to have an associated texture map and multiple actors can share one texture.

- `obj.SetMapper (vtkMapper )` - This is the method that is used to connect an actor to the end of a visualization pipeline, i.e. the mapper. This should be a subclass of vtkMapper. Typically vtkPolyDataMapper and vtkDataSetMapper will be used.

- `vtkMapper = obj.GetMapper ()` - Returns the Mapper that this actor is getting its data from.

- `obj.GetBounds (double bounds[6])` - Get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). (The method GetBounds(double bounds[6]) is available from the superclass.)

- `double = obj.GetBounds ()` - Get the bounds for this Actor as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). (The method GetBounds(double bounds[6]) is available from the superclass.)

- `obj.ApplyProperties ()` - Get the actors mtime plus consider its properties and texture if set.

- `long = obj.GetMTime ()` - Get the actors mtime plus consider its properties and texture if set.

- `long = obj.GetRedrawMTime ()` - Return the mtime of anything that would cause the rendered image to appear differently. Usually this involves checking the mtime of the prop plus anything else it depends on such as properties, textures etc.

- `obj.InitPartTraversal ()` - The following methods are for compatibility. The methods will be deprecated in the near future. Use vtkProp::GetNextPath() (and related functionality) to get the parts in an assembly (or more correctly, the paths in the assembly).

- `vtkActor = obj.GetNextPart ()` - The following methods are for compatibility. The methods will be deprecated in the near future. Use vtkProp::GetNextPath() (and related functionality) to get the parts in an assembly (or more correctly, the paths in the assembly).
- `int = obj.GetNumberOfParts ()` - The following methods are for compatibility. The methods will be deprecated in the near future. Use vtkProp::GetNextPath() (and related functionality) to get the parts in an assembly (or more correctly, the paths in the assembly).
- `bool = obj.GetSupportsSelection ()` - WARNING: INTERNAL METHOD - NOT INTENDED FOR GENERAL USE DO NOT USE THIS METHOD OUTSIDE OF THE RENDERING PROCESS Used by vtkHardwareSelector to determine if the prop supports hardware selection.

39.6 vtkActorCollection

39.6.1 Usage

vtkActorCollection represents and provides methods to manipulate a list of actors (i.e., vtkActor and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkActorCollection, simply invoke its constructor as follows

```
obj = vtkActorCollection
```

39.6.2 Methods

The class vtkActorCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkActorCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkActorCollection = obj.NewInstance ()`
- `vtkActorCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkActor a)` - Add an actor to the list.
- `vtkActor = obj.GetNextActor ()` - Get the next actor in the list.
- `vtkActor = obj.GetLastActor ()` - Get the last actor in the list.
- `vtkActor = obj.GetNextItem ()` - Access routines that are provided for compatibility with previous version of VTK. Please use the GetNextActor(), GetLastActor() variants where possible.
- `vtkActor = obj.GetLastItem ()` - Access routines that are provided for compatibility with previous version of VTK. Please use the GetNextActor(), GetLastActor() variants where possible.
- `obj.ApplyProperties (vtkProperty p)` - Apply properties to all actors in this collection.

39.7 vtkAreaPicker

39.7.1 Usage

The vtkAreaPicker picks all vtkProp3Ds that lie behind the screen space rectangle from x0,y0 and x1,y1. The selection is based upon the bounding box of the prop and is thus not exact.

Like vtkPicker, a pick results in a list of Prop3Ds because many props may lie within the pick frustum. You can also get an AssemblyPath, which in this case is defined to be the path to the one particular prop in the Prop3D list that lies nearest to the near plane.

This picker also returns the selection frustum, defined as either a vtkPlanes, or a set of eight corner vertices in world space. The vtkPlanes version is an ImplicitFunction, which is suitable for use with the vtkExtractGeometry. The six frustum planes are in order: left, right, bottom, top, near, far

Because this picker picks everything within a volume, the world pick point result is ill-defined. Therefore if you ask this class for the world pick position, you will get the centroid of the pick frustum. This may be outside of all props in the prop list.

To create an instance of class vtkAreaPicker, simply invoke its constructor as follows

```
obj = vtkAreaPicker
```

39.7.2 Methods

The class vtkAreaPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAreaPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAreaPicker = obj.NewInstance ()`
- `vtkAreaPicker = obj.SafeDownCast (vtkObject o)`
- `obj.SetPickCoords (double x0, double y0, double x1, double y1)` - Set the default screen rectangle to pick in.
- `obj.SetRenderer (vtkRenderer )` - Set the default renderer to pick on.
- `int = obj.Pick ()` - Perform an AreaPick within the default screen rectangle and renderer.
- `int = obj.AreaPick (double x0, double y0, double x1, double y1, vtkRenderer rendererNULL)` - Perform pick operation in volume behind the given screen coordinates. Props intersecting the selection frustum will be accesible via GetProp3D. GetPlanes returns a vtkImplicitFunciton suitable for vtkExtractGeometry.
- `int = obj.Pick (double x0, double y0, double , vtkRenderer rendererNULL)` - Perform pick operation in volume behind the given screen coordinate. This makes a thin frustum around the selected pixel. Note: this ignores Z in order to pick everying in a volume from z=0 to z=1.
- `vtkAbstractMapper3D = obj.GetMapper ()` - Return mapper that was picked (if any).
- `vtkDataSet = obj.GetDataSet ()` - Get a pointer to the dataset that was picked (if any). If nothing was picked then NULL is returned.
- `vtkProp3DCollection = obj.GetProp3Ds ()` - Return a collection of all the prop 3D's that were intersected by the pick ray. This collection is not sorted.
- `vtkPlanes = obj.GetFrustum ()` - Return the six planes that define the selection frustum. The implicit function defined by the planes evaluates to negative inside and positive outside.
- `vtkPoints = obj.GetClipPoints ()` - Return eight points that define the selection frustum.

39.8 vtkAssembly

39.8.1 Usage

vtkAssembly is an object that groups vtkProp3Ds, its subclasses, and other assemblies into a tree-like hierarchy. The vtkProp3Ds and assemblies can then be transformed together by transforming just the root assembly of the hierarchy.

A vtkAssembly object can be used in place of an vtkProp3D since it is a subclass of vtkProp3D. The difference is that vtkAssembly maintains a list of vtkProp3D instances (its "parts") that form the assembly. Then, any operation that transforms (i.e., scales, rotates, translates) the parent assembly will transform all its parts. Note that this process is recursive: you can create groups consisting of assemblies and/or vtkProp3Ds to arbitrary depth.

To add an assembly to the renderer's list of props, you only need to add the root of the assembly. During rendering, the parts of the assembly are rendered during a hierarchical traversal process.

To create an instance of class vtkAssembly, simply invoke its constructor as follows

```
obj = vtkAssembly
```

39.8.2 Methods

The class vtkAssembly has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssembly class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssembly = obj.NewInstance ()`
- `vtkAssembly = obj.SafeDownCast (vtkObject o)`
- `obj.AddPart (vtkProp3D )` - Add a part to the list of parts.
- `obj.RemovePart (vtkProp3D )` - Remove a part from the list of parts,
- `vtkProp3DCollection = obj.GetParts ()` - Return the parts (direct descendants) of this assembly.
- `obj.GetActors (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `obj.GetVolumes (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `int = obj.RenderOpaqueGeometry (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. Note that a mapper need not be defined. If not defined, then no geometry will be drawn for this assembly. This allows you to create "logical" assemblies; that is, assemblies that only serve to group and transform its parts.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. Note that a mapper need not be defined. If not defined, then no geometry will be drawn for this assembly. This allows you to create "logical" assemblies; that is, assemblies that only serve to group and transform its parts.
- `int = obj.RenderVolumetricGeometry (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. Note that a mapper need not be defined. If not defined, then no geometry will be drawn for this assembly. This allows you to create "logical" assemblies; that is, assemblies that only serve to group and transform its parts.

- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.InitPathTraversal ()` - Methods to traverse the parts of an assembly. Each part (starting from the root) will appear properly transformed and with the correct properties (depending upon the ApplyProperty and ApplyTransform ivars). Note that the part appears as an instance of vtkProp. These methods should be contrasted to those that traverse the list of parts using GetParts(). GetParts() returns a list of children of this assembly, not necessarily with the correct transformation or properties. To use the methods below - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted.
- `vtkAssemblyPath = obj.GetNextPath ()` - Methods to traverse the parts of an assembly. Each part (starting from the root) will appear properly transformed and with the correct properties (depending upon the ApplyProperty and ApplyTransform ivars). Note that the part appears as an instance of vtkProp. These methods should be contrasted to those that traverse the list of parts using GetParts(). GetParts() returns a list of children of this assembly, not necessarily with the correct transformation or properties. To use the methods below - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted.
- `int = obj.GetNumberOfPaths ()` - Methods to traverse the parts of an assembly. Each part (starting from the root) will appear properly transformed and with the correct properties (depending upon the ApplyProperty and ApplyTransform ivars). Note that the part appears as an instance of vtkProp. These methods should be contrasted to those that traverse the list of parts using GetParts(). GetParts() returns a list of children of this assembly, not necessarily with the correct transformation or properties. To use the methods below - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted.
- `obj.GetBounds (double bounds[6])` - Get the bounds for the assembly as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `double = obj.GetBounds ()` - Get the bounds for the assembly as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `long = obj.GetMTime ()` - Override default GetMTime method to also consider all of the assembly's parts.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an assembly. Overloads the virtual vtkProp method.

39.9 vtkAxisActor2D

39.9.1 Usage

vtkAxisActor2D creates an axis with tick marks, labels, and/or a title, depending on the particular instance variable settings. vtkAxisActor2D is a 2D actor; that is, it is drawn on the overlay plane and is not occluded by 3D geometry. To use this class, you typically specify two points defining the start and end points of the line (x-y definition using vtkCoordinate class), the number of labels, and the data range (min,max). You can also control what parts of the axis are visible including the line, the tick marks, the labels, and the title. You can also specify the label format (a printf style format).

This class decides what font size to use and how to locate the labels. It also decides how to create reasonable tick marks and labels. The number of labels and the range of values may not match the number specified, but should be close.

Labels are drawn on the "right" side of the axis. The "right" side is the side of the axis on the right as you move from Position to Position2. The way the labels and title line up with the axis and tick marks depends on whether the line is considered horizontal or vertical.

The vtkActor2D instance variables Position and Position2 are instances of vtkCoordinate. Note that the Position2 is an absolute position in that class (it was by default relative to Position in vtkActor2D).

What this means is that you can specify the axis in a variety of coordinate systems. Also, the axis does not have to be either horizontal or vertical. The tick marks are created so that they are perpendicular to the axis.

Set the text property/attributes of the title and the labels through the vtkTextProperty objects associated to this actor.

To create an instance of class vtkAxisActor2D, simply invoke its constructor as follows

```
obj = vtkAxisActor2D
```

39.9.2 Methods

The class vtkAxisActor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAxisActor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAxisActor2D = obj.NewInstance ()`
- `vtkAxisActor2D = obj.SafeDownCast (vtkObject o)`
- `vtkCoordinate = obj.GetPoint1Coordinate ()` - Specify the position of the first point defining the axis. Note: backward compatibility only, use vtkActor2D's Position instead.
- `obj.SetPoint1 (double x[2])` - Specify the position of the first point defining the axis. Note: backward compatibility only, use vtkActor2D's Position instead.
- `obj.SetPoint1 (double x, double y)` - Specify the position of the first point defining the axis. Note: backward compatibility only, use vtkActor2D's Position instead.
- `vtkCoordinate = obj.GetPoint2Coordinate ()` - Specify the position of the second point defining the axis. Note that the order from Point1 to Point2 controls which side the tick marks are drawn on (ticks are drawn on the right, if visible). Note: backward compatibility only, use vtkActor2D's Position2 instead.
- `obj.SetPoint2 (double x[2])` - Specify the position of the second point defining the axis. Note that the order from Point1 to Point2 controls which side the tick marks are drawn on (ticks are drawn on the right, if visible). Note: backward compatibility only, use vtkActor2D's Position2 instead.
- `obj.SetPoint2 (double x, double y)` - Specify the position of the second point defining the axis. Note that the order from Point1 to Point2 controls which side the tick marks are drawn on (ticks are drawn on the right, if visible). Note: backward compatibility only, use vtkActor2D's Position2 instead.
- `obj.SetRange (double , double )` - Specify the (min,max) axis range. This will be used in the generation of labels, if labels are visible.
- `obj.SetRange (double  a[2])` - Specify the (min,max) axis range. This will be used in the generation of labels, if labels are visible.
- `double = obj. GetRange ()` - Specify the (min,max) axis range. This will be used in the generation of labels, if labels are visible.
- `obj.SetNumberOfLabels (int )` - Set/Get the number of annotation labels to show.
- `int = obj.GetNumberOfLabelsMinValue ()` - Set/Get the number of annotation labels to show.

- `int = obj.GetNumberOfLabelsMaxValue ()` - Set/Get the number of annotation labels to show.
- `int = obj.GetNumberOfLabels ()` - Set/Get the number of annotation labels to show.
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the labels on the scalar bar.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the labels on the scalar bar.
- `obj.SetAdjustLabels (int )` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.
- `int = obj.GetAdjustLabels ()` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.
- `obj.AdjustLabelsOn ()` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.
- `obj.AdjustLabelsOff ()` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.
- `obj.GetAdjustedRange (double \_arg[2])` - Set/Get the flag that controls whether the labels and ticks are adjusted for "nice" numerical values to make it easier to read the labels. The adjustment is based in the Range instance variable. Call GetAdjustedRange and GetAdjustedNumberOfLabels to get the adjusted range and number of labels.
- `int = obj.GetAdjustedNumberOfLabels ()` - Set/Get the title of the scalar bar actor,
- `obj.SetTitle (string )` - Set/Get the title of the scalar bar actor,
- `string = obj.GetTitle ()` - Set/Get the title of the scalar bar actor,
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property.
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the labels text property.
- `obj.SetTickLength (int )` - Set/Get the length of the tick marks (expressed in pixels or display coordinates).
- `int = obj.GetTickLengthMinValue ()` - Set/Get the length of the tick marks (expressed in pixels or display coordinates).
- `int = obj.GetTickLengthMaxValue ()` - Set/Get the length of the tick marks (expressed in pixels or display coordinates).
- `int = obj.GetTickLength ()` - Set/Get the length of the tick marks (expressed in pixels or display coordinates).

- `obj.SetNumberOfMinorTicks (int )` - Number of minor ticks to be displayed between each tick. Default is 0.
- `int = obj.GetNumberOfMinorTicksMinValue ()` - Number of minor ticks to be displayed between each tick. Default is 0.
- `int = obj.GetNumberOfMinorTicksMaxValue ()` - Number of minor ticks to be displayed between each tick. Default is 0.
- `int = obj.GetNumberOfMinorTicks ()` - Number of minor ticks to be displayed between each tick. Default is 0.
- `obj.SetMinorTickLength (int )` - Set/Get the length of the minor tick marks (expressed in pixels or display coordinates).
- `int = obj.GetMinorTickLengthMinValue ()` - Set/Get the length of the minor tick marks (expressed in pixels or display coordinates).
- `int = obj.GetMinorTickLengthMaxValue ()` - Set/Get the length of the minor tick marks (expressed in pixels or display coordinates).
- `int = obj.GetMinorTickLength ()` - Set/Get the length of the minor tick marks (expressed in pixels or display coordinates).
- `obj.SetTickOffset (int )` - Set/Get the offset of the labels (expressed in pixels or display coordinates). The offset is the distance of labels from tick marks or other objects.
- `int = obj.GetTickOffsetMinValue ()` - Set/Get the offset of the labels (expressed in pixels or display coordinates). The offset is the distance of labels from tick marks or other objects.
- `int = obj.GetTickOffsetMaxValue ()` - Set/Get the offset of the labels (expressed in pixels or display coordinates). The offset is the distance of labels from tick marks or other objects.
- `int = obj.GetTickOffset ()` - Set/Get the offset of the labels (expressed in pixels or display coordinates). The offset is the distance of labels from tick marks or other objects.
- `obj.SetAxisVisibility (int )` - Set/Get visibility of the axis line.
- `int = obj.GetAxisVisibility ()` - Set/Get visibility of the axis line.
- `obj.AxisVisibilityOn ()` - Set/Get visibility of the axis line.
- `obj.AxisVisibilityOff ()` - Set/Get visibility of the axis line.
- `obj.SetTickVisibility (int )` - Set/Get visibility of the axis tick marks.
- `int = obj.GetTickVisibility ()` - Set/Get visibility of the axis tick marks.
- `obj.TickVisibilityOn ()` - Set/Get visibility of the axis tick marks.
- `obj.TickVisibilityOff ()` - Set/Get visibility of the axis tick marks.
- `obj.SetLabelVisibility (int )` - Set/Get visibility of the axis labels.
- `int = obj.GetLabelVisibility ()` - Set/Get visibility of the axis labels.
- `obj.LabelVisibilityOn ()` - Set/Get visibility of the axis labels.
- `obj.LabelVisibilityOff ()` - Set/Get visibility of the axis labels.
- `obj.SetTitleVisibility (int )` - Set/Get visibility of the axis title.
- `int = obj.GetTitleVisibility ()` - Set/Get visibility of the axis title.

- `obj.TitleVisibilityOn ()` - Set/Get visibility of the axis title.
- `obj.TitleVisibilityOff ()` - Set/Get visibility of the axis title.
- `obj.SetTitlePosition (double )` - Set/Get position of the axis title. 0 is at the start of the axis whereas 1 is at the end.
- `double = obj.GetTitlePosition ()` - Set/Get position of the axis title. 0 is at the start of the axis whereas 1 is at the end.
- `obj.SetFontFactor (double )` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes. This ivar used in conjunction with the LabelFactor can be used to control font sizes.
- `double = obj.GetFontFactorMinValue ()` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes. This ivar used in conjunction with the LabelFactor can be used to control font sizes.
- `double = obj.GetFontFactorMaxValue ()` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes. This ivar used in conjunction with the LabelFactor can be used to control font sizes.
- `double = obj.GetFontFactor ()` - Set/Get the factor that controls the overall size of the fonts used to label and title the axes. This ivar used in conjunction with the LabelFactor can be used to control font sizes.
- `obj.SetLabelFactor (double )` - Set/Get the factor that controls the relative size of the axis labels to the axis title.
- `double = obj.GetLabelFactorMinValue ()` - Set/Get the factor that controls the relative size of the axis labels to the axis title.
- `double = obj.GetLabelFactorMaxValue ()` - Set/Get the factor that controls the relative size of the axis labels to the axis title.
- `double = obj.GetLabelFactor ()` - Set/Get the factor that controls the relative size of the axis labels to the axis title.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Draw the axis.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Draw the axis.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.SetSizeFontRelativeToAxis (int )` - Specify whether to size the fonts relative to the viewport or relative to length of the axis. By default, fonts are resized relative to the axis.
- `int = obj.GetSizeFontRelativeToAxis ()` - Specify whether to size the fonts relative to the viewport or relative to length of the axis. By default, fonts are resized relative to the axis.
- `obj.SizeFontRelativeToAxisOn ()` - Specify whether to size the fonts relative to the viewport or relative to length of the axis. By default, fonts are resized relative to the axis.

- `obj.SizeFontRelativeToAxisOff ()` - Specify whether to size the fonts relative to the viewport or relative to length of the axis. By default, fonts are resized relative to the axis.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an axis actor. Overloads the virtual vtkProp method.

39.10 vtkCamera

39.10.1 Usage

vtkCamera is a virtual camera for 3D rendering. It provides methods to position and orient the view point and focal point. Convenience methods for moving about the focal point also are provided. More complex methods allow the manipulation of the computer graphics model including view up vector, clipping planes, and camera perspective.

To create an instance of class vtkCamera, simply invoke its constructor as follows

```
obj = vtkCamera
```

39.10.2 Methods

The class vtkCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCamera = obj.NewInstance ()`
- `vtkCamera = obj.SafeDownCast (vtkObject o)`
- `obj.SetPosition (double x, double y, double z)` - Set/Get the position of the camera in world coordinates. The default position is (0,0,1).
- `obj.SetPosition (double a[3])` - Set/Get the position of the camera in world coordinates. The default position is (0,0,1).
- `double = obj. GetPosition ()` - Set/Get the position of the camera in world coordinates. The default position is (0,0,1).
- `obj.SetFocalPoint (double x, double y, double z)` - Set/Get the focal of the camera in world coordinates. The default focal point is the origin.
- `obj.SetFocalPoint (double a[3])` - Set/Get the focal of the camera in world coordinates. The default focal point is the origin.
- `double = obj. GetFocalPoint ()` - Set/Get the focal of the camera in world coordinates. The default focal point is the origin.
- `obj.SetViewUp (double vx, double vy, double vz)` - Set/Get the view up direction for the camera. The default is (0,1,0).
- `obj.SetViewUp (double a[3])` - Set/Get the view up direction for the camera. The default is (0,1,0).
- `double = obj. GetViewUp ()` - Set/Get the view up direction for the camera. The default is (0,1,0).
- `obj.OrthogonalizeViewUp ()` - Recompute the ViewUp vector to force it to be perpendicular to camera-¿focalpoint vector. Unless you are going to use Yaw or Azimuth on the camera, there is no need to do this.

- `obj.SetDistance (double )` - Move the focal point so that it is the specified distance from the camera position. This distance must be positive.
- `double = obj.GetDistance ()` - Return the distance from the camera position to the focal point. This distance is positive.
- `double = obj. GetDirectionOfProjection ()` - Get the vector in the direction from the camera position to the focal point. This is usually the opposite of the ViewPlaneNormal, the vector perpendicular to the screen, unless the view is oblique.
- `obj.Dolly (double value)` - Divide the camera's distance from the focal point by the given dolly value. Use a value greater than one to dolly-in toward the focal point, and use a value less than one to dolly-out away from the focal point.
- `obj.SetRoll (double angle)` - Set the roll angle of the camera about the direction of projection.
- `double = obj.GetRoll ()` - Set the roll angle of the camera about the direction of projection.
- `obj.Roll (double angle)` - Rotate the camera about the direction of projection. This will spin the camera about its axis.
- `obj.Azimuth (double angle)` - Rotate the camera about the view up vector centered at the focal point. Note that the view up vector is whatever was set via SetViewUp, and is not necessarily perpendicular to the direction of projection. The result is a horizontal rotation of the camera.
- `obj.Yaw (double angle)` - Rotate the focal point about the view up vector, using the camera's position as the center of rotation. Note that the view up vector is whatever was set via SetViewUp, and is not necessarily perpendicular to the direction of projection. The result is a horizontal rotation of the scene.
- `obj.Elevation (double angle)` - Rotate the camera about the cross product of the negative of the direction of projection and the view up vector, using the focal point as the center of rotation. The result is a vertical rotation of the scene.
- `obj.Pitch (double angle)` - Rotate the focal point about the cross product of the view up vector and the direction of projection, using the camera's position as the center of rotation. The result is a vertical rotation of the camera.
- `obj.SetParallelProjection (int flag)` - Set/Get the value of the ParallelProjection instance variable. This determines if the camera should do a perspective or parallel projection.
- `int = obj.GetParallelProjection ()` - Set/Get the value of the ParallelProjection instance variable. This determines if the camera should do a perspective or parallel projection.
- `obj.ParallelProjectionOn ()` - Set/Get the value of the ParallelProjection instance variable. This determines if the camera should do a perspective or parallel projection.
- `obj.ParallelProjectionOff ()` - Set/Get the value of the ParallelProjection instance variable. This determines if the camera should do a perspective or parallel projection.
- `obj.SetUseHorizontalViewAngle (int flag)` - Set/Get the value of the UseHorizontalViewAngle instance variable. If set, the camera's view angle represents a horizontal view angle, rather than the default vertical view angle. This is useful if the application uses a display device which whose specs indicate a particular horizontal view angle, or if the application varies the window height but wants to keep the perspective transform unchanges.
- `int = obj.GetUseHorizontalViewAngle ()` - Set/Get the value of the UseHorizontalViewAngle instance variable. If set, the camera's view angle represents a horizontal view angle, rather than the default vertical view angle. This is useful if the application uses a display device which whose specs indicate a particular horizontal view angle, or if the application varies the window height but wants to keep the perspective transform unchanges.

- `obj.UseHorizontalViewAngleOn ()` - Set/Get the value of the UseHorizontalViewAngle instance variable. If set, the camera's view angle represents a horizontal view angle, rather than the default vertical view angle. This is useful if the application uses a display device which whose specs indicate a particular horizontal view angle, or if the application varies the window height but wants to keep the perspective transform unchanges.

- `obj.UseHorizontalViewAngleOff ()` - Set/Get the value of the UseHorizontalViewAngle instance variable. If set, the camera's view angle represents a horizontal view angle, rather than the default vertical view angle. This is useful if the application uses a display device which whose specs indicate a particular horizontal view angle, or if the application varies the window height but wants to keep the perspective transform unchanges.

- `obj.SetViewAngle (double angle)` - Set/Get the camera view angle, which is the angular height of the camera view measured in degrees. The default angle is 30 degrees. This method has no effect in parallel projection mode. The formula for setting the angle up for perfect perspective viewing is: angle = 2*atan((h/2)/d) where h is the height of the RenderWindow (measured by holding a ruler up to your screen) and d is the distance from your eyes to the screen.

- `double = obj.GetViewAngle ()` - Set/Get the camera view angle, which is the angular height of the camera view measured in degrees. The default angle is 30 degrees. This method has no effect in parallel projection mode. The formula for setting the angle up for perfect perspective viewing is: angle = 2*atan((h/2)/d) where h is the height of the RenderWindow (measured by holding a ruler up to your screen) and d is the distance from your eyes to the screen.

- `obj.SetParallelScale (double scale)` - Set/Get the scaling used for a parallel projection, i.e. the height of the viewport in world-coordinate distances. The default is 1. Note that the "scale" parameter works as an "inverse scale" — larger numbers produce smaller images. This method has no effect in perspective projection mode.

- `double = obj.GetParallelScale ()` - Set/Get the scaling used for a parallel projection, i.e. the height of the viewport in world-coordinate distances. The default is 1. Note that the "scale" parameter works as an "inverse scale" — larger numbers produce smaller images. This method has no effect in perspective projection mode.

- `obj.Zoom (double factor)` - In perspective mode, decrease the view angle by the specified factor. In parallel mode, decrease the parallel scale by the specified factor. A value greater than 1 is a zoom-in, a value less than 1 is a zoom-out.

- `obj.SetClippingRange (double dNear, double dFar)` - Set/Get the location of the near and far clipping planes along the direction of projection. Both of these values must be positive. How the clipping planes are set can have a large impact on how well z-buffering works. In particular the front clipping plane can make a very big difference. Setting it to 0.01 when it really could be 1.0 can have a big impact on your z-buffer resolution farther away. The default clipping range is (0.1,1000).

- `obj.SetClippingRange (double a[2])` - Set/Get the location of the near and far clipping planes along the direction of projection. Both of these values must be positive. How the clipping planes are set can have a large impact on how well z-buffering works. In particular the front clipping plane can make a very big difference. Setting it to 0.01 when it really could be 1.0 can have a big impact on your z-buffer resolution farther away. The default clipping range is (0.1,1000).

- `double = obj. GetClippingRange ()` - Set/Get the location of the near and far clipping planes along the direction of projection. Both of these values must be positive. How the clipping planes are set can have a large impact on how well z-buffering works. In particular the front clipping plane can make a very big difference. Setting it to 0.01 when it really could be 1.0 can have a big impact on your z-buffer resolution farther away. The default clipping range is (0.1,1000).

- `obj.SetThickness (double )` - Set the distance between clipping planes. This method adjusts the far clipping plane to be set a distance 'thickness' beyond the near clipping plane.

- `double = obj.GetThickness ()` - Set the distance between clipping planes. This method adjusts the far clipping plane to be set a distance 'thickness' beyond the near clipping plane.

- `obj.SetWindowCenter (double x, double y)` - Set/Get the center of the window in viewport coordinates. The viewport coordinate range is ([-1,+1],[-1,+1]). This method is for if you have one window which consists of several viewports, or if you have several screens which you want to act together as one large screen.

- `double = obj. GetWindowCenter ()` - Set/Get the center of the window in viewport coordinates. The viewport coordinate range is ([-1,+1],[-1,+1]). This method is for if you have one window which consists of several viewports, or if you have several screens which you want to act together as one large screen.

- `obj.SetObliqueAngles (double alpha, double beta)` - Get/Set the oblique viewing angles. The first angle, alpha, is the angle (measured from the horizontal) that rays along the direction of projection will follow once projected onto the 2D screen. The second angle, beta, is the angle between the view plane and the direction of projection. This creates a shear transform x' = x + dz*cos(alpha)/tan(beta), y' = dz*sin(alpha)/tan(beta) where dz is the distance of the point from the focal plane. The angles are (45,90) by default. Oblique projections commonly use (30,63.435).

- `obj.ApplyTransform (vtkTransform t)` - Apply a transform to the camera. The camera position, focal-point, and view-up are re-calculated using the transform's matrix to multiply the old points by the new transform.

- `double = obj. GetViewPlaneNormal ()` - Get the ViewPlaneNormal. This vector will point opposite to the direction of projection, unless you have created an sheared output view using SetViewShear/SetObliqueAngles.

- `obj.SetViewShear (double dxdz, double dydz, double center)` - Set/get the shear transform of the viewing frustum. Parameters are dx/dz, dy/dz, and center. center is a factor that describes where to shear around. The distance dshear from the camera where no shear occurs is given by (dshear = center * FocalDistance).

- `obj.SetViewShear (double d[3])` - Set/get the shear transform of the viewing frustum. Parameters are dx/dz, dy/dz, and center. center is a factor that describes where to shear around. The distance dshear from the camera where no shear occurs is given by (dshear = center * FocalDistance).

- `double = obj. GetViewShear ()` - Set/get the shear transform of the viewing frustum. Parameters are dx/dz, dy/dz, and center. center is a factor that describes where to shear around. The distance dshear from the camera where no shear occurs is given by (dshear = center * FocalDistance).

- `obj.SetEyeAngle (double )` - Set/Get the separation between eyes (in degrees). This is used when generating stereo images.

- `double = obj.GetEyeAngle ()` - Set/Get the separation between eyes (in degrees). This is used when generating stereo images.

- `obj.SetFocalDisk (double )` - Set the size of the cameras lens in world coordinates. This is only used when the renderer is doing focal depth rendering. When that is being done the size of the focal disk will effect how significant the depth effects will be.

- `double = obj.GetFocalDisk ()` - Set the size of the cameras lens in world coordinates. This is only used when the renderer is doing focal depth rendering. When that is being done the size of the focal disk will effect how significant the depth effects will be.

- `vtkMatrix4x4 = obj.GetViewTransformMatrix ()` - Return the matrix of the view transform. The ViewTransform depends on only three ivars: the Position, the FocalPoint, and the ViewUp vector. All the other methods are there simply for the sake of the users' convenience.

- `vtkTransform = obj.GetViewTransformObject ()` - Return the projection transform matrix, which converts from camera coordinates to viewport coordinates. The 'aspect' is the width/height for the viewport, and the nearz and farz are the Z-buffer values that map to the near and far clipping planes. The viewport coordinates of a point located inside the frustum are in the range ([-1,+1],[-1,+1],[nearz,farz]). WARNING: the name of the method is wrong, it should be GetProjectionTransformMatrix() (it is used also in parallel projection) @deprecated Replaced by GetProjectionTransformMatrix() as of VTK 5.4.

- `vtkMatrix4x4 = obj.GetPerspectiveTransformMatrix (double aspect, double nearz, double farz)` - Return the projection transform matrix, which converts from camera coordinates to viewport coordinates. The 'aspect' is the width/height for the viewport, and the nearz and farz are the Z-buffer values that map to the near and far clipping planes. The viewport coordinates of a point located inside the frustum are in the range ([-1,+1],[-1,+1],[nearz,farz]). WARNING: the name of the method is wrong, it should be GetProjectionTransformMatrix() (it is used also in parallel projection) @deprecated Replaced by GetProjectionTransformMatrix() as of VTK 5.4.

- `vtkMatrix4x4 = obj.GetProjectionTransformMatrix (double aspect, double nearz, double farz)` - Return the projection transform matrix, which converts from camera coordinates to viewport coordinates. The 'aspect' is the width/height for the viewport, and the nearz and farz are the Z-buffer values that map to the near and far clipping planes. The viewport coordinates of a point located inside the frustum are in the range ([-1,+1],[-1,+1],[nearz,farz]).

- `vtkPerspectiveTransform = obj.GetProjectionTransformObject (double aspect, double nearz, double far` - Return the projection transform matrix, which converts from camera coordinates to viewport coordinates. The 'aspect' is the width/height for the viewport, and the nearz and farz are the Z-buffer values that map to the near and far clipping planes. The viewport coordinates of a point located inside the frustum are in the range ([-1,+1],[-1,+1],[nearz,farz]).

- `vtkMatrix4x4 = obj.GetCompositePerspectiveTransformMatrix (double aspect, double nearz, double farz` - Return the concatenation of the ViewTransform and the ProjectionTransform. This transform will convert world coordinates to viewport coordinates. The 'aspect' is the width/height for the viewport, and the nearz and farz are the Z-buffer values that map to the near and far clipping planes. The viewport coordinates of a point located inside the frustum are in the range ([-1,+1],[-1,+1],[nearz,farz]). WARNING: the name of the method is wrong, it should be GetCompositeProjectionTransformMatrix() (it is used also in parallel projection) @deprecated Replaced by GetCompositeProjectionTransformMatrix() as of VTK 5.4.

- `vtkMatrix4x4 = obj.GetCompositeProjectionTransformMatrix (double aspect, double nearz, double farz)` - Return the concatenation of the ViewTransform and the ProjectionTransform. This transform will convert world coordinates to viewport coordinates. The 'aspect' is the width/height for the viewport, and the nearz and farz are the Z-buffer values that map to the near and far clipping planes. The viewport coordinates of a point located inside the frustum are in the range ([-1,+1],[-1,+1],[nearz,farz]).

- `obj.SetUserViewTransform (vtkHomogeneousTransform transform)` - In addition to the instance variables such as position and orientation, you can add an additional transformation for your own use. This transformation is concatenated to the camera's ViewTransform

- `vtkHomogeneousTransform = obj.GetUserViewTransform ()` - In addition to the instance variables such as position and orientation, you can add an additional transformation for your own use. This transformation is concatenated to the camera's ViewTransform

- `obj.SetUserTransform (vtkHomogeneousTransform transform)` - In addition to the instance variables such as position and orientation, you can add an additional transformation for your own use. This transformation is concatenated to the camera's ProjectionTransform

- `vtkHomogeneousTransform = obj.GetUserTransform ()` - In addition to the instance variables such as position and orientation, you can add an additional transformation for your own use. This transformation is concatenated to the camera's ProjectionTransform

- `obj.Render (vtkRenderer )` - Return the MTime that concerns recomputing the view rays of the camera.
- `long = obj.GetViewingRaysMTime ()` - Return the MTime that concerns recomputing the view rays of the camera.
- `obj.ViewingRaysModified ()` - Mark that something has changed which requires the view rays to be recomputed.
- `obj.GetFrustumPlanes (double aspect, double planes[24])` - Get the plane equations that bound the view frustum. The plane normals point inward. The planes array contains six plane equations of the form (Ax+By+Cz+D=0), the first four values are (A,B,C,D) which repeats for each of the planes. The planes are given in the following order: -x,+x,-y,+y,-z,+z. Warning: it means left,right,bottom,top,far,near (NOT near,far) The aspect of the viewport is needed to correctly compute the planes
- `double = obj.GetOrientation ()` - Get the orientation of the camera.
- `double = obj.GetOrientationWXYZ ()` - Get the orientation of the camera.
- `obj.SetViewPlaneNormal (double x, double y, double z)` - @deprecated The view plane normal is automatically set from the DirectionOfProjection according to the ViewShear.
- `obj.SetViewPlaneNormal (double a[3])` - @deprecated The view plane normal is automatically set from the DirectionOfProjection according to the ViewShear.
- `obj.ComputeViewPlaneNormal ()` - This method is called automatically whenever necessary, it should never be used outside of vtkCamera.cxx.
- `vtkMatrix4x4 = obj.GetCameraLightTransformMatrix ()` - Returns a transformation matrix for a coordinate frame attached to the camera, where the camera is located at (0, 0, 1) looking at the focal point at (0, 0, 0), with up being (0, 1, 0).
- `obj.UpdateViewport (vtkRenderer )` - Set the Left Eye setting
- `obj.SetLeftEye (int )` - Set the Left Eye setting
- `int = obj.GetLeftEye ()` - Set the Left Eye setting
- `obj.ShallowCopy (vtkCamera source)` - Copy the properties of 'source' into 'this'. Copy pointers of matrices.
- `obj.DeepCopy (vtkCamera source)` - Copy the properties of 'source' into 'this'. Copy the contents of the matrices.

39.11 vtkCameraActor

39.11.1 Usage

vtkCameraActor is an actor used to represent a camera by its wireframe frustum.

To create an instance of class vtkCameraActor, simply invoke its constructor as follows

```
obj = vtkCameraActor
```

39.11.2 Methods

The class vtkCameraActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCameraActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCameraActor = obj.NewInstance ()`
- `vtkCameraActor = obj.SafeDownCast (vtkObject o)`
- `obj.SetCamera (vtkCamera camera)` - The camera to represent. Initial value is NULL.
- `vtkCamera = obj.GetCamera ()` - The camera to represent. Initial value is NULL.
- `obj.SetWidthByHeightRatio (double )` - Ratio between the width and the height of the frustum. Initial value is 1.0 (square)
- `double = obj.GetWidthByHeightRatio ()` - Ratio between the width and the height of the frustum. Initial value is 1.0 (square)
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry? No.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `long = obj.GetMTime ()` - Get the actors mtime plus consider its properties and texture if set.
- `vtkProperty = obj.GetProperty ()` - Get property of the internal actor.
- `obj.SetProperty (vtkProperty p)` - Set property of the internal actor.

39.12 vtkCameraInterpolator

39.12.1 Usage

This class is used to interpolate a series of cameras to update a specified camera. Either linear interpolation or spline interpolation may be used. The instance variables currently interpolated include position, focal point, view up, view angle, parallel scale, and clipping range.

To use this class, specify the type of interpolation to use, and add a series of cameras at various times "t" to the list of cameras from which to interpolate. Then to interpolate in between cameras, simply invoke the function InterpolateCamera(t,camera) where "camera" is the camera to be updated with interpolated values. Note that "t" should be in the range (min,max) times specified with the AddCamera() method. If outside this range, the interpolation is clamped. This class copies the camera information (as compared to referencing the cameras) so you do not need to keep separate instances of the camera around for each camera added to the list of cameras to interpolate.

To create an instance of class vtkCameraInterpolator, simply invoke its constructor as follows

```
obj = vtkCameraInterpolator
```

39.12.2 Methods

The class vtkCameraInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCameraInterpolator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCameraInterpolator = obj.NewInstance ()`
- `vtkCameraInterpolator = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfCameras ()` - Return the number of cameras in the list of cameras.
- `double = obj.GetMinimumT ()` - Obtain some information about the interpolation range. The numbers returned are undefined if the list of cameras is empty.
- `double = obj.GetMaximumT ()` - Obtain some information about the interpolation range. The numbers returned are undefined if the list of cameras is empty.
- `obj.Initialize ()` - Clear the list of cameras.
- `obj.AddCamera (double t, vtkCamera camera)` - Add another camera to the list of cameras defining the camera function. Note that using the same time t value more than once replaces the previous camera value at t. At least one camera must be added to define a function.
- `obj.RemoveCamera (double t)` - Delete the camera at a particular parameter t. If there is no camera defined at location t, then the method does nothing.
- `obj.InterpolateCamera (double t, vtkCamera camera)` - Interpolate the list of cameras and determine a new camera (i.e., fill in the camera provided). If t is outside the range of (min,max) values, then t is clamped to lie within this range.
- `obj.SetInterpolationType (int )` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the instance variable interpolators (i.e., position, focal point, clipping range, orientation, etc.) interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.
- `int = obj.GetInterpolationTypeMinValue ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the instance variable interpolators (i.e., position, focal point, clipping range, orientation, etc.) interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.
- `int = obj.GetInterpolationTypeMaxValue ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the instance variable interpolators (i.e., position, focal point, clipping range, orientation, etc.) interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `int = obj.GetInterpolationType ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the instance variable interpolators (i.e., position, focal point, clipping range, orientation, etc.) interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `obj.SetInterpolationTypeToLinear ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the instance variable interpolators (i.e., position, focal point, clipping range, orientation, etc.) interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `obj.SetInterpolationTypeToSpline ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the instance variable interpolators (i.e., position, focal point, clipping range, orientation, etc.) interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `obj.SetInterpolationTypeToManual ()` - Set/Get the tuple interpolator used to interpolate the position portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `obj.SetPositionInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the position portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `vtkTupleInterpolator = obj.GetPositionInterpolator ()` - Set/Get the tuple interpolator used to interpolate the position portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `obj.SetFocalPointInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the focal point portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `vtkTupleInterpolator = obj.GetFocalPointInterpolator ()` - Set/Get the tuple interpolator used to interpolate the focal point portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `obj.SetViewUpInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the view up portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `vtkTupleInterpolator = obj.GetViewUpInterpolator ()` - Set/Get the tuple interpolator used to interpolate the view up portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `obj.SetViewAngleInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the view angle portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.

- `vtkTupleInterpolator = obj.GetViewAngleInterpolator ()` - Set/Get the tuple interpolator used to interpolate the view angle portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.
- `obj.SetParallelScaleInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the parallel scale portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.
- `vtkTupleInterpolator = obj.GetParallelScaleInterpolator ()` - Set/Get the tuple interpolator used to interpolate the parallel scale portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.
- `obj.SetClippingRangeInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the clipping range portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.
- `vtkTupleInterpolator = obj.GetClippingRangeInterpolator ()` - Set/Get the tuple interpolator used to interpolate the clipping range portion of the camera. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances directly.
- `long = obj.GetMTime ()` - Override GetMTime() because we depend on the interpolators which may be modified outside of this class.

39.13 vtkCameraPass

39.13.1 Usage

Render the camera.

It setups the projection and modelview matrices and can clear the background It calls its delegate once. After its delegate returns, it restore the modelview matrix stack.

Its delegate is usually set to a vtkSequencePass with a vtkLigthsPass and a list of passes for the geometry.

To create an instance of class vtkCameraPass, simply invoke its constructor as follows

```
obj = vtkCameraPass
```

39.13.2 Methods

The class vtkCameraPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCameraPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCameraPass = obj.NewInstance ()`
- `vtkCameraPass = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.

- `vtkRenderPass = obj.GetDelegatePass ()` - Delegate for rendering the geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkSequencePass with a vtkLigthsPass and a list of passes for the geometry. Initial value is a NULL pointer.

- `obj.SetDelegatePass (vtkRenderPass delegatePass)` - Delegate for rendering the geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkSequencePass with a vtkLigthsPass and a list of passes for the geometry. Initial value is a NULL pointer.

39.14 vtkCellCenterDepthSort

39.14.1 Usage

vtkCellCenterDepthSort is a simple and fast implementation of depth sort, but it only provides approximate results. The sorting algorithm finds the centroids of all the cells. It then performs the dot product of the centroids against a vector pointing in the direction of the camera transformed into object space. It then performs an ordinary sort on the result.

To create an instance of class vtkCellCenterDepthSort, simply invoke its constructor as follows

```
obj = vtkCellCenterDepthSort
```

39.14.2 Methods

The class vtkCellCenterDepthSort has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellCenterDepthSort class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkCellCenterDepthSort = obj.NewInstance ()`

- `vtkCellCenterDepthSort = obj.SafeDownCast (vtkObject o)`

- `obj.InitTraversal ()`

- `vtkIdTypeArray = obj.GetNextCells ()`

39.15 vtkCellPicker

39.15.1 Usage

vtkCellPicker will shoot a ray into a 3D scene and return information about the first object that the ray hits. It works for all Prop3Ds. For vtkVolume objects, it shoots a ray into the volume and returns the point where the ray intersects an isosurface of a chosen opacity. For vtkImageActor objects, it intersects the ray with the displayed slice. For vtkActor objects, it intersects the actor's polygons. If the object's mapper has ClippingPlanes, then it takes the clipping into account, and will return the Id of the clipping plane that was intersected. For all prop types, it returns point and cell information, plus the normal of the surface that was intersected at the pick position. For volumes and images, it also returns (i,j,k) coordinates for the point and the cell that were picked.

To create an instance of class vtkCellPicker, simply invoke its constructor as follows

```
obj = vtkCellPicker
```

39.15.2 Methods

The class vtkCellPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellPicker = obj.NewInstance ()`
- `vtkCellPicker = obj.SafeDownCast (vtkObject o)`
- `int = obj.Pick (double selectionX, double selectionY, double selectionZ, vtkRenderer renderer)` - Perform pick operation with selection point provided. Normally the first two values are the (x,y) pixel coordinates for the pick, and the third value is z=0. The return value will be non-zero if something was successfully picked.
- `obj.AddLocator (vtkAbstractCellLocator locator)` - Add a locator for one of the data sets that will be included in the scene. You must set up the locator with exactly the same data set that was input to the mapper of one or more of the actors in the scene. As well, you must either build the locator before doing the pick, or you must turn on LazyEvaluation in the locator to make it build itself on the first pick. Note that if you try to add the same locator to the picker twice, the second addition will be ignored.
- `obj.RemoveLocator (vtkAbstractCellLocator locator)` - Remove a locator that was previously added. If you try to remove a nonexistent locator, then nothing will happen and no errors will be raised.
- `obj.RemoveAllLocators ()` - Remove all locators associated with this picker.
- `obj.SetVolumeOpacityIsovalue (double )` - Set the opacity isovalue to use for defining volume surfaces. The pick will occur at the location along the pick ray where the opacity of the volume is equal to this isovalue. If you want to do the pick based on an actual data isovalue rather than the opacity, then pass the data value through the scalar opacity function before using this method.
- `double = obj.GetVolumeOpacityIsovalue ()` - Set the opacity isovalue to use for defining volume surfaces. The pick will occur at the location along the pick ray where the opacity of the volume is equal to this isovalue. If you want to do the pick based on an actual data isovalue rather than the opacity, then pass the data value through the scalar opacity function before using this method.
- `obj.SetUseVolumeGradientOpacity (int )` - Use the product of the scalar and gradient opacity functions when computing the opacity isovalue, instead of just using the scalar opacity. This parameter is only relevant to volume picking and is off by default.
- `obj.UseVolumeGradientOpacityOn ()` - Use the product of the scalar and gradient opacity functions when computing the opacity isovalue, instead of just using the scalar opacity. This parameter is only relevant to volume picking and is off by default.
- `obj.UseVolumeGradientOpacityOff ()` - Use the product of the scalar and gradient opacity functions when computing the opacity isovalue, instead of just using the scalar opacity. This parameter is only relevant to volume picking and is off by default.
- `int = obj.GetUseVolumeGradientOpacity ()` - Use the product of the scalar and gradient opacity functions when computing the opacity isovalue, instead of just using the scalar opacity. This parameter is only relevant to volume picking and is off by default.

- `obj.SetPickClippingPlanes (int )` - The PickClippingPlanes setting controls how clipping planes are handled by the pick. If it is On, then the clipping planes become pickable objects, even though they are usually invisible. This means that if the pick ray intersects a clipping plane before it hits anything else, the pick will stop at that clipping plane. The GetProp3D() and GetMapper() methods will return the Prop3D and Mapper that the clipping plane belongs to. The GetClippingPlaneId() method will return the index of the clipping plane so that you can retrieve it from the mapper, or -1 if no clipping plane was picked. The picking of vtkImageActors is not influenced by this setting, since they have no clipping planes.

- `obj.PickClippingPlanesOn ()` - The PickClippingPlanes setting controls how clipping planes are handled by the pick. If it is On, then the clipping planes become pickable objects, even though they are usually invisible. This means that if the pick ray intersects a clipping plane before it hits anything else, the pick will stop at that clipping plane. The GetProp3D() and GetMapper() methods will return the Prop3D and Mapper that the clipping plane belongs to. The GetClippingPlaneId() method will return the index of the clipping plane so that you can retrieve it from the mapper, or -1 if no clipping plane was picked. The picking of vtkImageActors is not influenced by this setting, since they have no clipping planes.

- `obj.PickClippingPlanesOff ()` - The PickClippingPlanes setting controls how clipping planes are handled by the pick. If it is On, then the clipping planes become pickable objects, even though they are usually invisible. This means that if the pick ray intersects a clipping plane before it hits anything else, the pick will stop at that clipping plane. The GetProp3D() and GetMapper() methods will return the Prop3D and Mapper that the clipping plane belongs to. The GetClippingPlaneId() method will return the index of the clipping plane so that you can retrieve it from the mapper, or -1 if no clipping plane was picked. The picking of vtkImageActors is not influenced by this setting, since they have no clipping planes.

- `int = obj.GetPickClippingPlanes ()` - The PickClippingPlanes setting controls how clipping planes are handled by the pick. If it is On, then the clipping planes become pickable objects, even though they are usually invisible. This means that if the pick ray intersects a clipping plane before it hits anything else, the pick will stop at that clipping plane. The GetProp3D() and GetMapper() methods will return the Prop3D and Mapper that the clipping plane belongs to. The GetClippingPlaneId() method will return the index of the clipping plane so that you can retrieve it from the mapper, or -1 if no clipping plane was picked. The picking of vtkImageActors is not influenced by this setting, since they have no clipping planes.

- `int = obj.GetClippingPlaneId ()` - Get the index of the clipping plane that was intersected during the pick. This will be set regardless of whether PickClippingPlanes is On, all that is required is that the pick intersected a clipping plane of the Prop3D that was picked. The result will be -1 if the Prop3D that was picked has no clipping planes, or if the ray didn't intersect the planes.

- `double = obj. GetPickNormal ()` - Return the normal of the picked surface at the PickPosition. If no surface was picked, then a vector pointing back at the camera is returned.

- `double = obj. GetMapperNormal ()` - Return the normal of the surface at the PickPosition in mapper coordinates. The result is undefined if no prop was picked.

- `int = obj. GetPointIJK ()` - Get the structured coordinates of the point at the PickPosition. Only valid for image actors and volumes with vtkImageData.

- `int = obj. GetCellIJK ()` - Get the structured coordinates of the cell at the PickPosition. Only valid for image actors and volumes with vtkImageData. Combine this with the PCoords to get the position within the cell.

- `vtkIdType = obj.GetPointId ()` - Get the id of the picked point. If PointId = -1, nothing was picked. This point will be a member of any cell that is picked.

- `vtkIdType = obj.GetCellId ()` - Get the id of the picked cell. If CellId = -1, nothing was picked.

- `int = obj.GetSubId ()` - Get the subId of the picked cell. This is useful, for example, if the data is made of triangle strips. If SubId = -1, nothing was picked.

- `double = obj. GetPCoords ()` - Get the parametric coordinates of the picked cell. Only valid if a prop was picked. The PCoords can be used to compute the weights that are needed to interpolate data values within the cell.

- `vtkTexture = obj.GetTexture ()` - Get the texture that was picked. This will always be set if the picked prop has a texture, and will always be null otherwise.

- `obj.SetPickTextureData (int )` - If this is "On" and if the picked prop has a texture, then the data returned by GetDataSet() will be the texture's data instead of the mapper's data. The GetPointId(), GetCellId(), GetPCoords() etc. will all return information for use with the texture's data. If the picked prop does not have any texture, then GetDataSet() will return the mapper's data instead and GetPointId() etc. will return information related to the mapper's data. The default value of PickTextureData is "Off".

- `obj.PickTextureDataOn ()` - If this is "On" and if the picked prop has a texture, then the data returned by GetDataSet() will be the texture's data instead of the mapper's data. The GetPointId(), GetCellId(), GetPCoords() etc. will all return information for use with the texture's data. If the picked prop does not have any texture, then GetDataSet() will return the mapper's data instead and GetPointId() etc. will return information related to the mapper's data. The default value of PickTextureData is "Off".

- `obj.PickTextureDataOff ()` - If this is "On" and if the picked prop has a texture, then the data returned by GetDataSet() will be the texture's data instead of the mapper's data. The GetPointId(), GetCellId(), GetPCoords() etc. will all return information for use with the texture's data. If the picked prop does not have any texture, then GetDataSet() will return the mapper's data instead and GetPointId() etc. will return information related to the mapper's data. The default value of PickTextureData is "Off".

- `int = obj.GetPickTextureData ()` - If this is "On" and if the picked prop has a texture, then the data returned by GetDataSet() will be the texture's data instead of the mapper's data. The GetPointId(), GetCellId(), GetPCoords() etc. will all return information for use with the texture's data. If the picked prop does not have any texture, then GetDataSet() will return the mapper's data instead and GetPointId() etc. will return information related to the mapper's data. The default value of PickTextureData is "Off".

39.16 vtkChooserPainter

39.16.1 Usage

This painter does not actually do any painting. Instead, it picks other painters based on the current state of itself and its poly data. It then delegates the work to these other painters.

To create an instance of class vtkChooserPainter, simply invoke its constructor as follows

```
obj = vtkChooserPainter
```

39.16.2 Methods

The class vtkChooserPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkChooserPainter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkChooserPainter = obj.NewInstance ()`
- `vtkChooserPainter = obj.SafeDownCast (vtkObject o)`
- `obj.SetVertPainter (vtkPolyDataPainter )`
- `obj.SetLinePainter (vtkPolyDataPainter )`
- `obj.SetPolyPainter (vtkPolyDataPainter )`
- `obj.SetStripPainter (vtkPolyDataPainter )`
- `obj.SetUseLinesPainterForWireframes (int )` - When set, the lines painter is used for drawing wireframes (off by default, except on Mac, where it's on by default).
- `int = obj.GetUseLinesPainterForWireframes ()` - When set, the lines painter is used for drawing wireframes (off by default, except on Mac, where it's on by default).
- `obj.UseLinesPainterForWireframesOn ()` - When set, the lines painter is used for drawing wireframes (off by default, except on Mac, where it's on by default).
- `obj.UseLinesPainterForWireframesOff ()` - When set, the lines painter is used for drawing wireframes (off by default, except on Mac, where it's on by default).

39.17 vtkClearZPass

39.17.1 Usage

Clear the depth buffer with a given value.

To create an instance of class vtkClearZPass, simply invoke its constructor as follows

```
obj = vtkClearZPass
```

39.17.2 Methods

The class vtkClearZPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClearZPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkClearZPass = obj.NewInstance ()`
- `vtkClearZPass = obj.SafeDownCast (vtkObject o)`
- `obj.SetDepth (double )` - Set/Get the depth value. Initial value is 1.0 (farest).
- `double = obj.GetDepthMinValue ()` - Set/Get the depth value. Initial value is 1.0 (farest).
- `double = obj.GetDepthMaxValue ()` - Set/Get the depth value. Initial value is 1.0 (farest).
- `double = obj.GetDepth ()` - Set/Get the depth value. Initial value is 1.0 (farest).

39.18 vtkCoincidentTopologyResolutionPainter

39.18.1 Usage

Provides the ability to shift the z-buffer to resolve coincident topology. For example, if you'd like to draw a mesh with some edges a different color, and the edges lie on the mesh, this feature can be useful to get nice looking lines.

To create an instance of class vtkCoincidentTopologyResolutionPainter, simply invoke its constructor as follows

```
obj = vtkCoincidentTopologyResolutionPainter
```

39.18.2 Methods

The class vtkCoincidentTopologyResolutionPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCoincidentTopologyResolutionPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCoincidentTopologyResolutionPainter = obj.NewInstance ()`
- `vtkCoincidentTopologyResolutionPainter = obj.SafeDownCast (vtkObject o)`

39.19 vtkColorMaterialHelper

39.19.1 Usage

vtkColorMaterialHelper is a helper to assist in simulating the ColorMaterial behaviour of the default OpenGL pipeline. Look at vtkColorMaterialHelper_s for available GLSL functions.

To create an instance of class vtkColorMaterialHelper, simply invoke its constructor as follows

```
obj = vtkColorMaterialHelper
```

39.19.2 Methods

The class vtkColorMaterialHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkColorMaterialHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkColorMaterialHelper = obj.NewInstance ()`
- `vtkColorMaterialHelper = obj.SafeDownCast (vtkObject o)`
- `obj.PrepareForRendering ()` - Prepares the shader i.e. reads color material paramters state from OpenGL. This must be called before the shader is bound.
- `obj.Render ()` - Uploads any uniforms needed. This must be called only after the shader has been bound, but before rendering the geometry.

39.20 vtkCompositePainter

39.20.1 Usage

vtkCompositePainter iterates over the leaves in a composite datasets. This painter can also handle the case when the dataset is not a composite dataset.

To create an instance of class vtkCompositePainter, simply invoke its constructor as follows

```
obj = vtkCompositePainter
```

39.20.2 Methods

The class vtkCompositePainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositePainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositePainter = obj.NewInstance ()`
- `vtkCompositePainter = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetOutput ()` - Get the output data object from this painter. The default implementation simply forwards the input data object as the output.

39.21 vtkCompositePolyDataMapper

39.21.1 Usage

This class uses a set of vtkPolyDataMappers to render input data which may be hierarchical. The input to this mapper may be either vtkPolyData or a vtkCompositeDataSet built from polydata. If something other than vtkPolyData is encountered, an error message will be produced.

To create an instance of class vtkCompositePolyDataMapper, simply invoke its constructor as follows

```
obj = vtkCompositePolyDataMapper
```

39.21.2 Methods

The class vtkCompositePolyDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositePolyDataMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositePolyDataMapper = obj.NewInstance ()`
- `vtkCompositePolyDataMapper = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren, vtkActor a)` - Standard method for rendering a mapper. This method will be called by the actor.
- `double = obj.GetBounds ()` - Standard vtkProp method to get 3D bounds of a 3D prop
- `obj.GetBounds (double bounds[6])` - Standard vtkProp method to get 3D bounds of a 3D prop
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release the underlying resources associated with this mapper

39.22 vtkCompositePolyDataMapper2

39.22.1 Usage

vtkCompositePolyDataMapper2 is similar to vtkCompositePolyDataMapper except that instead of creating individual mapper for each block in the composite dataset, it iterates over the blocks internally.

To create an instance of class vtkCompositePolyDataMapper2, simply invoke its constructor as follows

```
obj = vtkCompositePolyDataMapper2
```

39.22.2 Methods

The class vtkCompositePolyDataMapper2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositePolyDataMapper2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositePolyDataMapper2 = obj.NewInstance ()`
- `vtkCompositePolyDataMapper2 = obj.SafeDownCast (vtkObject o)`
- `obj.RenderPiece (vtkRenderer ren, vtkActor act)` - Implemented by sub classes. Actual rendering is done here.
- `double = obj.GetBounds ()` - Standard vtkProp method to get 3D bounds of a 3D prop
- `obj.GetBounds (double bounds[6])` - Standard vtkProp method to get 3D bounds of a 3D prop
- `obj.Render (vtkRenderer ren, vtkActor act)` - This calls RenderPiece (in a for loop is streaming is necessary). Basically a reimplementation for vtkPolyDataMapper::Render() since we don't want it to give up when vtkCompositeDataSet is encountered.
- `obj.SetColorBlocks (int )` - When set, each block is colored with a different color. Note that scalar coloring will be ignored.
- `int = obj.GetColorBlocks ()` - When set, each block is colored with a different color. Note that scalar coloring will be ignored.

39.23 vtkCuller

39.23.1 Usage

A culler has a cull method called by the vtkRenderer. The cull method is called before any rendering is performed, and it allows the culler to do some processing on the props and to modify their AllocatedRenderTime and re-order them in the prop list.

To create an instance of class vtkCuller, simply invoke its constructor as follows

```
obj = vtkCuller
```

39.23.2 Methods

The class vtkCuller has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCuller class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCuller = obj.NewInstance ()`
- `vtkCuller = obj.SafeDownCast (vtkObject o)`

39.24 vtkCullerCollection

39.24.1 Usage

vtkCullerCollection represents and provides methods to manipulate a list of Cullers (i.e., vtkCuller and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkCullerCollection, simply invoke its constructor as follows

```
obj = vtkCullerCollection
```

39.24.2 Methods

The class vtkCullerCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCullerCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCullerCollection = obj.NewInstance ()`
- `vtkCullerCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkCuller a)` - Get the next Culler in the list.
- `vtkCuller = obj.GetNextItem ()` - Get the last Culler in the list.
- `vtkCuller = obj.GetLastItem ()` - Get the last Culler in the list.

39.25 vtkDataSetMapper

39.25.1 Usage

vtkDataSetMapper is a mapper to map data sets (i.e., vtkDataSet and all derived classes) to graphics primitives. The mapping procedure is as follows: all 0D, 1D, and 2D cells are converted into points, lines, and polygons/triangle strips and then mapped to the graphics system. The 2D faces of 3D cells are mapped only if they are used by only one cell, i.e., on the boundary of the data set.

To create an instance of class vtkDataSetMapper, simply invoke its constructor as follows

```
obj = vtkDataSetMapper
```

39.25.2 Methods

The class vtkDataSetMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetMapper = obj.NewInstance ()`
- `vtkDataSetMapper = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren, vtkActor act)`
- `vtkPolyDataMapper = obj.GetPolyDataMapper ()` - Get the internal poly data mapper used to map data set to graphics system.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release.
- `long = obj.GetMTime ()` - Get the mtime also considering the lookup table.
- `obj.SetInput (vtkDataSet input)` - Set the Input of this mapper.
- `vtkDataSet = obj.GetInput ()` - Set the Input of this mapper.

39.26 vtkDataTransferHelper

39.26.1 Usage

vtkDataTransferHelper is a helper class that aids in transferring data between the CPU memory and the GPU memory. The data in GPU memory is stored as textures which that in CPU memory is stored as vtkDataArray. vtkDataTransferHelper provides API to transfer only a sub-extent of CPU structured data to/from the GPU.

To create an instance of class vtkDataTransferHelper, simply invoke its constructor as follows

```
obj = vtkDataTransferHelper
```

39.26.2 Methods

The class vtkDataTransferHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataTransferHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataTransferHelper = obj.NewInstance ()`
- `vtkDataTransferHelper = obj.SafeDownCast (vtkObject o)`
- `obj.SetContext (vtkRenderWindow context)` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.

- `vtkRenderWindow = obj.GetContext ()` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.

- `obj.SetCPUExtent (int , int , int , int , int , int )` - Set the CPU data extent. The extent matches the vtkDataArray size. If the vtkDataArray comes from an vtkImageData and it is part of the point data, it is usually the vtkImageData extent. It can be on cell data too, but in this case it does not match the vtkImageData extent. If the vtkDataArray comes from a vtkDataSet, just set it to a one-dimenstional extent equal to the number of tuples. Initial value is (0,0,0,0,0,0), a valid one tuple array.

- `obj.SetCPUExtent (int a[6])` - Set the CPU data extent. The extent matches the vtkDataArray size. If the vtkDataArray comes from an vtkImageData and it is part of the point data, it is usually the vtkImageData extent. It can be on cell data too, but in this case it does not match the vtkImageData extent. If the vtkDataArray comes from a vtkDataSet, just set it to a one-dimenstional extent equal to the number of tuples. Initial value is (0,0,0,0,0,0), a valid one tuple array.

- `int = obj. GetCPUExtent ()` - Set the CPU data extent. The extent matches the vtkDataArray size. If the vtkDataArray comes from an vtkImageData and it is part of the point data, it is usually the vtkImageData extent. It can be on cell data too, but in this case it does not match the vtkImageData extent. If the vtkDataArray comes from a vtkDataSet, just set it to a one-dimenstional extent equal to the number of tuples. Initial value is (0,0,0,0,0,0), a valid one tuple array.

- `obj.SetGPUExtent (int , int , int , int , int , int )` - Set the GPU data extent. This is the sub-extent to copy from or to the GPU. This extent matches the size of the data to transfer. GPUExtent and TextureExtent don't have to match (GPUExtent can be 1D whereas TextureExtent is 2D) but the number of elements have to match. Initial value is (0,0,0,0,0,0), a valid one tuple array.

- `obj.SetGPUExtent (int a[6])` - Set the GPU data extent. This is the sub-extent to copy from or to the GPU. This extent matches the size of the data to transfer. GPUExtent and TextureExtent don't have to match (GPUExtent can be 1D whereas TextureExtent is 2D) but the number of elements have to match. Initial value is (0,0,0,0,0,0), a valid one tuple array.

- `int = obj. GetGPUExtent ()` - Set the GPU data extent. This is the sub-extent to copy from or to the GPU. This extent matches the size of the data to transfer. GPUExtent and TextureExtent don't have to match (GPUExtent can be 1D whereas TextureExtent is 2D) but the number of elements have to match. Initial value is (0,0,0,0,0,0), a valid one tuple array.

- `obj.SetTextureExtent (int , int , int , int , int , int )` - Set the texture data extent. This is the extent of the texture image that will receive the data. This extent matches the size of the data to transfer. If it is set to an invalid extent, GPUExtent is used. See more comment on GPUExtent. Initial value is an invalid extent.

- `obj.SetTextureExtent (int a[6])` - Set the texture data extent. This is the extent of the texture image that will receive the data. This extent matches the size of the data to transfer. If it is set to an invalid extent, GPUExtent is used. See more comment on GPUExtent. Initial value is an invalid extent.

- `int = obj. GetTextureExtent ()` - Set the texture data extent. This is the extent of the texture image that will receive the data. This extent matches the size of the data to transfer. If it is set to an invalid extent, GPUExtent is used. See more comment on GPUExtent. Initial value is an invalid extent.

- `bool = obj.GetExtentIsValid (int extent)` - Tells if the given extent (6 int) is valid. True if min extent¡=max extent.

- `bool = obj.GetCPUExtentIsValid ()` - Tells if CPUExtent is valid. True if min extent¡=max extent.

- `bool = obj.GetGPUExtentIsValid ()` - Tells if GPUExtent is valid. True if min extent¡=max extent.

- `bool = obj.GetTextureExtentIsValid ()` - Tells if TextureExtent is valid. True if min extent¡=max extent.

- `obj.SetMinTextureDimension (int )` - Define the minimal dimension of the texture regardless of the dimensions of the TextureExtent. Initial value is 1. A texture extent can have a given dimension 0D (one value), 1D, 2D or 3D. By default 0D and 1D are translated into a 1D texture, 2D is translated into a 2D texture, 3D is translated into a 3D texture. To make life easier when writting GLSL code and use only one type of sampler (ex: sampler2d), the default behavior can be changed by forcing a type of texture with this ivar. 1: default behavior. Initial value. 2: force 0D and 1D to be in a 2D texture 3: force 0D, 1D and 2D texture to be in a 3D texture.

- `int = obj.GetMinTextureDimension ()` - Define the minimal dimension of the texture regardless of the dimensions of the TextureExtent. Initial value is 1. A texture extent can have a given dimension 0D (one value), 1D, 2D or 3D. By default 0D and 1D are translated into a 1D texture, 2D is translated into a 2D texture, 3D is translated into a 3D texture. To make life easier when writting GLSL code and use only one type of sampler (ex: sampler2d), the default behavior can be changed by forcing a type of texture with this ivar. 1: default behavior. Initial value. 2: force 0D and 1D to be in a 2D texture 3: force 0D, 1D and 2D texture to be in a 3D texture.

- `vtkDataArray = obj.GetArray ()` - Get/Set the CPU data buffer. Initial value is 0.

- `obj.SetArray (vtkDataArray array)` - Get/Set the CPU data buffer. Initial value is 0.

- `vtkTextureObject = obj.GetTexture ()` - Get/Set the GPU data buffer. Initial value is 0.

- `obj.SetTexture (vtkTextureObject texture)` - Get/Set the GPU data buffer. Initial value is 0.

- `bool = obj.Upload (int components, int componentListNULL)` - Old comment. Upload Extent from CPU data buffer to GPU. The WholeExtent must match the Array size. New comment. Upload GPUExtent from CPU vtkDataArray to GPU texture. It is possible to send a subset of the components or to specify and order of components or both. If components=0, componentList is ignored and all components are passed, a texture cannot have more than 4 components.

- `bool = obj.Download ()` - old comment: Downlad Extent from GPU data buffer to CPU. GPU data size must exactly match Extent. CPU data buffer will be resized to match WholeExtent in which only the Extent will be filled with the GPU data. new comment: Download GPUExtent from GPU texture to CPU vtkDataArray. If Array is not provided, it will be created with the size of CPUExtent. But only the tuples covered by GPUExtent will be download. In this case, if GPUExtent does not cover all GPUExtent, some of the vtkDataArray will be uninitialized. Reminder: A=¿B ¡=¿ !A——B

- `bool = obj.DownloadAsync1 ()` - Splits the download in two operations * Asynchronously download from texture memory to PBO (DownloadAsync1()). * Copy from pbo to user array (DownloadAsync2()).

- `bool = obj.DownloadAsync2 ()` - Splits the download in two operations * Asynchronously download from texture memory to PBO (DownloadAsync1()). * Copy from pbo to user array (DownloadAsync2()).

- `bool = obj.GetShaderSupportsTextureInt ()`

- `obj.SetShaderSupportsTextureInt (bool value)`

39.27 vtkDefaultPainter

39.27.1 Usage

This painter does not do any actual rendering. Sets up a default pipeline of painters to mimick the behaiour of old vtkPolyDataMapper. The chain is as follows: input–¿ vtkScalarsToColorsPainter –¿ vtkClipPlanesPainter –¿ vtkDisplayListPainter –¿ vtkCompositePainter –¿ vtkCoincidentTopologyResolutionPainter –¿ vtkLightingPainter –¿ vtkRepresentationPainter –¿ Delegate of vtkDefaultPainter. Typically, the delegate of the default painter be one that is capable of r rendering graphics primitives or a vtkChooserPainter which can select appropriate painters to do the rendering.

To create an instance of class vtkDefaultPainter, simply invoke its constructor as follows

```
obj = vtkDefaultPainter
```

39.27.2 Methods

The class vtkDefaultPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDefaultPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDefaultPainter = obj.NewInstance ()`
- `vtkDefaultPainter = obj.SafeDownCast (vtkObject o)`
- `obj.SetScalarsToColorsPainter (vtkScalarsToColorsPainter )` - Get/Set the painter that maps scalars to colors.
- `vtkScalarsToColorsPainter = obj.GetScalarsToColorsPainter ()` - Get/Set the painter that maps scalars to colors.
- `obj.SetClipPlanesPainter (vtkClipPlanesPainter )` - Get/Set the painter that handles clipping.
- `vtkClipPlanesPainter = obj.GetClipPlanesPainter ()` - Get/Set the painter that handles clipping.
- `obj.SetDisplayListPainter (vtkDisplayListPainter )` - Get/Set the painter that builds display lists.
- `vtkDisplayListPainter = obj.GetDisplayListPainter ()` - Get/Set the painter that builds display lists.
- `obj.SetCompositePainter (vtkCompositePainter )` - Get/Set the painter used to handle composite datasets.
- `vtkCompositePainter = obj.GetCompositePainter ()` - Get/Set the painter used to handle composite datasets.
- `obj.SetCoincidentTopologyResolutionPainter (vtkCoincidentTopologyResolutionPainter )` - Painter used to resolve coincident topology.
- `vtkCoincidentTopologyResolutionPainter = obj.GetCoincidentTopologyResolutionPainter ()` - Painter used to resolve coincident topology.
- `obj.SetLightingPainter (vtkLightingPainter )` - Get/Set the painter that controls lighting.
- `vtkLightingPainter = obj.GetLightingPainter ()` - Get/Set the painter that controls lighting.

- `obj.SetRepresentationPainter (vtkRepresentationPainter )` - Painter used to convert polydata to Wireframe/Points representation.
- `vtkRepresentationPainter = obj.GetRepresentationPainter ()` - Painter used to convert polydata to Wireframe/Points representation.
- `obj.SetDelegatePainter (vtkPainter )` - Set/Get the painter to which this painter should propagare its draw calls. These methods are overridden so that the delegate is set to the end of the Painter Chain.
- `vtkPainter = obj.GetDelegatePainter ()` - Overridden to setup the chain of painter depending on the actor representation. The chain is rebuilt if this-¿MTime has changed since last BuildPainterChain(); Building of the chain does not depend on input polydata, hence it does not check if the input has changed at all.
- `obj.Render (vtkRenderer renderer, vtkActor actor, long typeflags, bool forceCompileOnly)` - Overridden to setup the chain of painter depending on the actor representation. The chain is rebuilt if this-¿MTime has changed since last BuildPainterChain(); Building of the chain does not depend on input polydata, hence it does not check if the input has changed at all.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this painter. The parameter window could be used to determine which graphic resources to release. The call is propagated to the delegate painter, if any.
- `obj.UpdateBounds (double bounds[6])` - Expand or shrink the estimated bounds based on the geometric transformations applied in the painter. The bounds are left unchanged if the painter does not change the geometry.

39.28 vtkDefaultPass

39.28.1 Usage

vtkDefaultPass implements the basic standard render passes of VTK. Subclasses can easily be implemented by reusing some parts of the basic implementation.

It implements classic Render operations as well as versions with property key checking.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color.

To create an instance of class vtkDefaultPass, simply invoke its constructor as follows

```
obj = vtkDefaultPass
```

39.28.2 Methods

The class vtkDefaultPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDefaultPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDefaultPass = obj.NewInstance ()`
- `vtkDefaultPass = obj.SafeDownCast (vtkObject o)`

39.29 vtkDepthPeelingPass

39.29.1 Usage

Render the translucent polygonal geometry of a scene without sorting polygons in the view direction.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color. An opaque pass may have been performed right after the initialization.

The depth peeling algorithm works by rendering the translucent polygonal geometry multiple times (once for each peel). The actually rendering of the translucent polygonal geometry is peformed by its delegate TranslucentPass. This delegate is therefore used multiple times.

Its delegate is usually set to a vtkTranslucentPass.

To create an instance of class vtkDepthPeelingPass, simply invoke its constructor as follows

```
obj = vtkDepthPeelingPass
```

39.29.2 Methods

The class vtkDepthPeelingPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDepthPeelingPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDepthPeelingPass = obj.NewInstance ()`
- `vtkDepthPeelingPass = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.
- `vtkRenderPass = obj.GetTranslucentPass ()` - Delegate for rendering the translucent polygonal geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkTranslucentPass. Initial value is a NULL pointer.
- `obj.SetTranslucentPass (vtkRenderPass translucentPass)` - Delegate for rendering the translucent polygonal geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkTranslucentPass. Initial value is a NULL pointer.
- `obj.SetOcclusionRatio (double )` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.
- `double = obj.GetOcclusionRatioMinValue ()` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.
- `double = obj.GetOcclusionRatioMaxValue ()` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.

- `double = obj.GetOcclusionRatio ()` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.
- `obj.SetMaximumNumberOfPeels (int )` - In case of depth peeling, define the maximum number of peeling layers. Initial value is 4. A special value of 0 means no maximum limit. It has to be a positive value.
- `int = obj.GetMaximumNumberOfPeels ()` - In case of depth peeling, define the maximum number of peeling layers. Initial value is 4. A special value of 0 means no maximum limit. It has to be a positive value.
- `bool = obj.GetLastRenderingUsedDepthPeeling ()` - Tells if the last time this pass was executed, the depth peeling algorithm was actually used. Initial value is false.

39.30 vtkDistanceToCamera

39.30.1 Usage

This filter adds a double array containing the distance from each point to the camera. If Scaling is on, it will use the values in the input array to process in order to scale the size of the points. ScreenSize sets the size in screen pixels that you would want a rendered rectangle at that point to be, if it was scaled by the output array.

To create an instance of class vtkDistanceToCamera, simply invoke its constructor as follows

```
obj = vtkDistanceToCamera
```

39.30.2 Methods

The class vtkDistanceToCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistanceToCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDistanceToCamera = obj.NewInstance ()`
- `vtkDistanceToCamera = obj.SafeDownCast (vtkObject o)`
- `obj.SetRenderer (vtkRenderer ren)` - The renderer which will ultimately render these points.
- `vtkRenderer = obj.GetRenderer ()` - The renderer which will ultimately render these points.
- `obj.SetScreenSize (double )` - The desired screen size obtained by scaling glyphs by the distance array. It assumes the glyph at each point will be unit size.
- `double = obj.GetScreenSize ()` - The desired screen size obtained by scaling glyphs by the distance array. It assumes the glyph at each point will be unit size.
- `obj.SetScaling (bool )` - Whether to scale the distance by the input array to process.
- `bool = obj.GetScaling ()` - Whether to scale the distance by the input array to process.
- `obj.ScalingOn ()` - Whether to scale the distance by the input array to process.
- `obj.ScalingOff ()` - Whether to scale the distance by the input array to process.
- `long = obj.GetMTime ()` - The modified time of this filter.

39.31 vtkDummyGPUInfoList

39.31.1 Usage

vtkDummyGPUInfoList implements Probe() by just setting the count of GPUs to be zero. Useful when an OS specific implementation is not available.

To create an instance of class vtkDummyGPUInfoList, simply invoke its constructor as follows

```
obj = vtkDummyGPUInfoList
```

39.31.2 Methods

The class vtkDummyGPUInfoList has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDummyGPUInfoList class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDummyGPUInfoList = obj.NewInstance ()`
- `vtkDummyGPUInfoList = obj.SafeDownCast (vtkObject o)`
- `obj.Probe ()` - Build the list of vtkInfoGPU if not done yet.

39.32 vtkDynamic2DLabelMapper

39.32.1 Usage

vtkDynamic2DLabelMapper is a mapper that renders text at dataset points such that the labels do not overlap. Various items can be labeled including point ids, scalars, vectors, normals, texture coordinates, tensors, and field data components. This mapper assumes that the points are located on the x-y plane and that the camera remains perpendicular to that plane with a y-up axis (this can be constrained using vtkImageInteractor). On the first render, the mapper computes the visiblility of all labels at all scales, and queries this information on successive renders. This causes the first render to be much slower. The visibility algorithm is a greedy approach based on the point id, so the label for a point will be drawn unless the label for a point with lower id overlaps it.

To create an instance of class vtkDynamic2DLabelMapper, simply invoke its constructor as follows

```
obj = vtkDynamic2DLabelMapper
```

39.32.2 Methods

The class vtkDynamic2DLabelMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDynamic2DLabelMapper class.

- `string = obj.GetClassName ()` - Instantiate object with are labeled.
- `int = obj.IsA (string name)` - Instantiate object with are labeled.
- `vtkDynamic2DLabelMapper = obj.NewInstance ()` - Instantiate object with are labeled.
- `vtkDynamic2DLabelMapper = obj.SafeDownCast (vtkObject o)` - Instantiate object with are labeled.

- `obj.SetPriorityArrayName (string name)` - Set the points array name to use to give priority to labels. Defaults to "priority".
- `obj.SetReversePriority (bool )` - Whether to reverse the priority order (i.e. low values have high priority). Default is off.
- `bool = obj.GetReversePriority ()` - Whether to reverse the priority order (i.e. low values have high priority). Default is off.
- `obj.ReversePriorityOn ()` - Whether to reverse the priority order (i.e. low values have high priority). Default is off.
- `obj.ReversePriorityOff ()` - Whether to reverse the priority order (i.e. low values have high priority). Default is off.
- `obj.SetLabelHeightPadding (float )` - Set the label height padding as a percentage. The percentage is a percentage of your label height. Default is 50
- `float = obj.GetLabelHeightPadding ()` - Set the label height padding as a percentage. The percentage is a percentage of your label height. Default is 50
- `obj.SetLabelWidthPadding (float )` - Set the label width padding as a percentage. The percentage is a percentage of your label $\hat{h}$eight$\hat{(}$yes, not a typo). Default is 50
- `float = obj.GetLabelWidthPadding ()` - Set the label width padding as a percentage. The percentage is a percentage of your label $\hat{h}$eight$\hat{(}$yes, not a typo). Default is 50
- `obj.RenderOpaqueGeometry (vtkViewport viewport, vtkActor2D actor)` - Draw non-overlapping labels to the screen.
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Draw non-overlapping labels to the screen.

39.33 vtkExporter

39.33.1 Usage

vtkExporter is an abstract class that exports a scene to a file. It is very similar to vtkWriter except that a writer only writes out the geometric and topological data for an object, where an exporter can write out material properties, lighting, camera parameters etc. The concrete subclasses of this class may not write out all of this information. For example vtkOBJExporter writes out Wavefront obj files which do not include support for camera parameters.

vtkExporter provides the convenience methods StartWrite() and EndWrite(). These methods are executed before and after execution of the Write() method. You can also specify arguments to these methods. This class defines SetInput and GetInput methods which take or return a vtkRenderWindow.

To create an instance of class vtkExporter, simply invoke its constructor as follows

```
obj = vtkExporter
```

39.33.2 Methods

The class vtkExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkExporter = obj.NewInstance ()`
- `vtkExporter = obj.SafeDownCast (vtkObject o)`
- `obj.Write ()` - Write data to output. Method executes subclasses WriteData() method, as well as StartWrite() and EndWrite() methods.
- `obj.Update ()` - Convenient alias for Write() method.
- `obj.SetRenderWindow (vtkRenderWindow )` - Set/Get the rendering window that contains the scene to be written.
- `vtkRenderWindow = obj.GetRenderWindow ()` - Set/Get the rendering window that contains the scene to be written.
- `obj.SetInput (vtkRenderWindow renWin)` - These methods are provided for backward compatibility. Will disappear soon.
- `vtkRenderWindow = obj.GetInput ()` - These methods are provided for backward compatibility. Will disappear soon.
- `long = obj.GetMTime ()` - Returns the MTime also considering the RenderWindow.

39.34 vtkFollower

39.34.1 Usage

vtkFollower is a subclass of vtkActor that always follows its specified camera. More specifically it will not change its position or scale, but it will continually update its orientation so that it is right side up and facing the camera. This is typically used for text labels in a scene. All of the adjustments that can be made to an actor also will take effect with a follower. So, if you change the orientation of the follower by 90 degrees, then it will follow the camera, but be off by 90 degrees.

To create an instance of class vtkFollower, simply invoke its constructor as follows

```
obj = vtkFollower
```

39.34.2 Methods

The class vtkFollower has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFollower class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFollower = obj.NewInstance ()`
- `vtkFollower = obj.SafeDownCast (vtkObject o)`
- `obj.SetCamera (vtkCamera )` - Set/Get the camera to follow. If this is not set, then the follower won't know who to follow.
- `vtkCamera = obj.GetCamera ()` - Set/Get the camera to follow. If this is not set, then the follower won't know who to follow.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - This causes the actor to be rendered. It in turn will render the actor's property, texture map and then mapper. If a property hasn't been assigned, then the actor will create one automatically.

- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - This causes the actor to be rendered. It in turn will render the actor's property, texture map and then mapper. If a property hasn't been assigned, then the actor will create one automatically.
- `obj.Render (vtkRenderer ren)` - This causes the actor to be rendered. It in turn will render the actor's property, texture map and then mapper. If a property hasn't been assigned, then the actor will create one automatically.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.GetMatrix (vtkMatrix4x4 m)` - Copy the follower's composite 4x4 matrix into the matrix provided.
- `obj.GetMatrix (double m[16])` - Copy the follower's composite 4x4 matrix into the matrix provided.
- `vtkMatrix4x4 = obj.GetMatrix ()` - Shallow copy of a follower. Overloads the virtual vtkProp method.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of a follower. Overloads the virtual vtkProp method.

39.35 vtkFrameBufferObject

39.35.1 Usage

Encapsulates an OpenGL Frame Buffer Object. For use by vtkOpenGLFBORenderWindow, not to be used directly.

To create an instance of class vtkFrameBufferObject, simply invoke its constructor as follows

```
obj = vtkFrameBufferObject
```

39.35.2 Methods

The class vtkFrameBufferObject has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFrameBufferObject class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFrameBufferObject = obj.NewInstance ()`
- `vtkFrameBufferObject = obj.SafeDownCast (vtkObject o)`
- `obj.SetContext (vtkRenderWindow context)` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.
- `vtkRenderWindow = obj.GetContext ()` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.
- `bool = obj.Start (int width, int height, bool shaderSupportsTextureInt)` - User must take care that width/height match the dimensions of the user defined texture attachments. This method makes the "active buffers" the buffers that will get drawn into by subsequent drawing calls. Note that this does not clear the render buffers i.e. no glClear() calls are made by either of these methods. It's up to the caller to clear the buffers if needed.

- `bool = obj.StartNonOrtho (int width, int height, bool shaderSupportsTextureInt)` - User must take care that width/height match the dimensions of the user defined texture attachments. This method makes the "active buffers" the buffers that will get drawn into by subsequent drawing calls. Note that this does not clear the render buffers i.e. no glClear() calls are made by either of these methods. It's up to the caller to clear the buffers if needed.

- `obj.RenderQuad (int minX, int maxX, int minY, int maxY)` - Renders a quad at the given location with pixel coordinates. This method is provided as a convenience, since we often render quads in a FBO.

- `obj.Bind ()` - Save the current framebuffer and make the frame buffer active. Multiple calls to Bind has no effect.

- `obj.UnBind ()` - Restore the framebuffer saved with the call to Bind(). Multiple calls to UnBind has no effect.

- `obj.SetActiveBuffer (int index)` - Choose the buffer to render into. This is available only if the GL_ARB_draw_buffers extension is supported by the card.

- `obj.SetActiveBuffers (int numbuffers, int indices[])` - Choose the buffer to render into. This is available only if the GL_ARB_draw_buffers extension is supported by the card.

- `obj.SetColorBuffer (int index, vtkTextureObject texture, int zslice)`

- `vtkTextureObject = obj.GetColorBuffer (int index)`

- `obj.RemoveColorBuffer (int index)`

- `obj.RemoveAllColorBuffers ()`

- `obj.SetDepthBuffer (vtkTextureObject depthTexture)` - Set the texture to use as depth buffer.

- `obj.RemoveDepthBuffer ()` - Set the texture to use as depth buffer.

- `obj.SetDepthBufferNeeded (bool )` - If true, the frame buffer object will be initialized with a depth buffer. Initial value is true.

- `bool = obj.GetDepthBufferNeeded ()` - If true, the frame buffer object will be initialized with a depth buffer. Initial value is true.

- `obj.SetNumberOfRenderTargets (int )` - Set/Get the number of render targets to render into at once.

- `int = obj.GetNumberOfRenderTargets ()` - Set/Get the number of render targets to render into at once.

- `int = obj.GetMaximumNumberOfActiveTargets ()` - Returns the maximum number of targets that can be rendered to at one time. This limits the active targets set by SetActiveTargets(). The return value is valid only if GetContext is non-null.

- `int = obj.GetMaximumNumberOfRenderTargets ()` - Returns the maximum number of render targets available. This limits the available attachement points for SetColorAttachment(). The return value is valid only if GetContext is non-null.

- `int = obj. GetLastSize ()` - Dimensions in pixels of the framebuffer.

39.36 vtkFreeTypeLabelRenderStrategy

39.36.1 Usage

Uses the FreeType to render labels and compute label sizes. This strategy may be used with vtkLabelPlacementMapper.

To create an instance of class vtkFreeTypeLabelRenderStrategy, simply invoke its constructor as follows

```
obj = vtkFreeTypeLabelRenderStrategy
```

39.36.2 Methods

The class vtkFreeTypeLabelRenderStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFreeTypeLabelRenderStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFreeTypeLabelRenderStrategy = obj.NewInstance ()`
- `vtkFreeTypeLabelRenderStrategy = obj.SafeDownCast (vtkObject o)`
- `bool = obj.SupportsRotation ()` - The free type render strategy currently does not support bounded size labels.
- `bool = obj.SupportsBoundedSize ()` - Release any graphics resources that are being consumed by this strategy. The parameter window could be used to determine which graphic resources to release.
- `obj.ReleaseGraphicsResources (vtkWindow window)` - Release any graphics resources that are being consumed by this strategy. The parameter window could be used to determine which graphic resources to release.

39.37 vtkFrustumCoverageCuller

39.37.1 Usage

vtkFrustumCoverageCuller will cull props based on the coverage in the view frustum. The coverage is computed by enclosing the prop in a bounding sphere, projecting that to the viewing coordinate system, then taking a slice through the view frustum at the center of the sphere. This results in a circle on the plane slice through the view frustum. This circle is enclosed in a squared, and the fraction of the plane slice that this square covers is the coverage. This is a number between 0 and 1. If the number is less than the MinumumCoverage, the allocated render time for that prop is set to zero. If it is greater than the MaximumCoverage, the allocated render time is set to 1.0. In between, a linear ramp is used to convert coverage into allocated render time.

To create an instance of class vtkFrustumCoverageCuller, simply invoke its constructor as follows

```
obj = vtkFrustumCoverageCuller
```

39.37.2 Methods

The class vtkFrustumCoverageCuller has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFrustumCoverageCuller class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFrustumCoverageCuller = obj.NewInstance ()`
- `vtkFrustumCoverageCuller = obj.SafeDownCast (vtkObject o)`
- `obj.SetMinimumCoverage (double )` - Set/Get the minimum coverage - props with less coverage than this are given no time to render (they are culled)
- `double = obj.GetMinimumCoverage ()` - Set/Get the minimum coverage - props with less coverage than this are given no time to render (they are culled)
- `obj.SetMaximumCoverage (double )` - Set/Get the maximum coverage - props with more coverage than this are given an allocated render time of 1.0 (the maximum)
- `double = obj.GetMaximumCoverage ()` - Set/Get the maximum coverage - props with more coverage than this are given an allocated render time of 1.0 (the maximum)
- `obj.SetSortingStyle (int )` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `int = obj.GetSortingStyleMinValue ()` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `int = obj.GetSortingStyleMaxValue ()` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `int = obj.GetSortingStyle ()` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `obj.SetSortingStyleToNone ()` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `obj.SetSortingStyleToBackToFront ()` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `obj.SetSortingStyleToFrontToBack ()` - Set the sorting style - none, front-to-back or back-to-front The default is none
- `string = obj.GetSortingStyleAsString (void )` - Set the sorting style - none, front-to-back or back-to-front The default is none

39.38 vtkGaussianBlurPass

39.38.1 Usage

Blur the image renderered by its delegate. Blurring uses a Gaussian low-pass filter with a 5x5 kernel.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color. An opaque pass may have been performed right after the initialization.

The delegate is used once.

Its delegate is usually set to a vtkCameraPass or to a post-processing pass.

This pass requires a OpenGL context that supports texture objects (TO), framebuffer objects (FBO) and GLSL. If not, it will emit an error message and will render its delegate and return.

.SECTION Implementation As the filter is separable, it first blurs the image horizontally and then vertically. This reduces the number of texture sampling to 5 per pass. In addition, as texture sampling can already blend texel values in linear mode, by adjusting the texture coordinate accordingly, only 3 texture

sampling are actually necessary. Reference: OpenGL Bloom Toturial by Philip Rideout, section Exploit Hardware Filtering http://prideout.net/bloom/index.php#Sneaky

To create an instance of class vtkGaussianBlurPass, simply invoke its constructor as follows

```
obj = vtkGaussianBlurPass
```

39.38.2 Methods

The class vtkGaussianBlurPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGaussianBlurPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGaussianBlurPass = obj.NewInstance ()`
- `vtkGaussianBlurPass = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.

39.39 vtkGenericRenderWindowInteractor

39.39.1 Usage

vtkGenericRenderWindowInteractor provides a way to translate native mouse and keyboard events into vtk Events. By calling the methods on this class, vtk events will be invoked. This will allow scripting languages to use vtkInteractorStyles and 3D widgets.

To create an instance of class vtkGenericRenderWindowInteractor, simply invoke its constructor as follows

```
obj = vtkGenericRenderWindowInteractor
```

39.39.2 Methods

The class vtkGenericRenderWindowInteractor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericRenderWindowInteractor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericRenderWindowInteractor = obj.NewInstance ()`
- `vtkGenericRenderWindowInteractor = obj.SafeDownCast (vtkObject o)`
- `obj.MouseMoveEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.RightButtonPressEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.RightButtonReleaseEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.

- `obj.LeftButtonPressEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.LeftButtonReleaseEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.MiddleButtonPressEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.MiddleButtonReleaseEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.MouseWheelForwardEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.MouseWheelBackwardEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.ExposeEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.ConfigureEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.EnterEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.LeaveEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.TimerEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.KeyPressEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.KeyReleaseEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.CharEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.ExitEvent ()` - Fire various events. SetEventInformation should be called just prior to calling any of these methods. These methods will Invoke the corresponding vtk event.
- `obj.SetTimerEventResetsTimer (int )` - Flag that indicates whether the TimerEvent method should call ResetTimer to simulate repeating timers with an endless stream of one shot timers. By default this flag is on and all repeating timers are implemented as a stream of sequential one shot timers. If the observer of CreateTimerEvent actually creates a "natively repeating" timer, setting this flag to off will prevent (perhaps many many) unnecessary calls to ResetTimer. Having the flag on by default means that "natively one shot" timers can be either one shot or repeating timers with no additional work. Also, "natively repeating" timers still work with the default setting, but with potentially many create and destroy calls.
- `int = obj.GetTimerEventResetsTimer ()` - Flag that indicates whether the TimerEvent method should call ResetTimer to simulate repeating timers with an endless stream of one shot timers. By default this flag is on and all repeating timers are implemented as a stream of sequential one shot timers. If the observer of CreateTimerEvent actually creates a "natively repeating" timer, setting this flag to off will prevent (perhaps many many) unnecessary calls to ResetTimer. Having the flag on by default means that "natively one shot" timers can be either one shot or repeating timers with

no additional work. Also, "natively repeating" timers still work with the default setting, but with potentially many create and destroy calls.

- `obj.TimerEventResetsTimerOn ()` - Flag that indicates whether the TimerEvent method should call ResetTimer to simulate repeating timers with an endless stream of one shot timers. By default this flag is on and all repeating timers are implemented as a stream of sequential one shot timers. If the observer of CreateTimerEvent actually creates a "natively repeating" timer, setting this flag to off will prevent (perhaps many many) unnecessary calls to ResetTimer. Having the flag on by default means that "natively one shot" timers can be either one shot or repeating timers with no additional work. Also, "natively repeating" timers still work with the default setting, but with potentially many create and destroy calls.

- `obj.TimerEventResetsTimerOff ()` - Flag that indicates whether the TimerEvent method should call ResetTimer to simulate repeating timers with an endless stream of one shot timers. By default this flag is on and all repeating timers are implemented as a stream of sequential one shot timers. If the observer of CreateTimerEvent actually creates a "natively repeating" timer, setting this flag to off will prevent (perhaps many many) unnecessary calls to ResetTimer. Having the flag on by default means that "natively one shot" timers can be either one shot or repeating timers with no additional work. Also, "natively repeating" timers still work with the default setting, but with potentially many create and destroy calls.

39.40 vtkGenericVertexAttributeMapping

39.40.1 Usage

vtkGenericVertexAttributeMapping stores mapping between data arrays and generic vertex attributes. It is used by vtkPainterPolyDataMapper to pass the mappings to the painter which rendering the attributes. .SECTION Thanks Support for generic vertex attributes in VTK was contributed in collaboration with Stephane Ploix at EDF.

To create an instance of class vtkGenericVertexAttributeMapping, simply invoke its constructor as follows

```
obj = vtkGenericVertexAttributeMapping
```

39.40.2 Methods

The class vtkGenericVertexAttributeMapping has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericVertexAttributeMapping class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericVertexAttributeMapping = obj.NewInstance ()`
- `vtkGenericVertexAttributeMapping = obj.SafeDownCast (vtkObject o)`
- `obj.AddMapping (string attributeName, string arrayName, int fieldAssociation, int component)` - Select a data array from the point/cell data and map it to a generic vertex attribute. Note that indices change when a mapping is added/removed.
- `obj.AddMapping (int unit, string arrayName, int fieldAssociation, int component)` - Select a data array and use it as multitexture texture coordinates. Note the texture unit parameter should correspond to the texture unit set on the texture.
- `bool = obj.RemoveMapping (string attributeName)` - Remove a vertex attribute mapping.

- `obj.RemoveAllMappings ()` - Remove all mappings.
- `int = obj.GetNumberOfMappings ()` - Get number of mapppings.
- `string = obj.GetAttributeName (int index)` - Get the attribute name at the given index.
- `string = obj.GetArrayName (int index)` - Get the array name at the given index.
- `int = obj.GetFieldAssociation (int index)` - Get the field association at the given index.
- `int = obj.GetComponent (int index)` - Get the component no. at the given index.
- `int = obj.GetTextureUnit (int index)` - Get the component no. at the given index.

39.41 vtkGL2PSExporter

39.41.1 Usage

vtkGL2PSExporter is a concrete subclass of vtkExporter that writes high quality vector PostScript (PS/EPS), PDF or SVG files by using GL2PS. GL2PS can be obtained at: http://www.geuz.org/gl2ps/. This can be very useful when one requires publication quality pictures. This class works best with simple 3D scenes and most 2D plots. Please note that GL2PS has its limitations since PostScript is not an ideal language to represent complex 3D scenes. However, this class does allow one to write mixed vector/raster files by using the Write3DPropsAsRasterImage ivar. Please do read the caveats section of this documentation.

By default vtkGL2PSExporter generates Encapsulated PostScript (EPS) output along with the text in portrait orientation with the background color of the window being drawn. The generated output is also compressed using zlib. The various other options are set to sensible defaults.

The output file format (FileFormat) can be either PostScript (PS), Encapsulated PostScript (EPS), PDF, SVG or TeX. The file extension is generated automatically depending on the FileFormat. The default is EPS. When TeX output is chosen, only the text strings in the plot are generated and put into a picture environment. One can turn on and off the text when generating PS/EPS/PDF/SVG files by using the Text boolean variable. By default the text is drawn. The background color of the renderwindow is drawn by default. To make the background white instead use the DrawBackgroundOff function. Landscape figures can be generated by using the LandscapeOn function. Portrait orientation is used by default. Several of the GL2PS options can be set. The names of the ivars for these options are similar to the ones that GL2PS provides. Compress, SimpleLineOffset, Silent, BestRoot, PS3Shading and OcclusionCull are similar to the options provided by GL2PS. Please read the function documentation or the GL2PS documentation for more details. The ivar Write3DPropsAsRasterImage allows one to generate mixed vector/raster images. All the 3D props in the scene will be written as a raster image and all 2D actors will be written as vector graphic primitives. This makes it possible to handle transparency and complex 3D scenes. This ivar is set to Off by default. When drawing lines and points the OpenGL point size and line width are multiplied by a factor in order to generate PostScript lines and points of the right size. The Get/SetGlobalPointSizeFactor and Get/SetGlobalLineWidthFactor let one customize this ratio. The default value is such that the PostScript output looks close to what is seen on screen.

To use this class you need to turn on VTK_USE_GL2PS when configuring VTK.

To create an instance of class vtkGL2PSExporter, simply invoke its constructor as follows

```
obj = vtkGL2PSExporter
```

39.41.2 Methods

The class vtkGL2PSExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGL2PSExporter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkGL2PSExporter = obj.NewInstance ()`
- `vtkGL2PSExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilePrefix (string )` - Specify the prefix of the files to write out. The resulting filenames will have .ps or .eps or .tex appended to them depending on the other options chosen.
- `string = obj.GetFilePrefix ()` - Specify the prefix of the files to write out. The resulting filenames will have .ps or .eps or .tex appended to them depending on the other options chosen.
- `obj.SetFileFormat (int )` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `int = obj.GetFileFormatMinValue ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `int = obj.GetFileFormatMaxValue ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `int = obj.GetFileFormat ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `obj.SetFileFormatToPS ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `obj.SetFileFormatToEPS ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `obj.SetFileFormatToPDF ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `obj.SetFileFormatToTeX ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `obj.SetFileFormatToSVG ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `string = obj.GetFileFormatAsString ()` - Specify the format of file to write out. This can be one of: PS_FILE, EPS_FILE, PDF_FILE, TEX_FILE. Defaults to EPS_FILE. Depending on the option chosen it generates the appropriate file (with correct extension) when the Write function is called.
- `obj.SetSort (int )` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `int = obj.GetSortMinValue ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.

- `int = obj.GetSortMaxValue ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `int = obj.GetSort ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `obj.SetSortToOff ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `obj.SetSortToSimple ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `obj.SetSortToBSP ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `string = obj.GetSortAsString ()` - Set the the type of sorting algorithm to order primitives from back to front. Successive algorithms are more memory intensive. Simple is the default but BSP is perhaps the best.
- `obj.SetCompress (int )` - Turn on/off compression when generating PostScript or PDF output. By default compression is on.
- `int = obj.GetCompress ()` - Turn on/off compression when generating PostScript or PDF output. By default compression is on.
- `obj.CompressOn ()` - Turn on/off compression when generating PostScript or PDF output. By default compression is on.
- `obj.CompressOff ()` - Turn on/off compression when generating PostScript or PDF output. By default compression is on.
- `obj.SetDrawBackground (int )` - Turn on/off drawing the background frame. If off the background is treated as white. By default the background is drawn.
- `int = obj.GetDrawBackground ()` - Turn on/off drawing the background frame. If off the background is treated as white. By default the background is drawn.
- `obj.DrawBackgroundOn ()` - Turn on/off drawing the background frame. If off the background is treated as white. By default the background is drawn.
- `obj.DrawBackgroundOff ()` - Turn on/off drawing the background frame. If off the background is treated as white. By default the background is drawn.
- `obj.SetSimpleLineOffset (int )` - Turn on/off the GL2PS_SIMPLE_LINE_OFFSET option. When enabled a small offset is added in the z-buffer to all the lines in the plot. This results in an anti-aliasing like solution. Defaults to on.
- `int = obj.GetSimpleLineOffset ()` - Turn on/off the GL2PS_SIMPLE_LINE_OFFSET option. When enabled a small offset is added in the z-buffer to all the lines in the plot. This results in an anti-aliasing like solution. Defaults to on.
- `obj.SimpleLineOffsetOn ()` - Turn on/off the GL2PS_SIMPLE_LINE_OFFSET option. When enabled a small offset is added in the z-buffer to all the lines in the plot. This results in an anti-aliasing like solution. Defaults to on.
- `obj.SimpleLineOffsetOff ()` - Turn on/off the GL2PS_SIMPLE_LINE_OFFSET option. When enabled a small offset is added in the z-buffer to all the lines in the plot. This results in an anti-aliasing like solution. Defaults to on.

- `obj.SetSilent (int )` - Turn on/off GL2PS messages sent to stderr (GL2PS_SILENT). When enabled GL2PS messages are suppressed. Defaults to off.
- `int = obj.GetSilent ()` - Turn on/off GL2PS messages sent to stderr (GL2PS_SILENT). When enabled GL2PS messages are suppressed. Defaults to off.
- `obj.SilentOn ()` - Turn on/off GL2PS messages sent to stderr (GL2PS_SILENT). When enabled GL2PS messages are suppressed. Defaults to off.
- `obj.SilentOff ()` - Turn on/off GL2PS messages sent to stderr (GL2PS_SILENT). When enabled GL2PS messages are suppressed. Defaults to off.
- `obj.SetBestRoot (int )` - Turn on/off the GL2PS_BEST_ROOT option. When enabled the construction of the BSP tree is optimized by choosing the root primitives leading to the minimum number of splits. Defaults to on.
- `int = obj.GetBestRoot ()` - Turn on/off the GL2PS_BEST_ROOT option. When enabled the construction of the BSP tree is optimized by choosing the root primitives leading to the minimum number of splits. Defaults to on.
- `obj.BestRootOn ()` - Turn on/off the GL2PS_BEST_ROOT option. When enabled the construction of the BSP tree is optimized by choosing the root primitives leading to the minimum number of splits. Defaults to on.
- `obj.BestRootOff ()` - Turn on/off the GL2PS_BEST_ROOT option. When enabled the construction of the BSP tree is optimized by choosing the root primitives leading to the minimum number of splits. Defaults to on.
- `obj.SetText (int )` - Turn on/off drawing the text. If on (default) the text is drawn. If the FileFormat is set to TeX output then a LaTeX picture is generated with the text strings. If off text output is suppressed.
- `int = obj.GetText ()` - Turn on/off drawing the text. If on (default) the text is drawn. If the FileFormat is set to TeX output then a LaTeX picture is generated with the text strings. If off text output is suppressed.
- `obj.TextOn ()` - Turn on/off drawing the text. If on (default) the text is drawn. If the FileFormat is set to TeX output then a LaTeX picture is generated with the text strings. If off text output is suppressed.
- `obj.TextOff ()` - Turn on/off drawing the text. If on (default) the text is drawn. If the FileFormat is set to TeX output then a LaTeX picture is generated with the text strings. If off text output is suppressed.
- `obj.SetLandscape (int )` - Turn on/off landscape orientation. If off (default) the orientation is set to portrait.
- `int = obj.GetLandscape ()` - Turn on/off landscape orientation. If off (default) the orientation is set to portrait.
- `obj.LandscapeOn ()` - Turn on/off landscape orientation. If off (default) the orientation is set to portrait.
- `obj.LandscapeOff ()` - Turn on/off landscape orientation. If off (default) the orientation is set to portrait.
- `obj.SetPS3Shading (int )` - Turn on/off the GL2PS_PS3_SHADING option. When enabled the shfill PostScript level 3 operator is used. Read the GL2PS documentation for more details. Defaults to on.

- `int = obj.GetPS3Shading ()` - Turn on/off the GL2PS_PS3_SHADING option. When enabled the shfill PostScript level 3 operator is used. Read the GL2PS documentation for more details. Defaults to on.
- `obj.PS3ShadingOn ()` - Turn on/off the GL2PS_PS3_SHADING option. When enabled the shfill PostScript level 3 operator is used. Read the GL2PS documentation for more details. Defaults to on.
- `obj.PS3ShadingOff ()` - Turn on/off the GL2PS_PS3_SHADING option. When enabled the shfill PostScript level 3 operator is used. Read the GL2PS documentation for more details. Defaults to on.
- `obj.SetOcclusionCull (int )` - Turn on/off culling of occluded polygons (GL2PS_OCCLUSION_CULL). When enabled hidden polygons are removed. This reduces file size considerably. Defaults to on.
- `int = obj.GetOcclusionCull ()` - Turn on/off culling of occluded polygons (GL2PS_OCCLUSION_CULL). When enabled hidden polygons are removed. This reduces file size considerably. Defaults to on.
- `obj.OcclusionCullOn ()` - Turn on/off culling of occluded polygons (GL2PS_OCCLUSION_CULL). When enabled hidden polygons are removed. This reduces file size considerably. Defaults to on.
- `obj.OcclusionCullOff ()` - Turn on/off culling of occluded polygons (GL2PS_OCCLUSION_CULL). When enabled hidden polygons are removed. This reduces file size considerably. Defaults to on.
- `obj.SetWrite3DPropsAsRasterImage (int )` - Turn on/off writing 3D props as raster images. 2D props are rendered using vector graphics primitives. If you have hi-res actors and are using transparency you probably need to turn this on. Defaults to Off.
- `int = obj.GetWrite3DPropsAsRasterImage ()` - Turn on/off writing 3D props as raster images. 2D props are rendered using vector graphics primitives. If you have hi-res actors and are using transparency you probably need to turn this on. Defaults to Off.
- `obj.Write3DPropsAsRasterImageOn ()` - Turn on/off writing 3D props as raster images. 2D props are rendered using vector graphics primitives. If you have hi-res actors and are using transparency you probably need to turn this on. Defaults to Off.
- `obj.Write3DPropsAsRasterImageOff ()` - Turn on/off writing 3D props as raster images. 2D props are rendered using vector graphics primitives. If you have hi-res actors and are using transparency you probably need to turn this on. Defaults to Off.

39.42 vtkGLSLShader

39.42.1 Usage

vtkGLSLShader is a concrete class that creates and compiles hardware shaders written in the OpenGL Shadering Language (GLSL, OpenGL2.0). While step linking a vertex and a fragment shader is performed by vtkGLSLShaderProgram, all shader parameters are initialized in this class.

.Section vtkOpenGLExtensionManager All OpenGL calls are made through vtkOpenGLExtensionManager.

.Section Supported Basic Shader Types:

Scalar Types uniform float uniform int uniform int – boolean scalar not yet tested

Vector Types: uniform vec2—3—4 uniform ivec2—3—4 uniform bvec2—3—4 – boolean vector not yet tested

Matrix Types: uniform mat2—3—4

Texture Samplers: sample1D – Not yet implemented in this cless. sample2D – Not yet implemented in this class. sample3D – Not yet implemented in this class. sampler1DShadow – Not yet implemented in this class. sampler1DShadow – Not yet implemented in this class.

User-Defined structures: uniform struct NOTE: these must be defined and declared outside of the 'main' shader function.

.SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkGLSLShader, simply invoke its constructor as follows

```
obj = vtkGLSLShader
```

39.42.2 Methods

The class vtkGLSLShader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGLSLShader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGLSLShader = obj.NewInstance ()`
- `vtkGLSLShader = obj.SafeDownCast (vtkObject o)`
- `int = obj.Compile ()` - Called to compile the shader code. The subclasses must only compile the code in this method. Returns if the compile was successful. Subclasses should compile the code only if it was not already compiled.
- `int = obj.GetHandle ()` - The Shader needs the id of the ShaderProgram to obtain uniform variable locations. This is set by vtkGLSLShaderProgram.
- `obj.SetProgram (int )` - The Shader needs the id of the ShaderProgram to obtain uniform variable locations. This is set by vtkGLSLShaderProgram.
- `int = obj.GetProgram ()` - The Shader needs the id of the ShaderProgram to obtain uniform variable locations. This is set by vtkGLSLShaderProgram.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

39.43 vtkGLSLShaderDeviceAdapter

39.43.1 Usage

vtkShaderDeviceAdapter subclass for GLSL. .SECTION Thanks Support for generic vertex attributes in VTK was contributed in collaboration with Stephane Ploix at EDF.

To create an instance of class vtkGLSLShaderDeviceAdapter, simply invoke its constructor as follows

```
obj = vtkGLSLShaderDeviceAdapter
```

39.43.2 Methods

The class vtkGLSLShaderDeviceAdapter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGLSLShaderDeviceAdapter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkGLSLShaderDeviceAdapter = obj.NewInstance ()`
- `vtkGLSLShaderDeviceAdapter = obj.SafeDownCast (vtkObject o)`
- `obj.PrepareForRender ()`

39.44 vtkGLSLShaderDeviceAdapter2

39.44.1 Usage

vtkShaderDeviceAdapter subclass for vtkShaderProgram2.

To create an instance of class vtkGLSLShaderDeviceAdapter2, simply invoke its constructor as follows

```
obj = vtkGLSLShaderDeviceAdapter2
```

39.44.2 Methods

The class vtkGLSLShaderDeviceAdapter2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGLSLShaderDeviceAdapter2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGLSLShaderDeviceAdapter2 = obj.NewInstance ()`
- `vtkGLSLShaderDeviceAdapter2 = obj.SafeDownCast (vtkObject o)`
- `obj.PrepareForRender ()`

39.45 vtkGLSLShaderProgram

39.45.1 Usage

vtkGLSLShaderProgram is a concerete implementation of vtkShaderProgram. It's main function is to 'Link' a vertex and a fragment shader together and install them into the rendering pipeline by calling OpenGL2.0.

Initialization of shader parameters is delegated to instances of vtkShader (vtkGLSLShader in this case). .SECTION Thanks Shader support in VTK includes key contributions by Gary Templet at Sandia National Labs.

To create an instance of class vtkGLSLShaderProgram, simply invoke its constructor as follows

```
obj = vtkGLSLShaderProgram
```

39.45.2 Methods

The class vtkGLSLShaderProgram has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGLSLShaderProgram class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGLSLShaderProgram = obj.NewInstance ()`

- `vtkGLSLShaderProgram = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkActor actor, vtkRenderer renderer)`
- `obj.PostRender (vtkActor , vtkRenderer )` - Called to unload the shaders after the actor has been rendered.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `int = obj.GetProgram ()`

39.46 vtkGPUInfo

39.46.1 Usage

vtkGPUInfo stores information about GPU Video RAM. An host can have several GPUs. The values are set by vtkGPUInfoList.

To create an instance of class vtkGPUInfo, simply invoke its constructor as follows

```
obj = vtkGPUInfo
```

39.46.2 Methods

The class vtkGPUInfo has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGPUInfo class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGPUInfo = obj.NewInstance ()`
- `vtkGPUInfo = obj.SafeDownCast (vtkObject o)`
- `obj.SetDedicatedVideoMemory (vtkIdType )` - Set/Get dedicated video memory in bytes. Initial value is 0. Usually the fastest one. If it is not null, it should be take into account first and DedicatedSystemMemory or SharedSystemMemory should be ignored.
- `vtkIdType = obj.GetDedicatedVideoMemory ()` - Set/Get dedicated video memory in bytes. Initial value is 0. Usually the fastest one. If it is not null, it should be take into account first and DedicatedSystemMemory or SharedSystemMemory should be ignored.
- `obj.SetDedicatedSystemMemory (vtkIdType )` - Set/Get dedicated system memory in bytes. Initial value is 0. This is slow memory. If it is not null, this value should be taken into account only if there is no DedicatedVideoMemory and SharedSystemMemory should be ignored.
- `vtkIdType = obj.GetDedicatedSystemMemory ()` - Set/Get dedicated system memory in bytes. Initial value is 0. This is slow memory. If it is not null, this value should be taken into account only if there is no DedicatedVideoMemory and SharedSystemMemory should be ignored.
- `obj.SetSharedSystemMemory (vtkIdType )` - Set/Get shared system memory in bytes. Initial value is 0. Slowest memory. This value should be taken into account only if there is neither DedicatedVideoMemory nor DedicatedSystemMemory.
- `vtkIdType = obj.GetSharedSystemMemory ()` - Set/Get shared system memory in bytes. Initial value is 0. Slowest memory. This value should be taken into account only if there is neither DedicatedVideoMemory nor DedicatedSystemMemory.

39.47 vtkGPUInfoList

39.47.1 Usage

vtkGPUInfoList stores a list of vtkGPUInfo. An host can have several GPUs. It creates and sets the list by probing the host with system calls. This an abstract class. Concrete classes are OS specific.

To create an instance of class vtkGPUInfoList, simply invoke its constructor as follows

```
obj = vtkGPUInfoList
```

39.47.2 Methods

The class vtkGPUInfoList has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGPUInfoList class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGPUInfoList = obj.NewInstance ()`
- `vtkGPUInfoList = obj.SafeDownCast (vtkObject o)`
- `obj.Probe ()` - Build the list of vtkInfoGPU if not done yet. Default implementation created an empty list. Useful if there is no implementation available for a given architecture yet.
- `bool = obj.IsProbed ()` - Tells if the operating system has been probed. Initial value is false.
- `int = obj.GetNumberOfGPUs ()` - Return the number of GPUs.
- `vtkGPUInfo = obj.GetGPUInfo (int i)` - Return information about GPU i.

39.48 vtkGraphicsFactory

39.48.1 Usage

To create an instance of class vtkGraphicsFactory, simply invoke its constructor as follows

```
obj = vtkGraphicsFactory
```

39.48.2 Methods

The class vtkGraphicsFactory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphicsFactory class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphicsFactory = obj.NewInstance ()`
- `vtkGraphicsFactory = obj.SafeDownCast (vtkObject o)`

39.49 vtkGraphMapper

39.49.1 Usage

vtkGraphMapper is a mapper to map vtkGraph (and all derived classes) to graphics primitives.

To create an instance of class vtkGraphMapper, simply invoke its constructor as follows

```
obj = vtkGraphMapper
```

39.49.2 Methods

The class vtkGraphMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphMapper = obj.NewInstance ()`
- `vtkGraphMapper = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren, vtkActor act)`
- `obj.SetVertexColorArrayName (string name)` - The array to use for coloring vertices. Default is "color".
- `string = obj.GetVertexColorArrayName ()` - The array to use for coloring vertices. Default is "color".
- `obj.SetColorVertices (bool vis)` - Whether to color vertices. Default is off.
- `bool = obj.GetColorVertices ()` - Whether to color vertices. Default is off.
- `obj.ColorVerticesOn ()` - Whether to color vertices. Default is off.
- `obj.ColorVerticesOff ()` - Whether to color vertices. Default is off.
- `obj.SetScaledGlyphs (bool arg)` - Whether scaled glyphs are on or not. Default is off. By default this mapper uses vertex glyphs that do not scale. If you turn this option on you will get circles at each vertex and they will scale as you zoom in/out.
- `bool = obj.GetScaledGlyphs ()` - Whether scaled glyphs are on or not. Default is off. By default this mapper uses vertex glyphs that do not scale. If you turn this option on you will get circles at each vertex and they will scale as you zoom in/out.
- `obj.ScaledGlyphsOn ()` - Whether scaled glyphs are on or not. Default is off. By default this mapper uses vertex glyphs that do not scale. If you turn this option on you will get circles at each vertex and they will scale as you zoom in/out.
- `obj.ScaledGlyphsOff ()` - Whether scaled glyphs are on or not. Default is off. By default this mapper uses vertex glyphs that do not scale. If you turn this option on you will get circles at each vertex and they will scale as you zoom in/out.
- `obj.SetScalingArrayName (string )` - Glyph scaling array name. Default is "scale"
- `string = obj.GetScalingArrayName ()` - Glyph scaling array name. Default is "scale"
- `obj.SetEdgeVisibility (bool vis)` - Whether to show edges or not. Default is on.

- `bool = obj.GetEdgeVisibility ()` - Whether to show edges or not. Default is on.
- `obj.EdgeVisibilityOn ()` - Whether to show edges or not. Default is on.
- `obj.EdgeVisibilityOff ()` - Whether to show edges or not. Default is on.
- `obj.SetEdgeColorArrayName (string name)` - The array to use for coloring edges. Default is "color".
- `string = obj.GetEdgeColorArrayName ()` - The array to use for coloring edges. Default is "color".
- `obj.SetColorEdges (bool vis)` - Whether to color edges. Default is off.
- `bool = obj.GetColorEdges ()` - Whether to color edges. Default is off.
- `obj.ColorEdgesOn ()` - Whether to color edges. Default is off.
- `obj.ColorEdgesOff ()` - Whether to color edges. Default is off.
- `obj.SetEnabledEdgesArrayName (string )` - The array to use for coloring edges. Default is "color".
- `string = obj.GetEnabledEdgesArrayName ()` - The array to use for coloring edges. Default is "color".
- `obj.SetEnableEdgesByArray (int )` - Whether to enable/disable edges using array values. Default is off.
- `int = obj.GetEnableEdgesByArray ()` - Whether to enable/disable edges using array values. Default is off.
- `obj.EnableEdgesByArrayOn ()` - Whether to enable/disable edges using array values. Default is off.
- `obj.EnableEdgesByArrayOff ()` - Whether to enable/disable edges using array values. Default is off.
- `obj.SetEnabledVerticesArrayName (string )` - The array to use for coloring edges. Default is "color".
- `string = obj.GetEnabledVerticesArrayName ()` - The array to use for coloring edges. Default is "color".
- `obj.SetEnableVerticesByArray (int )` - Whether to enable/disable vertices using array values. Default is off.
- `int = obj.GetEnableVerticesByArray ()` - Whether to enable/disable vertices using array values. Default is off.
- `obj.EnableVerticesByArrayOn ()` - Whether to enable/disable vertices using array values. Default is off.
- `obj.EnableVerticesByArrayOff ()` - Whether to enable/disable vertices using array values. Default is off.
- `obj.SetIconArrayName (string name)` - The array to use for assigning icons.
- `string = obj.GetIconArrayName ()` - The array to use for assigning icons.
- `obj.AddIconType (string type, int index)` - Associate the icon at index "index" in the vtkTexture to all vertices containing "type" as a value in the vertex attribute array specified by IconArrayName.
- `obj.ClearIconTypes ()` - Clear all icon mappings.
- `obj.SetIconSize (int size)` - Specify the Width and Height, in pixels, of an icon in the icon sheet.

- `obj.SetIconAlignment (int alignment)` - Specify where the icons should be placed in relation to the vertex. See vtkIconGlyphFilter.h for possible values.
- `vtkTexture = obj.GetIconTexture ()` - The texture containing the icon sheet.
- `obj.SetIconTexture (vtkTexture texture)` - The texture containing the icon sheet.
- `obj.SetIconVisibility (bool vis)` - Whether to show icons. Default is off.
- `bool = obj.GetIconVisibility ()` - Whether to show icons. Default is off.
- `obj.IconVisibilityOn ()` - Whether to show icons. Default is off.
- `obj.IconVisibilityOff ()` - Whether to show icons. Default is off.
- `float = obj.GetVertexPointSize ()` - Get/Set the vertex point size
- `obj.SetVertexPointSize (float size)` - Get/Set the vertex point size
- `float = obj.GetEdgeLineWidth ()` - Get/Set the edge line width
- `obj.SetEdgeLineWidth (float width)` - Get/Set the edge line width
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply the theme to this view.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release.
- `long = obj.GetMTime ()` - Get the mtime also considering the lookup table.
- `obj.SetInput (vtkGraph input)` - Set the Input of this mapper.
- `vtkGraph = obj.GetInput ()` - Set the Input of this mapper.
- `double = obj.GetBounds ()` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.GetBounds (double bounds)` - Access to the lookup tables used by the vertex and edge mappers.
- `vtkLookupTable = obj.GetEdgeLookupTable ()` - Access to the lookup tables used by the vertex and edge mappers.
- `vtkLookupTable = obj.GetVertexLookupTable ()` - Access to the lookup tables used by the vertex and edge mappers.

39.50 vtkGraphToGlyphs

39.50.1 Usage

Converts a vtkGraph to a vtkPolyData containing a glyph for each vertex. This assumes that the points of the graph have already been filled (perhaps by vtkGraphLayout). The glyphs will automatically be scaled to be the same size in screen coordinates. To do this the filter requires a pointer to the renderer into which the glyphs will be rendered.

To create an instance of class vtkGraphToGlyphs, simply invoke its constructor as follows

```
obj = vtkGraphToGlyphs
```

39.50.2 Methods

The class vtkGraphToGlyphs has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphToGlyphs class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphToGlyphs = obj.NewInstance ()`
- `vtkGraphToGlyphs = obj.SafeDownCast (vtkObject o)`
- `obj.SetGlyphType (int )` - The glyph type, specified as one of the enumerated values in this class. VERTEX is a special glyph that cannot be scaled, but instead is rendered as an OpenGL vertex primitive. This may appear as a box or circle depending on the hardware.
- `int = obj.GetGlyphType ()` - The glyph type, specified as one of the enumerated values in this class. VERTEX is a special glyph that cannot be scaled, but instead is rendered as an OpenGL vertex primitive. This may appear as a box or circle depending on the hardware.
- `obj.SetFilled (bool )` - Whether to fill the glyph, or to just render the outline.
- `bool = obj.GetFilled ()` - Whether to fill the glyph, or to just render the outline.
- `obj.FilledOn ()` - Whether to fill the glyph, or to just render the outline.
- `obj.FilledOff ()` - Whether to fill the glyph, or to just render the outline.
- `obj.SetScreenSize (double )` - Set the desired screen size of each glyph. If you are using scaling, this will be the size of the glyph when rendering an object with scaling value 1.0.
- `double = obj.GetScreenSize ()` - Set the desired screen size of each glyph. If you are using scaling, this will be the size of the glyph when rendering an object with scaling value 1.0.
- `obj.SetRenderer (vtkRenderer ren)` - The renderer in which the glyphs will be placed.
- `vtkRenderer = obj.GetRenderer ()` - The renderer in which the glyphs will be placed.
- `obj.SetScaling (bool b)` - Whether to use the input array to process in order to scale the vertices.
- `bool = obj.GetScaling ()` - Whether to use the input array to process in order to scale the vertices.
- `long = obj.GetMTime ()` - The modified time of this filter.

39.51 vtkHardwareSelectionPolyDataPainter

39.51.1 Usage

vtkHardwareSelectionPolyDataPainter is a painter for polydata used when rendering hardware selection passes.

To create an instance of class vtkHardwareSelectionPolyDataPainter, simply invoke its constructor as follows

```
obj = vtkHardwareSelectionPolyDataPainter
```

39.51.2 Methods

The class vtkHardwareSelectionPolyDataPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHardwareSelectionPolyDataPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHardwareSelectionPolyDataPainter = obj.NewInstance ()`
- `vtkHardwareSelectionPolyDataPainter = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnableSelection (int )` - Enable/Disable vtkHardwareSelector class. Useful when using this painter as an internal painter. Default is enabled.
- `int = obj.GetEnableSelection ()` - Enable/Disable vtkHardwareSelector class. Useful when using this painter as an internal painter. Default is enabled.
- `obj.EnableSelectionOn ()` - Enable/Disable vtkHardwareSelector class. Useful when using this painter as an internal painter. Default is enabled.
- `obj.EnableSelectionOff ()` - Enable/Disable vtkHardwareSelector class. Useful when using this painter as an internal painter. Default is enabled.

39.52 vtkHardwareSelector

39.52.1 Usage

vtkHardwareSelector is a helper that orchestrates color buffer based selection. This relies on OpenGL. vtkHardwareSelector can be used to select visible cells or points within a given rectangle of the RenderWindow. To use it, call in order: SetRenderer() - to select the renderer in which we want to select the cells/points. SetArea() - to set the rectangular region in the render window to select in. SetFieldAssociation() - to select the attribute to select i.e. cells/points etc. Finally, call Select(). Select will cause the attached vtkRenderer to render in a special color mode, where each cell/point is given it own color so that later inspection of the Rendered Pixels can determine what cells are visible. Select() returns a new vtkSelection instance with the cells/points selected.

Limitations: Antialiasing will break this class. If your graphics card settings force their use this class will return invalid results.

Currently only cells from PolyDataMappers can be selected from. When vtkRenderer::Selector is non-null vtkPainterPolyDataMapper uses the vtkHardwareSelectionPolyDataPainter which make appropriate calls to BeginRenderProp(), EndRenderProp(), RenderAttributeId() to render colors correctly. Until alternatives to vtkHardwareSelectionPolyDataPainter exist that can do a similar coloration of other vtkDataSet types, only polygonal data can be selected. If you need to select other data types, consider using vtkDataSetMapper and turning on it's PassThroughCellIds feature, or using vtkFrustumExtractor.

Only Opaque geometry in Actors is selected from. Assemblies and LODMappers are not currently supported.

During selection, visible datasets that can not be selected from are temporarily hidden so as not to produce invalid indices from their colors.

To create an instance of class vtkHardwareSelector, simply invoke its constructor as follows

```
obj = vtkHardwareSelector
```

39.52.2 Methods

The class vtkHardwareSelector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHardwareSelector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHardwareSelector = obj.NewInstance ()`
- `vtkHardwareSelector = obj.SafeDownCast (vtkObject o)`
- `obj.SetRenderer (vtkRenderer )` - Get/Set the renderer to perform the selection on.
- `vtkRenderer = obj.GetRenderer ()` - Get/Set the renderer to perform the selection on.
- `obj.SetArea (int , int , int , int )` - Get/Set the area to select as (xmin, ymin, xmax, ymax).
- `obj.SetArea (int  a[4])` - Get/Set the area to select as (xmin, ymin, xmax, ymax).
- `int = obj. GetArea ()` - Get/Set the area to select as (xmin, ymin, xmax, ymax).
- `obj.SetFieldAssociation (int )` - Set the field type to select. Valid values are vtkDataObject::FIELD_ASSOCIATIO vtkDataObject::FIELD_ASSOCIATION_CELLS vtkDataObject::FIELD_ASSOCIATION_VERTICES vtkDataObject::FIELD_ASSOCIATION_EDGES vtkDataObject::FIELD_ASSOCIATION_ROWS Currently only FIELD_ASSOCIATION_POINTS and FIELD_ASSOCIATION_CELLS are supported.
- `int = obj.GetFieldAssociation ()` - Set the field type to select. Valid values are vtkDataObject::FIELD_ASSOCIATION_POINTS vtkDataObject::FIELD_ASSOCIATION_CELLS vtkDataObject::FIELD_ASSO vtkDataObject::FIELD_ASSOCIATION_EDGES vtkDataObject::FIELD_ASSOCIATION_ROWS Currently only FIELD_ASSOCIATION_POINTS and FIELD_ASSOCIATION_CELLS are supported.
- `vtkSelection = obj.Select ()` - Perform the selection. Returns a new instance of vtkSelection containing the selection on success.
- `bool = obj.CaptureBuffers ()` - It is possible to use the vtkHardwareSelector for a custom picking. (Look at vtkScenePicker). In that case instead of Select() on can use CaptureBuffers() to render the selection buffers and then get information about pixel locations suing GetPixelInformation(). Use ClearBuffers() to clear buffers after one's done with the scene. The optional final parameter maxDist will look for a cell within the specified number of pixels from display_position.
- `obj.ClearBuffers ()` - Called by any vtkMapper or vtkProp subclass to render an attribute's id.
- `obj.RenderAttributeId (vtkIdType attribid)` - Called by any vtkMapper or vtkProp subclass to render an attribute's id.
- `obj.BeginRenderProp ()` - Called by the mapper (vtkHardwareSelectionPolyDataPainter) before and after rendering each prop.
- `obj.EndRenderProp ()` - Called by the mapper (vtkHardwareSelectionPolyDataPainter) before and after rendering each prop.
- `obj.SetProcessID (int )` - Get/Set the process id. If process id ¡ 0 (default -1), then the PROCESS_PASS is not rendered.
- `int = obj.GetProcessID ()` - Get/Set the process id. If process id ¡ 0 (default -1), then the PROCESS_PASS is not rendered.
- `int = obj.GetCurrentPass ()` - Get the current pass number.

- `vtkSelection = obj.GenerateSelection ()` - Generates the vtkSelection from pixel buffers. Requires that CaptureBuffers() has already been called. Optionally you may pass a screen region (xmin, ymin, xmax, ymax) to generate a selection from. The region must be a subregion of the region specified by SetArea(), otherwise it will be clipped to that region.

- `vtkSelection = obj.GenerateSelection (int r[4])` - Generates the vtkSelection from pixel buffers. Requires that CaptureBuffers() has already been called. Optionally you may pass a screen region (xmin, ymin, xmax, ymax) to generate a selection from. The region must be a subregion of the region specified by SetArea(), otherwise it will be clipped to that region.

- `vtkSelection = obj.GenerateSelection (int x1, int y1, int x2, int y2)` - Generates the vtkSelection from pixel buffers. Requires that CaptureBuffers() has already been called. Optionally you may pass a screen region (xmin, ymin, xmax, ymax) to generate a selection from. The region must be a subregion of the region specified by SetArea(), otherwise it will be clipped to that region.

39.53 vtkHierarchicalPolyDataMapper

39.53.1 Usage

Legacy class. Use vtkCompositePolyDataMapper instead.

To create an instance of class vtkHierarchicalPolyDataMapper, simply invoke its constructor as follows

```
obj = vtkHierarchicalPolyDataMapper
```

39.53.2 Methods

The class vtkHierarchicalPolyDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalPolyDataMapper class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkHierarchicalPolyDataMapper = obj.NewInstance ()`

- `vtkHierarchicalPolyDataMapper = obj.SafeDownCast (vtkObject o)`

39.54 vtkIdentColoredPainter

39.54.1 Usage

DEPRECATED. Refer to vtkHardwareSelectionPolyDataPainter instead. This painter will color each polygon in a color that encodes an integer. Doing so allows us to determine what polygon is behind each pixel on the screen.

To create an instance of class vtkIdentColoredPainter, simply invoke its constructor as follows

```
obj = vtkIdentColoredPainter
```

39.54.2 Methods

The class vtkIdentColoredPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIdentColoredPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIdentColoredPainter = obj.NewInstance ()`
- `vtkIdentColoredPainter = obj.SafeDownCast (vtkObject o)`
- `obj.ResetCurrentId ()`
- `obj.ColorByConstant (int constant)`
- `obj.ColorByIncreasingIdent (int plane)`
- `obj.ColorByActorId (vtkProp ActorId)`
- `obj.ColorByVertex ()`
- `vtkProp = obj.GetActorFromId (vtkIdType id)`

39.55 vtkImageActor

39.55.1 Usage

vtkImageActor is used to render an image in a 3D scene. The image is placed at the origin of the image, and its size is controlled by the image dimensions and image spacing. The orientation of the image is orthogonal to one of the x-y-z axes depending on which plane the image is defined in. vtkImageActor duplicates the functionality of combinations of other VTK classes in a convenient, single class.

To create an instance of class vtkImageActor, simply invoke its constructor as follows

```
obj = vtkImageActor
```

39.55.2 Methods

The class vtkImageActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageActor = obj.NewInstance ()`
- `vtkImageActor = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData )` - Set/Get the image data input for the image actor.
- `vtkImageData = obj.GetInput ()` - Set/Get the image data input for the image actor.
- `int = obj.GetInterpolate ()` - Turn on/off linear interpolation of the image when rendering.
- `obj.SetInterpolate (int )` - Turn on/off linear interpolation of the image when rendering.
- `obj.InterpolateOn ()` - Turn on/off linear interpolation of the image when rendering.
- `obj.InterpolateOff ()` - Turn on/off linear interpolation of the image when rendering.
- `obj.SetOpacity (double )` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.

- `double = obj.GetOpacityMinValue ()` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `double = obj.GetOpacityMaxValue ()` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `double = obj.GetOpacity ()` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `obj.SetDisplayExtent (int extent[6])` - The image extent is generally set explicitly, but if not set it will be determined from the input image data.
- `obj.SetDisplayExtent (int minX, int maxX, int minY, int maxY, int minZ, int maxZ)` - The image extent is generally set explicitly, but if not set it will be determined from the input image data.
- `obj.GetDisplayExtent (int extent[6])` - The image extent is generally set explicitly, but if not set it will be determined from the input image data.
- `int = obj.GetDisplayExtent ()` - Get the bounds of this image actor. Either copy the bounds into a user provided array or return a pointer to an array. In either case the boudns is expressed as a 6-vector (xmin,xmax, ymin,ymax, zmin,zmax).
- `double = obj.GetBounds ()` - Get the bounds of this image actor. Either copy the bounds into a user provided array or return a pointer to an array. In either case the boudns is expressed as a 6-vector (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.GetBounds (double bounds[6])` - Get the bounds of this image actor. Either copy the bounds into a user provided array or return a pointer to an array. In either case the boudns is expressed as a 6-vector (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.GetDisplayBounds (double bounds[6])` - Get the bounds of the data that is displayed by this image actor. If the transformation matrix for this actor is the identity matrix, this will return the same value as GetBounds.
- `int = obj.GetSliceNumber ()` - Return the slice number (& min/max slice number) computed from the display extent.
- `int = obj.GetSliceNumberMax ()` - Return the slice number (& min/max slice number) computed from the display extent.
- `int = obj.GetSliceNumberMin ()` - Return the slice number (& min/max slice number) computed from the display extent.
- `obj.SetZSlice (int z)` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)
- `int = obj.GetZSlice ()` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)
- `int = obj.GetWholeZMin ()` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)

- `int = obj.GetWholeZMax ()` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)

39.56 vtkImageMapper

39.56.1 Usage

vtkImageMapper provides 2D image display support for vtk. It is a Mapper2D subclass that can be associated with an Actor2D and placed within a RenderWindow or ImageWindow.

To create an instance of class vtkImageMapper, simply invoke its constructor as follows

```
obj = vtkImageMapper
```

39.56.2 Methods

The class vtkImageMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMapper = obj.NewInstance ()`
- `vtkImageMapper = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Override Modifiedtime as we have added a lookuptable
- `obj.SetColorWindow (double )` - Set/Get the window value for window/level
- `double = obj.GetColorWindow ()` - Set/Get the window value for window/level
- `obj.SetColorLevel (double )` - Set/Get the level value for window/level
- `double = obj.GetColorLevel ()` - Set/Get the level value for window/level
- `obj.SetZSlice (int )` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)
- `int = obj.GetZSlice ()` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)
- `int = obj.GetWholeZMin ()` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)

- `int = obj.GetWholeZMax ()` - Set/Get the current slice number. The axis Z in ZSlice does not necessarily have any relation to the z axis of the data on disk. It is simply the axis orthogonal to the x,y, display plane. GetWholeZMax and Min are convenience methods for obtaining the number of slices that can be displayed. Again the number of slices is in reference to the display z axis, which is not necessarily the z axis on disk. (due to reformatting etc)

- `obj.RenderStart (vtkViewport viewport, vtkActor2D actor)` - Draw the image to the screen.

- `obj.RenderData (vtkViewport , vtkImageData , vtkActor2D )` - Function called by Render to actually draw the image to to the screen

- `double = obj.GetColorShift ()` - Methods used internally for performing the Window/Level mapping.

- `double = obj.GetColorScale ()` - Methods used internally for performing the Window/Level mapping.

- `obj.SetInput (vtkImageData input)` - Set the Input of a filter.

- `vtkImageData = obj.GetInput ()` - Set the Input of a filter.

- `obj.SetRenderToRectangle (int )` - If RenderToRectangle is set (by default not), then the imagemapper will render the image into the rectangle supplied by the Actor2D's PositionCoordinate and Position2Coordinate

- `int = obj.GetRenderToRectangle ()` - If RenderToRectangle is set (by default not), then the imagemapper will render the image into the rectangle supplied by the Actor2D's PositionCoordinate and Position2Coordinate

- `obj.RenderToRectangleOn ()` - If RenderToRectangle is set (by default not), then the imagemapper will render the image into the rectangle supplied by the Actor2D's PositionCoordinate and Position2Coordinate

- `obj.RenderToRectangleOff ()` - If RenderToRectangle is set (by default not), then the imagemapper will render the image into the rectangle supplied by the Actor2D's PositionCoordinate and Position2Coordinate

- `obj.SetUseCustomExtents (int )` - Usually, the entire image is displayed, if UseCustomExtents is set (by default not), then the region supplied in the CustomDisplayExtents is used in preference. Note that the Custom extents are x,y only and the zslice is still applied

- `int = obj.GetUseCustomExtents ()` - Usually, the entire image is displayed, if UseCustomExtents is set (by default not), then the region supplied in the CustomDisplayExtents is used in preference. Note that the Custom extents are x,y only and the zslice is still applied

- `obj.UseCustomExtentsOn ()` - Usually, the entire image is displayed, if UseCustomExtents is set (by default not), then the region supplied in the CustomDisplayExtents is used in preference. Note that the Custom extents are x,y only and the zslice is still applied

- `obj.UseCustomExtentsOff ()` - Usually, the entire image is displayed, if UseCustomExtents is set (by default not), then the region supplied in the CustomDisplayExtents is used in preference. Note that the Custom extents are x,y only and the zslice is still applied

- `obj.SetCustomDisplayExtents (int [4])` - The image extents which should be displayed with UseCustomExtents Note that the Custom extents are x,y only and the zslice is still applied

- `int = obj. GetCustomDisplayExtents ()` - The image extents which should be displayed with UseCustomExtents Note that the Custom extents are x,y only and the zslice is still applied

39.57 vtkImageProcessingPass

39.57.1 Usage

Abstract class with some convenient methods frequently used in subclasses.
.SECTION Implementation
To create an instance of class vtkImageProcessingPass, simply invoke its constructor as follows

```
obj = vtkImageProcessingPass
```

39.57.2 Methods

The class vtkImageProcessingPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageProcessingPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageProcessingPass = obj.NewInstance ()`
- `vtkImageProcessingPass = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.
- `vtkRenderPass = obj.GetDelegatePass ()` - Delegate for rendering the image to be processed. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkCameraPass or to a post-processing pass. Initial value is a NULL pointer.
- `obj.SetDelegatePass (vtkRenderPass delegatePass)` - Delegate for rendering the image to be processed. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkCameraPass or to a post-processing pass. Initial value is a NULL pointer.

39.58 vtkImageViewer

39.58.1 Usage

vtkImageViewer is a convenience class for displaying a 2d image. It packages up the functionality found in vtkRenderWindow, vtkRenderer, vtkActor2D and vtkImageMapper into a single easy to use class. Behind the scenes these four classes are actually used to to provide the required functionality. vtkImageViewer is simply a wrapper around them.

To create an instance of class vtkImageViewer, simply invoke its constructor as follows

```
obj = vtkImageViewer
```

39.58.2 Methods

The class vtkImageViewer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageViewer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkImageViewer = obj.NewInstance ()`
- `vtkImageViewer = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetWindowName ()` - Get name of rendering window
- `obj.Render (void )` - Render the resulting image.
- `obj.SetInput (vtkImageData in)` - Set/Get the input to the viewer.
- `vtkImageData = obj.GetInput ()` - Set/Get the input to the viewer.
- `obj.SetInputConnection (vtkAlgorithmOutput input)` - Set/Get the input to the viewer.
- `int = obj.GetWholeZMin ()` - What is the possible Min/ Max z slices available.
- `int = obj.GetWholeZMax ()` - What is the possible Min/ Max z slices available.
- `int = obj.GetZSlice ()` - Set/Get the current Z Slice to display
- `obj.SetZSlice (int s)` - Set/Get the current Z Slice to display
- `double = obj.GetColorWindow ()` - Sets window/level for mapping pixels to colors.
- `double = obj.GetColorLevel ()` - Sets window/level for mapping pixels to colors.
- `obj.SetColorWindow (double s)` - Sets window/level for mapping pixels to colors.
- `obj.SetColorLevel (double s)` - Sets window/level for mapping pixels to colors.
- `int = obj.GetGrayScaleHint ()` - By default this is a color viewer. GrayScaleHintOn will improve the appearance of gray scale images on some systems.
- `obj.SetGrayScaleHint (int )` - By default this is a color viewer. GrayScaleHintOn will improve the appearance of gray scale images on some systems.
- `obj.GrayScaleHintOn ()` - By default this is a color viewer. GrayScaleHintOn will improve the appearance of gray scale images on some systems.
- `obj.GrayScaleHintOff ()` - By default this is a color viewer. GrayScaleHintOn will improve the appearance of gray scale images on some systems.
- `int = obj.GetPosition ()` - Set/Get the position in screen coordinates of the rendering window.
- `obj.SetPosition (int a, int b)` - Set/Get the position in screen coordinates of the rendering window.
- `obj.SetPosition (int a[2])` - Set/Get the position in screen coordinates of the rendering window.
- `int = obj.GetSize ()` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetSize (int a, int b)` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetSize (int a[2])` - Set/Get the size of the window in screen coordinates in pixels.
- `vtkRenderWindow = obj.GetRenderWindow ()` - Get the internal objects
- `vtkRenderer = obj.GetRenderer ()` - Get the internal objects
- `vtkImageMapper = obj.GetImageMapper ()` - Get the internal objects
- `vtkActor2D = obj.GetActor2D ()` - Get the internal objects
- `obj.SetupInteractor (vtkRenderWindowInteractor )` - Create and attach an interactor for this window

- `obj.SetOffScreenRendering (int )` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `int = obj.GetOffScreenRendering ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.OffScreenRenderingOn ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.OffScreenRenderingOff ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.

39.59 vtkImageViewer2

39.59.1 Usage

vtkImageViewer2 is a convenience class for displaying a 2D image. It packages up the functionality found in vtkRenderWindow, vtkRenderer, vtkImageActor and vtkImageMapToWindowLevelColors into a single easy to use class. This class also creates an image interactor style (vtkInteractorStyleImage) that allows zooming and panning of images, and supports interactive window/level operations on the image. Note that vtkImageViewer2 is simply a wrapper around these classes.

vtkImageViewer2 uses the 3D rendering and texture mapping engine to draw an image on a plane. This allows for rapid rendering, zooming, and panning. The image is placed in the 3D scene at a depth based on the z-coordinate of the particular image slice. Each call to SetSlice() changes the image data (slice) displayed AND changes the depth of the displayed slice in the 3D scene. This can be controlled by the AutoAdjustCameraClippingRange ivar of the InteractorStyle member.

It is possible to mix images and geometry, using the methods:

viewer-¿SetInput(myImage); viewer-¿GetRenderer()-¿AddActor(myActor);

This can be used to annotate an image with a PolyData of "edges" or or highlight sections of an image or display a 3D isosurface with a slice from the volume, etc. Any portions of your geometry that are in front of the displayed slice will be visible; any portions of your geometry that are behind the displayed slice will be obscured. A more general framework (with respect to viewing direction) for achieving this effect is provided by the vtkImagePlaneWidget .

Note that pressing 'r' will reset the window/level and pressing shift+'r' or control+'r' will reset the camera.

To create an instance of class vtkImageViewer2, simply invoke its constructor as follows

```
obj = vtkImageViewer2
```

39.59.2 Methods

The class vtkImageViewer2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageViewer2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageViewer2 = obj.NewInstance ()`
- `vtkImageViewer2 = obj.SafeDownCast (vtkObject o)`

- `string = obj.GetWindowName ()` - Get the name of rendering window.
- `obj.Render (void )` - Render the resulting image.
- `obj.SetInput (vtkImageData in)` - Set/Get the input image to the viewer.
- `vtkImageData = obj.GetInput ()` - Set/Get the input image to the viewer.
- `obj.SetInputConnection (vtkAlgorithmOutput input)` - Set/Get the input image to the viewer.
- `int = obj.GetSliceOrientation ()` - Set/get the slice orientation
- `obj.SetSliceOrientation (int orientation)` - Set/get the slice orientation
- `obj.SetSliceOrientationToXY ()` - Set/get the slice orientation
- `obj.SetSliceOrientationToYZ ()` - Set/get the slice orientation
- `obj.SetSliceOrientationToXZ ()` - Set/get the slice orientation
- `int = obj.GetSlice ()` - Set/Get the current slice to display (depending on the orientation this can be in X, Y or Z).
- `obj.SetSlice (int s)` - Set/Get the current slice to display (depending on the orientation this can be in X, Y or Z).
- `obj.UpdateDisplayExtent ()` - Update the display extent manually so that the proper slice for the given orientation is displayed. It will also try to set a reasonable camera clipping range. This method is called automatically when the Input is changed, but most of the time the input of this class is likely to remain the same, i.e. connected to the output of a filter, or an image reader. When the input of this filter or reader itself is changed, an error message might be displayed since the current display extent is probably outside the new whole extent. Calling this method will ensure that the display extent is reset properly.
- `int = obj.GetSliceMin ()` - Return the minimum and maximum slice values (depending on the orientation this can be in X, Y or Z).
- `int = obj.GetSliceMax ()` - Return the minimum and maximum slice values (depending on the orientation this can be in X, Y or Z).
- `obj.GetSliceRange (int range[2])` - Return the minimum and maximum slice values (depending on the orientation this can be in X, Y or Z).
- `double = obj.GetColorWindow ()` - Set window and level for mapping pixels to colors.
- `double = obj.GetColorLevel ()` - Set window and level for mapping pixels to colors.
- `obj.SetColorWindow (double s)` - Set window and level for mapping pixels to colors.
- `obj.SetColorLevel (double s)` - Set window and level for mapping pixels to colors.
- `obj.SetPosition (int a, int b)` - Set/Get the position in screen coordinates of the rendering window.
- `obj.SetPosition (int a[2])` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetSize (int a, int b)` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetSize (int a[2])` - Get the internal render window, renderer, image actor, and image map instances.
- `vtkRenderWindow = obj.GetRenderWindow ()` - Get the internal render window, renderer, image actor, and image map instances.

- `vtkRenderer = obj.GetRenderer ()` - Get the internal render window, renderer, image actor, and image map instances.
- `vtkImageActor = obj.GetImageActor ()` - Get the internal render window, renderer, image actor, and image map instances.
- `vtkImageMapToWindowLevelColors = obj.GetWindowLevel ()` - Get the internal render window, renderer, image actor, and image map instances.
- `vtkInteractorStyleImage = obj.GetInteractorStyle ()` - Get the internal render window, renderer, image actor, and image map instances.
- `obj.SetRenderWindow (vtkRenderWindow arg)` - Set your own renderwindow and renderer
- `obj.SetRenderer (vtkRenderer arg)` - Set your own renderwindow and renderer
- `obj.SetupInteractor (vtkRenderWindowInteractor )` - Attach an interactor for the internal render window.
- `obj.SetOffScreenRendering (int )` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `int = obj.GetOffScreenRendering ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.OffScreenRenderingOn ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.OffScreenRenderingOff ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `int = obj.GetWholeZMin ()` - @deprecated Replaced by vtkImageViewer2::GetSliceMin() as of VTK 5.0.
- `int = obj.GetWholeZMax ()` - @deprecated Replaced by vtkImageViewer2::GetSliceMax() as of VTK 5.0.
- `int = obj.GetZSlice ()` - @deprecated Replaced by vtkImageViewer2::GetSlice() as of VTK 5.0.
- `obj.SetZSlice (int )` - @deprecated Replaced by vtkImageViewer2::SetSlice() as of VTK 5.0.

39.60 vtkImagingFactory

39.60.1 Usage

To create an instance of class vtkImagingFactory, simply invoke its constructor as follows

```
obj = vtkImagingFactory
```

39.60.2 Methods

The class vtkImagingFactory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImagingFactory class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImagingFactory = obj.NewInstance ()`
- `vtkImagingFactory = obj.SafeDownCast (vtkObject o)`

39.61 vtkImporter

39.61.1 Usage

vtkImporter is an abstract class that specifies the protocol for importing actors, cameras, lights and properties into a vtkRenderWindow. The following takes place: 1) Create a RenderWindow and Renderer if none is provided. 2) Call ImportBegin, if ImportBegin returns False, return 3) Call ReadData, which calls: a) Import the Actors b) Import the cameras c) Import the lights d) Import the Properties 7) Call ImportEnd

Subclasses optionally implement the ImportActors, ImportCameras, ImportLights and ImportProperties or ReadData methods. An ImportBegin and ImportEnd can optionally be provided to perform Importer-specific initialization and termination. The Read method initiates the import process. If a RenderWindow is provided, its Renderer will contained the imported objects. If the RenderWindow has no Renderer, one is created. If no RenderWindow is provided, both a RenderWindow and Renderer will be created. Both the RenderWindow and Renderer can be accessed using Get methods.

To create an instance of class vtkImporter, simply invoke its constructor as follows

```
obj = vtkImporter
```

39.61.2 Methods

The class vtkImporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImporter = obj.NewInstance ()`
- `vtkImporter = obj.SafeDownCast (vtkObject o)`
- `vtkRenderer = obj.GetRenderer ()`
- `obj.SetRenderWindow (vtkRenderWindow )`
- `vtkRenderWindow = obj.GetRenderWindow ()`
- `obj.Read ()`
- `obj.Update ()`

39.62 vtkInteractorEventRecorder

39.62.1 Usage

vtkInteractorEventRecorder records all VTK events invoked from a vtkRenderWindowInteractor. The events are recorded to a file. vtkInteractorEventRecorder can also be used to play those events back and invoke them on an vtkRenderWindowInteractor. (Note: the events can also be played back from a file or string.)

The format of the event file is simple. It is: EventName X Y ctrl shift keycode repeatCount keySym The format also allows "#" comments.

To create an instance of class vtkInteractorEventRecorder, simply invoke its constructor as follows

```
obj = vtkInteractorEventRecorder
```

39.62.2 Methods

The class vtkInteractorEventRecorder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorEventRecorder class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorEventRecorder = obj.NewInstance ()`
- `vtkInteractorEventRecorder = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )`
- `obj.SetInteractor (vtkRenderWindowInteractor iren)`
- `obj.SetFileName (string )` - Set/Get the name of a file events should be written to/from.
- `string = obj.GetFileName ()` - Set/Get the name of a file events should be written to/from.
- `obj.Record ()` - Invoke this method to begin recording events. The events will be recorded to the filename indicated.
- `obj.Play ()` - Invoke this method to begin playing events from the current position. The events will be played back from the filename indicated.
- `obj.Stop ()` - Invoke this method to stop recording/playing events.
- `obj.Rewind ()` - Rewind to the beginning of the file.
- `obj.SetReadFromInputString (int )` - Enable reading from an InputString as compared to the default behavior, which is to read from a file.
- `int = obj.GetReadFromInputString ()` - Enable reading from an InputString as compared to the default behavior, which is to read from a file.
- `obj.ReadFromInputStringOn ()` - Enable reading from an InputString as compared to the default behavior, which is to read from a file.
- `obj.ReadFromInputStringOff ()` - Enable reading from an InputString as compared to the default behavior, which is to read from a file.
- `obj.SetInputString (string )` - Set/Get the string to read from.
- `string = obj.GetInputString ()` - Set/Get the string to read from.

39.63 vtkInteractorObserver

39.63.1 Usage

vtkInteractorObserver is an abstract superclass for subclasses that observe events invoked by vtkRenderWindowInteractor. These subclasses are typically things like 3D widgets; objects that interact with actors in the scene, or interactively probe the scene for information.

vtkInteractorObserver defines the method SetInteractor() and enables and disables the processing of events by the vtkInteractorObserver. Use the methods EnabledOn() or SetEnabled(1) to turn on the interactor observer, and the methods EnabledOff() or SetEnabled(0) to turn off the interactor. Initial value is 0.

To support interactive manipulation of objects, this class (and subclasses) invoke the events StartInteractionEvent, InteractionEvent, and EndInteractionEvent. These events are invoked when the vtkInteractorObserver enters a state where rapid response is desired: mouse motion, etc. The events can be used, for example, to set the desired update frame rate (StartInteractionEvent), operate on data or update a pipeline (InteractionEvent), and set the desired frame rate back to normal values (EndInteractionEvent). Two other events, EnableEvent and DisableEvent, are invoked when the interactor observer is enabled or disabled.

To create an instance of class vtkInteractorObserver, simply invoke its constructor as follows

```
obj = vtkInteractorObserver
```

39.63.2 Methods

The class vtkInteractorObserver has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorObserver class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorObserver = obj.NewInstance ()`
- `vtkInteractorObserver = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods for turning the interactor observer on and off, and determining its state. All subclasses must provide the SetEnabled() method. Enabling a vtkInteractorObserver has the side effect of adding observers; disabling it removes the observers. Prior to enabling the vtkInteractorObserver you must set the render window interactor (via SetInteractor()). Initial value is 0.
- `int = obj.GetEnabled ()` - Methods for turning the interactor observer on and off, and determining its state. All subclasses must provide the SetEnabled() method. Enabling a vtkInteractorObserver has the side effect of adding observers; disabling it removes the observers. Prior to enabling the vtkInteractorObserver you must set the render window interactor (via SetInteractor()). Initial value is 0.
- `obj.EnabledOn ()` - Methods for turning the interactor observer on and off, and determining its state. All subclasses must provide the SetEnabled() method. Enabling a vtkInteractorObserver has the side effect of adding observers; disabling it removes the observers. Prior to enabling the vtkInteractorObserver you must set the render window interactor (via SetInteractor()). Initial value is 0.
- `obj.EnabledOff ()` - Methods for turning the interactor observer on and off, and determining its state. All subclasses must provide the SetEnabled() method. Enabling a vtkInteractorObserver has the side effect of adding observers; disabling it removes the observers. Prior to enabling the vtkInteractorObserver you must set the render window interactor (via SetInteractor()). Initial value is 0.

- `obj.On ()` - Methods for turning the interactor observer on and off, and determining its state. All subclasses must provide the SetEnabled() method. Enabling a vtkInteractorObserver has the side effect of adding observers; disabling it removes the observers. Prior to enabling the vtkInteractorObserver you must set the render window interactor (via SetInteractor()). Initial value is 0.

- `obj.Off ()` - This method is used to associate the widget with the render window interactor. Observers of the appropriate events invoked in the render window interactor are set up as a result of this method invocation. The SetInteractor() method must be invoked prior to enabling the vtkInteractorObserver.

- `obj.SetInteractor (vtkRenderWindowInteractor iren)` - This method is used to associate the widget with the render window interactor. Observers of the appropriate events invoked in the render window interactor are set up as a result of this method invocation. The SetInteractor() method must be invoked prior to enabling the vtkInteractorObserver.

- `vtkRenderWindowInteractor = obj.GetInteractor ()` - This method is used to associate the widget with the render window interactor. Observers of the appropriate events invoked in the render window interactor are set up as a result of this method invocation. The SetInteractor() method must be invoked prior to enabling the vtkInteractorObserver.

- `obj.SetPriority (float )` - Set/Get the priority at which events are processed. This is used when multiple interactor observers are used simultaneously. The default value is 0.0 (lowest priority.) Note that when multiple interactor observer have the same priority, then the last observer added will process the event first. (Note: once the SetInteractor() method has been called, changing the priority does not effect event processing. You will have to SetInteractor(NULL), change priority, and then SetInteractor(iren) to have the priority take effect.)

- `float = obj.GetPriorityMinValue ()` - Set/Get the priority at which events are processed. This is used when multiple interactor observers are used simultaneously. The default value is 0.0 (lowest priority.) Note that when multiple interactor observer have the same priority, then the last observer added will process the event first. (Note: once the SetInteractor() method has been called, changing the priority does not effect event processing. You will have to SetInteractor(NULL), change priority, and then SetInteractor(iren) to have the priority take effect.)

- `float = obj.GetPriorityMaxValue ()` - Set/Get the priority at which events are processed. This is used when multiple interactor observers are used simultaneously. The default value is 0.0 (lowest priority.) Note that when multiple interactor observer have the same priority, then the last observer added will process the event first. (Note: once the SetInteractor() method has been called, changing the priority does not effect event processing. You will have to SetInteractor(NULL), change priority, and then SetInteractor(iren) to have the priority take effect.)

- `float = obj.GetPriority ()` - Set/Get the priority at which events are processed. This is used when multiple interactor observers are used simultaneously. The default value is 0.0 (lowest priority.) Note that when multiple interactor observer have the same priority, then the last observer added will process the event first. (Note: once the SetInteractor() method has been called, changing the priority does not effect event processing. You will have to SetInteractor(NULL), change priority, and then SetInteractor(iren) to have the priority take effect.)

- `obj.SetKeyPressActivation (int )` - Enable/Disable of the use of a keypress to turn on and off the interactor observer. (By default, the keypress is 'i' for "interactor observer".) Set the KeyPressActivationValue to change which key activates the widget.)

- `int = obj.GetKeyPressActivation ()` - Enable/Disable of the use of a keypress to turn on and off the interactor observer. (By default, the keypress is 'i' for "interactor observer".) Set the KeyPressActivationValue to change which key activates the widget.)

- `obj.KeyPressActivationOn ()` - Enable/Disable of the use of a keypress to turn on and off the interactor observer. (By default, the keypress is 'i' for "interactor observer".) Set the KeyPressActivationValue to change which key activates the widget.)

- `obj.KeyPressActivationOff ()` - Enable/Disable of the use of a keypress to turn on and off the interactor observer. (By default, the keypress is 'i' for "interactor observer".) Set the KeyPressActivationValue to change which key activates the widget.)

- `obj.SetKeyPressActivationValue (char )` - Specify which key press value to use to activate the interactor observer (if key press activation is enabled). By default, the key press activation value is 'i'. Note: once the SetInteractor() method is invoked, changing the key press activation value will not affect the key press until SetInteractor(NULL)/SetInteractor(iren) is called.

- `char = obj.GetKeyPressActivationValue ()` - Specify which key press value to use to activate the interactor observer (if key press activation is enabled). By default, the key press activation value is 'i'. Note: once the SetInteractor() method is invoked, changing the key press activation value will not affect the key press until SetInteractor(NULL)/SetInteractor(iren) is called.

- `vtkRenderer = obj.GetDefaultRenderer ()` - Set/Get the default renderer to use when activating the interactor observer. Normally when the widget is activated (SetEnabled(1) or when keypress activation takes place), the renderer over which the mouse pointer is positioned is used. Alternatively, you can specify the renderer to bind the interactor to when the interactor observer is activated.

- `obj.SetDefaultRenderer (vtkRenderer )` - Set/Get the default renderer to use when activating the interactor observer. Normally when the widget is activated (SetEnabled(1) or when keypress activation takes place), the renderer over which the mouse pointer is positioned is used. Alternatively, you can specify the renderer to bind the interactor to when the interactor observer is activated.

- `vtkRenderer = obj.GetCurrentRenderer ()` - Set/Get the current renderer. Normally when the widget is activated (SetEnabled(1) or when keypress activation takes place), the renderer over which the mouse pointer is positioned is used and assigned to this Ivar. Alternatively, you might want to set the CurrentRenderer explicitly. WARNING: note that if the DefaultRenderer Ivar is set (see above), it will always override the parameter passed to SetCurrentRenderer, unless it is NULL. (i.e., SetCurrentRenderer(foo) = SetCurrentRenderer(DefaultRenderer).

- `obj.SetCurrentRenderer (vtkRenderer )` - Set/Get the current renderer. Normally when the widget is activated (SetEnabled(1) or when keypress activation takes place), the renderer over which the mouse pointer is positioned is used and assigned to this Ivar. Alternatively, you might want to set the CurrentRenderer explicitly. WARNING: note that if the DefaultRenderer Ivar is set (see above), it will always override the parameter passed to SetCurrentRenderer, unless it is NULL. (i.e., SetCurrentRenderer(foo) = SetCurrentRenderer(DefaultRenderer).

- `obj.OnChar ()` - Sets up the keypress-i event.

39.64 vtkInteractorStyle

39.64.1 Usage

vtkInteractorStyle is a base class implementing the majority of motion control routines and defines an event driven interface to support vtkRenderWindowInteractor. vtkRenderWindowInteractor implements platform dependent key/mouse routing and timer control, which forwards events in a neutral form to vtkInteractorStyle.

vtkInteractorStyle implements the "joystick" style of interaction. That is, holding down the mouse keys generates a stream of events that cause continuous actions (e.g., rotate, translate, pan, zoom). (The class vtkInteractorStyleTrackball implements a grab and move style.) The event bindings for this class include the following: - Keypress j / Keypress t: toggle between joystick (position sensitive) and trackball (motion sensitive) styles. In joystick style, motion occurs continuously as long as a mouse button is pressed. In trackball style, motion occurs when the mouse button is pressed and the mouse pointer moves. - Keypress c / Keypress a: toggle between camera and actor modes. In camera mode, mouse events affect the camera position and focal point. In actor mode, mouse events affect the actor that is under the mouse pointer. -

Button 1: rotate the camera around its focal point (if camera mode) or rotate the actor around its origin (if actor mode). The rotation is in the direction defined from the center of the renderer's viewport towards the mouse position. In joystick mode, the magnitude of the rotation is determined by the distance the mouse is from the center of the render window. - Button 2: pan the camera (if camera mode) or translate the actor (if actor mode). In joystick mode, the direction of pan or translation is from the center of the viewport towards the mouse position. In trackball mode, the direction of motion is the direction the mouse moves. (Note: with 2-button mice, pan is defined as Shift-Button 1.) - Button 3: zoom the camera (if camera mode) or scale the actor (if actor mode). Zoom in/increase scale if the mouse position is in the top half of the viewport; zoom out/decrease scale if the mouse position is in the bottom half. In joystick mode, the amount of zoom is controlled by the distance of the mouse pointer from the horizontal centerline of the window. - Keypress 3: toggle the render window into and out of stereo mode. By default, red-blue stereo pairs are created. Some systems support Crystal Eyes LCD stereo glasses; you have to invoke SetStereoTypeToCrystalEyes() on the rendering window. - Keypress e: exit the application. - Keypress f: fly to the picked point - Keypress p: perform a pick operation. The render window interactor has an internal instance of vtkCellPicker that it uses to pick. - Keypress r: reset the camera view along the current view direction. Centers the actors and moves the camera so that all actors are visible. - Keypress s: modify the representation of all actors so that they are surfaces. - Keypress u: invoke the user-defined function. Typically, this keypress will bring up an interactor that you can type commands in. Typing u calls UserCallBack() on the vtkRenderWindowInteractor, which invokes a vtkCommand::UserEvent. In other words, to define a user-defined callback, just add an observer to the vtkCommand::UserEvent on the vtkRenderWindowInteractor object. - Keypress w: modify the representation of all actors so that they are wireframe.

vtkInteractorStyle can be subclassed to provide new interaction styles and a facility to override any of the default mouse/key operations which currently handle trackball or joystick styles is provided. Note that this class will fire a variety of events that can be watched using an observer, such as LeftButtonPressEvent, LeftButtonReleaseEvent, MiddleButtonPressEvent, MiddleButtonReleaseEvent, RightButtonPressEvent, RightButtonReleaseEvent, EnterEvent, LeaveEvent, KeyPressEvent, KeyReleaseEvent, CharEvent, ExposeEvent, ConfigureEvent, TimerEvent, MouseMoveEvent,

To create an instance of class vtkInteractorStyle, simply invoke its constructor as follows

```
obj = vtkInteractorStyle
```

39.64.2 Methods

The class vtkInteractorStyle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyle = obj.NewInstance ()`
- `vtkInteractorStyle = obj.SafeDownCast (vtkObject o)`
- `obj.SetInteractor (vtkRenderWindowInteractor interactor)` - Set/Get the Interactor wrapper being controlled by this object. (Satisfy superclass API.)
- `obj.SetEnabled (int )` - Turn on/off this interactor. Interactor styles operate a little bit differently than other types of interactor observers. When the SetInteractor() method is invoked, the automatically enable themselves. This is a legacy requirement, and convenient for the user.
- `obj.SetAutoAdjustCameraClippingRange (int )` - If AutoAdjustCameraClippingRange is on, then before each render the camera clipping range will be adjusted to "fit" the whole scene. Clipping will still occur if objects in the scene are behind the camera or come very close. If AutoAdjustCameraClippingRange is off, no adjustment will be made per render, but the camera clipping range will still be reset when the camera is reset.

- `int = obj.GetAutoAdjustCameraClippingRangeMinValue ()` - If AutoAdjustCameraClippingRange is on, then before each render the camera clipping range will be adjusted to "fit" the whole scene. Clipping will still occur if objects in the scene are behind the camera or come very close. If AutoAdjustCameraClippingRange is off, no adjustment will be made per render, but the camera clipping range will still be reset when the camera is reset.

- `int = obj.GetAutoAdjustCameraClippingRangeMaxValue ()` - If AutoAdjustCameraClippingRange is on, then before each render the camera clipping range will be adjusted to "fit" the whole scene. Clipping will still occur if objects in the scene are behind the camera or come very close. If AutoAdjustCameraClippingRange is off, no adjustment will be made per render, but the camera clipping range will still be reset when the camera is reset.

- `int = obj.GetAutoAdjustCameraClippingRange ()` - If AutoAdjustCameraClippingRange is on, then before each render the camera clipping range will be adjusted to "fit" the whole scene. Clipping will still occur if objects in the scene are behind the camera or come very close. If AutoAdjustCameraClippingRange is off, no adjustment will be made per render, but the camera clipping range will still be reset when the camera is reset.

- `obj.AutoAdjustCameraClippingRangeOn ()` - If AutoAdjustCameraClippingRange is on, then before each render the camera clipping range will be adjusted to "fit" the whole scene. Clipping will still occur if objects in the scene are behind the camera or come very close. If AutoAdjustCameraClippingRange is off, no adjustment will be made per render, but the camera clipping range will still be reset when the camera is reset.

- `obj.AutoAdjustCameraClippingRangeOff ()` - If AutoAdjustCameraClippingRange is on, then before each render the camera clipping range will be adjusted to "fit" the whole scene. Clipping will still occur if objects in the scene are behind the camera or come very close. If AutoAdjustCameraClippingRange is off, no adjustment will be made per render, but the camera clipping range will still be reset when the camera is reset.

- `obj.FindPokedRenderer (int , int )` - When an event occurs, we must determine which Renderer the event occurred within, since one RenderWindow may contain multiple renderers.

- `int = obj.GetState ()` - Some useful information for interaction

- `int = obj.GetUseTimers ()` - Set/Get timer hint

- `obj.SetUseTimers (int )` - Set/Get timer hint

- `obj.UseTimersOn ()` - Set/Get timer hint

- `obj.UseTimersOff ()` - Set/Get timer hint

- `obj.SetTimerDuration (long )` - If using timers, specify the default timer interval (in milliseconds). Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `GetTimerDurationMinValue = obj.()` - If using timers, specify the default timer interval (in milliseconds). Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `GetTimerDurationMaxValue = obj.()` - If using timers, specify the default timer interval (in milliseconds). Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `long = obj.GetTimerDuration ()` - If using timers, specify the default timer interval (in milliseconds). Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `obj.SetHandleObservers (int )` - Does ProcessEvents handle observers on this class or not
- `int = obj.GetHandleObservers ()` - Does ProcessEvents handle observers on this class or not
- `obj.HandleObserversOn ()` - Does ProcessEvents handle observers on this class or not
- `obj.HandleObserversOff ()` - Does ProcessEvents handle observers on this class or not
- `obj.OnMouseMove ()` - Generic event bindings can be overridden in subclasses
- `obj.OnLeftButtonDown ()` - Generic event bindings can be overridden in subclasses
- `obj.OnLeftButtonUp ()` - Generic event bindings can be overridden in subclasses
- `obj.OnMiddleButtonDown ()` - Generic event bindings can be overridden in subclasses
- `obj.OnMiddleButtonUp ()` - Generic event bindings can be overridden in subclasses
- `obj.OnRightButtonDown ()` - Generic event bindings can be overridden in subclasses
- `obj.OnRightButtonUp ()` - Generic event bindings can be overridden in subclasses
- `obj.OnMouseWheelForward ()` - Generic event bindings can be overridden in subclasses
- `obj.OnMouseWheelBackward ()` - Generic event bindings can be overridden in subclasses
- `obj.OnChar ()` - OnChar is triggered when an ASCII key is pressed. Some basic key presses are handled here ('q' for Quit, 'p' for Pick, etc)
- `obj.OnKeyDown ()`
- `obj.OnKeyUp ()`
- `obj.OnKeyPress ()`
- `obj.OnKeyRelease ()`
- `obj.OnExpose ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnConfigure ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnEnter ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnLeave ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnTimer ()` - OnTimer calls Rotate, Rotate etc which should be overridden by style subclasses.
- `obj.Rotate ()` - These methods for the different interactions in different modes are overridden in subclasses to perform the correct motion. Since they might be called from OnTimer, they do not have mouse coord parameters (use interactor's GetEventPosition and GetLastEventPosition)
- `obj.Spin ()` - These methods for the different interactions in different modes are overridden in subclasses to perform the correct motion. Since they might be called from OnTimer, they do not have mouse coord parameters (use interactor's GetEventPosition and GetLastEventPosition)
- `obj.Pan ()` - These methods for the different interactions in different modes are overridden in subclasses to perform the correct motion. Since they might be called from OnTimer, they do not have mouse coord parameters (use interactor's GetEventPosition and GetLastEventPosition)
- `obj.Dolly ()` - These methods for the different interactions in different modes are overridden in subclasses to perform the correct motion. Since they might be called from OnTimer, they do not have mouse coord parameters (use interactor's GetEventPosition and GetLastEventPosition)

- `obj.Zoom ()` - These methods for the different interactions in different modes are overridden in subclasses to perform the correct motion. Since they might be called from OnTimer, they do not have mouse coord parameters (use interactor's GetEventPosition and GetLastEventPosition)
- `obj.UniformScale ()` - These methods for the different interactions in different modes are overridden in subclasses to perform the correct motion. Since they might be called from OnTimer, they do not have mouse coord parameters (use interactor's GetEventPosition and GetLastEventPosition)
- `obj.StartState (int newstate)` - utility routines used by state changes
- `obj.StopState ()` - utility routines used by state changes
- `obj.StartAnimate ()` - Interaction mode entry points used internally.
- `obj.StopAnimate ()` - Interaction mode entry points used internally.
- `obj.StartRotate ()` - Interaction mode entry points used internally.
- `obj.EndRotate ()` - Interaction mode entry points used internally.
- `obj.StartZoom ()` - Interaction mode entry points used internally.
- `obj.EndZoom ()` - Interaction mode entry points used internally.
- `obj.StartPan ()` - Interaction mode entry points used internally.
- `obj.EndPan ()` - Interaction mode entry points used internally.
- `obj.StartSpin ()` - Interaction mode entry points used internally.
- `obj.EndSpin ()` - Interaction mode entry points used internally.
- `obj.StartDolly ()` - Interaction mode entry points used internally.
- `obj.EndDolly ()` - Interaction mode entry points used internally.
- `obj.StartUniformScale ()` - Interaction mode entry points used internally.
- `obj.EndUniformScale ()` - Interaction mode entry points used internally.
- `obj.StartTimer ()` - Interaction mode entry points used internally.
- `obj.EndTimer ()` - Interaction mode entry points used internally.
- `obj.HighlightProp (vtkProp prop)` - When picking successfully selects an actor, this method highlights the picked prop appropriately. Currently this is done by placing a bounding box around a picked vtkProp3D, and using the PickColor to highlight a vtkProp2D.
- `obj.HighlightActor2D (vtkActor2D actor2D)` - When picking successfully selects an actor, this method highlights the picked prop appropriately. Currently this is done by placing a bounding box around a picked vtkProp3D, and using the PickColor to highlight a vtkProp2D.
- `obj.HighlightProp3D (vtkProp3D prop3D)` - When picking successfully selects an actor, this method highlights the picked prop appropriately. Currently this is done by placing a bounding box around a picked vtkProp3D, and using the PickColor to highlight a vtkProp2D.
- `obj.SetPickColor (double , double , double )` - Set/Get the pick color (used by default to color vtkActor2D's). The color is expressed as red/green/blue values between (0.0,1.0).
- `obj.SetPickColor (double  a[3])` - Set/Get the pick color (used by default to color vtkActor2D's). The color is expressed as red/green/blue values between (0.0,1.0).

- `double = obj. GetPickColor ()` - Set/Get the pick color (used by default to color vtkActor2D's). The color is expressed as red/green/blue values between (0.0,1.0).
- `obj.SetMouseWheelMotionFactor (double )` - Set/Get the mouse wheel motion factor. Default to 1.0. Set it to a different value to emphasize or de-emphasize the action triggered by mouse wheel motion.
- `double = obj.GetMouseWheelMotionFactor ()` - Set/Get the mouse wheel motion factor. Default to 1.0. Set it to a different value to emphasize or de-emphasize the action triggered by mouse wheel motion.
- `vtkTDxInteractorStyle = obj.GetTDxStyle ()` - 3Dconnexion device interactor style. Initial value is a pointer to an object of class vtkTdxInteractorStyleCamera.
- `obj.SetTDxStyle (vtkTDxInteractorStyle tdxStyle)` - 3Dconnexion device interactor style. Initial value is a pointer to an object of class vtkTdxInteractorStyleCamera.

39.65 vtkInteractorStyleFlight

39.65.1 Usage

Left mouse button press produces forward motion. Right mouse button press produces reverse motion. Moving mouse during motion steers user in desired direction. Keyboard controls are: Left/Right/Up/Down Arrows for steering direction 'A' forward, 'Z' reverse motion Ctrl Key causes sidestep instead of steering in mouse and key modes Shift key is accelerator in mouse and key modes Ctrl and Shift together causes Roll in mouse and key modes

By default, one "step" of motion corresponds to 1/250th of the diagonal of bounding box of visible actors, '+' and '-' keys allow user to increase or decrease step size.

To create an instance of class vtkInteractorStyleFlight, simply invoke its constructor as follows

```
obj = vtkInteractorStyleFlight
```

39.65.2 Methods

The class vtkInteractorStyleFlight has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleFlight class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleFlight = obj.NewInstance ()`
- `vtkInteractorStyleFlight = obj.SafeDownCast (vtkObject o)`
- `obj.JumpTo (double campos[3], double focpos[3])` - Move the Eye/Camera to a specific location (no intermediate steps are taken
- `obj.SetMotionStepSize (double )` - Set the basic unit step size : by default 1/250 of bounding diagonal
- `double = obj.GetMotionStepSize ()` - Set the basic unit step size : by default 1/250 of bounding diagonal
- `obj.SetMotionAccelerationFactor (double )` - Set acceleration factor when shift key is applied : default 10

- `double = obj.GetMotionAccelerationFactor ()` - Set acceleration factor when shift key is applied : default 10
- `obj.SetAngleStepSize (double )` - Set the basic angular unit for turning : default 1 degree
- `double = obj.GetAngleStepSize ()` - Set the basic angular unit for turning : default 1 degree
- `obj.SetAngleAccelerationFactor (double )` - Set angular acceleration when shift key is applied : default 5
- `double = obj.GetAngleAccelerationFactor ()` - Set angular acceleration when shift key is applied : default 5
- `obj.SetDisableMotion (int )` - Disable motion (temporarily - for viewing etc)
- `int = obj.GetDisableMotion ()` - Disable motion (temporarily - for viewing etc)
- `obj.DisableMotionOn ()` - Disable motion (temporarily - for viewing etc)
- `obj.DisableMotionOff ()` - Disable motion (temporarily - for viewing etc)
- `obj.SetRestoreUpVector (int )` - When flying, apply a restorative force to the "Up" vector. This is activated when the current 'up' is close to the actual 'up' (as defined in DefaultUpVector). This prevents excessive twisting forces when viewing from arbitrary angles, but keep the horizon level when the user is flying over terrain.
- `int = obj.GetRestoreUpVector ()` - When flying, apply a restorative force to the "Up" vector. This is activated when the current 'up' is close to the actual 'up' (as defined in DefaultUpVector). This prevents excessive twisting forces when viewing from arbitrary angles, but keep the horizon level when the user is flying over terrain.
- `obj.RestoreUpVectorOn ()` - When flying, apply a restorative force to the "Up" vector. This is activated when the current 'up' is close to the actual 'up' (as defined in DefaultUpVector). This prevents excessive twisting forces when viewing from arbitrary angles, but keep the horizon level when the user is flying over terrain.
- `obj.RestoreUpVectorOff ()` - When flying, apply a restorative force to the "Up" vector. This is activated when the current 'up' is close to the actual 'up' (as defined in DefaultUpVector). This prevents excessive twisting forces when viewing from arbitrary angles, but keep the horizon level when the user is flying over terrain.
- `double = obj. GetDefaultUpVector ()`
- `obj.SetDefaultUpVector (double [3])`
- `obj.OnMouseMove ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnLeftButtonDown ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnLeftButtonUp ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnMiddleButtonDown ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnMiddleButtonUp ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnRightButtonDown ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnRightButtonUp ()` - Concrete implementation of Mouse event bindings for flight
- `obj.OnChar ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.OnKeyDown ()` - Concrete implementation of Keyboard event bindings for flight

- `obj.OnKeyUp ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.OnTimer ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.ForwardFly ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.ReverseFly ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.StartForwardFly ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.EndForwardFly ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.StartReverseFly ()` - Concrete implementation of Keyboard event bindings for flight
- `obj.EndReverseFly ()` - Concrete implementation of Keyboard event bindings for flight

39.66 vtkInteractorStyleImage

39.66.1 Usage

vtkInteractorStyleImage allows the user to interactively manipulate (rotate, pan, zoomm etc.) the camera. vtkInteractorStyleImage is specially designed to work with images that are being rendered with vtkImage-Actor. Several events are overloaded from its superclass vtkInteractorStyle, hence the mouse bindings are different. (The bindings keep the camera's view plane normal perpendicular to the x-y plane.) In summary the mouse events are as follows: + Left Mouse button triggers window level events + CTRL Left Mouse spins the camera around its view plane normal + SHIFT Left Mouse pans the camera + CTRL SHIFT Left Mouse dollys (a positional zoom) the camera + Middle mouse button pans the camera + Right mouse button dollys the camera. + SHIFT Right Mouse triggers pick events

Note that the renderer's actors are not moved; instead the camera is moved.

To create an instance of class vtkInteractorStyleImage, simply invoke its constructor as follows

```
obj = vtkInteractorStyleImage
```

39.66.2 Methods

The class vtkInteractorStyleImage has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleImage class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleImage = obj.NewInstance ()`
- `vtkInteractorStyleImage = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetWindowLevelStartPosition ()` - Some useful information for handling window level
- `int = obj. GetWindowLevelCurrentPosition ()` - Some useful information for handling window level
- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.

- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnChar ()` - Override the "fly-to" (f keypress) for images.
- `obj.WindowLevel ()`
- `obj.Pick ()`
- `obj.StartWindowLevel ()`
- `obj.EndWindowLevel ()`
- `obj.StartPick ()`
- `obj.EndPick ()`

39.67 vtkInteractorStyleJoystickActor

39.67.1 Usage

The class vtkInteractorStyleJoystickActor allows the user to interact with (rotate, zoom, etc.) separate objects in the scene independent of each other. The position of the mouse relative to the center of the object determines the speed of the object's motion. The mouse's velocity detemines the acceleration of the object's motion, so the object will continue moving even when the mouse is not moving. For a 3-button mouse, the left button is for rotation, the right button for zooming, the middle button for panning, and ctrl + left button for spinning. (With fewer mouse buttons, ctrl + shift + left button is for zooming, and shift + left button is for panning.)

To create an instance of class vtkInteractorStyleJoystickActor, simply invoke its constructor as follows

```
obj = vtkInteractorStyleJoystickActor
```

39.67.2 Methods

The class vtkInteractorStyleJoystickActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleJoystickActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleJoystickActor = obj.NewInstance ()`
- `vtkInteractorStyleJoystickActor = obj.SafeDownCast (vtkObject o)`
- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.

- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.Rotate ()`
- `obj.Spin ()`
- `obj.Pan ()`
- `obj.Dolly ()`
- `obj.UniformScale ()`

39.68 vtkInteractorStyleJoystickCamera

39.68.1 Usage

vtkInteractorStyleJoystickCamera allows the user to move (rotate, pan, etc.) the camera, the point of view for the scene. The position of the mouse relative to the center of the scene determines the speed at which the camera moves, and the speed of the mouse movement determines the acceleration of the camera, so the camera continues to move even if the mouse if not moving. For a 3-button mouse, the left button is for rotation, the right button for zooming, the middle button for panning, and ctrl + left button for spinning. (With fewer mouse buttons, ctrl + shift + left button is for zooming, and shift + left button is for panning.)

To create an instance of class vtkInteractorStyleJoystickCamera, simply invoke its constructor as follows

```
obj = vtkInteractorStyleJoystickCamera
```

39.68.2 Methods

The class vtkInteractorStyleJoystickCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleJoystickCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleJoystickCamera = obj.NewInstance ()`
- `vtkInteractorStyleJoystickCamera = obj.SafeDownCast (vtkObject o)`
- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.

- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMouseWheelForward ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMouseWheelBackward ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.Rotate ()`
- `obj.Spin ()`
- `obj.Pan ()`
- `obj.Dolly ()`

39.69 vtkInteractorStyleRubberBand2D

39.69.1 Usage

vtkInteractorStyleRubberBand2D manages interaction in a 2D view. Camera rotation is not allowed with this interactor style. The style also allows draws a rubber band using the left button. All camera changes invoke InteractionBeginEvent when the button is pressed, InteractionEvent when the mouse (or wheel) is moved, and InteractionEndEvent when the button is released. The bindings are as follows: Left mouse - Select (invokes a SelectionChangedEvent). Right mouse - Zoom. Middle mouse - Pan. Scroll wheel - Zoom.

To create an instance of class vtkInteractorStyleRubberBand2D, simply invoke its constructor as follows

```
obj = vtkInteractorStyleRubberBand2D
```

39.69.2 Methods

The class vtkInteractorStyleRubberBand2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleRubberBand2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleRubberBand2D = obj.NewInstance ()`
- `vtkInteractorStyleRubberBand2D = obj.SafeDownCast (vtkObject o)`
- `obj.OnLeftButtonDown ()`
- `obj.OnLeftButtonUp ()`

- `obj.OnMiddleButtonDown ()`
- `obj.OnMiddleButtonUp ()`
- `obj.OnRightButtonDown ()`
- `obj.OnRightButtonUp ()`
- `obj.OnMouseMove ()`
- `obj.OnMouseWheelForward ()`
- `obj.OnMouseWheelBackward ()`
- `obj.SetRenderOnMouseMove (bool )` - Whether to invoke a render when the mouse moves.
- `bool = obj.GetRenderOnMouseMove ()` - Whether to invoke a render when the mouse moves.
- `obj.RenderOnMouseMoveOn ()` - Whether to invoke a render when the mouse moves.
- `obj.RenderOnMouseMoveOff ()` - Whether to invoke a render when the mouse moves.
- `int = obj.GetInteraction ()` - Current interaction state

39.70 vtkInteractorStyleRubberBand3D

39.70.1 Usage

vtkInteractorStyleRubberBand3D manages interaction in a 3D view. The style also allows draws a rubber band using the left button. All camera changes invoke InteractionBeginEvent when the button is pressed, InteractionEvent when the mouse (or wheel) is moved, and InteractionEndEvent when the button is released. The bindings are as follows: Left mouse - Select (invokes a SelectionChangedEvent). Right mouse - Rotate. Shift + right mouse - Zoom. Middle mouse - Pan. Scroll wheel - Zoom.

To create an instance of class vtkInteractorStyleRubberBand3D, simply invoke its constructor as follows

```
obj = vtkInteractorStyleRubberBand3D
```

39.70.2 Methods

The class vtkInteractorStyleRubberBand3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleRubberBand3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleRubberBand3D = obj.NewInstance ()`
- `vtkInteractorStyleRubberBand3D = obj.SafeDownCast (vtkObject o)`
- `obj.OnLeftButtonDown ()`
- `obj.OnLeftButtonUp ()`
- `obj.OnMiddleButtonDown ()`
- `obj.OnMiddleButtonUp ()`
- `obj.OnRightButtonDown ()`

- `obj.OnRightButtonUp ()`
- `obj.OnMouseMove ()`
- `obj.OnMouseWheelForward ()`
- `obj.OnMouseWheelBackward ()`
- `obj.SetRenderOnMouseMove (bool )` - Whether to invoke a render when the mouse moves.
- `bool = obj.GetRenderOnMouseMove ()` - Whether to invoke a render when the mouse moves.
- `obj.RenderOnMouseMoveOn ()` - Whether to invoke a render when the mouse moves.
- `obj.RenderOnMouseMoveOff ()` - Whether to invoke a render when the mouse moves.
- `int = obj.GetInteraction ()` - Current interaction state

39.71 vtkInteractorStyleRubberBandPick

39.71.1 Usage

This interactor style allows the user to draw a rectangle in the render window by hitting 'r' and then using the left mouse button. When the mouse button is released, the attached picker operates on the pixel in the center of the selection rectangle. If the picker happens to be a vtkAreaPicker it will operate on the entire selection rectangle. When the 'p' key is hit the above pick operation occurs on a 1x1 rectangle. In other respects it behaves the same as its parent class.

To create an instance of class vtkInteractorStyleRubberBandPick, simply invoke its constructor as follows

```
obj = vtkInteractorStyleRubberBandPick
```

39.71.2 Methods

The class vtkInteractorStyleRubberBandPick has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleRubberBandPick class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleRubberBandPick = obj.NewInstance ()`
- `vtkInteractorStyleRubberBandPick = obj.SafeDownCast (vtkObject o)`
- `obj.StartSelect ()`
- `obj.OnMouseMove ()` - Event bindings
- `obj.OnLeftButtonDown ()` - Event bindings
- `obj.OnLeftButtonUp ()` - Event bindings
- `obj.OnChar ()` - Event bindings

39.72 vtkInteractorStyleRubberBandZoom

39.72.1 Usage

This interactor style allows the user to draw a rectangle in the render window using the left mouse button. When the mouse button is released, the current camera zooms by an amount determined from the shorter side of the drawn rectangle.

To create an instance of class vtkInteractorStyleRubberBandZoom, simply invoke its constructor as follows

```
obj = vtkInteractorStyleRubberBandZoom
```

39.72.2 Methods

The class vtkInteractorStyleRubberBandZoom has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleRubberBandZoom class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleRubberBandZoom = obj.NewInstance ()`
- `vtkInteractorStyleRubberBandZoom = obj.SafeDownCast (vtkObject o)`
- `obj.OnMouseMove ()` - Event bindings
- `obj.OnLeftButtonDown ()` - Event bindings
- `obj.OnLeftButtonUp ()` - Event bindings

39.73 vtkInteractorStyleSwitch

39.73.1 Usage

The class vtkInteractorStyleSwitch allows handles interactively switching between four interactor styles – joystick actor, joystick camera, trackball actor, and trackball camera. Type 'j' or 't' to select joystick or trackball, and type 'c' or 'a' to select camera or actor. The default interactor style is joystick camera.

To create an instance of class vtkInteractorStyleSwitch, simply invoke its constructor as follows

```
obj = vtkInteractorStyleSwitch
```

39.73.2 Methods

The class vtkInteractorStyleSwitch has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleSwitch class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleSwitch = obj.NewInstance ()`
- `vtkInteractorStyleSwitch = obj.SafeDownCast (vtkObject o)`
- `obj.SetInteractor (vtkRenderWindowInteractor iren)` - The sub styles need the interactor too.

- `obj.SetAutoAdjustCameraClippingRange (int value)` - We must override this method in order to pass the setting down to the underlying styles
- `vtkInteractorStyle = obj.GetCurrentStyle ()` - Set/Get current style
- `obj.SetCurrentStyleToJoystickActor ()` - Set/Get current style
- `obj.SetCurrentStyleToJoystickCamera ()` - Set/Get current style
- `obj.SetCurrentStyleToTrackballActor ()` - Set/Get current style
- `obj.SetCurrentStyleToTrackballCamera ()` - Set/Get current style
- `obj.OnChar ()` - Only care about the char event, which is used to switch between different styles.
- `obj.SetDefaultRenderer (vtkRenderer )` - Overridden from vtkInteractorObserver because the interactor styles used by this class must also be updated.
- `obj.SetCurrentRenderer (vtkRenderer )` - Overridden from vtkInteractorObserver because the interactor styles used by this class must also be updated.

39.74 vtkInteractorStyleTerrain

39.74.1 Usage

vtkInteractorStyleTerrain is used to manipulate a camera which is viewing a scene with a natural view up, e.g., terrain. The camera in such a scene is manipulated by specifying azimuth (angle around the view up vector) and elevation (the angle from the horizon).

The mouse binding for this class is as follows. Left mouse click followed rotates the camera around the focal point using both elevation and azimuth invocations on the camera. Left mouse motion in the horizontal direction results in azimuth motion; left mouse motion in the vertical direction results in elevation motion. Therefore, diagonal motion results in a combination of azimuth and elevation. (If the shift key is held during motion, then only one of elevation or azimuth is invoked, depending on the whether the mouse motion is primarily horizontal or vertical.) Middle mouse button pans the camera across the scene (again the shift key has a similar effect on limiting the motion to the vertical or horizontal direction. The right mouse is used to dolly (e.g., a type of zoom) towards or away from the focal point.

The class also supports some keypress events. The "r" key resets the camera. The "e" key invokes the exit callback and by default exits the program. The "f" key sets a new camera focal point and flys towards that point. The "u" key invokes the user event. The "3" key toggles between stereo and non-stero mode. The "l" key toggles on/off a latitude/longitude markers that can be used to estimate/control position.

To create an instance of class vtkInteractorStyleTerrain, simply invoke its constructor as follows

```
obj = vtkInteractorStyleTerrain
```

39.74.2 Methods

The class vtkInteractorStyleTerrain has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleTerrain class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleTerrain = obj.NewInstance ()`
- `vtkInteractorStyleTerrain = obj.SafeDownCast (vtkObject o)`

- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnChar ()` - Override the "fly-to" (f keypress) for images.
- `obj.Rotate ()`
- `obj.Pan ()`
- `obj.Dolly ()`
- `obj.SetLatLongLines (int )` - Turn on/off the latitude/longitude lines.
- `int = obj.GetLatLongLines ()` - Turn on/off the latitude/longitude lines.
- `obj.LatLongLinesOn ()` - Turn on/off the latitude/longitude lines.
- `obj.LatLongLinesOff ()` - Turn on/off the latitude/longitude lines.

39.75 vtkInteractorStyleTrackball

39.75.1 Usage

vtkInteractorStyleTrackball is an implementation of vtkInteractorStyle that defines the trackball style. It is now deprecated and as such a subclass of vtkInteractorStyleSwitch

To create an instance of class vtkInteractorStyleTrackball, simply invoke its constructor as follows

```
obj = vtkInteractorStyleTrackball
```

39.75.2 Methods

The class vtkInteractorStyleTrackball has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleTrackball class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleTrackball = obj.NewInstance ()`
- `vtkInteractorStyleTrackball = obj.SafeDownCast (vtkObject o)`

39.76 vtkInteractorStyleTrackballActor

39.76.1 Usage

vtkInteractorStyleTrackballActor allows the user to interact with (rotate, pan, etc.) objects in the scene indendent of each other. In trackball interaction, the magnitude of the mouse motion is proportional to the actor motion associated with a particular mouse binding. For example, small left-button motions cause small changes in the rotation of the actor around its center point.

The mouse bindings are as follows. For a 3-button mouse, the left button is for rotation, the right button for zooming, the middle button for panning, and ctrl + left button for spinning. (With fewer mouse buttons, ctrl + shift + left button is for zooming, and shift + left button is for panning.)

To create an instance of class vtkInteractorStyleTrackballActor, simply invoke its constructor as follows

```
obj = vtkInteractorStyleTrackballActor
```

39.76.2 Methods

The class vtkInteractorStyleTrackballActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleTrackballActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleTrackballActor = obj.NewInstance ()`
- `vtkInteractorStyleTrackballActor = obj.SafeDownCast (vtkObject o)`
- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.Rotate ()`
- `obj.Spin ()`
- `obj.Pan ()`
- `obj.Dolly ()`
- `obj.UniformScale ()`

39.77 vtkInteractorStyleTrackballCamera

39.77.1 Usage

vtkInteractorStyleTrackballCamera allows the user to interactively manipulate (rotate, pan, etc.) the camera, the viewpoint of the scene. In trackball interaction, the magnitude of the mouse motion is proportional to the camera motion associated with a particular mouse binding. For example, small left-button motions cause small changes in the rotation of the camera around its focal point. For a 3-button mouse, the left button is for rotation, the right button for zooming, the middle button for panning, and ctrl + left button for spinning. (With fewer mouse buttons, ctrl + shift + left button is for zooming, and shift + left button is for panning.)

To create an instance of class vtkInteractorStyleTrackballCamera, simply invoke its constructor as follows

```
obj = vtkInteractorStyleTrackballCamera
```

39.77.2 Methods

The class vtkInteractorStyleTrackballCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleTrackballCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleTrackballCamera = obj.NewInstance ()`
- `vtkInteractorStyleTrackballCamera = obj.SafeDownCast (vtkObject o)`
- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMouseWheelForward ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMouseWheelBackward ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.Rotate ()`
- `obj.Spin ()`

- `obj.Pan ()`
- `obj.Dolly ()`
- `obj.SetMotionFactor (double )` - Set the apparent sensitivity of the interactor style to mouse motion.
- `double = obj.GetMotionFactor ()` - Set the apparent sensitivity of the interactor style to mouse motion.

39.78 vtkInteractorStyleUnicam

39.78.1 Usage

UniCam is a camera interactor. Here, just the primary features of the UniCam technique are implemented. UniCam requires just one mouse button and supports context sensitive dollying, panning, and rotation. (In this implementation, it uses the right mouse button, leaving the middle and left available for other functions.) For more information, see the paper at:

ftp://ftp.cs.brown.edu/pub/papers/graphics/research/unicam.pdf

The following is a brief description of the UniCam Camera Controls. You can perform 3 operations on the camera: rotate, pan, and dolly the camera. All operations are reached through the right mouse button & mouse movements.

IMPORTANT: UniCam assumes there is an axis that makes sense as a "up" vector for the world. By default, this axis is defined to be the vector ¡0,0,1¿. You can set it explicitly for the data you are viewing with the 'SetWorldUpVector(..)' method in C++, or similarly in Tcl/Tk (or other interpreted languages).

1. ROTATE:

Position the cursor over the point you wish to rotate around and press and release the left mouse button. A 'focus dot' appears indicating the point that will be the center of rotation. To rotate, press and hold the left mouse button and drag the mouse.. release the button to complete the rotation.

Rotations can be done without placing a focus dot first by moving the mouse cursor to within 10left button followed by dragging the mouse. The last focus dot position will be re-used.

2. PAN:

Click and hold the left mouse button, and initially move the mouse left or right. The point under the initial pick will pick correlate w/ the mouse tip– (i.e., direct manipulation).

3. DOLLY (+ PAN):

Click and hold the left mouse button, and initially move the mouse up or down. Moving the mouse down will dolly towards the picked point, and moving the mouse up will dolly away from it. Dollying occurs relative to the picked point which simplifies the task of dollying towards a region of interest. Left and right mouse movements will pan the camera left and right.

To create an instance of class vtkInteractorStyleUnicam, simply invoke its constructor as follows

```
obj = vtkInteractorStyleUnicam
```

39.78.2 Methods

The class vtkInteractorStyleUnicam has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleUnicam class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleUnicam = obj.NewInstance ()`
- `vtkInteractorStyleUnicam = obj.SafeDownCast (vtkObject o)`

- `obj.SetWorldUpVector (double a[3])`
- `obj.SetWorldUpVector (double x, double y, double z)`
- `double = obj. GetWorldUpVector ()`
- `obj.OnMouseMove ()` - Concrete implementation of event bindings
- `obj.OnLeftButtonDown ()` - Concrete implementation of event bindings
- `obj.OnLeftButtonUp ()` - Concrete implementation of event bindings
- `obj.OnLeftButtonMove ()` - Concrete implementation of event bindings
- `obj.OnTimer ()` - OnTimer calls RotateCamera, RotateActor etc which should be overridden by style subclasses.

39.79 vtkInteractorStyleUser

39.79.1 Usage

The most common way to customize user interaction is to write a subclass of vtkInteractorStyle: vtkInteractorStyleUser allows you to customize the interaction to without subclassing vtkInteractorStyle. This is particularly useful for setting up custom interaction modes in scripting languages such as Tcl and Python. This class allows you to hook into the MouseMove, ButtonPress/Release, KeyPress/Release, etc. events. If you want to hook into just a single mouse button, but leave the interaction modes for the others unchanged, you must use e.g. SetMiddleButtonPressMethod() instead of the more general SetButtonPressMethod().

To create an instance of class vtkInteractorStyleUser, simply invoke its constructor as follows

```
obj = vtkInteractorStyleUser
```

39.79.2 Methods

The class vtkInteractorStyleUser has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleUser class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleUser = obj.NewInstance ()`
- `vtkInteractorStyleUser = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetLastPos ()` - Get the most recent mouse position during mouse motion. In your user interaction method, you must use this to track the mouse movement. Do not use GetEventPosition(), which records the last position where a mouse button was pressed.
- `int = obj. GetOldPos ()` - Get the previous mouse position during mouse motion, or after a key press. This can be used to calculate the relative displacement of the mouse.
- `int = obj.GetShiftKey ()` - Test whether modifiers were held down when mouse button or key was pressed
- `int = obj.GetCtrlKey ()` - Test whether modifiers were held down when mouse button or key was pressed
- `int = obj.GetChar ()` - Get the character for a Char event.

- `string = obj.GetKeySym ()` - Get the KeySym (in the same format as Tk KeySyms) for a KeyPress or KeyRelease method.
- `int = obj.GetButton ()` - Get the mouse button that was last pressed inside the window (returns zero when the button is released).
- `obj.OnMouseMove ()` - Generic event bindings
- `obj.OnLeftButtonDown ()` - Generic event bindings
- `obj.OnLeftButtonUp ()` - Generic event bindings
- `obj.OnMiddleButtonDown ()` - Generic event bindings
- `obj.OnMiddleButtonUp ()` - Generic event bindings
- `obj.OnRightButtonDown ()` - Generic event bindings
- `obj.OnRightButtonUp ()` - Generic event bindings
- `obj.OnChar ()` - Keyboard functions
- `obj.OnKeyPress ()` - Keyboard functions
- `obj.OnKeyRelease ()` - Keyboard functions
- `obj.OnExpose ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnConfigure ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnEnter ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnLeave ()` - These are more esoteric events, but are useful in some cases.
- `obj.OnTimer ()`

39.80 vtkIVExporter

39.80.1 Usage

vtkIVExporter is a concrete subclass of vtkExporter that writes OpenInventor 2.0 files.

To create an instance of class vtkIVExporter, simply invoke its constructor as follows

```
obj = vtkIVExporter
```

39.80.2 Methods

The class vtkIVExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIVExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIVExporter = obj.NewInstance ()`
- `vtkIVExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the name of the OpenInventor file to write.
- `string = obj.GetFileName ()` - Specify the name of the OpenInventor file to write.

39.81 vtkLabeledDataMapper

39.81.1 Usage

vtkLabeledDataMapper is a mapper that renders text at dataset points. Various items can be labeled including point ids, scalars, vectors, normals, texture coordinates, tensors, and field data components.

The format with which the label is drawn is specified using a printf style format string. The font attributes of the text can be set through the vtkTextProperty associated to this mapper.

By default, all the components of multi-component data such as vectors, normals, texture coordinates, tensors, and multi-component scalars are labeled. However, you can specify a single component if you prefer. (Note: the label format specifies the format to use for a single component. The label is creating by looping over all components and using the label format to render each component.)

To create an instance of class vtkLabeledDataMapper, simply invoke its constructor as follows

```
obj = vtkLabeledDataMapper
```

39.81.2 Methods

The class vtkLabeledDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabeledDataMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabeledDataMapper = obj.NewInstance ()`
- `vtkLabeledDataMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the labels. This should be a printf-style format string.

  By default, the mapper will try to print each component of the tuple using a sane format: doubles, format, set it here. You can do things like limit the number of significant digits, add prefixes/suffixes, basically anything that printf can do. If you only want to print one component of a vector, see the ivar LabeledComponent.

- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the labels. This should be a printf-style format string.

  By default, the mapper will try to print each component of the tuple using a sane format: doubles, format, set it here. You can do things like limit the number of significant digits, add prefixes/suffixes, basically anything that printf can do. If you only want to print one component of a vector, see the ivar LabeledComponent.

- `obj.SetLabeledComponent (int )` - Set/Get the component number to label if the data to print has more than one component. For example, all the components of scalars, vectors, normals, etc. are labeled by default (LabeledComponent=(-1)). However, if this ivar is nonnegative, then only the one component specified is labeled.

- `int = obj.GetLabeledComponent ()` - Set/Get the component number to label if the data to print has more than one component. For example, all the components of scalars, vectors, normals, etc. are labeled by default (LabeledComponent=(-1)). However, if this ivar is nonnegative, then only the one component specified is labeled.

- `obj.SetFieldDataArray (int arrayIndex)` - Set/Get the field data array to label. This instance variable is only applicable if field data is labeled. This will clear FieldDataName when set.

- `int = obj.GetFieldDataArray ()` - Set/Get the field data array to label. This instance variable is only applicable if field data is labeled. This will clear FieldDataName when set.
- `obj.SetFieldDataName (string arrayName)` - Set/Get the name of the field data array to label. This instance variable is only applicable if field data is labeled. This will override FieldDataArray when set.
- `string = obj.GetFieldDataName ()` - Set/Get the name of the field data array to label. This instance variable is only applicable if field data is labeled. This will override FieldDataArray when set.
- `obj.SetInput (vtkDataObject )` - Set the input dataset to the mapper. This mapper handles any type of data.
- `vtkDataSet = obj.GetInput ()` - Use GetInputDataObject() to get the input data object for composite datasets.
- `obj.SetLabelMode (int )` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `int = obj.GetLabelMode ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelIds ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelScalars ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelVectors ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelNormals ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelTCoords ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelTensors ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelModeToLabelFieldData ()` - Specify which data to plot: IDs, scalars, vectors, normals, texture coords, tensors, or field data. If the data has more than one component, use the method SetLabeledComponent to control which components to plot. The default is VTK_LABEL_IDS.
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the text property. If an integer argument is provided, you may provide different text properties for different label types. The type is determined by an optional type input array.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the text property. If an integer argument is provided, you may provide different text properties for different label types. The type is determined by an optional type input array.

- `obj.SetLabelTextProperty (vtkTextProperty p, int type)` - Set/Get the text property. If an integer argument is provided, you may provide different text properties for different label types. The type is determined by an optional type input array.

- `vtkTextProperty = obj.GetLabelTextProperty (int type)` - Set/Get the text property. If an integer argument is provided, you may provide different text properties for different label types. The type is determined by an optional type input array.

- `obj.RenderOpaqueGeometry (vtkViewport viewport, vtkActor2D actor)` - Draw the text to the screen at each input point.

- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Draw the text to the screen at each input point.

- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor.

- `vtkTransform = obj.GetTransform ()` - The transform to apply to the labels before mapping to 2D.

- `obj.SetTransform (vtkTransform t)` - The transform to apply to the labels before mapping to 2D.

- `int = obj.GetCoordinateSystem ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.

- `obj.SetCoordinateSystem (int )` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.

- `int = obj.GetCoordinateSystemMinValue ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.

- `int = obj.GetCoordinateSystemMaxValue ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.

- `obj.CoordinateSystemWorld ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.

- `obj.CoordinateSystemDisplay ()` - Return the modified time for this object.

- `long = obj.GetMTime ()` - Return the modified time for this object.

39.82 vtkLabeledTreeMapDataMapper

39.82.1 Usage

vtkLabeledTreeMapDataMapper is a mapper that renders text on a tree map. A tree map is a vtkTree with an associated 4-tuple array used for storing the boundary rectangle for each vertex in the tree. The user must specify the array name used for storing the rectangles.

The mapper iterates through the tree and attempts and renders a label inside the vertex's rectangle as long as the following conditions hold: 1. The vertex level is within the range of levels specified for labeling. 2. The label can fully fit inside its box. 3. The label does not overlap an ancestor's label.

To create an instance of class vtkLabeledTreeMapDataMapper, simply invoke its constructor as follows

```
obj = vtkLabeledTreeMapDataMapper
```

39.82.2 Methods

The class vtkLabeledTreeMapDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabeledTreeMapDataMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabeledTreeMapDataMapper = obj.NewInstance ()`
- `vtkLabeledTreeMapDataMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOpaqueGeometry (vtkViewport viewport, vtkActor2D actor)` - Draw the text to the screen at each input point.
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Draw the text to the screen at each input point.
- `vtkTree = obj.GetInputTree ()` - The input to this filter.
- `obj.SetRectanglesArrayName (string name)` - The name of the 4-tuple array used for
- `int = obj.GetClipTextMode ()` - Indicates if the label can be displayed clipped by the Window mode = 0 - ok to clip labels 1 - auto center labels w/r to the area of the vertex's clipped region
- `obj.SetClipTextMode (int )` - Indicates if the label can be displayed clipped by the Window mode = 0 - ok to clip labels 1 - auto center labels w/r to the area of the vertex's clipped region
- `int = obj.GetChildMotion ()` - Indicates if the label can be moved by its ancestors
- `obj.SetChildMotion (int )` - Indicates if the label can be moved by its ancestors
- `int = obj.GetDynamicLevel ()` - Indicates at which level labeling should be dynamic
- `obj.SetDynamicLevel (int )` - Indicates at which level labeling should be dynamic
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor.
- `obj.SetFontSizeRange (int maxSize, int minSize, int delta)` - The range of font sizes to use when rendering the labels.
- `obj.GetFontSizeRange (int range[3])` - The range of font sizes to use when rendering the labels.
- `obj.SetLevelRange (int startLevel, int endLevel)` - The range of levels to attempt to label. The level of a vertex is the length of the path to the root (the root has level 0).
- `obj.GetLevelRange (int range[2])` - The range of levels to attempt to label. The level of a vertex is the length of the path to the root (the root has level 0).

39.83 vtkLabelHierarchy

39.83.1 Usage

This class represents labels in a hierarchy used to denote rendering priority. A binary tree of labels is maintained that subdivides the bounds of the of the label anchors spatially. Which level of the tree a label occupies determines its priority; those at higher levels of the tree will be more likely to render than those at lower levels of the tree.

Pass vtkLabelHierarchy objects to a vtkLabelPlacementMapper filter for dynamic, non-overlapping, per-frame placement of labels.

Note that if we have a d-dimensional binary tree and we want a fixed number n of labels in each node (all nodes, not just leaves), we can compute the depth of tree required assuming a uniform distribution of points. Given a total of N points we know that $\frac{N}{|T|} = n$, where $|T|$ is the cardinality of the tree (i.e., the number of nodes it contains). Because we have a uniform distribution, the tree will be uniformly subdivided and thus $|T| = 1 + 2^d + \left(2^d\right)^2 + \cdots + \left(2^d\right)^k$, where d is the dimensionality of the input points (fixed at 3 for now). As k becomes large, $|T|pprox2\left(2^d\right)^k$. Using this approximation, we can solve for k:

$$k = \frac{\log \frac{N}{2n}}{\log 2^d}$$

Given a set of N input label anchors, we'll compute k and then bin the anchors into tree nodes at level k of the tree. After this, all the nodes will be in the leaves of the tree and those leaves will be at the k-th level; no anchors will be in levels $1, 2, \ldots, k-1$. To fix that, we'll choose to move some anchors upwards. The exact number to move upwards depends on TargetLabelCount. We'll move as many up as required to have TargetLabelCount at each node.

You should avoid situations where MaximumDepth does not allow for TargetLabelCount or fewer entries at each node. The MaximumDepth is a hard limit while TargetLabelCount is a suggested optimum. You will end up with many more than TargetLabelCount entries per node and things will be sloooow.

To create an instance of class vtkLabelHierarchy, simply invoke its constructor as follows

```
obj = vtkLabelHierarchy
```

39.83.2 Methods

The class vtkLabelHierarchy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelHierarchy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelHierarchy = obj.NewInstance ()`
- `vtkLabelHierarchy = obj.SafeDownCast (vtkObject o)`
- `obj.SetPoints (vtkPoints )` - Override SetPoints so we can reset the hierarchy when the points change.
- `obj.ComputeHierarchy ()` - Fill the hierarchy with the input labels.
- `obj.SetTargetLabelCount (int )` - The number of labels that is ideally present at any octree node. It is best if this is a multiple of 2^d.
- `int = obj.GetTargetLabelCount ()` - The number of labels that is ideally present at any octree node. It is best if this is a multiple of 2^d.

- `obj.SetMaximumDepth (int )` - The maximum depth of the octree.
- `int = obj.GetMaximumDepth ()` - The maximum depth of the octree.
- `obj.SetTextProperty (vtkTextProperty tprop)` - The default text property assigned to labels in this hierarchy.
- `vtkTextProperty = obj.GetTextProperty ()` - The default text property assigned to labels in this hierarchy.
- `obj.SetPriorities (vtkDataArray arr)` - Set/get the array specifying the importance (priority) of each label.
- `vtkDataArray = obj.GetPriorities ()` - Set/get the array specifying the importance (priority) of each label.
- `obj.SetLabels (vtkAbstractArray arr)` - Set/get the array specifying the text of each label.
- `vtkAbstractArray = obj.GetLabels ()` - Set/get the array specifying the text of each label.
- `obj.SetOrientations (vtkDataArray arr)` - Set/get the array specifying the orientation of each label.
- `vtkDataArray = obj.GetOrientations ()` - Set/get the array specifying the orientation of each label.
- `obj.SetIconIndices (vtkIntArray arr)` - Set/get the array specifying the icon index of each label.
- `vtkIntArray = obj.GetIconIndices ()` - Set/get the array specifying the icon index of each label.
- `obj.SetSizes (vtkDataArray arr)` - Set/get the array specifying the size of each label.
- `vtkDataArray = obj.GetSizes ()` - Set/get the array specifying the size of each label.
- `obj.SetBoundedSizes (vtkDataArray arr)` - Set/get the array specifying the maximum width and height in world coordinates of each label.
- `vtkDataArray = obj.GetBoundedSizes ()` - Set/get the array specifying the maximum width and height in world coordinates of each label.
- `obj.GetDiscreteNodeCoordinatesFromWorldPoint (int ijk[3], double pt[3], int level)` - Given a depth in the hierarchy (level) and a point pt in world space, compute ijk. This is used to find other octree nodes at the same level that are within the search radius for candidate labels to be placed. It is called with pt set to the camera eye point and pythagorean quadruples increasingly distant from the origin are added to ijk to identify octree nodes whose labels should be placed. @param[out] ijk - discrete coordinates of the octree node at level containing pt. @param[in] pt - input world point coordinates @param[in] level - input octree level to be considered
- `vtkIdType = obj.GetNumberOfCells ()` - Inherited members (from vtkDataSet)
- `vtkCell = obj.GetCell (vtkIdType )` - Inherited members (from vtkDataSet)
- `obj.GetCell (vtkIdType , vtkGenericCell )` - Inherited members (from vtkDataSet)
- `int = obj.GetCellType (vtkIdType )` - Inherited members (from vtkDataSet)
- `obj.GetCellPoints (vtkIdType , vtkIdList )` - Inherited members (from vtkDataSet)
- `obj.GetPointCells (vtkIdType , vtkIdList )` - Inherited members (from vtkDataSet)
- `int = obj.GetMaxCellSize ()` - Inherited members (from vtkDataSet)
- `vtkPoints = obj.GetCenterPts ()` - Provide access to original coordinates of sets of coincident points

- `vtkCoincidentPoints = obj.GetCoincidentPoints ()` - Provide access to the set of coincident points that have been perturbed by the hierarchy in order to render labels for each without overlap.

39.84 vtkLabelHierarchyAlgorithm

39.84.1 Usage

vtkLabelHierarchyAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be DataObjects. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as RequestData and RequestInformation. You should implement RequestData(request, inputVec, outputVec) in subclasses.

To create an instance of class vtkLabelHierarchyAlgorithm, simply invoke its constructor as follows

```
obj = vtkLabelHierarchyAlgorithm
```

39.84.2 Methods

The class vtkLabelHierarchyAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelHierarchyAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelHierarchyAlgorithm = obj.NewInstance ()`
- `vtkLabelHierarchyAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkLabelHierarchy = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkLabelHierarchy = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `vtkLabelHierarchy = obj.GetLabelHierarchyInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

39.85 vtkLabelHierarchyCompositeIterator

39.85.1 Usage

Iterates over child iterators in a round-robin order. Each iterator may have its own count, which is the number of times it is repeated until moving to the next iterator.

For example, if you initialize the iterator with

```
it->AddIterator(A, 1);
it->AddIterator(B, 3);
```

The order of iterators will be A,B,B,B,A,B,B,B,...

To create an instance of class vtkLabelHierarchyCompositeIterator, simply invoke its constructor as follows

```
obj = vtkLabelHierarchyCompositeIterator
```

39.85.2 Methods

The class vtkLabelHierarchyCompositeIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelHierarchyCompositeIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelHierarchyCompositeIterator = obj.NewInstance ()`
- `vtkLabelHierarchyCompositeIterator = obj.SafeDownCast (vtkObject o)`
- `obj.AddIterator (vtkLabelHierarchyIterator it)` - Adds a label iterator to this composite iterator. The second optional argument is the number of times to repeat the iterator before moving to the next one round-robin style. Default is 1.
- `obj.AddIterator (vtkLabelHierarchyIterator it, int count)` - Adds a label iterator to this composite iterator. The second optional argument is the number of times to repeat the iterator before moving to the next one round-robin style. Default is 1.
- `obj.ClearIterators ()` - Remove all iterators from this composite iterator.
- `obj.Begin (vtkIdTypeArray )` - Initializes the iterator. lastLabels is an array holding labels which should be traversed before any other labels in the hierarchy. This could include labels placed during a previous rendering or a label located under the mouse pointer. You may pass a null pointer.
- `obj.Next ()` - Advance the iterator.
- `bool = obj.IsAtEnd ()` - Returns true if the iterator is at the end.

- `vtkIdType = obj.GetLabelId ()` - Retrieves the current label id.
- `vtkLabelHierarchy = obj.GetHierarchy ()` - Retrieve the current label hierarchy.
- `obj.BoxNode ()` - Not implemented.
- `obj.BoxAllNodes (vtkPolyData )`

39.86 vtkLabelHierarchyIterator

39.86.1 Usage

Abstract superclass for iterators over vtkLabelHierarchy.

To create an instance of class vtkLabelHierarchyIterator, simply invoke its constructor as follows

```
obj = vtkLabelHierarchyIterator
```

39.86.2 Methods

The class vtkLabelHierarchyIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelHierarchyIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelHierarchyIterator = obj.NewInstance ()`
- `vtkLabelHierarchyIterator = obj.SafeDownCast (vtkObject o)`
- `obj.Begin (vtkIdTypeArray )` - Advance the iterator.
- `obj.Next ()` - Returns true if the iterator is at the end.
- `bool = obj.IsAtEnd ()` - Retrieves the current label location.
- `obj.GetPoint (double x[3])` - Retrieves the current label location.
- `obj.GetSize (double sz[2])` - Retrieves the current label size.
- `obj.GetBoundedSize (double sz[2])` - Retrieves the current label maximum width in world coordinates.
- `int = obj.GetType ()` - Retrieves the current label type.
- `double = obj.GetOrientation ()` - Retrieves the current label orientation.
- `vtkIdType = obj.GetLabelId ()` - Get the label hierarchy associated with the current label.
- `vtkLabelHierarchy = obj.GetHierarchy ()` - Get the label hierarchy associated with the current label.
- `obj.SetTraversedBounds (vtkPolyData )` - Sets a polydata to fill with geometry representing the bounding boxes of the traversed octree nodes.
- `obj.BoxNode ()` - Add a representation to TraversedBounds for the current octree node. This should be called by subclasses inside Next(). Does nothing if TraversedBounds is NULL.

- `obj.BoxAllNodes (vtkPolyData )` - Add a representation for all existing octree nodes to the specified polydata. This is equivalent to setting TraversedBounds, iterating over the entire hierarchy, and then resetting TraversedBounds to its original value.
- `obj.SetAllBounds (int )` - Set/get whether all nodes in the hierarchy should be added to the TraversedBounds polydata or only those traversed. When non-zero, all nodes will be added. By default, AllBounds is 0.
- `int = obj.GetAllBounds ()` - Set/get whether all nodes in the hierarchy should be added to the TraversedBounds polydata or only those traversed. When non-zero, all nodes will be added. By default, AllBounds is 0.

39.87 vtkLabelPlacementMapper

39.87.1 Usage

To use this mapper, first send your data through vtkPointSetToLabelHierarchy, which takes a set of points, associates special arrays to the points (label, priority, etc.), and produces a prioritized spatial tree of labels.

This mapper then takes that hierarchy (or hierarchies) as input, and every frame will decide which labels and/or icons to place in order of priority, and will render only those labels/icons. A label render strategy is used to render the labels, and can use e.g. FreeType or Qt for rendering.

To create an instance of class vtkLabelPlacementMapper, simply invoke its constructor as follows

```
obj = vtkLabelPlacementMapper
```

39.87.2 Methods

The class vtkLabelPlacementMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelPlacementMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelPlacementMapper = obj.NewInstance ()`
- `vtkLabelPlacementMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Draw non-overlapping labels to the screen.
- `obj.SetRenderStrategy (vtkLabelRenderStrategy s)` - Set the label rendering strategy.
- `vtkLabelRenderStrategy = obj.GetRenderStrategy ()` - Set the label rendering strategy.
- `obj.SetMaximumLabelFraction (double )` - The maximum fraction of the screen that the labels may cover. Label placement stops when this fraction is reached.
- `double = obj.GetMaximumLabelFractionMinValue ()` - The maximum fraction of the screen that the labels may cover. Label placement stops when this fraction is reached.
- `double = obj.GetMaximumLabelFractionMaxValue ()` - The maximum fraction of the screen that the labels may cover. Label placement stops when this fraction is reached.
- `double = obj.GetMaximumLabelFraction ()` - The maximum fraction of the screen that the labels may cover. Label placement stops when this fraction is reached.

- `obj.SetIteratorType (int )` - The type of iterator used when traversing the labels. May be vtkLabelHierarchy::FRUSTUM or vtkLabelHierarchy::FULL_SORT
- `int = obj.GetIteratorType ()` - The type of iterator used when traversing the labels. May be vtkLabelHierarchy::FRUSTUM or vtkLabelHierarchy::FULL_SORT
- `obj.SetUseUnicodeStrings (bool )` - Set whether, or not, to use unicode strings.
- `bool = obj.GetUseUnicodeStrings ()` - Set whether, or not, to use unicode strings.
- `obj.UseUnicodeStringsOn ()` - Set whether, or not, to use unicode strings.
- `obj.UseUnicodeStringsOff ()` - Set whether, or not, to use unicode strings.
- `bool = obj.GetPositionsAsNormals ()` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `obj.SetPositionsAsNormals (bool )` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `obj.PositionsAsNormalsOn ()` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `obj.PositionsAsNormalsOff ()` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `bool = obj.GetGeneratePerturbedLabelSpokes ()` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `obj.SetGeneratePerturbedLabelSpokes (bool )` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `obj.GeneratePerturbedLabelSpokesOn ()` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `obj.GeneratePerturbedLabelSpokesOff ()` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `bool = obj.GetUseDepthBuffer ()` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.SetUseDepthBuffer (bool )` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.UseDepthBufferOn ()` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.UseDepthBufferOff ()` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.SetPlaceAllLabels (bool )` - Tells the placer to place every label regardless of overlap. Off by default.
- `bool = obj.GetPlaceAllLabels ()` - Tells the placer to place every label regardless of overlap. Off by default.
- `obj.PlaceAllLabelsOn ()` - Tells the placer to place every label regardless of overlap. Off by default.

- `obj.PlaceAllLabelsOff ()` - Tells the placer to place every label regardless of overlap. Off by default.
- `obj.SetOutputTraversedBounds (bool )` - Whether to render traversed bounds. Off by default.
- `bool = obj.GetOutputTraversedBounds ()` - Whether to render traversed bounds. Off by default.
- `obj.OutputTraversedBoundsOn ()` - Whether to render traversed bounds. Off by default.
- `obj.OutputTraversedBoundsOff ()` - Whether to render traversed bounds. Off by default.
- `obj.SetShape (int )` - The shape of the label background, should be one of the values in the LabelShape enumeration.
- `int = obj.GetShapeMinValue ()` - The shape of the label background, should be one of the values in the LabelShape enumeration.
- `int = obj.GetShapeMaxValue ()` - The shape of the label background, should be one of the values in the LabelShape enumeration.
- `int = obj.GetShape ()` - The shape of the label background, should be one of the values in the LabelShape enumeration.
- `obj.SetShapeToNone ()` - The shape of the label background, should be one of the values in the LabelShape enumeration.
- `obj.SetShapeToRect ()` - The shape of the label background, should be one of the values in the LabelShape enumeration.
- `obj.SetShapeToRoundedRect ()` - The style of the label background shape, should be one of the values in the LabelStyle enumeration.
- `obj.SetStyle (int )` - The style of the label background shape, should be one of the values in the LabelStyle enumeration.
- `int = obj.GetStyleMinValue ()` - The style of the label background shape, should be one of the values in the LabelStyle enumeration.
- `int = obj.GetStyleMaxValue ()` - The style of the label background shape, should be one of the values in the LabelStyle enumeration.
- `int = obj.GetStyle ()` - The style of the label background shape, should be one of the values in the LabelStyle enumeration.
- `obj.SetStyleToFilled ()` - The style of the label background shape, should be one of the values in the LabelStyle enumeration.
- `obj.SetStyleToOutline ()` - The size of the margin on the label background shape. Default is 5.
- `obj.SetMargin (double )` - The size of the margin on the label background shape. Default is 5.
- `double = obj.GetMargin ()` - The size of the margin on the label background shape. Default is 5.
- `obj.SetBackgroundColor (double , double , double )` - The color of the background shape.
- `obj.SetBackgroundColor (double  a[3])` - The color of the background shape.
- `double = obj. GetBackgroundColor ()` - The color of the background shape.
- `obj.SetBackgroundOpacity (double )` - The opacity of the background shape.
- `double = obj.GetBackgroundOpacityMinValue ()` - The opacity of the background shape.
- `double = obj.GetBackgroundOpacityMaxValue ()` - The opacity of the background shape.
- `double = obj.GetBackgroundOpacity ()` - The opacity of the background shape.
- `vtkCoordinate = obj.GetAnchorTransform ()` - Get the transform for the anchor points.

39.88 vtkLabelPlacer

39.88.1 Usage

¡b¿This class is deprecated and will be removed from VTK in a future release. Use vtkLabelPlacementMapper instead.¡/b¿

This should probably be a mapper unto itself (given that the polydata output could be large and will realistically always be iterated over exactly once before being tossed for the next frame of the render).

In any event, it takes as input one (or more, eventually) vtkLabelHierarchies that represent prioritized lists of labels sorted by their placement in space. As output, it provides vtkPolyData containing only VTK_QUAD cells, each representing a single label from the input. Each quadrilateral has cell data indicating what label in the input it corresponds to (via an array named "LabelId").

To create an instance of class vtkLabelPlacer, simply invoke its constructor as follows

```
obj = vtkLabelPlacer
```

39.88.2 Methods

The class vtkLabelPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelPlacer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelPlacer = obj.NewInstance ()`
- `vtkLabelPlacer = obj.SafeDownCast (vtkObject o)`
- `vtkRenderer = obj.GetRenderer ()`
- `obj.SetRenderer (vtkRenderer )`
- `vtkCoordinate = obj.GetAnchorTransform ()`
- `obj.SetGravity (int gravity)` - The placement of the label relative to the anchor point.
- `int = obj.GetGravity ()` - The placement of the label relative to the anchor point.
- `obj.SetMaximumLabelFraction (double )` - The maximum amount of screen space labels can take up before placement terminates.
- `double = obj.GetMaximumLabelFractionMinValue ()` - The maximum amount of screen space labels can take up before placement terminates.
- `double = obj.GetMaximumLabelFractionMaxValue ()` - The maximum amount of screen space labels can take up before placement terminates.
- `double = obj.GetMaximumLabelFraction ()` - The maximum amount of screen space labels can take up before placement terminates.
- `obj.SetIteratorType (int )` - The type of iterator used when traversing the labels. May be vtkLabelHierarchy::FRUSTUM or vtkLabelHierarchy::FULL_SORT.
- `int = obj.GetIteratorType ()` - The type of iterator used when traversing the labels. May be vtkLabelHierarchy::FRUSTUM or vtkLabelHierarchy::FULL_SORT.
- `obj.SetUseUnicodeStrings (bool )` - Set whether, or not, to use unicode strings.

- `bool = obj.GetUseUnicodeStrings ()` - Set whether, or not, to use unicode strings.
- `obj.UseUnicodeStringsOn ()` - Set whether, or not, to use unicode strings.
- `obj.UseUnicodeStringsOff ()` - Set whether, or not, to use unicode strings.
- `long = obj.GetMTime ()`
- `bool = obj.GetPositionsAsNormals ()` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `obj.SetPositionsAsNormals (bool )` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `obj.PositionsAsNormalsOn ()` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `obj.PositionsAsNormalsOff ()` - Use label anchor point coordinates as normal vectors and eliminate those pointing away from the camera. Valid only when points are on a sphere centered at the origin (such as a 3D geographic view). Off by default.
- `bool = obj.GetGeneratePerturbedLabelSpokes ()` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `obj.SetGeneratePerturbedLabelSpokes (bool )` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `obj.GeneratePerturbedLabelSpokesOn ()` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `obj.GeneratePerturbedLabelSpokesOff ()` - Enable drawing spokes (lines) to anchor point coordinates that were perturbed for being coincident with other anchor point coordinates.
- `bool = obj.GetUseDepthBuffer ()` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.SetUseDepthBuffer (bool )` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.UseDepthBufferOn ()` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `obj.UseDepthBufferOff ()` - Use the depth buffer to test each label to see if it should not be displayed if it would be occluded by other objects in the scene. Off by default.
- `bool = obj.GetOutputTraversedBounds ()` - In the second output, output the geometry of the traversed octree nodes.
- `obj.SetOutputTraversedBounds (bool )` - In the second output, output the geometry of the traversed octree nodes.
- `obj.OutputTraversedBoundsOn ()` - In the second output, output the geometry of the traversed octree nodes.
- `obj.OutputTraversedBoundsOff ()` - In the second output, output the geometry of the traversed octree nodes.
- `int = obj.GetOutputCoordinateSystem ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.

- `obj.SetOutputCoordinateSystem (int )` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.
- `int = obj.GetOutputCoordinateSystemMinValue ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.
- `int = obj.GetOutputCoordinateSystemMaxValue ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.
- `obj.OutputCoordinateSystemWorld ()` - Set/get the coordinate system used for output labels. The output datasets may have point coordinates reported in the world space or display space.
- `obj.OutputCoordinateSystemDisplay ()`

39.89 vtkLabelRenderStrategy

39.89.1 Usage

These methods should only be called within a mapper.

To create an instance of class vtkLabelRenderStrategy, simply invoke its constructor as follows

```
obj = vtkLabelRenderStrategy
```

39.89.2 Methods

The class vtkLabelRenderStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelRenderStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelRenderStrategy = obj.NewInstance ()`
- `vtkLabelRenderStrategy = obj.SafeDownCast (vtkObject o)`
- `bool = obj.SupportsRotation ()` - Whether the text rendering strategy supports bounded size. The superclass returns true. Subclasses should override this to return the appropriate value. Subclasses that return true from this method should implement the version of RenderLabel() that takes a maximum size (see RenderLabel()).
- `bool = obj.SupportsBoundedSize ()` - Set the renderer associated with this strategy.
- `obj.SetRenderer (vtkRenderer ren)` - Set the renderer associated with this strategy.
- `vtkRenderer = obj.GetRenderer ()` - Set the renderer associated with this strategy.
- `obj.SetDefaultTextProperty (vtkTextProperty tprop)` - Set the default text property for the strategy.
- `vtkTextProperty = obj.GetDefaultTextProperty ()` - Set the default text property for the strategy.
- `obj.StartFrame ()` - End a rendering frame.
- `obj.EndFrame ()` - Release any graphics resources that are being consumed by this strategy. The parameter window could be used to determine which graphic resources to release.
- `obj.ReleaseGraphicsResources (vtkWindow )`

39.90 vtkLabelSizeCalculator

39.90.1 Usage

This filter takes an input dataset, an array to process (which must be a string array), and a text property. It creates a new output array (named "LabelSize" by default) with 4 components per tuple that contain the width, height, horizontal offset, and descender height (in that order) of each string in the array.

Use the inherited SelectInputArrayToProcess to indicate a string array. In no input array is specified, the first of the following that is a string array is used: point scalars, cell scalars, field scalars.

The second input array to process is an array specifying the type of each label. Different label types may have different font properties. This array must be a vtkIntArray. Any type that does not map to a font property that was set will be set to the type 0's type property.

To create an instance of class vtkLabelSizeCalculator, simply invoke its constructor as follows

```
obj = vtkLabelSizeCalculator
```

39.90.2 Methods

The class vtkLabelSizeCalculator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLabelSizeCalculator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLabelSizeCalculator = obj.NewInstance ()`
- `vtkLabelSizeCalculator = obj.SafeDownCast (vtkObject o)`
- `obj.SetFontProperty (vtkTextProperty fontProp, int type)` - Get/Set the font used compute label sizes. This defaults to "Arial" at 12 points. If type is provided, it refers to the type of the text label provided in the optional label type array. The default type is type 0.
- `vtkTextProperty = obj.GetFontProperty (int type)` - Get/Set the font used compute label sizes. This defaults to "Arial" at 12 points. If type is provided, it refers to the type of the text label provided in the optional label type array. The default type is type 0.
- `obj.SetLabelSizeArrayName (string )` - The name of the output array containing text label sizes This defaults to "LabelSize"
- `string = obj.GetLabelSizeArrayName ()` - The name of the output array containing text label sizes This defaults to "LabelSize"

39.91 vtkLeaderActor2D

39.91.1 Usage

vtkLeaderActor2D creates a leader with an optional label and arrows. (A leader is typically used to indicate distance between points.) vtkLeaderActor2D is a type of vtkActor2D; that is, it is drawn on the overlay plane and is not occluded by 3D geometry. To use this class, you typically specify two points defining the start and end points of the line (x-y definition using vtkCoordinate class), whether to place arrows on one or both end points, and whether to label the leader. Also, this class has a special feature that allows curved leaders to be created by specifying a radius.

Use the vtkLeaderActor2D uses its superclass vtkActor2D instance variables Position and Position2 vtkCoordinates to place an instance of vtkLeaderActor2D (i.e., these two data members represent the start

and end points of the leader). Using these vtkCoordinates you can specify the position of the leader in a variety of coordinate systems.

To control the appearance of the actor, use the superclasses vtkActor2D::vtkProperty2D and the vtkTextProperty objects associated with this actor.

To create an instance of class vtkLeaderActor2D, simply invoke its constructor as follows

```
obj = vtkLeaderActor2D
```

39.91.2 Methods

The class vtkLeaderActor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLeaderActor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLeaderActor2D = obj.NewInstance ()`
- `vtkLeaderActor2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetRadius (double )` - Set/Get a radius which can be used to curve the leader. If a radius is specified whose absolute value is greater than one half the distance between the two points defined by the superclasses' Position and Position2 ivars, then the leader will be curved. A positive radius will produce a curve such that the center is to the right of the line from Position and Position2; a negative radius will produce a curve in the opposite sense. By default, the radius is set to zero and thus there is no curvature. Note that the radius is expresses as a multiple of the distance between (Position,Position2); this avoids issues relative to coordinate system transformations.
- `double = obj.GetRadius ()` - Set/Get a radius which can be used to curve the leader. If a radius is specified whose absolute value is greater than one half the distance between the two points defined by the superclasses' Position and Position2 ivars, then the leader will be curved. A positive radius will produce a curve such that the center is to the right of the line from Position and Position2; a negative radius will produce a curve in the opposite sense. By default, the radius is set to zero and thus there is no curvature. Note that the radius is expresses as a multiple of the distance between (Position,Position2); this avoids issues relative to coordinate system transformations.
- `obj.SetLabel (string )` - Set/Get the label for the leader. If the label is an empty string, then it will not be drawn.
- `string = obj.GetLabel ()` - Set/Get the label for the leader. If the label is an empty string, then it will not be drawn.
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the text property of the label.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the text property of the label.
- `obj.SetLabelFactor (double )` - Set/Get the factor that controls the overall size of the fonts used to label the leader.
- `double = obj.GetLabelFactorMinValue ()` - Set/Get the factor that controls the overall size of the fonts used to label the leader.
- `double = obj.GetLabelFactorMaxValue ()` - Set/Get the factor that controls the overall size of the fonts used to label the leader.
- `double = obj.GetLabelFactor ()` - Set/Get the factor that controls the overall size of the fonts used to label the leader.

- `obj.SetArrowPlacement (int )` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `int = obj.GetArrowPlacementMinValue ()` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `int = obj.GetArrowPlacementMaxValue ()` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `int = obj.GetArrowPlacement ()` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `obj.SetArrowPlacementToNone ()` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `obj.SetArrowPlacementToPoint1 ()` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `obj.SetArrowPlacementToPoint2 ()` - Control whether arrow heads are drawn on the leader. Arrows may be drawn on one end, both ends, or not at all.
- `obj.SetArrowPlacementToBoth ()` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `obj.SetArrowStyle (int )` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `int = obj.GetArrowStyleMinValue ()` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `int = obj.GetArrowStyleMaxValue ()` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `int = obj.GetArrowStyle ()` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `obj.SetArrowStyleToFilled ()` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `obj.SetArrowStyleToOpen ()` - Control the appearance of the arrow heads. A solid arrow head is a filled triangle; a open arrow looks like a "V"; and a hollow arrow looks like a non-filled triangle.
- `obj.SetArrowStyleToHollow ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `obj.SetArrowLength (double )` - Specify the arrow length and base width (in normalized viewport coordinates).
- `double = obj.GetArrowLengthMinValue ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `double = obj.GetArrowLengthMaxValue ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `double = obj.GetArrowLength ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `obj.SetArrowWidth (double )` - Specify the arrow length and base width (in normalized viewport coordinates).

- `double = obj.GetArrowWidthMinValue ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `double = obj.GetArrowWidthMaxValue ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `double = obj.GetArrowWidth ()` - Specify the arrow length and base width (in normalized viewport coordinates).
- `obj.SetMinimumArrowSize (double )` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `double = obj.GetMinimumArrowSizeMinValue ()` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `double = obj.GetMinimumArrowSizeMaxValue ()` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `double = obj.GetMinimumArrowSize ()` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `obj.SetMaximumArrowSize (double )` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `double = obj.GetMaximumArrowSizeMinValue ()` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `double = obj.GetMaximumArrowSizeMaxValue ()` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `double = obj.GetMaximumArrowSize ()` - Limit the minimum and maximum size of the arrows. These values are expressed in pixels and clamp the minimum/maximum possible size for the width/length of the arrow head. (When clamped, the ratio between length and width is preserved.)
- `obj.SetAutoLabel (int )` - Enable auto-labelling. In this mode, the label is automatically updated based on distance (in world coordinates) between the two end points; or if a curved leader is being generated, the angle in degrees between the two points.
- `int = obj.GetAutoLabel ()` - Enable auto-labelling. In this mode, the label is automatically updated based on distance (in world coordinates) between the two end points; or if a curved leader is being generated, the angle in degrees between the two points.
- `obj.AutoLabelOn ()` - Enable auto-labelling. In this mode, the label is automatically updated based on distance (in world coordinates) between the two end points; or if a curved leader is being generated, the angle in degrees between the two points.
- `obj.AutoLabelOff ()` - Enable auto-labelling. In this mode, the label is automatically updated based on distance (in world coordinates) between the two end points; or if a curved leader is being generated, the angle in degrees between the two points.
- `obj.SetLabelFormat (string )` - Specify the format to use for auto-labelling.
- `string = obj.GetLabelFormat ()` - Specify the format to use for auto-labelling.

- `double = obj.GetLength ()` - Obtain the length of the leader if the leader is not curved, otherwise obtain the angle that the leader circumscribes.
- `double = obj.GetAngle ()` - Obtain the length of the leader if the leader is not curved, otherwise obtain the angle that the leader circumscribes.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp and vtkActor2D superclasses.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods required by vtkProp and vtkActor2D superclasses.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `obj.ShallowCopy (vtkProp prop)`

39.92 vtkLight

39.92.1 Usage

vtkLight is a virtual light for 3D rendering. It provides methods to locate and point the light, turn it on and off, and set its brightness and color. In addition to the basic infinite distance point light source attributes, you also can specify the light attenuation values and cone angle. These attributes are only used if the light is a positional light. The default is a directional light (e.g. infinite point light source).

Lights have a type that describes how the light should move with respect to the camera. A Headlight is always located at the current camera position and shines on the camera's focal point. A CameraLight also moves with the camera, but may not be coincident to it. CameraLights are defined in a normalized coordinate space where the camera is located at (0, 0, 1), the camera is looking at (0, 0, 0), and up is (0, 1, 0). Finally, a SceneLight is part of the scene itself and does not move with the camera. (Renderers are responsible for moving the light based on its type.)

Lights have a transformation matrix that describes the space in which they are positioned. A light's world space position and focal point are defined by their local position and focal point, transformed by their transformation matrix (if it exists).

To create an instance of class vtkLight, simply invoke its constructor as follows

```
obj = vtkLight
```

39.92.2 Methods

The class vtkLight has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLight class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLight = obj.NewInstance ()`
- `vtkLight = obj.SafeDownCast (vtkObject o)`

- `vtkLight = obj.ShallowClone ()` - Create a new light object with the same light parameters than the current object (any ivar from the superclasses (vtkObject and vtkObjectBase), like reference counting, timestamp and observers are not copied). This is a shallow clone (TransformMatrix is referenced)

- `obj.Render (vtkRenderer , int )` - Abstract interface to renderer. Each concrete subclass of vtkLight will load its data into the graphics system in response to this method invocation. The actual loading is performed by a vtkLightDevice subclass, which will get created automatically.

- `obj.SetAmbientColor (double , double , double )` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetAmbientColor (double a[3])` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `double = obj. GetAmbientColor ()` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetDiffuseColor (double , double , double )` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetDiffuseColor (double a[3])` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `double = obj. GetDiffuseColor ()` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetSpecularColor (double , double , double )` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetSpecularColor (double a[3])` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `double = obj. GetSpecularColor ()` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetColor (double , double , double )` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetColor (double a[3])` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.GetColor (double rgb[3])` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `double = obj.GetColor ()` - Set/Get the color of the light. It is possible to set the ambient, diffuse and specular colors separately. The SetColor() method sets the diffuse and specular colors to the same color (this is a feature to preserve backward compatbility.)

- `obj.SetPosition (double , double , double )` - Set/Get the position of the light. Note: The position of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space position, use vtkGetTransformedPosition() instead of vtkGetPosition().
- `obj.SetPosition (double a[3])` - Set/Get the position of the light. Note: The position of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space position, use vtkGetTransformedPosition() instead of vtkGetPosition().
- `double = obj. GetPosition ()` - Set/Get the position of the light. Note: The position of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space position, use vtkGetTransformedPosition() instead of vtkGetPosition().
- `obj.SetPosition (float a)` - Set/Get the position of the light. Note: The position of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space position, use vtkGetTransformedPosition() instead of vtkGetPosition().
- `obj.SetFocalPoint (double , double , double )` - Set/Get the point at which the light is shining. Note: The focal point of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space focal point, use vtkGetTransformedFocalPoint() instead of vtkGetFocalPoint().
- `obj.SetFocalPoint (double a[3])` - Set/Get the point at which the light is shining. Note: The focal point of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space focal point, use vtkGetTransformedFocalPoint() instead of vtkGetFocalPoint().
- `double = obj. GetFocalPoint ()` - Set/Get the point at which the light is shining. Note: The focal point of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space focal point, use vtkGetTransformedFocalPoint() instead of vtkGetFocalPoint().
- `obj.SetFocalPoint (float a)` - Set/Get the point at which the light is shining. Note: The focal point of the light is defined in the coordinate space indicated by its transformation matrix (if it exists). Thus, to get the light's world space focal point, use vtkGetTransformedFocalPoint() instead of vtkGetFocalPoint().
- `obj.SetIntensity (double )` - Set/Get the brightness of the light (from one to zero).
- `double = obj.GetIntensity ()` - Set/Get the brightness of the light (from one to zero).
- `obj.SetSwitch (int )` - Turn the light on or off.
- `int = obj.GetSwitch ()` - Turn the light on or off.
- `obj.SwitchOn ()` - Turn the light on or off.
- `obj.SwitchOff ()` - Turn the light on or off.
- `obj.SetPositional (int )` - Turn positional lighting on or off.
- `int = obj.GetPositional ()` - Turn positional lighting on or off.
- `obj.PositionalOn ()` - Turn positional lighting on or off.
- `obj.PositionalOff ()` - Turn positional lighting on or off.
- `obj.SetExponent (double )` - Set/Get the exponent of the cosine used in positional lighting.
- `double = obj.GetExponentMinValue ()` - Set/Get the exponent of the cosine used in positional lighting.

- `double = obj.GetExponentMaxValue ()` - Set/Get the exponent of the cosine used in positional lighting.
- `double = obj.GetExponent ()` - Set/Get the exponent of the cosine used in positional lighting.
- `obj.SetConeAngle (double )` - Set/Get the lighting cone angle of a positional light in degrees. This is the angle between the axis of the cone and a ray along the edge of the cone. A value of 180 indicates that you want no spot lighting effects just a positional light.
- `double = obj.GetConeAngle ()` - Set/Get the lighting cone angle of a positional light in degrees. This is the angle between the axis of the cone and a ray along the edge of the cone. A value of 180 indicates that you want no spot lighting effects just a positional light.
- `obj.SetAttenuationValues (double , double , double )` - Set/Get the quadratic attenuation constants. They are specified as constant, linear, and quadratic, in that order.
- `obj.SetAttenuationValues (double a[3])` - Set/Get the quadratic attenuation constants. They are specified as constant, linear, and quadratic, in that order.
- `double = obj. GetAttenuationValues ()` - Set/Get the quadratic attenuation constants. They are specified as constant, linear, and quadratic, in that order.
- `obj.SetTransformMatrix (vtkMatrix4x4 )` - Set/Get the light's transformation matrix. If a matrix is set for a light, the light's parameters (position and focal point) are transformed by the matrix before being rendered.
- `vtkMatrix4x4 = obj.GetTransformMatrix ()` - Set/Get the light's transformation matrix. If a matrix is set for a light, the light's parameters (position and focal point) are transformed by the matrix before being rendered.
- `obj.GetTransformedPosition (double a[3])` - Get the position of the light, modified by the transformation matrix (if it exists).
- `double = obj.GetTransformedPosition ()` - Get the position of the light, modified by the transformation matrix (if it exists).
- `obj.GetTransformedFocalPoint (double a[3])` - Get the focal point of the light, modified by the transformation matrix (if it exists).
- `double = obj.GetTransformedFocalPoint ()` - Get the focal point of the light, modified by the transformation matrix (if it exists).
- `obj.SetDirectionAngle (double elevation, double azimuth)` - Set the position and focal point of a light based on elevation and azimuth. The light is moved so it is shining from the given angle. Angles are given in degrees. If the light is a positional light, it is made directional instead.
- `obj.SetDirectionAngle (double ang[2])` - Set the position and focal point of a light based on elevation and azimuth. The light is moved so it is shining from the given angle. Angles are given in degrees. If the light is a positional light, it is made directional instead.
- `obj.DeepCopy (vtkLight light)` - Perform deep copy of this light.
- `obj.SetLightType (int )` - Set/Get the type of the light. A SceneLight is a light located in the world coordinate space. A light is initially created as a scene light.

  A Headlight is always located at the camera and is pointed at the camera's focal point. The renderer is free to modify the position and focal point of the camera at any time.

  A CameraLight is also attached to the camera, but is not necessarily located at the camera's position. CameraLights are defined in a coordinate space where the camera is located at (0, 0, 1), looking towards (0, 0, 0) at a distance of 1, with up being (0, 1, 0).

  Note: Use SetLightTypeToSceneLight, rather than SetLightType(3), since the former clears the light's transform matrix.

- `int = obj.GetLightType ()` - Set/Get the type of the light. A SceneLight is a light located in the world coordinate space. A light is initially created as a scene light.

  A Headlight is always located at the camera and is pointed at the camera's focal point. The renderer is free to modify the position and focal point of the camera at any time.

  A CameraLight is also attached to the camera, but is not necessarily located at the camera's position. CameraLights are defined in a coordinate space where the camera is located at (0, 0, 1), looking towards (0, 0, 0) at a distance of 1, with up being (0, 1, 0).

  Note: Use SetLightTypeToSceneLight, rather than SetLightType(3), since the former clears the light's transform matrix.

- `obj.SetLightTypeToHeadlight ()` - Set/Get the type of the light. A SceneLight is a light located in the world coordinate space. A light is initially created as a scene light.

  A Headlight is always located at the camera and is pointed at the camera's focal point. The renderer is free to modify the position and focal point of the camera at any time.

  A CameraLight is also attached to the camera, but is not necessarily located at the camera's position. CameraLights are defined in a coordinate space where the camera is located at (0, 0, 1), looking towards (0, 0, 0) at a distance of 1, with up being (0, 1, 0).

  Note: Use SetLightTypeToSceneLight, rather than SetLightType(3), since the former clears the light's transform matrix.

- `obj.SetLightTypeToSceneLight ()` - Set/Get the type of the light. A SceneLight is a light located in the world coordinate space. A light is initially created as a scene light.

  A Headlight is always located at the camera and is pointed at the camera's focal point. The renderer is free to modify the position and focal point of the camera at any time.

  A CameraLight is also attached to the camera, but is not necessarily located at the camera's position. CameraLights are defined in a coordinate space where the camera is located at (0, 0, 1), looking towards (0, 0, 0) at a distance of 1, with up being (0, 1, 0).

  Note: Use SetLightTypeToSceneLight, rather than SetLightType(3), since the former clears the light's transform matrix.

- `obj.SetLightTypeToCameraLight ()` - Query the type of the light.

- `int = obj.LightTypeIsHeadlight ()` - Query the type of the light.

- `int = obj.LightTypeIsSceneLight ()` - Query the type of the light.

- `int = obj.LightTypeIsCameraLight ()` - Query the type of the light.

39.93 vtkLightActor

39.93.1 Usage

vtkLightActor is a composite actor used to represent a spotlight. The cone angle is equal to the spotlight angle, the cone apex is at the position of the light, the direction of the light goes from the cone apex to the center of the base of the cone. The square frustum position is the light position, the frustum focal point is in the direction of the light direction. The frustum vertical view angle (aperture) (this is also the horizontal view angle as the frustum is square) is equal to twice the cone angle. The clipping range of the frustum is arbitrary set by the user (initially at 0.5,11.0).

To create an instance of class vtkLightActor, simply invoke its constructor as follows

```
obj = vtkLightActor
```

39.93.2 Methods

The class vtkLightActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLightActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLightActor = obj.NewInstance ()`
- `vtkLightActor = obj.SafeDownCast (vtkObject o)`
- `obj.SetLight (vtkLight light)` - The spotlight to represent. Initial value is NULL.
- `vtkLight = obj.GetLight ()` - The spotlight to represent. Initial value is NULL.
- `obj.SetClippingRange (double dNear, double dFar)` - Set/Get the location of the near and far clipping planes along the direction of projection. Both of these values must be positive. Initial values are (0.5,11.0)
- `obj.SetClippingRange (double a[2])` - Set/Get the location of the near and far clipping planes along the direction of projection. Both of these values must be positive. Initial values are (0.5,11.0)
- `double = obj. GetClippingRange ()` - Set/Get the location of the near and far clipping planes along the direction of projection. Both of these values must be positive. Initial values are (0.5,11.0)
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry? No.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `long = obj.GetMTime ()` - Get the actors mtime plus consider its properties and texture if set.

39.94 vtkLightCollection

39.94.1 Usage

vtkLightCollection represents and provides methods to manipulate a list of lights (i.e., vtkLight and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkLightCollection, simply invoke its constructor as follows

```
obj = vtkLightCollection
```

39.94.2 Methods

The class vtkLightCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLightCollection class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkLightCollection = obj.NewInstance ()`
- `vtkLightCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkLight a)` - Add a light to the list.
- `vtkLight = obj.GetNextItem ()` - Get the next light in the list. NULL is returned when the collection is exhausted.

39.95 vtkLightKit

39.95.1 Usage

vtkLightKit is designed to make general purpose lighting of vtk scenes simple, flexible, and attractive (or at least not horribly ugly without significant effort). Use a LightKit when you want more control over your lighting than you can get with the default vtk light, which is a headlight located at the camera. (HeadLights are very simple to use, but they don't show the shape of objects very well, don't give a good sense of "up" and "down", and don't evenly light the object.)

A LightKit consists of three lights, a key light, a fill light, and a headlight. The main light is the key light. It is usually positioned so that it appears like an overhead light (like the sun, or a ceiling light). It is generally positioned to shine down on the scene from about a 45 degree angle vertically and at least a little offset side to side. The key light usually at least about twice as bright as the total of all other lights in the scene to provide good modeling of object features.

The other lights in the kit (the fill light, headlight, and a pair of back lights) are weaker sources that provide extra illumination to fill in the spots that the key light misses. The fill light is usually positioned across from or opposite from the key light (though still on the same side of the object as the camera) in order to simulate diffuse reflections from other objects in the scene. The headlight, always located at the position of the camera, reduces the contrast between areas lit by the key and fill light. The two back lights, one on the left of the object as seen from the observer and one on the right, fill on the high-contrast areas behind the object. To enforce the relationship between the different lights, the intensity of the fill, back and headlights are set as a ratio to the key light brightness. Thus, the brightness of all the lights in the scene can be changed by changing the key light intensity.

All lights are directional lights (infinitely far away with no falloff). Lights move with the camera.

For simplicity, the position of lights in the LightKit can only be specified using angles: the elevation (latitude) and azimuth (longitude) of each light with respect to the camera, expressed in degrees. (Lights always shine on the camera's lookat point.) For example, a light at (elevation=0, azimuth=0) is located at the camera (a headlight). A light at (elevation=90, azimuth=0) is above the lookat point, shining down. Negative azimuth values move the lights clockwise as seen above, positive values counter-clockwise. So, a light at (elevation=45, azimuth=-20) is above and in front of the object and shining slightly from the left side.

vtkLightKit limits the colors that can be assigned to any light to those of incandescent sources such as light bulbs and sunlight. It defines a special color spectrum called "warmth" from which light colors can be chosen, where 0 is cold blue, 0.5 is neutral white, and 1 is deep sunset red. Colors close to 0.5 are "cool whites" and "warm whites," respectively.

Since colors far from white on the warmth scale appear less bright, key-to-fill and key-to-headlight ratios are skewed by key, fill, and headlight colors. If the flag MaintainLuminance is set, vtkLightKit will attempt to compensate for these perceptual differences by increasing the brightness of more saturated colors.

A LightKit is not explicitly part of the vtk pipeline. Rather, it is a composite object that controls the behavior of lights using a unified user interface. Every time a parameter of vtkLightKit is adjusted, the properties of its lights are modified.

.SECTION Credits vtkLightKit was originally written and contributed to vtk by Michael Halle (mhalle@bwh.harvard.edu) at the Surgical Planning Lab, Brigham and Women's Hospital.

To create an instance of class vtkLightKit, simply invoke its constructor as follows

```
obj = vtkLightKit
```

39.95.2 Methods

The class vtkLightKit has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLightKit class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLightKit = obj.NewInstance ()`
- `vtkLightKit = obj.SafeDownCast (vtkObject o)`
- `obj.SetKeyLightIntensity (double )` - Set/Get the intensity of the key light. The key light is the brightest light in the scene. The intensities of the other two lights are ratios of the key light's intensity.
- `double = obj.GetKeyLightIntensity ()` - Set/Get the intensity of the key light. The key light is the brightest light in the scene. The intensities of the other two lights are ratios of the key light's intensity.
- `obj.SetKeyToFillRatio (double )` - Set/Get the key-to-fill ratio. This ratio controls how bright the fill light is compared to the key light: larger values correspond to a dimmer fill light. The purpose of the fill light is to light parts of the object not lit by the key light, while still maintaining constrast. This type of lighting may correspond to indirect illumination from the key light, bounced off a wall, floor, or other object. The fill light should never be brighter than the key light: a good range for the key-to-fill ratio is between 2 and 10.
- `double = obj.GetKeyToFillRatioMinValue ()` - Set/Get the key-to-fill ratio. This ratio controls how bright the fill light is compared to the key light: larger values correspond to a dimmer fill light. The purpose of the fill light is to light parts of the object not lit by the key light, while still maintaining constrast. This type of lighting may correspond to indirect illumination from the key light, bounced off a wall, floor, or other object. The fill light should never be brighter than the key light: a good range for the key-to-fill ratio is between 2 and 10.
- `double = obj.GetKeyToFillRatioMaxValue ()` - Set/Get the key-to-fill ratio. This ratio controls how bright the fill light is compared to the key light: larger values correspond to a dimmer fill light. The purpose of the fill light is to light parts of the object not lit by the key light, while still maintaining constrast. This type of lighting may correspond to indirect illumination from the key light, bounced off a wall, floor, or other object. The fill light should never be brighter than the key light: a good range for the key-to-fill ratio is between 2 and 10.
- `double = obj.GetKeyToFillRatio ()` - Set/Get the key-to-fill ratio. This ratio controls how bright the fill light is compared to the key light: larger values correspond to a dimmer fill light. The purpose of the fill light is to light parts of the object not lit by the key light, while still maintaining constrast. This type of lighting may correspond to indirect illumination from the key light, bounced off a wall, floor, or other object. The fill light should never be brighter than the key light: a good range for the key-to-fill ratio is between 2 and 10.
- `obj.SetKeyToHeadRatio (double )` - Set/Get the key-to-headlight ratio. Similar to the key-to-fill ratio, this ratio controls how bright the headlight light is compared to the key light: larger values correspond to a dimmer headlight light. The headlight is special kind of fill light, lighting only the parts of the object that the camera can see. As such, a headlight tends to reduce the contrast of a scene. It can be used to fill in "shadows" of the object missed by the key and fill lights. The headlight should always be significantly dimmer than the key light: ratios of 2 to 15 are typical.

- `double = obj.GetKeyToHeadRatioMinValue ()` - Set/Get the key-to-headlight ratio. Similar to the key-to-fill ratio, this ratio controls how bright the headlight light is compared to the key light: larger values correspond to a dimmer headlight light. The headlight is special kind of fill light, lighting only the parts of the object that the camera can see. As such, a headlight tends to reduce the contrast of a scene. It can be used to fill in "shadows" of the object missed by the key and fill lights. The headlight should always be significantly dimmer than the key light: ratios of 2 to 15 are typical.

- `double = obj.GetKeyToHeadRatioMaxValue ()` - Set/Get the key-to-headlight ratio. Similar to the key-to-fill ratio, this ratio controls how bright the headlight light is compared to the key light: larger values correspond to a dimmer headlight light. The headlight is special kind of fill light, lighting only the parts of the object that the camera can see. As such, a headlight tends to reduce the contrast of a scene. It can be used to fill in "shadows" of the object missed by the key and fill lights. The headlight should always be significantly dimmer than the key light: ratios of 2 to 15 are typical.

- `double = obj.GetKeyToHeadRatio ()` - Set/Get the key-to-headlight ratio. Similar to the key-to-fill ratio, this ratio controls how bright the headlight light is compared to the key light: larger values correspond to a dimmer headlight light. The headlight is special kind of fill light, lighting only the parts of the object that the camera can see. As such, a headlight tends to reduce the contrast of a scene. It can be used to fill in "shadows" of the object missed by the key and fill lights. The headlight should always be significantly dimmer than the key light: ratios of 2 to 15 are typical.

- `obj.SetKeyToBackRatio (double )` - Set/Get the key-to-back light ratio. This ratio controls how bright the back lights are compared to the key light: larger values correspond to dimmer back lights. The back lights fill in the remaining high-contrast regions behind the object. Values between 2 and 10 are good.

- `double = obj.GetKeyToBackRatioMinValue ()` - Set/Get the key-to-back light ratio. This ratio controls how bright the back lights are compared to the key light: larger values correspond to dimmer back lights. The back lights fill in the remaining high-contrast regions behind the object. Values between 2 and 10 are good.

- `double = obj.GetKeyToBackRatioMaxValue ()` - Set/Get the key-to-back light ratio. This ratio controls how bright the back lights are compared to the key light: larger values correspond to dimmer back lights. The back lights fill in the remaining high-contrast regions behind the object. Values between 2 and 10 are good.

- `double = obj.GetKeyToBackRatio ()` - Set/Get the key-to-back light ratio. This ratio controls how bright the back lights are compared to the key light: larger values correspond to dimmer back lights. The back lights fill in the remaining high-contrast regions behind the object. Values between 2 and 10 are good.

- `obj.SetKeyLightWarmth (double )` - Set the warmth of each the lights. Warmth is a parameter that varies from 0 to 1, where 0 is "cold" (looks icy or lit by a very blue sky), 1 is "warm" (the red of a very red sunset, or the embers of a campfire), and 0.5 is a neutral white. The warmth scale is non-linear. Warmth values close to 0.5 are subtly "warmer" or "cooler," much like a warmer tungsten incandescent bulb, a cooler halogen, or daylight (cooler still). Moving further away from 0.5, colors become more quickly varying towards blues and reds. With regards to aesthetics, extremes of warmth should be used sparingly.

- `double = obj.GetKeyLightWarmth ()` - Set the warmth of each the lights. Warmth is a parameter that varies from 0 to 1, where 0 is "cold" (looks icy or lit by a very blue sky), 1 is "warm" (the red of a very red sunset, or the embers of a campfire), and 0.5 is a neutral white. The warmth scale is non-linear. Warmth values close to 0.5 are subtly "warmer" or "cooler," much like a warmer tungsten incandescent bulb, a cooler halogen, or daylight (cooler still). Moving further away from 0.5, colors become more quickly varying towards blues and reds. With regards to aesthetics, extremes of warmth should be used sparingly.

- `obj.SetFillLightWarmth (double )`
- `double = obj.GetFillLightWarmth ()`
- `obj.SetHeadLightWarmth (double )`
- `double = obj.GetHeadLightWarmth ()`
- `obj.SetBackLightWarmth (double )`
- `double = obj.GetBackLightWarmth ()`
- `double = obj. GetKeyLightColor ()` - Returns the floating-point RGB values of each of the light's color.
- `double = obj. GetFillLightColor ()` - Returns the floating-point RGB values of each of the light's color.
- `double = obj. GetHeadLightColor ()` - Returns the floating-point RGB values of each of the light's color.
- `double = obj. GetBackLightColor ()` - Returns the floating-point RGB values of each of the light's color.
- `obj.SetHeadlightWarmth (double v)` - To maintain a deprecation API:
- `double = obj.GetHeadlightWarmth ()` - To maintain a deprecation API:
- `obj.GetHeadlightColor (double color)` - To maintain a deprecation API:
- `obj.MaintainLuminanceOn ()` - If MaintainLuminance is set, the LightKit will attempt to maintain the apparent intensity of lights based on their perceptual brightnesses. By default, MaintainLuminance is off.
- `obj.MaintainLuminanceOff ()` - If MaintainLuminance is set, the LightKit will attempt to maintain the apparent intensity of lights based on their perceptual brightnesses. By default, MaintainLuminance is off.
- `int = obj.GetMaintainLuminance ()` - If MaintainLuminance is set, the LightKit will attempt to maintain the apparent intensity of lights based on their perceptual brightnesses. By default, MaintainLuminance is off.
- `obj.SetMaintainLuminance (int )` - If MaintainLuminance is set, the LightKit will attempt to maintain the apparent intensity of lights based on their perceptual brightnesses. By default, MaintainLuminance is off.
- `obj.SetKeyLightAngle (double elevation, double azimuth)` - Get/Set the position of the key, fill, and back lights using angular methods. Elevation corresponds to latitude, azimuth to longitude. It is recommended that the key light always be on the viewer's side of the object and above the object, while the fill light generally lights the part of the object not lit by the fill light. The headlight, which is always located at the viewer, can then be used to reduce the contrast in the image. There are a pair of back lights. They are located at the same elevation and at opposing azimuths (ie, one to the left, and one to the right). They are generally set at the equator (elevation = 0), and at approximately 120 degrees (lighting from each side and behind).
- `obj.SetKeyLightAngle (double angle[2])` - Get/Set the position of the key, fill, and back lights using angular methods. Elevation corresponds to latitude, azimuth to longitude. It is recommended that the key light always be on the viewer's side of the object and above the object, while the fill light generally lights the part of the object not lit by the fill light. The headlight, which is always located at the viewer, can then be used to reduce the contrast in the image. There are a pair of back lights. They

are located at the same elevation and at opposing azimuths (ie, one to the left, and one to the right). They are generally set at the equator (elevation = 0), and at approximately 120 degrees (lighting from each side and behind).

- `obj.SetKeyLightElevation (double x)`
- `obj.SetKeyLightAzimuth (double x)`
- `double = obj. GetKeyLightAngle ()`
- `double = obj.GetKeyLightElevation ()`
- `double = obj.GetKeyLightAzimuth ()`
- `obj.SetFillLightAngle (double elevation, double azimuth)`
- `obj.SetFillLightAngle (double angle[2])`
- `obj.SetFillLightElevation (double x)`
- `obj.SetFillLightAzimuth (double x)`
- `double = obj. GetFillLightAngle ()`
- `double = obj.GetFillLightElevation ()`
- `double = obj.GetFillLightAzimuth ()`
- `obj.SetBackLightAngle (double elevation, double azimuth)`
- `obj.SetBackLightAngle (double angle[2])`
- `obj.SetBackLightElevation (double x)`
- `obj.SetBackLightAzimuth (double x)`
- `double = obj. GetBackLightAngle ()`
- `double = obj.GetBackLightElevation ()`
- `double = obj.GetBackLightAzimuth ()`
- `obj.AddLightsToRenderer (vtkRenderer renderer)` - Add lights to, or remove lights from, a renderer. Lights may be added to more than one renderer, if desired.
- `obj.RemoveLightsFromRenderer (vtkRenderer renderer)` - Add lights to, or remove lights from, a renderer. Lights may be added to more than one renderer, if desired.
- `obj.DeepCopy (vtkLightKit kit)`
- `obj.Modified ()`
- `obj.Update ()`

39.96 vtkLightsPass

39.96.1 Usage

Render the lights.

This pass expects an initialized camera. It disables all the lights, apply transformations for lights following the camera, and turn on the enables lights.

To create an instance of class vtkLightsPass, simply invoke its constructor as follows

```
obj = vtkLightsPass
```

39.96.2 Methods

The class vtkLightsPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLightsPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLightsPass = obj.NewInstance ()`
- `vtkLightsPass = obj.SafeDownCast (vtkObject o)`

39.97 vtkLineIntegralConvolution2D

39.97.1 Usage

This class resorts to GLSL to implement GPU-based Line Integral Convolution (LIC) for visualizing a 2D vector field that may be obtained by projecting an original 3D vector field onto a surface (such that the resulting 2D vector at each grid point on the surface is tangential to the local normal, as done in vtkSurfaceLICPainter).

As an image-based technique, 2D LIC works by (1) integrating a bidirectional streamline from the center of each pixel (of the LIC output image), (2) locating the pixels along / hit by this streamline as the correlated pixels of the starting pixel (seed point / pixel), (3) indexing a (usually white) noise texture (another input to LIC, in addition to the 2D vector field, usually with the same size as that of the 2D vetor field) to determine the values (colors) of these pixels (the starting and the correlated pixels), typically through bilinear interpolation, and (4) performing convolution (weighted averaging) on these values, by adopting a low-pass filter (such as box, ramp, and Hanning kernels), to obtain the result value (color) that is then assigned to the seed pixel.

The GLSL-based GPU implementation herein maps the aforementioned pipeline to fragment shaders and a box kernel is employed. Both the white noise and the vector field are provided to the GPU as texture objects (supported by the multi-texturing capability). In addition, there are four texture objects (color buffers) allocated to constitute two pairs that work in a ping-pong fashion, with one as the read buffers and the other as the write / render targets. Maintained by a frame buffer object (GL_EXT_framebuffer_object), each pair employs one buffer to store the current (dynamically updated) position (by means of the texture coordinate that keeps being warped by the underlying vector) of the (virtual) particle initially released from each fragment while using the bother buffer to store the current (dynamically updated too) accumulated texture value that each seed fragment (before the 'mesh' is warped) collects. Given NumberOfSteps integration steps in each direction, there are a total of (2 * NumberOfSteps + 1) fragments (including the seed fragment) are convolved and each contributes 1 / (2 * NumberOfSteps + 1) of the associated texture value to fulfill the box filter.

One pass of LIC (basic LIC) tends to produce low-contrast / blurred images and vtkLineIntegralConvolution2D provides an option for creating enhanced LIC images. Enhanced LIC improves image quality by increasing inter-streamline contrast while suppressing artifacts. It performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. Enhanced LIC automatically degenerates to basic LIC during user interaction.

vtkLineIntegralConvolution2D applies masking to zero-vector fragments so that un-filtered white noise areas are made totally transparent by class vtkSurfaceLICPainter to show the underlying geometry surface.

.SECTION Required OpenGL Extensins GL_ARB_texture_non_power_of_two GL_VERSION_2_0 GL_ARB_texture_float GL_ARB_draw_buffers GL_EXT_framebuffer_object

To create an instance of class vtkLineIntegralConvolution2D, simply invoke its constructor as follows

```
obj = vtkLineIntegralConvolution2D
```

39.97.2 Methods

The class vtkLineIntegralConvolution2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLineIntegralConvolution2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLineIntegralConvolution2D = obj.NewInstance ()`
- `vtkLineIntegralConvolution2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnhancedLIC (int )` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `int = obj.GetEnhancedLIC ()` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `obj.EnhancedLICOn ()` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `obj.EnhancedLICOff ()` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `obj.SetLICForSurface (int )`
- `int = obj.GetLICForSurface ()`
- `obj.LICForSurfaceOn ()`
- `obj.LICForSurfaceOff ()`
- `obj.SetNumberOfSteps (int )` - Number of streamline integration steps (initial value is 1). In term of visual quality, the greater (within some range) the better.
- `int = obj.GetNumberOfSteps ()` - Number of streamline integration steps (initial value is 1). In term of visual quality, the greater (within some range) the better.
- `obj.SetLICStepSize (double )` - Get/Set the streamline integration step size (0.01 by default). This is the length of each step in normalized image space i.e. in range [0, 1]. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is, but GPU only supports float. Thus it will be converted to float in the execution of the algorithm.
- `double = obj.GetLICStepSizeMinValue ()` - Get/Set the streamline integration step size (0.01 by default). This is the length of each step in normalized image space i.e. in range [0, 1]. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is, but GPU only supports float. Thus it will be converted to float in the execution of the algorithm.

- `double = obj.GetLICStepSizeMaxValue ()` - Get/Set the streamline integration step size (0.01 by default). This is the length of each step in normalized image space i.e. in range [0, 1]. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is, but GPU only supports float. Thus it will be converted to float in the execution of the algorithm.

- `double = obj.GetLICStepSize ()` - Get/Set the streamline integration step size (0.01 by default). This is the length of each step in normalized image space i.e. in range [0, 1]. In term of visual quality, the smaller the better. The type for the interface is double as VTK interface is, but GPU only supports float. Thus it will be converted to float in the execution of the algorithm.

- `obj.SetNoise (vtkTextureObject noise)` - Set/Get the input white noise texture (initial value is NULL).

- `vtkTextureObject = obj.GetNoise ()` - Set/Get the input white noise texture (initial value is NULL).

- `obj.SetVectorField (vtkTextureObject vectorField)` - Set/Get the vector field (initial value is NULL).

- `vtkTextureObject = obj.GetVectorField ()` - Set/Get the vector field (initial value is NULL).

- `obj.SetComponentIds (int , int )` - If VectorField has ¿= 3 components, we must choose which 2 components form the (X, Y) components for the vector field. Must be in the range [0, 3].

- `obj.SetComponentIds (int a[2])` - If VectorField has ¿= 3 components, we must choose which 2 components form the (X, Y) components for the vector field. Must be in the range [0, 3].

- `int = obj. GetComponentIds ()` - If VectorField has ¿= 3 components, we must choose which 2 components form the (X, Y) components for the vector field. Must be in the range [0, 3].

- `obj.SetGridSpacings (double , double )` - Set/Get the spacing in each dimension of the plane on which the vector field is defined. This class performs LIC in the normalized image space and hence generally it needs to transform the input vector field (given in physical space) to the normalized image space. The Spacing is needed to determine the tranform. Default is (1.0, 1.0). It is possible to disable vector transformation by setting TransformVectors to 0.

- `obj.SetGridSpacings (double a[2])` - Set/Get the spacing in each dimension of the plane on which the vector field is defined. This class performs LIC in the normalized image space and hence generally it needs to transform the input vector field (given in physical space) to the normalized image space. The Spacing is needed to determine the tranform. Default is (1.0, 1.0). It is possible to disable vector transformation by setting TransformVectors to 0.

- `double = obj. GetGridSpacings ()` - Set/Get the spacing in each dimension of the plane on which the vector field is defined. This class performs LIC in the normalized image space and hence generally it needs to transform the input vector field (given in physical space) to the normalized image space. The Spacing is needed to determine the tranform. Default is (1.0, 1.0). It is possible to disable vector transformation by setting TransformVectors to 0.

- `obj.SetTransformVectors (int )` - This class performs LIC in the normalized image space. Hence, by default it transforms the input vectors to the normalized image space (using the GridSpacings and input vector field dimensions). Set this to 0 to disable tranformation if the vectors are already tranformed.

- `int = obj.GetTransformVectorsMinValue ()` - This class performs LIC in the normalized image space. Hence, by default it transforms the input vectors to the normalized image space (using the GridSpacings and input vector field dimensions). Set this to 0 to disable tranformation if the vectors are already tranformed.

- `int = obj.GetTransformVectorsMaxValue ()` - This class performs LIC in the normalized image space. Hence, by default it transforms the input vectors to the normalized image space (using the GridSpacings and input vector field dimensions). Set this to 0 to disable tranformation if the vectors are already tranformed.

- `obj.TransformVectorsOn ()` - This class performs LIC in the normalized image space. Hence, by default it transforms the input vectors to the normalized image space (using the GridSpacings and input vector field dimensions). Set this to 0 to disable tranformation if the vectors are already tranformed.

- `obj.TransformVectorsOff ()` - This class performs LIC in the normalized image space. Hence, by default it transforms the input vectors to the normalized image space (using the GridSpacings and input vector field dimensions). Set this to 0 to disable tranformation if the vectors are already tranformed.

- `int = obj.GetTransformVectors ()` - This class performs LIC in the normalized image space. Hence, by default it transforms the input vectors to the normalized image space (using the GridSpacings and input vector field dimensions). Set this to 0 to disable tranformation if the vectors are already tranformed.

- `obj.SetMagnification (int )` - The the magnification factor (default is 1.0).

- `int = obj.GetMagnificationMinValue ()` - The the magnification factor (default is 1.0).

- `int = obj.GetMagnificationMaxValue ()` - The the magnification factor (default is 1.0).

- `int = obj.GetMagnification ()` - The the magnification factor (default is 1.0).

- `obj.SetVectorShiftScale (double shift, double scale)` - Returns if the context supports the required extensions.

- `int = obj.Execute ()` - Perform the LIC and obtain the LIC texture. Return 1 if no error.

- `int = obj.Execute (int extent[4])` - Same as Execute() except that the LIC operation is performed only on a window (given by the ęxtent) in the input VectorField. The ęxtent is relative to the input VectorField. The output LIC image will be of the size specified by extent.

- `int = obj.Execute (int extent[4])` - Same as Execute() except that the LIC operation is performed only on a window (given by the ęxtent) in the input VectorField. The ęxtent is relative to the input VectorField. The output LIC image will be of the size specified by extent.

- `obj.SetLIC (vtkTextureObject lic)` - LIC texture (initial value is NULL) set by Execute().

- `vtkTextureObject = obj.GetLIC ()` - LIC texture (initial value is NULL) set by Execute().

39.98 vtkLinesPainter

39.98.1 Usage

This painter tries to paint lines efficiently. Request to Render any other primitive are ignored and not passed to the delegate painter, if any. This painter cannot handle cell colors/normals. If they are present the request is passed on to the Delegate painter. If this class is able to render the primitive, the render request is not propagated to the delegate painter.

To create an instance of class vtkLinesPainter, simply invoke its constructor as follows

```
obj = vtkLinesPainter
```

39.98.2 Methods

The class vtkLinesPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLinesPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLinesPainter = obj.NewInstance ()`
- `vtkLinesPainter = obj.SafeDownCast (vtkObject o)`

39.99 vtkLODActor

39.99.1 Usage

vtkLODActor is an actor that stores multiple levels of detail (LOD) and can automatically switch between them. It selects which level of detail to use based on how much time it has been allocated to render. Currently a very simple method of TotalTime/NumberOfActors is used. (In the future this should be modified to dynamically allocate the rendering time between different actors based on their needs.)

There are three levels of detail by default. The top level is just the normal data. The lowest level of detail is a simple bounding box outline of the actor. The middle level of detail is a point cloud of a fixed number of points that have been randomly sampled from the mapper's input data. Point attributes are copied over to the point cloud. These two lower levels of detail are accomplished by creating instances of a vtkOutlineFilter (low-res) and vtkMaskPoints (medium-res). Additional levels of detail can be add using the AddLODMapper() method.

To control the frame rate, you typically set the vtkRenderWindowInteractor DesiredUpdateRate and StillUpdateRate. This then will cause vtkLODActor to adjust its LOD to fulfill the requested update rate.

For greater control on levels of detail, see also vtkLODProp3D. That class allows arbitrary definition of each LOD.

To create an instance of class vtkLODActor, simply invoke its constructor as follows

```
obj = vtkLODActor
```

39.99.2 Methods

The class vtkLODActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLODActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLODActor = obj.NewInstance ()`
- `vtkLODActor = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer , vtkMapper )` - This causes the actor to be rendered. It, in turn, will render the actor's property and then mapper.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - This method is used internally by the rendering process. We overide the superclass method to properly set the estimated render time.

- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.AddLODMapper (vtkMapper mapper)` - Add another level of detail. They do not have to be in any order of complexity.
- `obj.SetLowResFilter (vtkPolyDataAlgorithm )` - You may plug in your own filters to decimate/subsample the input. The default is to use a vtkOutlineFilter (low-res) and vtkMaskPoints (medium-res).
- `obj.SetMediumResFilter (vtkPolyDataAlgorithm )` - You may plug in your own filters to decimate/subsample the input. The default is to use a vtkOutlineFilter (low-res) and vtkMaskPoints (medium-res).
- `vtkPolyDataAlgorithm = obj.GetLowResFilter ()` - You may plug in your own filters to decimate/subsample the input. The default is to use a vtkOutlineFilter (low-res) and vtkMaskPoints (medium-res).
- `vtkPolyDataAlgorithm = obj.GetMediumResFilter ()` - You may plug in your own filters to decimate/subsample the input. The default is to use a vtkOutlineFilter (low-res) and vtkMaskPoints (medium-res).
- `int = obj.GetNumberOfCloudPoints ()` - Set/Get the number of random points for the point cloud.
- `obj.SetNumberOfCloudPoints (int )` - Set/Get the number of random points for the point cloud.
- `vtkMapperCollection = obj.GetLODMappers ()` - All the mappers for different LODs are stored here. The order is not important.
- `obj.Modified ()` - When this objects gets modified, this method also modifies the object.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an LOD actor. Overloads the virtual vtkProp method.

39.100 vtkLODProp3D

39.100.1 Usage

vtkLODProp3D is a class to support level of detail rendering for Prop3D. Any number of mapper/property/texture items can be added to this object. Render time will be measured, and will be used to select a LOD based on the AllocatedRenderTime of this Prop3D. Depending on the type of the mapper/property, a vtkActor or a vtkVolume will be created behind the scenes.

To create an instance of class vtkLODProp3D, simply invoke its constructor as follows

```
obj = vtkLODProp3D
```

39.100.2 Methods

The class vtkLODProp3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLODProp3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLODProp3D = obj.NewInstance ()`

- `vtkLODProp3D = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetBounds ()` - Standard vtkProp method to get 3D bounds of a 3D prop
- `obj.GetBounds (double bounds[6])` - Standard vtkProp method to get 3D bounds of a 3D prop
- `int = obj.AddLOD (vtkMapper m, vtkProperty p, vtkProperty back, vtkTexture t, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkMapper m, vtkProperty p, vtkTexture t, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkMapper m, vtkProperty p, vtkProperty back, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkMapper m, vtkProperty p, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkMapper m, vtkTexture t, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkMapper m, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkAbstractVolumeMapper m, vtkVolumeProperty p, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.
- `int = obj.AddLOD (vtkAbstractVolumeMapper m, double time)` - Add a level of detail with a given mapper, property, backface property, texture, and guess of rendering time. The property and texture fields can be set to NULL (the other methods are included for script access where null variables

are not allowed). The time field can be set to 0.0 indicating that no initial guess for rendering time is being supplied. The returned integer value is an ID that can be used later to delete this LOD, or set it as the selected LOD.

- `int = obj.GetNumberOfLODs ()` - Get the current number of LODs.
- `int = obj.GetCurrentIndex ()` - Get the current index, used to determine the ID of the next LOD that is added. Useful for guessing what IDs have been used (with NumberOfLODs, without depending on the constructor initialization to 1000.
- `obj.RemoveLOD (int id)` - Delete a level of detail given an ID. This is the ID returned by the AddLOD method
- `obj.SetLODProperty (int id, vtkProperty p)` - Methods to set / get the property of an LOD. Since the LOD could be a volume or an actor, you have to pass in the pointer to the property to get it. The returned property will be NULL if the id is not valid, or the property is of the wrong type for the corresponding Prop3D.
- `obj.SetLODProperty (int id, vtkVolumeProperty p)` - Methods to set / get the property of an LOD. Since the LOD could be a volume or an actor, you have to pass in the pointer to the property to get it. The returned property will be NULL if the id is not valid, or the property is of the wrong type for the corresponding Prop3D.
- `obj.SetLODMapper (int id, vtkMapper m)` - Methods to set / get the mapper of an LOD. Since the LOD could be a volume or an actor, you have to pass in the pointer to the mapper to get it. The returned mapper will be NULL if the id is not valid, or the mapper is of the wrong type for the corresponding Prop3D.
- `obj.SetLODMapper (int id, vtkAbstractVolumeMapper m)` - Methods to set / get the mapper of an LOD. Since the LOD could be a volume or an actor, you have to pass in the pointer to the mapper to get it. The returned mapper will be NULL if the id is not valid, or the mapper is of the wrong type for the corresponding Prop3D.
- `vtkAbstractMapper3D = obj.GetLODMapper (int id)` - Get the LODMapper as an vtkAbstractMapper3D. It is the user's respondibility to safe down cast this to a vtkMapper or vtkVolumeMapper as appropriate.
- `obj.SetLODBackfaceProperty (int id, vtkProperty t)` - Methods to set / get the backface property of an LOD. This method is only valid for LOD ids that are Actors (not Volumes)
- `obj.SetLODTexture (int id, vtkTexture t)` - Methods to set / get the texture of an LOD. This method is only valid for LOD ids that are Actors (not Volumes)
- `obj.EnableLOD (int id)` - Enable / disable a particular LOD. If it is disabled, it will not be used during automatic selection, but can be selected as the LOD if automatic LOD selection is off.
- `obj.DisableLOD (int id)` - Enable / disable a particular LOD. If it is disabled, it will not be used during automatic selection, but can be selected as the LOD if automatic LOD selection is off.
- `int = obj.IsLODEnabled (int id)` - Enable / disable a particular LOD. If it is disabled, it will not be used during automatic selection, but can be selected as the LOD if automatic LOD selection is off.
- `obj.SetLODLevel (int id, double level)` - Set the level of a particular LOD. When a LOD is selected for rendering because it has the largest render time that fits within the allocated time, all LOD are then checked to see if any one can render faster but has a lower (more resolution/better) level. This quantity is a double to ensure that a level can be inserted between 2 and 3.
- `double = obj.GetLODLevel (int id)` - Set the level of a particular LOD. When a LOD is selected for rendering because it has the largest render time that fits within the allocated time, all LOD are then checked to see if any one can render faster but has a lower (more resolution/better) level. This quantity is a double to ensure that a level can be inserted between 2 and 3.

- `double = obj.GetLODIndexLevel (int index)` - Set the level of a particular LOD. When a LOD is selected for rendering because it has the largest render time that fits within the allocated time, all LOD are then checked to see if any one can render faster but has a lower (more resolution/better) level. This quantity is a double to ensure that a level can be inserted between 2 and 3.
- `double = obj.GetLODEstimatedRenderTime (int id)` - Access method that can be used to find out the estimated render time (the thing used to select an LOD) for a given LOD ID or index. Value is returned in seconds.
- `double = obj.GetLODIndexEstimatedRenderTime (int index)` - Access method that can be used to find out the estimated render time (the thing used to select an LOD) for a given LOD ID or index. Value is returned in seconds.
- `obj.SetAutomaticLODSelection (int )` - Turn on / off automatic selection of LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `int = obj.GetAutomaticLODSelectionMinValue ()` - Turn on / off automatic selection of LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `int = obj.GetAutomaticLODSelectionMaxValue ()` - Turn on / off automatic selection of LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `int = obj.GetAutomaticLODSelection ()` - Turn on / off automatic selection of LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `obj.AutomaticLODSelectionOn ()` - Turn on / off automatic selection of LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `obj.AutomaticLODSelectionOff ()` - Turn on / off automatic selection of LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `obj.SetSelectedLODID (int )` - Set the id of the LOD that is to be drawn when automatic LOD selection is turned off.
- `int = obj.GetSelectedLODID ()` - Set the id of the LOD that is to be drawn when automatic LOD selection is turned off.
- `int = obj.GetLastRenderedLODID ()` - Get the ID of the previously (during the last render) selected LOD index
- `int = obj.GetPickLODID (void )` - Get the ID of the appropriate pick LOD index
- `obj.GetActors (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `obj.GetVolumes (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `obj.SetSelectedPickLODID (int id)` - Set the id of the LOD that is to be used for picking when automatic LOD pick selection is turned off.
- `int = obj.GetSelectedPickLODID ()` - Set the id of the LOD that is to be used for picking when automatic LOD pick selection is turned off.
- `obj.SetAutomaticPickLODSelection (int )` - Turn on / off automatic selection of picking LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.

- `int = obj.GetAutomaticPickLODSelectionMinValue ()` - Turn on / off automatic selection of picking LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `int = obj.GetAutomaticPickLODSelectionMaxValue ()` - Turn on / off automatic selection of picking LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `int = obj.GetAutomaticPickLODSelection ()` - Turn on / off automatic selection of picking LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `obj.AutomaticPickLODSelectionOn ()` - Turn on / off automatic selection of picking LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `obj.AutomaticPickLODSelectionOff ()` - Turn on / off automatic selection of picking LOD. This is on by default. If it is off, then the SelectedLODID is rendered regardless of rendering time or desired update rate.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this vtkLODProp3D.

39.101 vtkMapArrayValues

39.101.1 Usage

vtkMapArrayValues allows you to associate certain values of an attribute array (on either a vertex, edge, point, or cell) with different values in a newly created attribute array.

vtkMapArrayValues manages an internal STL map of vtkVariants that can be added to or cleared. When this filter executes, each "key" is searched for in the input array and the indices of the output array at which there were matches the set to the mapped "value".

You can control whether the input array values are passed to the output before the mapping occurs (using PassArray) or, if not, what value to set the unmapped indices to (using FillValue).

One application of this filter is to help address the dirty data problem. For example, using vtkMapArrayValues you could associate the vertex values "Foo, John", "Foo, John.", and "John Foo" with a single entity.

To create an instance of class vtkMapArrayValues, simply invoke its constructor as follows

```
obj = vtkMapArrayValues
```

39.101.2 Methods

The class vtkMapArrayValues has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMapArrayValues class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMapArrayValues = obj.NewInstance ()`
- `vtkMapArrayValues = obj.SafeDownCast (vtkObject o)`
- `obj.SetFieldType (int )` - Set/Get where the data is located that is being mapped. See FieldType enumeration for possible values. Default is POINT_DATA.

- `int = obj.GetFieldType ()` - Set/Get where the data is located that is being mapped. See FieldType enumeration for possible values. Default is POINT_DATA.
- `obj.SetPassArray (int )` - Set/Get whether to copy the data from the input array to the output array before the mapping occurs. If turned off, FillValue is used to initialize any unmapped array indices. Default is off.
- `int = obj.GetPassArray ()` - Set/Get whether to copy the data from the input array to the output array before the mapping occurs. If turned off, FillValue is used to initialize any unmapped array indices. Default is off.
- `obj.PassArrayOn ()` - Set/Get whether to copy the data from the input array to the output array before the mapping occurs. If turned off, FillValue is used to initialize any unmapped array indices. Default is off.
- `obj.PassArrayOff ()` - Set/Get whether to copy the data from the input array to the output array before the mapping occurs. If turned off, FillValue is used to initialize any unmapped array indices. Default is off.
- `obj.SetFillValue (double )` - Set/Get whether to copy the data from the input array to the output array before the mapping occurs. If turned off, FillValue is used to initialize any unmapped array indices. Default is -1.
- `double = obj.GetFillValue ()` - Set/Get whether to copy the data from the input array to the output array before the mapping occurs. If turned off, FillValue is used to initialize any unmapped array indices. Default is -1.
- `obj.SetInputArrayName (string )` - Set/Get the name of the input array. This must be set prior to execution.
- `string = obj.GetInputArrayName ()` - Set/Get the name of the input array. This must be set prior to execution.
- `obj.SetOutputArrayName (string )` - Set/Get the name of the output array. Default is "ArrayMap".
- `string = obj.GetOutputArrayName ()` - Set/Get the name of the output array. Default is "ArrayMap".
- `int = obj.GetOutputArrayType ()` - Set/Get the type of the output array. See vtkSetGet.h for possible values. Default is VTK_INT.
- `obj.SetOutputArrayType (int )` - Set/Get the type of the output array. See vtkSetGet.h for possible values. Default is VTK_INT.
- `obj.AddToMap (int from, int to)` - Add to the internal STL map. "from" should be a value in the input array and "to" should be the new value it gets assigned in the output array.
- `obj.AddToMap (int from, string to)` - Add to the internal STL map. "from" should be a value in the input array and "to" should be the new value it gets assigned in the output array.
- `obj.AddToMap (string from, int to)` - Add to the internal STL map. "from" should be a value in the input array and "to" should be the new value it gets assigned in the output array.
- `obj.AddToMap (string from, string to)` - Add to the internal STL map. "from" should be a value in the input array and "to" should be the new value it gets assigned in the output array.
- `obj.ClearMap ()` - Clear the internal map.
- `int = obj.GetMapSize ()` - Get the size of the internal map.

39.102 vtkMapper

39.102.1 Usage

vtkMapper is an abstract class to specify interface between data and graphics primitives. Subclasses of vtkMapper map data through a lookuptable and control the creation of rendering primitives that interface to the graphics library. The mapping can be controlled by supplying a lookup table and specifying a scalar range to map data through.

There are several important control mechanisms affecting the behavior of this object. The ScalarVisibility flag controls whether scalar data (if any) controls the color of the associated actor(s) that refer to the mapper. The ScalarMode ivar is used to determine whether scalar point data or cell data is used to color the object. By default, point data scalars are used unless there are none, in which cell scalars are used. Or you can explicitly control whether to use point or cell scalar data. Finally, the mapping of scalars through the lookup table varies depending on the setting of the ColorMode flag. See the documentation for the appropriate methods for an explanation.

Another important feature of this class is whether to use immediate mode rendering (ImmediateModeRenderingOn) or display list rendering (ImmediateModeRenderingOff). If display lists are used, a data structure is constructed (generally in the rendering library) which can then be rapidly traversed and rendered by the rendering library. The disadvantage of display lists is that they require additionally memory which may affect the performance of the system.

Another important feature of the mapper is the ability to shift the z-buffer to resolve coincident topology. For example, if you'd like to draw a mesh with some edges a different color, and the edges lie on the mesh, this feature can be useful to get nice looking lines. (See the ResolveCoincidentTopology-related methods.)

To create an instance of class vtkMapper, simply invoke its constructor as follows

```
obj = vtkMapper
```

39.102.2 Methods

The class vtkMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMapper = obj.NewInstance ()`
- `vtkMapper = obj.SafeDownCast (vtkObject o)`
- `obj.ShallowCopy (vtkAbstractMapper m)` - Make a shallow copy of this mapper.
- `long = obj.GetMTime ()` - Overload standard modified time function. If lookup table is modified, then this object is modified as well.
- `obj.Render (vtkRenderer ren, vtkActor a)` - Method initiates the mapping process. Generally sent by the actor as each frame is rendered.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release.
- `obj.SetLookupTable (vtkScalarsToColors lut)` - Specify a lookup table for the mapper to use.
- `vtkScalarsToColors = obj.GetLookupTable ()` - Specify a lookup table for the mapper to use.
- `obj.CreateDefaultLookupTable ()` - Create default lookup table. Generally used to create one when none is available with the scalar data.

- `obj.SetScalarVisibility (int )` - Turn on/off flag to control whether scalar data is used to color objects.
- `int = obj.GetScalarVisibility ()` - Turn on/off flag to control whether scalar data is used to color objects.
- `obj.ScalarVisibilityOn ()` - Turn on/off flag to control whether scalar data is used to color objects.
- `obj.ScalarVisibilityOff ()` - Turn on/off flag to control whether scalar data is used to color objects.
- `obj.SetStatic (int )` - Turn on/off flag to control whether the mapper's data is static. Static data means that the mapper does not propagate updates down the pipeline, greatly decreasing the time it takes to update many mappers. This should only be used if the data never changes.
- `int = obj.GetStatic ()` - Turn on/off flag to control whether the mapper's data is static. Static data means that the mapper does not propagate updates down the pipeline, greatly decreasing the time it takes to update many mappers. This should only be used if the data never changes.
- `obj.StaticOn ()` - Turn on/off flag to control whether the mapper's data is static. Static data means that the mapper does not propagate updates down the pipeline, greatly decreasing the time it takes to update many mappers. This should only be used if the data never changes.
- `obj.StaticOff ()` - Turn on/off flag to control whether the mapper's data is static. Static data means that the mapper does not propagate updates down the pipeline, greatly decreasing the time it takes to update many mappers. This should only be used if the data never changes.
- `obj.SetColorMode (int )` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the SelectColorArray() method.)
- `int = obj.GetColorMode ()` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the SelectColorArray() method.)
- `obj.SetColorModeToDefault ()` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the SelectColorArray() method.)
- `obj.SetColorModeToMapScalars ()` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the SelectColorArray() method.)
- `string = obj.GetColorModeAsString ()` - Return the method of coloring scalar data.
- `obj.SetInterpolateScalarsBeforeMapping (int )` - By default, vertex color is used to map colors to a surface. Colors are interpolated after being mapped. This option avoids color interpolation by using a one dimensional texture map for the colors.
- `int = obj.GetInterpolateScalarsBeforeMapping ()` - By default, vertex color is used to map colors to a surface. Colors are interpolated after being mapped. This option avoids color interpolation by using a one dimensional texture map for the colors.

- `obj.InterpolateScalarsBeforeMappingOn ()` - By default, vertex color is used to map colors to a surface. Colors are interpolated after being mapped. This option avoids color interpolation by using a one dimensional texture map for the colors.
- `obj.InterpolateScalarsBeforeMappingOff ()` - By default, vertex color is used to map colors to a surface. Colors are interpolated after being mapped. This option avoids color interpolation by using a one dimensional texture map for the colors.
- `obj.SetUseLookupTableScalarRange (int )` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.
- `int = obj.GetUseLookupTableScalarRange ()` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.
- `obj.UseLookupTableScalarRangeOn ()` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.
- `obj.UseLookupTableScalarRangeOff ()` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.
- `obj.SetScalarRange (double , double )` - Specify range in terms of scalar minimum and maximum (smin,smax). These values are used to map scalars into lookup table. Has no effect when UseLookupTableScalarRange is true.
- `obj.SetScalarRange (double a[2])` - Specify range in terms of scalar minimum and maximum (smin,smax). These values are used to map scalars into lookup table. Has no effect when UseLookupTableScalarRange is true.
- `double = obj. GetScalarRange ()` - Specify range in terms of scalar minimum and maximum (smin,smax). These values are used to map scalars into lookup table. Has no effect when UseLookupTableScalarRange is true.
- `obj.SetImmediateModeRendering (int )` - Turn on/off flag to control whether data is rendered using immediate mode or note. Immediate mode rendering tends to be slower but it can handle larger datasets. The default value is immediate mode off. If you are having problems rendering a large dataset you might want to consider using immediate more rendering.
- `int = obj.GetImmediateModeRendering ()` - Turn on/off flag to control whether data is rendered using immediate mode or note. Immediate mode rendering tends to be slower but it can handle larger datasets. The default value is immediate mode off. If you are having problems rendering a large dataset you might want to consider using immediate more rendering.
- `obj.ImmediateModeRenderingOn ()` - Turn on/off flag to control whether data is rendered using immediate mode or note. Immediate mode rendering tends to be slower but it can handle larger datasets. The default value is immediate mode off. If you are having problems rendering a large dataset you might want to consider using immediate more rendering.

- `obj.ImmediateModeRenderingOff ()` - Turn on/off flag to control whether data is rendered using immediate mode or note. Immediate mode rendering tends to be slower but it can handle larger datasets. The default value is immediate mode off. If you are having problems rendering a large dataset you might want to consider using immediate more rendering.

- `obj.SetScalarMode (int )` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `int = obj.GetScalarMode ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `obj.SetScalarModeToDefault ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `obj.SetScalarModeToUsePointData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `obj.SetScalarModeToUseCellData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call

SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `obj.SetScalarModeToUsePointFieldData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `obj.SetScalarModeToUseCellFieldData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call SelectColorArray before you call GetColors. When ScalarMode is set to use Field Data (ScalarModeToFieldData), you must call SelectColorArray to choose the field data array to be used to color cells. In this mode, if the poly data has triangle strips, the field data is treated as the celldata for each mini-cell formed by a triangle in the strip rather than the entire strip.

- `obj.SetScalarModeToUseFieldData ()` - When ScalarMode is set to UsePointFieldData or UseCellFieldData, you can specify which array to use for coloring using these methods. The lookup table will decide how to convert vectors to colors.

- `obj.SelectColorArray (int arrayNum)` - When ScalarMode is set to UsePointFieldData or UseCellFieldData, you can specify which array to use for coloring using these methods. The lookup table will decide how to convert vectors to colors.

- `obj.SelectColorArray (string arrayName)` - When ScalarMode is set to UsePointFieldData or UseCellFieldData, you can specify which array to use for coloring using these methods. The lookup table will decide how to convert vectors to colors.

- `obj.ColorByArrayComponent (int arrayNum, int component)` - Legacy: These methods used to be used to specify the array component. It is better to do this in the lookup table.

- `obj.ColorByArrayComponent (string arrayName, int component)` - Legacy: These methods used to be used to specify the array component. It is better to do this in the lookup table.

- `string = obj.GetArrayName ()` - Get the array name or number and component to color by.

- `int = obj.GetArrayId ()` - Get the array name or number and component to color by.

- `int = obj.GetArrayAccessMode ()` - Get the array name or number and component to color by.

- `int = obj.GetArrayComponent ()` - Return the method for obtaining scalar data.

- `string = obj.GetScalarModeAsString ()` - Return the method for obtaining scalar data.

- `double = obj.GetBounds ()` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).

- `obj.GetBounds (double bounds[6])` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.SetRenderTime (double time)` - This instance variable is used by vtkLODActor to determine which mapper to use. It is an estimate of the time necessary to render. Setting the render time does not modify the mapper.
- `double = obj.GetRenderTime ()` - This instance variable is used by vtkLODActor to determine which mapper to use. It is an estimate of the time necessary to render. Setting the render time does not modify the mapper.
- `vtkDataSet = obj.GetInputAsDataSet ()` - Map the scalars (if there are any scalars and ScalarVisibility is on) through the lookup table, returning an unsigned char RGBA array. This is typically done as part of the rendering process. The alpha parameter allows the blending of the scalars with an additional alpha (typically which comes from a vtkActor, etc.)
- `vtkUnsignedCharArray = obj.MapScalars (double alpha)` - Map the scalars (if there are any scalars and ScalarVisibility is on) through the lookup table, returning an unsigned char RGBA array. This is typically done as part of the rendering process. The alpha parameter allows the blending of the scalars with an additional alpha (typically which comes from a vtkActor, etc.)
- `obj.SetScalarMaterialMode (int )` - Set/Get the light-model color mode.
- `int = obj.GetScalarMaterialMode ()` - Set/Get the light-model color mode.
- `obj.SetScalarMaterialModeToDefault ()` - Set/Get the light-model color mode.
- `obj.SetScalarMaterialModeToAmbient ()` - Set/Get the light-model color mode.
- `obj.SetScalarMaterialModeToDiffuse ()` - Set/Get the light-model color mode.
- `obj.SetScalarMaterialModeToAmbientAndDiffuse ()` - Set/Get the light-model color mode.
- `string = obj.GetScalarMaterialModeAsString ()` - Return the light-model color mode.
- `bool = obj.GetSupportsSelection ()` - WARNING: INTERNAL METHOD - NOT INTENDED FOR GENERAL USE DO NOT USE THIS METHOD OUTSIDE OF THE RENDERING PROCESS Used by vtkHardwareSelector to determine if the prop supports hardware selection.

39.103 vtkMapperCollection

39.103.1 Usage

vtkMapperCollection represents and provides methods to manipulate a list of mappers (i.e., vtkMapper and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkMapperCollection, simply invoke its constructor as follows

```
obj = vtkMapperCollection
```

39.103.2 Methods

The class vtkMapperCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMapperCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkMapperCollection = obj.NewInstance ()`
- `vtkMapperCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkMapper a)` - Add an mapper to the list.
- `vtkMapper = obj.GetNextItem ()` - Get the next mapper in the list.
- `vtkMapper = obj.GetLastItem ()` - Get the last mapper in the list.

39.104 vtkOBJExporter

39.104.1 Usage

vtkOBJExporter is a concrete subclass of vtkExporter that writes wavefront .OBJ files in ASCII form. It also writes out a mtl file that contains the material properties. The filenames are derived by appending the .obj and .mtl suffix onto the user specified FilePrefix.

To create an instance of class vtkOBJExporter, simply invoke its constructor as follows

```
obj = vtkOBJExporter
```

39.104.2 Methods

The class vtkOBJExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOBJExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOBJExporter = obj.NewInstance ()`
- `vtkOBJExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFilePrefix (string )` - Specify the prefix of the files to write out. The resulting filenames will have .obj and .mtl appended to them.
- `string = obj.GetFilePrefix ()` - Specify the prefix of the files to write out. The resulting filenames will have .obj and .mtl appended to them.

39.105 vtkObserverMediator

39.105.1 Usage

The vtkObserverMediator is a helper class that manages requests for cursor changes from multiple interactor observers (e.g. widgets). It keeps a list of widgets (and their priorities) and their current requests for cursor shape. It then satisfies requests based on widget priority and the relative importance of the request (e.g., a lower priority widget requesting a particular cursor shape will overrule a higher priority widget requesting a default shape).

To create an instance of class vtkObserverMediator, simply invoke its constructor as follows

```
obj = vtkObserverMediator
```

39.105.2 Methods

The class vtkObserverMediator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkObserverMediator class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkObserverMediator = obj.NewInstance ()` - Standard macros.
- `vtkObserverMediator = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetInteractor (vtkRenderWindowInteractor iren)` - Specify the instance of vtkRenderWindow whose cursor shape is to be managed.
- `vtkRenderWindowInteractor = obj.GetInteractor ()` - Specify the instance of vtkRenderWindow whose cursor shape is to be managed.
- `int = obj.RequestCursorShape (vtkInteractorObserver , int cursorShape)` - Method used to request a cursor shape. Note that the shape is specified using one of the integral values determined in vtkRenderWindow.h. The method returns a non-zero value if the shape was successfully changed.
- `obj.RemoveAllCursorShapeRequests (vtkInteractorObserver )` - Remove all requests for cursor shape from a given interactor.

39.106 vtkOOGLExporter

39.106.1 Usage

vtkOOGLExporter is a concrete subclass of vtkExporter that writes Geomview OOGL files.

To create an instance of class vtkOOGLExporter, simply invoke its constructor as follows

```
obj = vtkOOGLExporter
```

39.106.2 Methods

The class vtkOOGLExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOOGLExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOOGLExporter = obj.NewInstance ()`
- `vtkOOGLExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the name of the Geomview file to write.
- `string = obj.GetFileName ()` - Specify the name of the Geomview file to write.

39.107 vtkOpaquePass

39.107.1 Usage

vtkOpaquePass renders the opaque geometry of all the props that have the keys contained in vtkRenderState.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color.

To create an instance of class vtkOpaquePass, simply invoke its constructor as follows

```
obj = vtkOpaquePass
```

39.107.2 Methods

The class vtkOpaquePass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpaquePass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpaquePass = obj.NewInstance ()`
- `vtkOpaquePass = obj.SafeDownCast (vtkObject o)`

39.108 vtkOpenGLActor

39.108.1 Usage

vtkOpenGLActor is a concrete implementation of the abstract class vtkActor. vtkOpenGLActor interfaces to the OpenGL rendering library.

To create an instance of class vtkOpenGLActor, simply invoke its constructor as follows

```
obj = vtkOpenGLActor
```

39.108.2 Methods

The class vtkOpenGLActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLActor = obj.NewInstance ()`
- `vtkOpenGLActor = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren, vtkMapper mapper)` - Actual actor render method.

39.109 vtkOpenGLCamera

39.109.1 Usage

vtkOpenGLCamera is a concrete implementation of the abstract class vtkCamera. vtkOpenGLCamera interfaces to the OpenGL rendering library.

To create an instance of class vtkOpenGLCamera, simply invoke its constructor as follows

```
obj = vtkOpenGLCamera
```

39.109.2 Methods

The class vtkOpenGLCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLCamera = obj.NewInstance ()`
- `vtkOpenGLCamera = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren)` - Implement base class method.
- `obj.UpdateViewport (vtkRenderer ren)`

39.110 vtkOpenGLClipPlanesPainter

39.110.1 Usage

This painter is an openGL specific painter which handles clipplanes. This painter must typically be placed before the painter that do the primitive rendering.

To create an instance of class vtkOpenGLClipPlanesPainter, simply invoke its constructor as follows

```
obj = vtkOpenGLClipPlanesPainter
```

39.110.2 Methods

The class vtkOpenGLClipPlanesPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLClipPlanesPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLClipPlanesPainter = obj.NewInstance ()`
- `vtkOpenGLClipPlanesPainter = obj.SafeDownCast (vtkObject o)`

39.111 vtkOpenGLCoincidentTopologyResolutionPainter

39.111.1 Usage

Implementation for vtkCoincidentTopologyResolutionPainter using OpenGL.

To create an instance of class vtkOpenGLCoincidentTopologyResolutionPainter, simply invoke its constructor as follows

```
obj = vtkOpenGLCoincidentTopologyResolutionPainter
```

39.111.2 Methods

The class vtkOpenGLCoincidentTopologyResolutionPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLCoincidentTopologyResolutionPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLCoincidentTopologyResolutionPainter = obj.NewInstance ()`
- `vtkOpenGLCoincidentTopologyResolutionPainter = obj.SafeDownCast (vtkObject o)`

39.112 vtkOpenGLDisplayListPainter

39.112.1 Usage

vtkOpenGLDisplayListPainter creates an OpenGL display list for rendering. This painter creates a different display list for every render request with a different set of typeflags. If any of the data or inputs change, then all display lists are discarded.

To create an instance of class vtkOpenGLDisplayListPainter, simply invoke its constructor as follows

```
obj = vtkOpenGLDisplayListPainter
```

39.112.2 Methods

The class vtkOpenGLDisplayListPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLDisplayListPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLDisplayListPainter = obj.NewInstance ()`
- `vtkOpenGLDisplayListPainter = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release. In this case, releases the display lists.

39.113 vtkOpenGLExtensionManager

39.113.1 Usage

vtkOpenGLExtensionManager acts as an interface to OpenGL extensions. It provides methods to query OpenGL extensions on the current or a given render window and to load extension function pointers. Currently does not support GLU extensions since the GLU library is not linked to VTK.

Before using vtkOpenGLExtensionManager, an OpenGL context must be created. This is generally done with a vtkRenderWindow. Note that simply creating the vtkRenderWindow is not sufficient. Usually you have to call Render before the actual OpenGL context is created. You can specify the RenderWindow with the SetRenderWindow method.

```
vtkOpenGLExtensionManager *extensions = vtkOpenGLExtensionManager::New();
extensions->SetRenderWindow(renwin);
```

If no vtkRenderWindow is specified, the current OpenGL context (if any) is used.

Generally speaking, when using OpenGL extensions, you will need an vtkOpenGLExtensionManager and the prototypes defined in vtkgl.h.

```
\#include ''vtkOpenGLExtensionManager.h''
\#include ''vtkgl.h''
```

The vtkgl.h include file contains all the constants and function pointers required for using OpenGL extensions in a portable and namespace safe way. vtkgl.h is built from parsed glext.h, glxext.h, and wglext.h files. Snapshots of these files are distributed with VTK, but you can also set CMake options to use other files.

To use an OpenGL extension, you first need to make an instance of vtkOpenGLExtensionManager and give it a vtkRenderWindow. You can then query the vtkOpenGLExtensionManager to see if the extension is supported with the ExtensionSupported method. Valid names for extensions are given in the OpenGL extension registry at http://www.opengl.org/registry/ . You can also grep vtkgl.h (which will be in the binary build directory if VTK is not installed) for appropriate names. There are also special extensions GL_VERSION_X_X (where X_X is replaced with a major and minor version, respectively) which contain all the constants and functions for OpenGL versions for which the gl.h header file is of an older version than the driver.

```
if (   !extensions->ExtensionSupported(''GL\_VERSION\_1\_2'')
    || !extensions->ExtensionSupported(''GL\_ARB\_multitexture'') ) {
  {
  vtkErrorMacro(''Required extensions not supported!'');
  }
```

Once you have verified that the extensions you want exist, before you use them you have to load them with the LoadExtension method.

```
extensions->LoadExtension(''GL\_VERSION\_1\_2'');
extensions->LoadExtension(''GL\_ARB\_multitexture'');
```

Alternatively, you can use the LoadSupportedExtension method, which checks whether the requested extension is supported and, if so, loads it. The LoadSupportedExtension method will not raise any errors or warnings if it fails, so it is important for callers to pay attention to the return value.

```
if (   extensions->LoadSupportedExtension(''GL\_VERSION\_1\_2'')
    \&\& extensions->LoadSupportedExtension(''GL\_ARB\_multitexture'') ) {
  {
```

```
  vtkgl::ActiveTexture(vtkgl::TEXTURE0\_ARB);
  }
else
  {
  vtkErrorMacro(''Required extensions could not be loaded!'');
  }
```

Once you have queried and loaded all of the extensions you need, you can delete the vtkOpenGLExtensionManager. To use a constant of an extension, simply replace the "GL_" prefix with "vtkgl::". Likewise, replace the "gl" prefix of functions with "vtkgl::". In rare cases, an extension will add a type. In this case, add vtkgl:: to the type (i.e. vtkgl::GLchar).

```
extensions->Delete();
...
vtkgl::ActiveTexture(vtkgl::TEXTURE0\_ARB);
```

For wgl extensions, replace the "WGL_" and "wgl" prefixes with "vtkwgl::". For glX extensions, replace the "GLX_" and "glX" prefixes with "vtkglX::".

To create an instance of class vtkOpenGLExtensionManager, simply invoke its constructor as follows

```
obj = vtkOpenGLExtensionManager
```

39.113.2 Methods

The class vtkOpenGLExtensionManager has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLExtensionManager class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLExtensionManager = obj.NewInstance ()`
- `vtkOpenGLExtensionManager = obj.SafeDownCast (vtkObject o)`
- `vtkRenderWindow = obj.GetRenderWindow ()` - Set/Get the render window to query extensions on. If set to null, justs queries the current render window.
- `obj.SetRenderWindow (vtkRenderWindow renwin)` - Set/Get the render window to query extensions on. If set to null, justs queries the current render window.
- `obj.Update ()` - Updates the extensions string.
- `string = obj.GetExtensionsString ()` - Returns a string listing all available extensions. Call Update first to validate this string.
- `int = obj.ExtensionSupported (string name)` - Returns true if the extension is supported, false otherwise.
- `obj.LoadExtension (string name)` - Loads all the functions associated with the given extension into the appropriate static members of vtkgl. This method emits a warning if the requested extension is not supported. It emits an error if the extension does not load successfully.

- `int = obj.LoadSupportedExtension (string name)` - Returns true if the extension is supported and loaded successfully, false otherwise. This method will "fail silently/gracefully" if the extension is not supported or does not load properly. It emits neither warnings nor errors. It is up to the caller to determine if the extension loaded properly by paying attention to the return value.

- `obj.LoadCorePromotedExtension (string name)` - Loads all the functions associated with the given core-promoted extension into the appropriate static members of vtkgl associated with the OpenGL version that promoted the extension as a core feature. This method emits a warning if the requested extension is not supported. It emits an error if the extension does not load successfully.

  For instance, extension GL_ARB_multitexture was promoted as a core feature into OpenGL 1.3. An implementation that uses this feature has to (IN THIS ORDER), check if OpenGL 1.3 is supported with ExtensionSupported("GL_VERSION_1_3"), if true, load the extension with LoadExtension("GL_VERSION_1_3"). If false, test for the extension with ExtensionSupported("GL_ARB_multitexture"),if true load the extension with this method LoadCorePromotedExtension("GL_ARB_multitexture"). If any of those loading stage succeeded, use vtgl::ActiveTexture() in any case, NOT vtgl::ActiveTextureARB(). This method avoids the use of if statements everywhere in implementations using core-promoted extensions. Without this method, the implementation code should look like:

```
int opengl\_1\_3=extensions->ExtensionSupported(''GL\_VERSION\_1\_3'');
if(opengl\_1\_3)
{
  extensions->LoadExtension(''GL\_VERSION\_1\_3'');
}
else
{
 if(extensions->ExtensionSupported(''GL\_ARB\_multitexture''))
 {
  extensions->LoadCorePromotedExtension(''GL\_ARB\_multitexture'');
 }
 else
 {
  vtkErrorMacro(''Required multitexture feature is not supported!'');
 }
}
...
if(opengl\_1\_3)
{
 vtkgl::ActiveTexture(vtkgl::TEXTURE0)
}
else
{
 vtkgl::ActiveTextureARB(vtkgl::TEXTURE0\_ARB)
}
```

  Thanks to this method, the code looks like:

```
int opengl\_1\_3=extensions->ExtensionSupported(''GL\_VERSION\_1\_3'');
if(opengl\_1\_3)
{
  extensions->LoadExtension(''GL\_VERSION\_1\_3'');
}
else
{
```

```
 if(extensions->ExtensionSupported(''GL\_ARB\_multitexture''))
 {
  extensions->LoadCorePromotedExtension(''GL\_ARB\_multitexture'');
 }
 else
 {
  vtkErrorMacro(''Required multitexture feature is not supported!'');
 }
}
...
vtkgl::ActiveTexture(vtkgl::TEXTURE0);
```

39.114 vtkOpenGLFreeTypeTextMapper

39.114.1 Usage

vtkOpenGLFreeTypeTextMapper provides 2D text annotation support for VTK using the FreeType and FTGL libraries. Normally the user should use vtktextMapper which in turn will use this class.

To create an instance of class vtkOpenGLFreeTypeTextMapper, simply invoke its constructor as follows

```
obj = vtkOpenGLFreeTypeTextMapper
```

39.114.2 Methods

The class vtkOpenGLFreeTypeTextMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLFreeTypeTextMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLFreeTypeTextMapper = obj.NewInstance ()`
- `vtkOpenGLFreeTypeTextMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Actally draw the text.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.GetSize (vtkViewport viewport, int size[2])` - What is the size of the rectangle required to draw this mapper ?

39.115 vtkOpenGLHardwareSupport

39.115.1 Usage

vtkOpenGLHardwareSupport is an implementation of methods used to query OpenGL and the hardware of what kind of graphics support is available. When VTK supports more than one Graphics API an abstract super class vtkHardwareSupport should be implemented for this class to derive from.

To create an instance of class vtkOpenGLHardwareSupport, simply invoke its constructor as follows

```
obj = vtkOpenGLHardwareSupport
```

39.115.2 Methods

The class vtkOpenGLHardwareSupport has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLHardwareSupport class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLHardwareSupport = obj.NewInstance ()`
- `vtkOpenGLHardwareSupport = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfFixedTextureUnits ()` - Return the number of fixed-function texture units.
- `int = obj.GetNumberOfTextureUnits ()` - Return the total number of texture image units accessible by a shader program.
- `bool = obj.GetSupportsMultiTexturing ()` - Test if MultiTexturing is supported.
- `vtkOpenGLExtensionManager = obj.GetExtensionManager ()` - Set/Get a reference to a vtkRenderWindow which is Required for most methods of this class to work.
- `obj.SetExtensionManager (vtkOpenGLExtensionManager extensionManager)` - Set/Get a reference to a vtkRenderWindow which is Required for most methods of this class to work.

39.116 vtkOpenGLImageActor

39.116.1 Usage

vtkOpenGLImageActor is a concrete implementation of the abstract class vtkImageActor. vtkOpenGLImageActor interfaces to the OpenGL rendering library.

To create an instance of class vtkOpenGLImageActor, simply invoke its constructor as follows

```
obj = vtkOpenGLImageActor
```

39.116.2 Methods

The class vtkOpenGLImageActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLImageActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLImageActor = obj.NewInstance ()`
- `vtkOpenGLImageActor = obj.SafeDownCast (vtkObject o)`
- `obj.Load (vtkRenderer ren)` - Implement base class method.
- `obj.Render (vtkRenderer ren)` - Implement base class method.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this texture. The parameter window could be used to determine which graphic resources to release. Using the same texture object in multiple render windows is NOT currently supported.

39.117 vtkOpenGLImageMapper

39.117.1 Usage

vtkOpenGLImageMapper is a concrete subclass of vtkImageMapper that renders images under OpenGL

To create an instance of class vtkOpenGLImageMapper, simply invoke its constructor as follows

```
obj = vtkOpenGLImageMapper
```

39.117.2 Methods

The class vtkOpenGLImageMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLImageMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLImageMapper = obj.NewInstance ()`
- `vtkOpenGLImageMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Called by the Render function in vtkImageMapper. Actually draws the image to the screen.
- `obj.RenderData (vtkViewport viewport, vtkImageData data, vtkActor2D actor)` - Called by the Render function in vtkImageMapper. Actually draws the image to the screen.

39.118 vtkOpenGLLight

39.118.1 Usage

vtkOpenGLLight is a concrete implementation of the abstract class vtkLight. vtkOpenGLLight interfaces to the OpenGL rendering library.

To create an instance of class vtkOpenGLLight, simply invoke its constructor as follows

```
obj = vtkOpenGLLight
```

39.118.2 Methods

The class vtkOpenGLLight has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLLight class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLLight = obj.NewInstance ()`
- `vtkOpenGLLight = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren, int light\_index)` - Implement base class method.

39.119 vtkOpenGLLightingPainter

39.119.1 Usage

This painter manages lighting. Ligting is disabled when rendering points/lines and no normals are present or rendering Polygons/TStrips and representation is points and no normals are present.

To create an instance of class vtkOpenGLLightingPainter, simply invoke its constructor as follows

```
obj = vtkOpenGLLightingPainter
```

39.119.2 Methods

The class vtkOpenGLLightingPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLLightingPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLLightingPainter = obj.NewInstance ()`
- `vtkOpenGLLightingPainter = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetTimeToDraw ()` - This painter overrides GetTimeToDraw() to never pass the request to the delegate. This is done since this class may propagate a single render request multiple times to the delegate. In that case the time accumulation responsibility is borne by the painter causing the multiple rendering requests i.e. this painter itself.

39.120 vtkOpenGLPainterDeviceAdapter

39.120.1 Usage

An adapter between vtkPainter and the OpenGL rendering system. Only a handful of attributes with special meaning are supported. The OpenGL attribute used for each attribute is given below.

```
vtkDataSetAttributes::NORMALS          glNormal
vtkDataSetAttributes:::SCALARS         glColor
vtkDataSetAttributes::TCOORDS          glTexCoord
vtkDataSetAttributes::NUM\_ATTRIBUTES   glVertex
```

To create an instance of class vtkOpenGLPainterDeviceAdapter, simply invoke its constructor as follows

```
obj = vtkOpenGLPainterDeviceAdapter
```

39.120.2 Methods

The class vtkOpenGLPainterDeviceAdapter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLPainterDeviceAdapter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLPainterDeviceAdapter = obj.NewInstance ()`

- `vtkOpenGLPainterDeviceAdapter = obj.SafeDownCast (vtkObject o)`
- `obj.BeginPrimitive (int mode)` - Converts mode from VTK_* to GL_* and calls glBegin.
- `obj.EndPrimitive ()` - Calls glEnd.
- `int = obj.IsAttributesSupported (int attribute)` - Returns if the given attribute type is supported by the device. Returns 1 is supported, 0 otherwise.
- `obj.EnableAttributeArray (int index)` - Calls glEnableClientState or glDisableClientState.
- `obj.DisableAttributeArray (int index)` - Calls glEnableClientState or glDisableClientState.
- `obj.DrawArrays (int mode, vtkIdType first, vtkIdType count)` - Calls glDrawArrays. Mode is converted from VTK_* to GL_*.
- `int = obj.Compatible (vtkRenderer renderer)` - Returns true if renderer is a vtkOpenGLRenderer.
- `obj.MakeLighting (int mode)` - Turns lighting on and off.
- `int = obj.QueryLighting ()` - Returns current lighting setting.
- `obj.MakeMultisampling (int mode)` - Turns antialiasing on and off.
- `int = obj.QueryMultisampling ()` - Returns current antialiasing setting.
- `obj.MakeBlending (int mode)` - Turns blending on and off.
- `int = obj.QueryBlending ()` - Returns current blending setting.
- `obj.MakeVertexEmphasis (bool mode)` - Turns emphasis of vertices on or off for vertex selection. When emphasized verts are drawn nearer to the camera and are drawn larger than normal to make selection of them more reliable.
- `obj.MakeVertexEmphasisWithStencilCheck (int mode)` - @deprecated
- `obj.Stencil (int on)` - Control use of the stencil buffer (for vertex selection).
- `obj.WriteStencil (vtkIdType value)` - Control use of the stencil buffer (for vertex selection).
- `obj.TestStencil (vtkIdType value)` - Control use of the stencil buffer (for vertex selection).

39.121 vtkOpenGLPolyDataMapper

39.121.1 Usage

vtkOpenGLPolyDataMapper is a subclass of vtkPolyDataMapper. vtkOpenGLPolyDataMapper is a geometric PolyDataMapper for the OpenGL rendering library.

To create an instance of class vtkOpenGLPolyDataMapper, simply invoke its constructor as follows

```
obj = vtkOpenGLPolyDataMapper
```

39.121.2 Methods

The class vtkOpenGLPolyDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLPolyDataMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLPolyDataMapper = obj.NewInstance ()`
- `vtkOpenGLPolyDataMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderPiece (vtkRenderer ren, vtkActor a)` - Implement superclass render method.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release.
- `int = obj.Draw (vtkRenderer ren, vtkActor a)` - Draw method for OpenGL.

39.122 vtkOpenGLPolyDataMapper2D

39.122.1 Usage

vtkOpenGLPolyDataMapper2D provides 2D PolyData annotation support for vtk under OpenGL. Normally the user should use vtkPolyDataMapper2D which in turn will use this class.

To create an instance of class vtkOpenGLPolyDataMapper2D, simply invoke its constructor as follows

```
obj = vtkOpenGLPolyDataMapper2D
```

39.122.2 Methods

The class vtkOpenGLPolyDataMapper2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLPolyDataMapper2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLPolyDataMapper2D = obj.NewInstance ()`
- `vtkOpenGLPolyDataMapper2D = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Actually draw the poly data.

39.123 vtkOpenGLProperty

39.123.1 Usage

vtkOpenGLProperty is a concrete implementation of the abstract class vtkProperty. vtkOpenGLProperty interfaces to the OpenGL rendering library.

To create an instance of class vtkOpenGLProperty, simply invoke its constructor as follows

```
obj = vtkOpenGLProperty
```

39.123.2 Methods

The class vtkOpenGLProperty has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLProperty class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLProperty = obj.NewInstance ()`
- `vtkOpenGLProperty = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkActor a, vtkRenderer ren)` - Implement base class method.
- `obj.BackfaceRender (vtkActor a, vtkRenderer ren)` - Implement base class method.
- `obj.AddShaderVariable (string name, int numVars, int x)` - Provide values to initialize shader variables. Useful to initialize shader variables that change over time (animation, GUI widgets inputs, etc.) - name - hardware name of the uniform variable - numVars - number of variables being set - x - values
- `obj.AddShaderVariable (string name, int numVars, float x)` - Provide values to initialize shader variables. Useful to initialize shader variables that change over time (animation, GUI widgets inputs, etc.) - name - hardware name of the uniform variable - numVars - number of variables being set - x - values
- `obj.AddShaderVariable (string name, int numVars, double x)` - Provide values to initialize shader variables. Useful to initialize shader variables that change over time (animation, GUI widgets inputs, etc.) - name - hardware name of the uniform variable - numVars - number of variables being set - x - values

39.124 vtkOpenGLRenderer

39.124.1 Usage

vtkOpenGLRenderer is a concrete implementation of the abstract class vtkRenderer. vtkOpenGLRenderer interfaces to the OpenGL graphics library.

To create an instance of class vtkOpenGLRenderer, simply invoke its constructor as follows

```
obj = vtkOpenGLRenderer
```

39.124.2 Methods

The class vtkOpenGLRenderer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLRenderer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLRenderer = obj.NewInstance ()`
- `vtkOpenGLRenderer = obj.SafeDownCast (vtkObject o)`
- `obj.DeviceRender (void )` - Concrete open gl render method.

- `obj.DeviceRenderTranslucentPolygonalGeometry ()` - Render translucent polygonal geometry. Default implementation just call UpdateTranslucentPolygonalGeometry(). Subclasses of vtkRenderer that can deal with depth peeling must override this method.
- `obj.ClearLights (void )` - Internal method temporarily removes lights before reloading them into graphics pipeline.
- `obj.Clear (void )`
- `int = obj.UpdateLights (void )` - Ask lights to load themselves into graphics pipeline.
- `int = obj.GetDepthPeelingHigherLayer ()` - Is rendering at translucent geometry stage using depth peeling and rendering a layer other than the first one? (Boolean value) If so, the uniform variables UseTexture and Texture can be set. (Used by vtkOpenGLProperty or vtkOpenGLTexture)

39.125 vtkOpenGLRenderWindow

39.125.1 Usage

vtkOpenGLRenderWindow is a concrete implementation of the abstract class vtkRenderWindow. vtkOpenGLRenderer interfaces to the OpenGL graphics library. Application programmers should normally use vtkRenderWindow instead of the OpenGL specific version.

To create an instance of class vtkOpenGLRenderWindow, simply invoke its constructor as follows

```
obj = vtkOpenGLRenderWindow
```

39.125.2 Methods

The class vtkOpenGLRenderWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLRenderWindow class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLRenderWindow = obj.NewInstance ()`
- `vtkOpenGLRenderWindow = obj.SafeDownCast (vtkObject o)`
- `obj.StereoUpdate ()` - Update system if needed due to stereo rendering.
- `int = obj.GetPixelData (int x, int y, int x2, int y2, int front, vtkUnsignedCharArray data)` - Set/Get the pixel data of an image, transmitted as RGBRGB...
- `int = obj.SetPixelData (int x, int y, int x2, int y2, string data, int front)` - Set/Get the pixel data of an image, transmitted as RGBRGB...
- `int = obj.SetPixelData (int x, int y, int x2, int y2, vtkUnsignedCharArray data, int front)` - Set/Get the pixel data of an image, transmitted as RGBRGB...
- `int = obj.GetRGBAPixelData (int x, int y, int x2, int y2, int front, vtkFloatArray data)` - Set/Get the pixel data of an image, transmitted as RGBARGBA...
- `int = obj.SetRGBAPixelData (int x, int y, int x2, int y2, float data, int front, int blend)` - Set/Get the pixel data of an image, transmitted as RGBARGBA...
- `int = obj.SetRGBAPixelData (int x, int y, int x2, int y2, vtkFloatArray data, int front, int blend)` - Set/Get the pixel data of an image, transmitted as RGBARGBA...

- `obj.ReleaseRGBAPixelData (float data)` - Set/Get the pixel data of an image, transmitted as RGBARGBA...
- `int = obj.GetRGBACharPixelData (int x, int y, int x2, int y2, int front, vtkUnsignedCharArray data)` - Set/Get the pixel data of an image, transmitted as RGBARGBA...
- `int = obj.SetRGBACharPixelData (int x, int y, int x2, int y2, string data, int front, int blend)` - Set/Get the pixel data of an image, transmitted as RGBARGBA...
- `int = obj.SetRGBACharPixelData (int x, int y, int x2, int y2, vtkUnsignedCharArray data, int front,` - Set/Get the pixel data of an image, transmitted as RGBARGBA...
- `int = obj.GetZbufferData (int x1, int y1, int x2, int y2, float z)` - Set/Get the zbuffer data from an image
- `int = obj.GetZbufferData (int x1, int y1, int x2, int y2, vtkFloatArray z)` - Set/Get the zbuffer data from an image
- `int = obj.SetZbufferData (int x1, int y1, int x2, int y2, float buffer)` - Set/Get the zbuffer data from an image
- `int = obj.SetZbufferData (int x1, int y1, int x2, int y2, vtkFloatArray buffer)` - Set/Get the zbuffer data from an image
- `int = obj.GetDepthBufferSize ()` - Get the size of the depth buffer.
- `int = obj.GetColorBufferSizes (int rgba)` - Get the size of the color buffer. Returns 0 if not able to determine otherwise sets R G B and A into buffer.
- `obj.OpenGLInit ()` - Initialize OpenGL for this window.
- `int = obj.GetBackLeftBuffer ()` - Return the OpenGL name of the back left buffer. It is GL_BACK_LEFT if GL is bound to the window-system-provided framebuffer. It is vtkgl::COLOR_ATTACHMENT0_EXT if GL is bound to an application-created framebuffer object (GPU-based offscreen rendering) It is used by vtkOpenGLCamera.
- `int = obj.GetBackRightBuffer ()` - Return the OpenGL name of the back right buffer. It is GL_BACK_RIGHT if GL is bound to the window-system-provided framebuffer. It is vtkgl::COLOR_ATTACHMENT0_E if GL is bound to an application-created framebuffer object (GPU-based offscreen rendering) It is used by vtkOpenGLCamera.
- `int = obj.GetFrontLeftBuffer ()` - Return the OpenGL name of the front left buffer. It is GL_FRONT_LEFT if GL is bound to the window-system-provided framebuffer. It is vtkgl::COLOR_ATTACHMENT0_EXT if GL is bound to an application-created framebuffer object (GPU-based offscreen rendering) It is used by vtkOpenGLCamera.
- `int = obj.GetFrontRightBuffer ()` - Return the OpenGL name of the front right buffer. It is GL_FRONT_RIGHT if GL is bound to the window-system-provided framebuffer. It is vtkgl::COLOR_ATTACHMENT0_ if GL is bound to an application-created framebuffer object (GPU-based offscreen rendering) It is used by vtkOpenGLCamera.
- `int = obj.GetBackBuffer ()` - Return the OpenGL name of the back left buffer. It is GL_BACK if GL is bound to the window-system-provided framebuffer. It is vtkgl::COLOR_ATTACHMENT0_EXT if GL is bound to an application-created framebuffer object (GPU-based offscreen rendering) It is used by vtkOpenGLCamera.
- `int = obj.GetFrontBuffer ()` - Return the OpenGL name of the front left buffer. It is GL_FRONT if GL is bound to the window-system-provided framebuffer. It is vtkgl::COLOR_ATTACHMENT0_EXT if GL is bound to an application-created framebuffer object (GPU-based offscreen rendering) It is used by vtkOpenGLCamera.

- `obj.CheckGraphicError ()` - Update graphic error status, regardless of ReportGraphicErrors flag. It means this method can be used in any context and is not restricted to debug mode.
- `int = obj.HasGraphicError ()` - Return the last graphic error status. Initial value is false.
- `string = obj.GetLastGraphicErrorString ()` - Return a string matching the last graphic error status.
- `vtkOpenGLExtensionManager = obj.GetExtensionManager ()` - Returns the extension manager. A new one will be created if one hasn't already been set up.
- `vtkOpenGLHardwareSupport = obj.GetHardwareSupport ()` - Returns an Hardware Support object. A new one will be created if one hasn't already been set up.
- `obj.WaitForCompletion ()` - Block the thread until the actual rendering is finished(). Useful for measurement only.

39.126 vtkOpenGLRepresentationPainter

39.126.1 Usage

This is OpenGL implementation of a painter handling representation i.e. Points, Wireframe, Surface.

To create an instance of class vtkOpenGLRepresentationPainter, simply invoke its constructor as follows

```
obj = vtkOpenGLRepresentationPainter
```

39.126.2 Methods

The class vtkOpenGLRepresentationPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLRepresentationPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLRepresentationPainter = obj.NewInstance ()`
- `vtkOpenGLRepresentationPainter = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetTimeToDraw ()`

39.127 vtkOpenGLScalarsToColorsPainter

39.127.1 Usage

vtkOpenGLScalarsToColorsPainter is a concrete subclass of vtkScalarsToColorsPainter which uses OpenGL for color mapping.

To create an instance of class vtkOpenGLScalarsToColorsPainter, simply invoke its constructor as follows

```
obj = vtkOpenGLScalarsToColorsPainter
```

39.127.2 Methods

The class vtkOpenGLScalarsToColorsPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLScalarsToColorsPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLScalarsToColorsPainter = obj.NewInstance ()`
- `vtkOpenGLScalarsToColorsPainter = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release.
- `int = obj.GetPremultiplyColorsWithAlpha (vtkActor actor)`

39.128 vtkOpenGLTexture

39.128.1 Usage

vtkOpenGLTexture is a concrete implementation of the abstract class vtkTexture. vtkOpenGLTexture interfaces to the OpenGL rendering library.

To create an instance of class vtkOpenGLTexture, simply invoke its constructor as follows

```
obj = vtkOpenGLTexture
```

39.128.2 Methods

The class vtkOpenGLTexture has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLTexture class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLTexture = obj.NewInstance ()`
- `vtkOpenGLTexture = obj.SafeDownCast (vtkObject o)`
- `obj.Load (vtkRenderer ren)` - Implement base class method.
- `obj.PostRender (vtkRenderer ren)`
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this texture. The parameter window could be used to determine which graphic resources to release. Using the same texture object in multiple render windows is NOT currently supported.
- `long = obj.GetIndex ()` - Get the openGL texture name to which this texture is bound. This is available only if GL version ¿= 1.1

39.129 vtkOverlayPass

39.129.1 Usage

vtkOverlayPass renders the overlay geometry of all the props that have the keys contained in vtkRenderState.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color.

To create an instance of class vtkOverlayPass, simply invoke its constructor as follows

```
obj = vtkOverlayPass
```

39.129.2 Methods

The class vtkOverlayPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOverlayPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOverlayPass = obj.NewInstance ()`
- `vtkOverlayPass = obj.SafeDownCast (vtkObject o)`

39.130 vtkPainter

39.130.1 Usage

This defines the interface for a Painter. Painters are helpers used by Mapper to perform the rendering. The mapper sets up a chain of painters and passes the render request to the painter. Every painter may have a delegate painter to which the render request is forwarded. The Painter may modify the request or data before passing it to the delegate painter. All the information to control the rendering must be passed to the painter using the vtkInformation object. A concrete painter may read special keys from the vtkInformation object and affect the rendering.

To create an instance of class vtkPainter, simply invoke its constructor as follows

```
obj = vtkPainter
```

39.130.2 Methods

The class vtkPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPainter = obj.NewInstance ()`
- `vtkPainter = obj.SafeDownCast (vtkObject o)`
- `vtkInformation = obj.GetInformation ()` - Get/Set the information object associated with this painter.
- `obj.SetInformation (vtkInformation )` - Get/Set the information object associated with this painter.

- `vtkPainter = obj.GetDelegatePainter ()` - Set/Get the painter to which this painter should propagare its draw calls.
- `obj.SetDelegatePainter (vtkPainter )` - Set/Get the painter to which this painter should propagare its draw calls.
- `obj.Register (vtkObjectBase o)` - Take part in garbage collection.
- `obj.UnRegister (vtkObjectBase o)` - Take part in garbage collection.
- `obj.Render (vtkRenderer renderer, vtkActor actor, long typeflags, bool forceCompileOnly)` - Generates rendering primitives of appropriate type(s). Multiple types of primitives can be requested by or-ring the primitive flags. Default implementation calls UpdateDelegatePainter() to update the deletagate painter and then calls RenderInternal(). forceCompileOnly is passed to the display list painters.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this painter. The parameter window could be used to determine which graphic resources to release. The call is propagated to the delegate painter, if any.
- `obj.SetProgress (double )` - Set/Get the execution progress of a process object.
- `double = obj.GetProgressMinValue ()` - Set/Get the execution progress of a process object.
- `double = obj.GetProgressMaxValue ()` - Set/Get the execution progress of a process object.
- `double = obj.GetProgress ()` - Set/Get the execution progress of a process object.
- `double = obj.GetTimeToDraw ()` - Get the time required to draw the geometry last time it was rendered. Default implementation adds the current TimeToDraw with that of the delegate painter.
- `obj.UpdateBounds (double bounds[6])` - Expand or shrink the estimated bounds of the object based on the geometric transformations performed in the painter. If the painter does not modify the geometry, the bounds are passed through.
- `obj.SetInput (vtkDataObject )` - Set the data object to paint. Currently we only support one data object per painter chain.
- `vtkDataObject = obj.GetInput ()` - Set the data object to paint. Currently we only support one data object per painter chain.
- `vtkDataObject = obj.GetOutput ()`

39.131 vtkPainterDeviceAdapter

39.131.1 Usage

This class is an adapter between a vtkPainter and a rendering device (such as an OpenGL machine). Having an abstract adapter allows vtkPainters to be re-used for any rendering system.

Although VTK really only uses OpenGL right now, there are reasons to swap out the rendering functions. Sometimes MESA with mangled names is used. Also, different shader extensions use different functions. Furthermore, Cg also has its own interface.

The interface for this class should be familier to anyone experienced with OpenGL.

To create an instance of class vtkPainterDeviceAdapter, simply invoke its constructor as follows

```
obj = vtkPainterDeviceAdapter
```

39.131.2 Methods

The class vtkPainterDeviceAdapter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPainterDeviceAdapter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPainterDeviceAdapter = obj.NewInstance ()`
- `vtkPainterDeviceAdapter = obj.SafeDownCast (vtkObject o)`
- `obj.BeginPrimitive (int mode)` - Signals the start of sending a primitive to the graphics card. The mode is one of VTK_VERTEX, VTK_POLY_VERTEX, VTK_LINE, VTK_POLY_LINE, VTK_TRIANGLE, VTK_TRIANGLE_STRIP, VTK_POLYGON, or VTK_QUAD. The primitive is defined by the attributes sent between the calls to BeginPrimitive and EndPrimitive. You do not need to call EndPrimitive/BeginPrimitive between primitives that have a constant number of points (i.e. VTK_VERTEX, VTK_LINE, VTK_TRIANGLE, and VTK_QUAD).
- `obj.EndPrimitive ()` - Signals the end of sending a primitive to the graphics card.
- `int = obj.IsAttributesSupported (int attribute)` - Returns if the given attribute type is supported by the device. Returns 1 is supported, 0 otherwise.
- `obj.SetAttributePointer (int index, vtkDataArray attributeArray)` - Sets an array of attributes. This allows you to send all the data for a particular attribute with one call, thus greatly reducing function call overhead. Once set, the array is enabled with EnableAttributeArray, and the data is sent with a call to DrawArrays DrawElements.
- `obj.EnableAttributeArray (int index)` - Enable/disable the attribute array set with SetAttributePointer.
- `obj.DisableAttributeArray (int index)` - Enable/disable the attribute array set with SetAttributePointer.
- `obj.DrawArrays (int mode, vtkIdType first, vtkIdType count)` - Send a section of the enabled attribute pointers to the graphics card to define a primitive. The mode is one of VTK_VERTEX, VTK_POLY_VERTEX, VTK_LINE, VTK_POLY_LINE, VTK_TRIANGLE, VTK_TRIANGLE_STRIP, VTK_POLYGON, or VTK_QUAD. It identifies which type of primitive the attribute data is defining. The parameters first and count identify what part of the attribute arrays define the given primitive. If mode is a primitive that has a constant number of points (i.e. VTK_VERTEX, VTK_LINE, VTK_TRIANGLE, and VTK_QUAD), you may draw multiple primitives with one call to DrawArrays.
- `int = obj.Compatible (vtkRenderer renderer)` - Returns true if this device adapter is compatable with the given vtkRenderer.
- `obj.MakeLighting (int mode)` - Turns lighting on and off.
- `int = obj.QueryLighting ()` - Returns current lighting setting.
- `obj.MakeMultisampling (int mode)` - Turns antialiasing on and off.
- `int = obj.QueryMultisampling ()` - Returns current antialiasing setting.
- `obj.MakeBlending (int mode)` - Turns blending on and off.
- `int = obj.QueryBlending ()` - Returns current blending setting.

- `obj.MakeVertexEmphasis (bool mode)` - Turns emphasis of vertices on or off for vertex selection.
- `obj.MakeVertexEmphasisWithStencilCheck (int )` - @deprecated
- `obj.Stencil (int on)` - Control use of the stencil buffer (for vertex selection).
- `obj.WriteStencil (vtkIdType value)` - Control use of the stencil buffer (for vertex selection).
- `obj.TestStencil (vtkIdType value)` - Control use of the stencil buffer (for vertex selection).

39.132 vtkPainterPolyDataMapper

39.132.1 Usage

PolyDataMapper that uses painters to do the actual rendering. .SECTION Thanks Support for generic vertex attributes in VTK was contributed in collaboration with Stephane Ploix at EDF.

To create an instance of class vtkPainterPolyDataMapper, simply invoke its constructor as follows

```
obj = vtkPainterPolyDataMapper
```

39.132.2 Methods

The class vtkPainterPolyDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPainterPolyDataMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPainterPolyDataMapper = obj.NewInstance ()`
- `vtkPainterPolyDataMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderPiece (vtkRenderer ren, vtkActor act)` - Implemented by sub classes. Actual rendering is done here.
- `vtkPainter = obj.GetPainter ()` - Get/Set the painter used to do the actual rendering. By default, vtkDefaultPainter is used to build the rendering painter chain for color mapping/clipping etc. followed by a vtkChooserPainter which renders the primitives.
- `obj.SetPainter (vtkPainter )` - Get/Set the painter used to do the actual rendering. By default, vtkDefaultPainter is used to build the rendering painter chain for color mapping/clipping etc. followed by a vtkChooserPainter which renders the primitives.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release. Merely propagates the call to the painter.
- `obj.GetBounds (double bounds[6])` - Re-implement the superclass GetBounds method.
- `double = obj.GetBounds ()` - Re-implement the superclass GetBounds method.
- `obj.MapDataArrayToVertexAttribute (string vertexAttributeName, string dataArrayName, int fieldAssoc` - Select a data array from the point/cell data and map it to a generic vertex attribute. vertexAttributeName is the name of the vertex attribute. dataArrayName is the name of the data array. fieldAssociation indicates when the data array is a point data array or cell data array (vtkDataObject::FIELD_ASSOCIATION_POINTS or (vtkDataObject::FIELD_ASSOCIATION_CELLS). componentno indicates which component from the data array must be passed as the attribute. If -1, then all components are passed.

- `obj.MapDataArrayToMultiTextureAttribute (int unit, string dataArrayName, int fieldAssociation, int`
- `obj.RemoveVertexAttributeMapping (string vertexAttributeName)` - Remove a vertex attribute mapping.
- `obj.RemoveAllVertexAttributeMappings ()` - Remove all vertex attributes.
- `vtkPainter = obj.GetSelectionPainter ()` - Get/Set the painter used when rendering the selection pass.
- `obj.SetSelectionPainter (vtkPainter )` - Get/Set the painter used when rendering the selection pass.
- `bool = obj.GetSupportsSelection ()`

39.133 vtkParallelCoordinatesActor

39.133.1 Usage

vtkParallelCoordinatesActor generates a parallel coordinates plot from an input field (i.e., vtkDataObject). Parallel coordinates represent N-dimensional data by using a set of N parallel axes (not orthogonal like the usual x-y-z Cartesian axes). Each N-dimensional point is plotted as a polyline, were each of the N components of the point lie on one of the N axes, and the components are connected by straight lines.

To use this class, you must specify an input data object. You'll probably also want to specify the position of the plot be setting the Position and Position2 instance variables, which define a rectangle in which the plot lies. Another important parameter is the IndependentVariables ivar, which tells the instance how to interpret the field data (independent variables as the rows or columns of the field). There are also many other instance variables that control the look of the plot includes its title, attributes, number of ticks on the axes, etc.

Set the text property/attributes of the title and the labels through the vtkTextProperty objects associated to this actor.

To create an instance of class vtkParallelCoordinatesActor, simply invoke its constructor as follows

```
obj = vtkParallelCoordinatesActor
```

39.133.2 Methods

The class vtkParallelCoordinatesActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelCoordinatesActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelCoordinatesActor = obj.NewInstance ()`
- `vtkParallelCoordinatesActor = obj.SafeDownCast (vtkObject o)`
- `obj.SetIndependentVariables (int )` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `int = obj.GetIndependentVariablesMinValue ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.

- `int = obj.GetIndependentVariablesMaxValue ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `int = obj.GetIndependentVariables ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `obj.SetIndependentVariablesToColumns ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `obj.SetIndependentVariablesToRows ()` - Specify whether to use the rows or columns as independent variables. If columns, then each row represents a separate point. If rows, then each column represents a separate point.
- `obj.SetTitle (string )` - Set/Get the title of the parallel coordinates plot.
- `string = obj.GetTitle ()` - Set/Get the title of the parallel coordinates plot.
- `obj.SetNumberOfLabels (int )` - Set/Get the number of annotation labels to show along each axis. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `int = obj.GetNumberOfLabelsMinValue ()` - Set/Get the number of annotation labels to show along each axis. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `int = obj.GetNumberOfLabelsMaxValue ()` - Set/Get the number of annotation labels to show along each axis. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `int = obj.GetNumberOfLabels ()` - Set/Get the number of annotation labels to show along each axis. This values is a suggestion: the number of labels may vary depending on the particulars of the data.
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the labels on the axes.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the labels on the axes.
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property.
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the labels text property.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Draw the parallel coordinates plot.
- `int = obj.RenderOverlay (vtkViewport )` - Draw the parallel coordinates plot.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Does this prop have some translucent polygonal geometry?
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.SetInput (vtkDataObject )` - Set the input to the parallel coordinates actor.
- `vtkDataObject = obj.GetInput ()` - Remove a dataset from the list of data to append.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.

39.134 vtkParallelCoordinatesInteractorStyle

39.134.1 Usage

vtkParallelCoordinatesInteractorStyle allows the user to interactively manipulate (rotate, pan, zoomm etc.) the camera. Several events are overloaded from its superclass vtkParallelCoordinatesInteractorStyle, hence the mouse bindings are different. (The bindings keep the camera's view plane normal perpendicular to the x-y plane.) In summary the mouse events are as follows: + Left Mouse button triggers window level events + CTRL Left Mouse spins the camera around its view plane normal + SHIFT Left Mouse pans the camera + CTRL SHIFT Left Mouse dollys (a positional zoom) the camera + Middle mouse button pans the camera + Right mouse button dollys the camera. + SHIFT Right Mouse triggers pick events

Note that the renderer's actors are not moved; instead the camera is moved.

To create an instance of class vtkParallelCoordinatesInteractorStyle, simply invoke its constructor as follows

```
obj = vtkParallelCoordinatesInteractorStyle
```

39.134.2 Methods

The class vtkParallelCoordinatesInteractorStyle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelCoordinatesInteractorStyle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelCoordinatesInteractorStyle = obj.NewInstance ()`
- `vtkParallelCoordinatesInteractorStyle = obj.SafeDownCast (vtkObject o)`
- `int = obj. GetCursorStartPosition ()` - Get the cursor positions in pixel coords
- `int = obj. GetCursorCurrentPosition ()` - Get the cursor positions in pixel coords
- `int = obj. GetCursorLastPosition ()` - Get the cursor positions in pixel coords
- `obj.GetCursorStartPosition (vtkViewport viewport, double pos[2])` - Get the cursor positions in a given coordinate system
- `obj.GetCursorCurrentPosition (vtkViewport viewport, double pos[2])` - Get the cursor positions in a given coordinate system
- `obj.GetCursorLastPosition (vtkViewport viewport, double pos[2])` - Get the cursor positions in a given coordinate system
- `obj.OnMouseMove ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeftButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnMiddleButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.

- `obj.OnRightButtonDown ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnRightButtonUp ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.OnLeave ()` - Event bindings controlling the effects of pressing mouse buttons or moving the mouse.
- `obj.StartInspect (int x, int y)`
- `obj.Inspect (int x, int y)`
- `obj.EndInspect ()`
- `obj.StartZoom ()`
- `obj.Zoom ()`
- `obj.EndZoom ()`
- `obj.StartPan ()`
- `obj.Pan ()`
- `obj.EndPan ()`
- `obj.OnChar ()` - Override the "fly-to" (f keypress) for images.

39.135 vtkPicker

39.135.1 Usage

vtkPicker is used to select instances of vtkProp3D by shooting a ray into a graphics window and intersecting with the actor's bounding box. The ray is defined from a point defined in window (or pixel) coordinates, and a point located from the camera's position.

vtkPicker may return more than one vtkProp3D, since more than one bounding box may be intersected. vtkPicker returns an unsorted list of props that were hit, and a list of the corresponding world points of the hits. For the vtkProp3D that is closest to the camera, vtkPicker returns the pick coordinates in world and untransformed mapper space, the prop itself, the data set, and the mapper. For vtkPicker the closest prop is the one whose center point (i.e., center of bounding box) projected on the view ray is closest to the camera. Subclasses of vtkPicker use other methods for computing the pick point.

To create an instance of class vtkPicker, simply invoke its constructor as follows

```
obj = vtkPicker
```

39.135.2 Methods

The class vtkPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPicker = obj.NewInstance ()`
- `vtkPicker = obj.SafeDownCast (vtkObject o)`

- `obj.SetTolerance (double )` - Specify tolerance for performing pick operation. Tolerance is specified as fraction of rendering window size. (Rendering window size is measured across diagonal.)
- `double = obj.GetTolerance ()` - Specify tolerance for performing pick operation. Tolerance is specified as fraction of rendering window size. (Rendering window size is measured across diagonal.)
- `double = obj. GetMapperPosition ()` - Return position in mapper (i.e., non-transformed) coordinates of pick point.
- `vtkAbstractMapper3D = obj.GetMapper ()` - Return mapper that was picked (if any).
- `vtkDataSet = obj.GetDataSet ()` - Get a pointer to the dataset that was picked (if any). If nothing was picked then NULL is returned.
- `vtkProp3DCollection = obj.GetProp3Ds ()` - Return a collection of all the prop 3D's that were intersected by the pick ray. This collection is not sorted.
- `vtkActorCollection = obj.GetActors ()` - Return a collection of all the actors that were intersected. This collection is not sorted. (This is a convenience method to maintain backward compatibility.)
- `vtkPoints = obj.GetPickedPositions ()` - Return a list of the points the the actors returned by GetProp3Ds were intersected at. The order of this list will match the order of GetProp3Ds.
- `int = obj.Pick (double selectionX, double selectionY, double selectionZ, vtkRenderer renderer)` - Perform pick operation with selection point provided. Normally the first two values for the selection point are x-y pixel coordinate, and the third value is =0. Return non-zero if something was successfully picked.
- `int = obj.Pick (double selectionPt[3], vtkRenderer ren)` - Perform pick operation with selection point provided. Normally the first two values for the selection point are x-y pixel coordinate, and the third value is =0. Return non-zero if something was successfully picked.

39.136 vtkPixelBufferObject

39.136.1 Usage

Provides low-level access to GPU memory. Used to pass raw data to GPU. The data is uploaded into a pixel buffer.

To create an instance of class vtkPixelBufferObject, simply invoke its constructor as follows

```
obj = vtkPixelBufferObject
```

39.136.2 Methods

The class vtkPixelBufferObject has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPixelBufferObject class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPixelBufferObject = obj.NewInstance ()`
- `vtkPixelBufferObject = obj.SafeDownCast (vtkObject o)`

- `obj.SetContext (vtkRenderWindow context)` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.
- `vtkRenderWindow = obj.GetContext ()` - Get/Set the context. Context must be a vtkOpenGLRenderWindow. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.
- `int = obj.GetUsage ()` - Usage is a performance hint. Valid values are: - StreamDraw specified once by A, used few times S - StreamRead specified once by R, queried a few times by A - StreamCopy specified once by R, used a few times S - StaticDraw specified once by A, used many times S - StaticRead specificed once by R, queried many times by A - StaticCopy specified once by R, used many times S - DynamicDraw respecified repeatedly by A, used many times S - DynamicRead respecified repeatedly by R, queried many times by A - DynamicCopy respecified repeatedly by R, used many times S A: the application S: as the source for GL drawing and image specification commands. R: reading data from the GL Initial value is StaticDraw, as in OpenGL spec.
- `obj.SetUsage (int )` - Usage is a performance hint. Valid values are: - StreamDraw specified once by A, used few times S - StreamRead specified once by R, queried a few times by A - StreamCopy specified once by R, used a few times S - StaticDraw specified once by A, used many times S - StaticRead specificed once by R, queried many times by A - StaticCopy specified once by R, used many times S - DynamicDraw respecified repeatedly by A, used many times S - DynamicRead respecified repeatedly by R, queried many times by A - DynamicCopy respecified repeatedly by R, used many times S A: the application S: as the source for GL drawing and image specification commands. R: reading data from the GL Initial value is StaticDraw, as in OpenGL spec.
- `int = obj.GetType ()` - Get the type with which the data is loaded into the GPU. eg. VTK_FLOAT for float32, VTK_CHAR for byte, VTK_UNSIGNED_CHAR for unsigned byte etc.
- `int = obj.GetSize ()` - Get the size of the data loaded into the GPU. Size is in the number of elements of the uploaded Type.
- `int = obj.GetHandle ()` - Get the openGL buffer handle.
- `obj.BindToPackedBuffer ()`
- `obj.BindToUnPackedBuffer ()` - Inactivate the buffer.
- `obj.UnBind ()` - Inactivate the buffer.

39.137 vtkPointPicker

39.137.1 Usage

To create an instance of class vtkPointPicker, simply invoke its constructor as follows

```
obj = vtkPointPicker
```

39.137.2 Methods

The class vtkPointPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkPointPicker = obj.NewInstance ()`
- `vtkPointPicker = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetPointId ()` - Get the id of the picked point. If PointId = -1, nothing was picked.

39.138 vtkPointSetToLabelHierarchy

39.138.1 Usage

Every point in the input vtkPoints object is taken to be an anchor point for a label. Statistics on the input points are used to subdivide an octree referencing the points until the points each octree node contains have a variance close to the node size and a limited population (¡ 100).

To create an instance of class vtkPointSetToLabelHierarchy, simply invoke its constructor as follows

```
obj = vtkPointSetToLabelHierarchy
```

39.138.2 Methods

The class vtkPointSetToLabelHierarchy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointSetToLabelHierarchy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointSetToLabelHierarchy = obj.NewInstance ()`
- `vtkPointSetToLabelHierarchy = obj.SafeDownCast (vtkObject o)`
- `obj.SetTargetLabelCount (int )` - Set/get the "ideal" number of labels to associate with each node in the output hierarchy.
- `int = obj.GetTargetLabelCount ()` - Set/get the "ideal" number of labels to associate with each node in the output hierarchy.
- `obj.SetMaximumDepth (int )` - Set/get the maximum tree depth in the output hierarchy.
- `int = obj.GetMaximumDepth ()` - Set/get the maximum tree depth in the output hierarchy.
- `obj.SetUseUnicodeStrings (bool )` - Whether to use unicode strings.
- `bool = obj.GetUseUnicodeStrings ()` - Whether to use unicode strings.
- `obj.UseUnicodeStringsOn ()` - Whether to use unicode strings.
- `obj.UseUnicodeStringsOff ()` - Whether to use unicode strings.
- `obj.SetLabelArrayName (string name)` - Set/get the label array name.
- `string = obj.GetLabelArrayName ()` - Set/get the label array name.
- `obj.SetSizeArrayName (string name)` - Set/get the priority array name.
- `string = obj.GetSizeArrayName ()` - Set/get the priority array name.
- `obj.SetPriorityArrayName (string name)` - Set/get the priority array name.

- `string = obj.GetPriorityArrayName ()` - Set/get the priority array name.
- `obj.SetIconIndexArrayName (string name)` - Set/get the icon index array name.
- `string = obj.GetIconIndexArrayName ()` - Set/get the icon index array name.
- `obj.SetOrientationArrayName (string name)` - Set/get the text orientation array name.
- `string = obj.GetOrientationArrayName ()` - Set/get the text orientation array name.
- `obj.SetBoundedSizeArrayName (string name)` - Set/get the maximum text width (in world coordinates) array name.
- `string = obj.GetBoundedSizeArrayName ()` - Set/get the maximum text width (in world coordinates) array name.
- `obj.SetTextProperty (vtkTextProperty tprop)` - Set/get the text property assigned to the hierarchy.
- `vtkTextProperty = obj.GetTextProperty ()` - Set/get the text property assigned to the hierarchy.

39.139 vtkPointsPainter

39.139.1 Usage

This painter tries to paint points efficiently. Request to Render any other primitive are ignored and not passed to the delegate painter, if any. This painter cannot handle cell colors/normals. If they are present the request is passed on to the Delegate painter. If this class is able to render the primitive, the render request is not propagated to the delegate painter.

To create an instance of class vtkPointsPainter, simply invoke its constructor as follows

```
obj = vtkPointsPainter
```

39.139.2 Methods

The class vtkPointsPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointsPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointsPainter = obj.NewInstance ()`
- `vtkPointsPainter = obj.SafeDownCast (vtkObject o)`

39.140 vtkPolyDataMapper

39.140.1 Usage

vtkPolyDataMapper is a class that maps polygonal data (i.e., vtkPolyData) to graphics primitives. vtkPolyDataMapper serves as a superclass for device-specific poly data mappers, that actually do the mapping to the rendering/graphics hardware/software.

To create an instance of class vtkPolyDataMapper, simply invoke its constructor as follows

```
obj = vtkPolyDataMapper
```

39.140.2 Methods

The class vtkPolyDataMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataMapper = obj.NewInstance ()`
- `vtkPolyDataMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderPiece (vtkRenderer ren, vtkActor act)` - Implemented by sub classes. Actual rendering is done here.
- `obj.Render (vtkRenderer ren, vtkActor act)` - This calls RenderPiece (in a for loop is streaming is necessary).
- `obj.SetInput (vtkPolyData in)` - Specify the input data to map.
- `vtkPolyData = obj.GetInput ()` - Specify the input data to map.
- `obj.Update ()` - Update that sets the update piece first.
- `obj.SetPiece (int )` - If you want only a part of the data, specify by setting the piece.
- `int = obj.GetPiece ()` - If you want only a part of the data, specify by setting the piece.
- `obj.SetNumberOfPieces (int )` - If you want only a part of the data, specify by setting the piece.
- `int = obj.GetNumberOfPieces ()` - If you want only a part of the data, specify by setting the piece.
- `obj.SetNumberOfSubPieces (int )` - If you want only a part of the data, specify by setting the piece.
- `int = obj.GetNumberOfSubPieces ()` - If you want only a part of the data, specify by setting the piece.
- `obj.SetGhostLevel (int )` - Set the number of ghost cells to return.
- `int = obj.GetGhostLevel ()` - Set the number of ghost cells to return.
- `double = obj.GetBounds ()` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.GetBounds (double bounds[6])` - Return bounding box (array of six doubles) of data expressed as (xmin,xmax, ymin,ymax, zmin,zmax).
- `obj.ShallowCopy (vtkAbstractMapper m)` - Make a shallow copy of this mapper.
- `obj.MapDataArrayToVertexAttribute (string vertexAttributeName, string dataArrayName, int fieldAssoc` - Select a data array from the point/cell data and map it to a generic vertex attribute. vertexAttributeName is the name of the vertex attribute. dataArrayName is the name of the data array. fieldAssociation indicates when the data array is a point data array or cell data array (vtkDataObject::FIELD_ASSOCIATION_POINTS or (vtkDataObject::FIELD_ASSOCIATION_CELLS). componentno indicates which component from the data array must be passed as the attribute. If -1, then all components are passed.
- `obj.MapDataArrayToMultiTextureAttribute (int unit, string dataArrayName, int fieldAssociation, int`
- `obj.RemoveVertexAttributeMapping (string vertexAttributeName)` - Remove a vertex attribute mapping.
- `obj.RemoveAllVertexAttributeMappings ()` - Remove all vertex attributes.

39.141 vtkPolyDataMapper2D

39.141.1 Usage

vtkPolyDataMapper2D is a mapper that renders 3D polygonal data (vtkPolyData) onto the 2D image plane (i.e., the renderer's viewport). By default, the 3D data is transformed into 2D data by ignoring the z-coordinate of the 3D points in vtkPolyData, and taking the x-y values as local display values (i.e., pixel coordinates). Alternatively, you can provide a vtkCoordinate object that will transform the data into local display coordinates (use the vtkCoordinate::SetCoordinateSystem() methods to indicate which coordinate system you are transforming the data from).

To create an instance of class vtkPolyDataMapper2D, simply invoke its constructor as follows

```
obj = vtkPolyDataMapper2D
```

39.141.2 Methods

The class vtkPolyDataMapper2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataMapper2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataMapper2D = obj.NewInstance ()`
- `vtkPolyDataMapper2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkPolyData in)` - Set the input to the mapper.
- `vtkPolyData = obj.GetInput ()` - Set the input to the mapper.
- `obj.SetLookupTable (vtkScalarsToColors lut)` - Specify a lookup table for the mapper to use.
- `vtkScalarsToColors = obj.GetLookupTable ()` - Specify a lookup table for the mapper to use.
- `obj.CreateDefaultLookupTable ()` - Create default lookup table. Generally used to create one when none is available with the scalar data.
- `obj.SetScalarVisibility (int )` - Turn on/off flag to control whether scalar data is used to color objects.
- `int = obj.GetScalarVisibility ()` - Turn on/off flag to control whether scalar data is used to color objects.
- `obj.ScalarVisibilityOn ()` - Turn on/off flag to control whether scalar data is used to color objects.
- `obj.ScalarVisibilityOff ()` - Turn on/off flag to control whether scalar data is used to color objects.
- `obj.SetColorMode (int )` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the ColorByArrayComponent() method.)
- `int = obj.GetColorMode ()` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the ColorByArrayComponent() method.)

- `obj.SetColorModeToDefault ()` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the ColorByArrayComponent() method.)

- `obj.SetColorModeToMapScalars ()` - Control how the scalar data is mapped to colors. By default (ColorModeToDefault), unsigned char scalars are treated as colors, and NOT mapped through the lookup table, while everything else is. Setting ColorModeToMapScalars means that all scalar data will be mapped through the lookup table. (Note that for multi-component scalars, the particular component to use for mapping can be specified using the ColorByArrayComponent() method.)

- `string = obj.GetColorModeAsString ()` - Return the method of coloring scalar data.

- `obj.SetUseLookupTableScalarRange (int )` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.

- `int = obj.GetUseLookupTableScalarRange ()` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.

- `obj.UseLookupTableScalarRangeOn ()` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.

- `obj.UseLookupTableScalarRangeOff ()` - Control whether the mapper sets the lookuptable range based on its own ScalarRange, or whether it will use the LookupTable ScalarRange regardless of it's own setting. By default the Mapper is allowed to set the LookupTable range, but users who are sharing LookupTables between mappers/actors will probably wish to force the mapper to use the LookupTable unchanged.

- `obj.SetScalarRange (double , double )` - Specify range in terms of scalar minimum and maximum (smin,smax). These values are used to map scalars into lookup table. Has no effect when UseLookupTableScalarRange is true.

- `obj.SetScalarRange (double  a[2])` - Specify range in terms of scalar minimum and maximum (smin,smax). These values are used to map scalars into lookup table. Has no effect when UseLookupTableScalarRange is true.

- `double = obj. GetScalarRange ()` - Specify range in terms of scalar minimum and maximum (smin,smax). These values are used to map scalars into lookup table. Has no effect when UseLookupTableScalarRange is true.

- `obj.SetScalarMode (int )` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `int = obj.GetScalarMode ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `obj.SetScalarModeToDefault ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `obj.SetScalarModeToUsePointData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `obj.SetScalarModeToUseCellData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `obj.SetScalarModeToUsePointFieldData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `obj.SetScalarModeToUseCellFieldData ()` - Control how the filter works with scalar point data and cell attribute data. By default (ScalarModeToDefault), the filter will use point data, and if no point data is available, then cell data is used. Alternatively you can explicitly set the filter to use point data (ScalarModeToUsePointData) or cell data (ScalarModeToUseCellData). You can also choose to get the scalars from an array in point field data (ScalarModeToUsePointFieldData) or cell field data (ScalarModeToUseCellFieldData). If scalars are coming from a field data array, you must call ColorByArrayComponent before you call GetColors.

- `obj.ColorByArrayComponent (int arrayNum, int component)` - Choose which component of which field data array to color by.

- `obj.ColorByArrayComponent (string arrayName, int component)` - Choose which component of which field data array to color by.

- `string = obj.GetArrayName ()` - Get the array name or number and component to color by.

- `int = obj.GetArrayId ()` - Get the array name or number and component to color by.

- `int = obj.GetArrayAccessMode ()` - Get the array name or number and component to color by.
- `int = obj.GetArrayComponent ()` - Overload standard modified time function. If lookup table is modified, then this object is modified as well.
- `long = obj.GetMTime ()` - Overload standard modified time function. If lookup table is modified, then this object is modified as well.
- `obj.SetTransformCoordinate (vtkCoordinate )` - Specify a vtkCoordinate object to be used to transform the vtkPolyData point coordinates. By default (no vtkCoordinate specified), the point coordinates are taken as local display coordinates.
- `vtkCoordinate = obj.GetTransformCoordinate ()` - Specify a vtkCoordinate object to be used to transform the vtkPolyData point coordinates. By default (no vtkCoordinate specified), the point coordinates are taken as local display coordinates.
- `vtkUnsignedCharArray = obj.MapScalars (double alpha)` - Map the scalars (if there are any scalars and ScalarVisibility is on) through the lookup table, returning an unsigned char RGBA array. This is typically done as part of the rendering process. The alpha parameter allows the blending of the scalars with an additional alpha (typically which comes from a vtkActor, etc.)
- `obj.ShallowCopy (vtkAbstractMapper m)` - Make a shallow copy of this mapper.

39.142 vtkPolyDataPainter

39.142.1 Usage

vtkPolyDataPainter encapsulates a method of drawing poly data. This is a subset of what a mapper does. The painter does no maintenance of the rendering state (camera, lights, etc.). It is solely responsible for issuing rendering commands that build graphics primitives.

To simplify coding, an implementation of vtkPolyDataPainter is allowed to support only certain types of poly data or certain types of primitives.

To create an instance of class vtkPolyDataPainter, simply invoke its constructor as follows

```
obj = vtkPolyDataPainter
```

39.142.2 Methods

The class vtkPolyDataPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataPainter = obj.NewInstance ()`
- `vtkPolyDataPainter = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetInputAsPolyData ()` - Get/set the poly data to render.
- `vtkPolyData = obj.GetOutputAsPolyData ()` - Get the output polydata from this Painter. The default implementation forwards the input polydata as the output.
- `obj.Render (vtkRenderer renderer, vtkActor actor, long typeflags, bool forceCompileOnly)` - Overridden to stop the render call if input polydata is not set, since PolyDataPainter cannot paint without any polydata input.

39.143 vtkPolygonsPainter

39.143.1 Usage

This painter renders Polys in vtkPolyData. It can render the polys in any representation (VTK_POINTS, VTK_WIREFRAME, VTK_SURFACE).

To create an instance of class vtkPolygonsPainter, simply invoke its constructor as follows

```
obj = vtkPolygonsPainter
```

39.143.2 Methods

The class vtkPolygonsPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolygonsPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolygonsPainter = obj.NewInstance ()`
- `vtkPolygonsPainter = obj.SafeDownCast (vtkObject o)`

39.144 vtkPOVExporter

39.144.1 Usage

This Exporter can be attached to a render window in order to generate scene description files for the Persistance of Vision Raytracer www.povray.org.

.SECTION Thanks Li-Ta Lo (ollie@lanl.gov) and Jim Ahrens (ahrens@lanl.gov) Los Alamos National Laboratory

To create an instance of class vtkPOVExporter, simply invoke its constructor as follows

```
obj = vtkPOVExporter
```

39.144.2 Methods

The class vtkPOVExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPOVExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPOVExporter = obj.NewInstance ()`
- `vtkPOVExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )`
- `string = obj.GetFileName ()`

39.145 vtkPrimitivePainter

39.145.1 Usage

This is the abstract superclass for classes that handle single type of primitive i.e. verts, lines, polys or tstrips. Concrete subclasses will pass a Render() call to the delegate painter, if any, only if it could not render. .SECTION Thanks Support for generic vertex attributes in VTK was contributed in collaboration with Stephane Ploix at EDF.

To create an instance of class vtkPrimitivePainter, simply invoke its constructor as follows

```
obj = vtkPrimitivePainter
```

39.145.2 Methods

The class vtkPrimitivePainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPrimitivePainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPrimitivePainter = obj.NewInstance ()`
- `vtkPrimitivePainter = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetSupportedPrimitive ()` - Get the type of primitive supported by this painter. This must be set by concrete subclasses.

39.146 vtkProp3D

39.146.1 Usage

vtkProp3D is an abstract class used to represent an entity in a rendering scene (i.e., vtkProp3D is a vtkProp with an associated transformation matrix). It handles functions related to the position, orientation and scaling. It combines these instance variables into one 4x4 transformation matrix as follows: [x y z 1] = [x y z 1] Translate(-origin) Scale(scale) Rot(y) Rot(x) Rot (z) Trans(origin) Trans(position). Both vtkActor and vtkVolume are specializations of class vtkProp. The constructor defaults to: origin(0,0,0) position=(0,0,0) orientation=(0,0,0), no user defined matrix or transform, and no texture map.

To create an instance of class vtkProp3D, simply invoke its constructor as follows

```
obj = vtkProp3D
```

39.146.2 Methods

The class vtkProp3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProp3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProp3D = obj.NewInstance ()`
- `vtkProp3D = obj.SafeDownCast (vtkObject o)`
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this vtkProp3D.

- `obj.SetPosition (double \_arg1, double \_arg2, double \_arg3)` - Set/Get/Add the position of the Prop3D in world coordinates.
- `obj.SetPosition (double \_arg[3])` - Set/Get/Add the position of the Prop3D in world coordinates.
- `double = obj. GetPosition ()` - Set/Get/Add the position of the Prop3D in world coordinates.
- `obj.AddPosition (double deltaPosition[3])` - Set/Get/Add the position of the Prop3D in world coordinates.
- `obj.AddPosition (double deltaX, double deltaY, double deltaZ)` - Set/Get/Add the position of the Prop3D in world coordinates.
- `obj.SetOrigin (double \_arg1, double \_arg2, double \_arg3)` - Set/Get the origin of the Prop3D. This is the point about which all rotations take place.
- `obj.SetOrigin (double \_arg[3])` - Set/Get the origin of the Prop3D. This is the point about which all rotations take place.
- `double = obj. GetOrigin ()` - Set/Get the origin of the Prop3D. This is the point about which all rotations take place.
- `obj.SetScale (double \_arg1, double \_arg2, double \_arg3)` - Set/Get the scale of the actor. Scaling in performed independently on the X, Y and Z axis. A scale of zero is illegal and will be replaced with one.
- `obj.SetScale (double \_arg[3])` - Set/Get the scale of the actor. Scaling in performed independently on the X, Y and Z axis. A scale of zero is illegal and will be replaced with one.
- `double = obj. GetScale ()` - Set/Get the scale of the actor. Scaling in performed independently on the X, Y and Z axis. A scale of zero is illegal and will be replaced with one.
- `obj.SetScale (double s)` - Method to set the scale isotropically
- `obj.SetUserTransform (vtkLinearTransform transform)` - In addition to the instance variables such as position and orientation, you can add an additional transformation for your own use. This transformation is concatenated with the actor's internal transformation, which you implicitly create through the use of SetPosition(), SetOrigin() and SetOrientation(). ¡p¿If the internal transformation is identity (i.e. if you don't set the Position, Origin, or Orientation) then the actors final transformation will be the UserTransform, concatenated with the UserMatrix if the UserMatrix is present.
- `vtkLinearTransform = obj.GetUserTransform ()` - In addition to the instance variables such as position and orientation, you can add an additional transformation for your own use. This transformation is concatenated with the actor's internal transformation, which you implicitly create through the use of SetPosition(), SetOrigin() and SetOrientation(). ¡p¿If the internal transformation is identity (i.e. if you don't set the Position, Origin, or Orientation) then the actors final transformation will be the UserTransform, concatenated with the UserMatrix if the UserMatrix is present.
- `obj.SetUserMatrix (vtkMatrix4x4 matrix)` - The UserMatrix can be used in place of UserTransform.
- `vtkMatrix4x4 = obj.GetUserMatrix ()` - The UserMatrix can be used in place of UserTransform.
- `obj.GetMatrix (vtkMatrix4x4 m)` - Return a reference to the Prop3D's 4x4 composite matrix. Get the matrix from the position, origin, scale and orientation This matrix is cached, so multiple GetMatrix() calls will be efficient.
- `obj.GetMatrix (double m[16])` - Return a reference to the Prop3D's 4x4 composite matrix. Get the matrix from the position, origin, scale and orientation This matrix is cached, so multiple GetMatrix() calls will be efficient.

- `obj.GetBounds (double bounds[6])` - Get the bounds for this Prop3D as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `double = obj.GetBounds ()` - Get the bounds for this Prop3D as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax).
- `double = obj.GetCenter ()` - Get the center of the bounding box in world coordinates.
- `double = obj.GetXRange ()` - Get the Prop3D's x range in world coordinates.
- `double = obj.GetYRange ()` - Get the Prop3D's y range in world coordinates.
- `double = obj.GetZRange ()` - Get the Prop3D's z range in world coordinates.
- `double = obj.GetLength ()` - Get the length of the diagonal of the bounding box.
- `obj.RotateX (double )` - Rotate the Prop3D in degrees about the X axis using the right hand rule. The axis is the Prop3D's X axis, which can change as other rotations are performed. To rotate about the world X axis use RotateWXYZ (angle, 1, 0, 0). This rotation is applied before all others in the current transformation matrix.
- `obj.RotateY (double )` - Rotate the Prop3D in degrees about the Y axis using the right hand rule. The axis is the Prop3D's Y axis, which can change as other rotations are performed. To rotate about the world Y axis use RotateWXYZ (angle, 0, 1, 0). This rotation is applied before all others in the current transformation matrix.
- `obj.RotateZ (double )` - Rotate the Prop3D in degrees about the Z axis using the right hand rule. The axis is the Prop3D's Z axis, which can change as other rotations are performed. To rotate about the world Z axis use RotateWXYZ (angle, 0, 0, 1). This rotation is applied before all others in the current transformation matrix.
- `obj.RotateWXYZ (double , double , double , double )` - Rotate the Prop3D in degrees about an arbitrary axis specified by the last three arguments. The axis is specified in world coordinates. To rotate an about its model axes, use RotateX, RotateY, RotateZ.
- `obj.SetOrientation (double , double , double )` - Sets the orientation of the Prop3D. Orientation is specified as X,Y and Z rotations in that order, but they are performed as RotateZ, RotateX, and finally RotateY.
- `obj.SetOrientation (double a[3])` - Sets the orientation of the Prop3D. Orientation is specified as X,Y and Z rotations in that order, but they are performed as RotateZ, RotateX, and finally RotateY.
- `double = obj.GetOrientation ()` - Returns the orientation of the Prop3D as s vector of X,Y and Z rotation. The ordering in which these rotations must be done to generate the same matrix is RotateZ, RotateX, and finally RotateY. See also SetOrientation.
- `obj.GetOrientation (double o[3])` - Returns the orientation of the Prop3D as s vector of X,Y and Z rotation. The ordering in which these rotations must be done to generate the same matrix is RotateZ, RotateX, and finally RotateY. See also SetOrientation.
- `double = obj.GetOrientationWXYZ ()` - Returns the WXYZ orientation of the Prop3D.
- `obj.AddOrientation (double , double , double )` - Add to the current orientation. See SetOrientation and GetOrientation for more details. This basically does a GetOrientation, adds the passed in arguments, and then calls SetOrientation.
- `obj.AddOrientation (double a[3])` - Add to the current orientation. See SetOrientation and GetOrientation for more details. This basically does a GetOrientation, adds the passed in arguments, and then calls SetOrientation.

- `obj.PokeMatrix (vtkMatrix4x4 matrix)` - This method modifies the vtkProp3D so that its transformation state is set to the matrix specified. The method does this by setting appropriate transformation-related ivars to initial values (i.e., not transformed), and placing the user-supplied matrix into the UserMatrix of this vtkProp3D. If the method is called again with a NULL matrix, then the original state of the vtkProp3D will be restored. This method is used to support picking and assembly structures.
- `obj.InitPathTraversal ()` - Overload vtkProp's method for setting up assembly paths. See the documentation for vtkProp.
- `long = obj.GetMTime ()` - Get the vtkProp3D's mtime
- `long = obj.GetUserTransformMatrixMTime ()` - Get the modified time of the user matrix or user transform.
- `obj.ComputeMatrix ()` - Generate the matrix based on ivars
- `vtkMatrix4x4 = obj.GetMatrix ()` - Is the matrix for this actor identity
- `int = obj.GetIsIdentity ()` - Is the matrix for this actor identity

39.147 vtkProp3DCollection

39.147.1 Usage

vtkProp3DCollection represents and provides methods to manipulate a list of 3D props (i.e., vtkProp3D and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkProp3DCollection, simply invoke its constructor as follows

```
obj = vtkProp3DCollection
```

39.147.2 Methods

The class vtkProp3DCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProp3DCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProp3DCollection = obj.NewInstance ()`
- `vtkProp3DCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkProp3D p)` - Add an actor to the list.
- `vtkProp3D = obj.GetNextProp3D ()` - Get the next actor in the list.
- `vtkProp3D = obj.GetLastProp3D ()` - Get the last actor in the list.

39.148 vtkProperty

39.148.1 Usage

vtkProperty is an object that represents lighting and other surface properties of a geometric object. The primary properties that can be set are colors (overall, ambient, diffuse, specular, and edge color); specular power; opacity of the object; the representation of the object (points, wireframe, or surface); and the shading

method to be used (flat, Gouraud, and Phong). Also, some special graphics features like backface properties can be set and manipulated with this object.

To create an instance of class vtkProperty, simply invoke its constructor as follows

```
obj = vtkProperty
```

39.148.2 Methods

The class vtkProperty has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProperty class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProperty = obj.NewInstance ()`
- `vtkProperty = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkProperty p)` - Assign one property to another.
- `obj.Render (vtkActor , vtkRenderer )` - This method causes the property to set up whatever is required for its instance variables. This is actually handled by a subclass of vtkProperty, which is created automatically. This method includes the invoking actor as an argument which can be used by property devices that require the actor.
- `obj.BackfaceRender (vtkActor , vtkRenderer )` - This method renders the property as a backface property. TwoSidedLighting must be turned off to see any backface properties. Note that only colors and opacity are used for backface properties. Other properties such as Representation, Culling are specified by the Property.
- `bool = obj.GetLighting ()` - Set/Get lighting flag for an object. Initial value is true.
- `obj.SetLighting (bool )` - Set/Get lighting flag for an object. Initial value is true.
- `obj.LightingOn ()` - Set/Get lighting flag for an object. Initial value is true.
- `obj.LightingOff ()` - Set/Get lighting flag for an object. Initial value is true.
- `obj.SetInterpolation (int )` - Set the shading interpolation method for an object.
- `int = obj.GetInterpolationMinValue ()` - Set the shading interpolation method for an object.
- `int = obj.GetInterpolationMaxValue ()` - Set the shading interpolation method for an object.
- `int = obj.GetInterpolation ()` - Set the shading interpolation method for an object.
- `obj.SetInterpolationToFlat ()` - Set the shading interpolation method for an object.
- `obj.SetInterpolationToGouraud ()` - Set the shading interpolation method for an object.
- `obj.SetInterpolationToPhong ()` - Set the shading interpolation method for an object.
- `string = obj.GetInterpolationAsString ()` - Set the shading interpolation method for an object.
- `obj.SetRepresentation (int )` - Control the surface geometry representation for the object.
- `int = obj.GetRepresentationMinValue ()` - Control the surface geometry representation for the object.
- `int = obj.GetRepresentationMaxValue ()` - Control the surface geometry representation for the object.

- `int = obj.GetRepresentation ()` - Control the surface geometry representation for the object.
- `obj.SetRepresentationToPoints ()` - Control the surface geometry representation for the object.
- `obj.SetRepresentationToWireframe ()` - Control the surface geometry representation for the object.
- `obj.SetRepresentationToSurface ()` - Control the surface geometry representation for the object.
- `string = obj.GetRepresentationAsString ()` - Control the surface geometry representation for the object.
- `obj.SetColor (double r, double g, double b)` - Set the color of the object. Has the side effect of setting the ambient diffuse and specular colors as well. This is basically a quick overall color setting method.
- `obj.SetColor (double a[3])` - Set the color of the object. Has the side effect of setting the ambient diffuse and specular colors as well. This is basically a quick overall color setting method.
- `double = obj.GetColor ()` - Set the color of the object. Has the side effect of setting the ambient diffuse and specular colors as well. This is basically a quick overall color setting method.
- `obj.GetColor (double rgb[3])` - Set the color of the object. Has the side effect of setting the ambient diffuse and specular colors as well. This is basically a quick overall color setting method.
- `obj.SetAmbient (double )` - Set/Get the ambient lighting coefficient.
- `double = obj.GetAmbientMinValue ()` - Set/Get the ambient lighting coefficient.
- `double = obj.GetAmbientMaxValue ()` - Set/Get the ambient lighting coefficient.
- `double = obj.GetAmbient ()` - Set/Get the ambient lighting coefficient.
- `obj.SetDiffuse (double )` - Set/Get the diffuse lighting coefficient.
- `double = obj.GetDiffuseMinValue ()` - Set/Get the diffuse lighting coefficient.
- `double = obj.GetDiffuseMaxValue ()` - Set/Get the diffuse lighting coefficient.
- `double = obj.GetDiffuse ()` - Set/Get the diffuse lighting coefficient.
- `obj.SetSpecular (double )` - Set/Get the specular lighting coefficient.
- `double = obj.GetSpecularMinValue ()` - Set/Get the specular lighting coefficient.
- `double = obj.GetSpecularMaxValue ()` - Set/Get the specular lighting coefficient.
- `double = obj.GetSpecular ()` - Set/Get the specular lighting coefficient.
- `obj.SetSpecularPower (double )` - Set/Get the specular power.
- `double = obj.GetSpecularPowerMinValue ()` - Set/Get the specular power.
- `double = obj.GetSpecularPowerMaxValue ()` - Set/Get the specular power.
- `double = obj.GetSpecularPower ()` - Set/Get the specular power.
- `obj.SetOpacity (double )` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `double = obj.GetOpacityMinValue ()` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `double = obj.GetOpacityMaxValue ()` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.

- `double = obj.GetOpacity ()` - Set/Get the object's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `obj.SetAmbientColor (double , double , double )` - Set/Get the ambient surface color. Not all renderers support separate ambient and diffuse colors. From a physical standpoint it really doesn't make too much sense to have both. For the rendering libraries that don't support both, the diffuse color is used.
- `obj.SetAmbientColor (double a[3])` - Set/Get the ambient surface color. Not all renderers support separate ambient and diffuse colors. From a physical standpoint it really doesn't make too much sense to have both. For the rendering libraries that don't support both, the diffuse color is used.
- `double = obj. GetAmbientColor ()` - Set/Get the ambient surface color. Not all renderers support separate ambient and diffuse colors. From a physical standpoint it really doesn't make too much sense to have both. For the rendering libraries that don't support both, the diffuse color is used.
- `obj.SetDiffuseColor (double , double , double )` - Set/Get the diffuse surface color.
- `obj.SetDiffuseColor (double a[3])` - Set/Get the diffuse surface color.
- `double = obj. GetDiffuseColor ()` - Set/Get the diffuse surface color.
- `obj.SetSpecularColor (double , double , double )` - Set/Get the specular surface color.
- `obj.SetSpecularColor (double a[3])` - Set/Get the specular surface color.
- `double = obj. GetSpecularColor ()` - Set/Get the specular surface color.
- `int = obj.GetEdgeVisibility ()` - Turn on/off the visibility of edges. On some renderers it is possible to render the edges of geometric primitives separately from the interior.
- `obj.SetEdgeVisibility (int )` - Turn on/off the visibility of edges. On some renderers it is possible to render the edges of geometric primitives separately from the interior.
- `obj.EdgeVisibilityOn ()` - Turn on/off the visibility of edges. On some renderers it is possible to render the edges of geometric primitives separately from the interior.
- `obj.EdgeVisibilityOff ()` - Turn on/off the visibility of edges. On some renderers it is possible to render the edges of geometric primitives separately from the interior.
- `obj.SetEdgeColor (double , double , double )` - Set/Get the color of primitive edges (if edge visibility is enabled).
- `obj.SetEdgeColor (double a[3])` - Set/Get the color of primitive edges (if edge visibility is enabled).
- `double = obj. GetEdgeColor ()` - Set/Get the color of primitive edges (if edge visibility is enabled).
- `obj.SetLineWidth (float )` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetLineWidthMinValue ()` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetLineWidthMaxValue ()` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetLineWidth ()` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `obj.SetLineStipplePattern (int )` - Set/Get the stippling pattern of a Line, as a 16-bit binary pattern (1 = pixel on, 0 = pixel off). This is only implemented for OpenGL. The default is 0xFFFF.

- `int = obj.GetLineStipplePattern ()` - Set/Get the stippling pattern of a Line, as a 16-bit binary pattern (1 = pixel on, 0 = pixel off). This is only implemented for OpenGL. The default is 0xFFFF.
- `obj.SetLineStippleRepeatFactor (int )` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `int = obj.GetLineStippleRepeatFactorMinValue ()` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `int = obj.GetLineStippleRepeatFactorMaxValue ()` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `int = obj.GetLineStippleRepeatFactor ()` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `obj.SetPointSize (float )` - Set/Get the diameter of a point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetPointSizeMinValue ()` - Set/Get the diameter of a point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetPointSizeMaxValue ()` - Set/Get the diameter of a point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetPointSize ()` - Set/Get the diameter of a point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `int = obj.GetBackfaceCulling ()` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If backface culling is on, polygons facing away from camera are not drawn.
- `obj.SetBackfaceCulling (int )` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If backface culling is on, polygons facing away from camera are not drawn.
- `obj.BackfaceCullingOn ()` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If backface culling is on, polygons facing away from camera are not drawn.
- `obj.BackfaceCullingOff ()` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If backface culling is on, polygons facing away from camera are not drawn.
- `int = obj.GetFrontfaceCulling ()` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If frontface culling is on, polygons facing towards camera are not drawn.
- `obj.SetFrontfaceCulling (int )` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If frontface culling is on, polygons facing towards camera are not drawn.
- `obj.FrontfaceCullingOn ()` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If frontface culling is on, polygons facing towards camera are not drawn.
- `obj.FrontfaceCullingOff ()` - Turn on/off fast culling of polygons based on orientation of normal with respect to camera. If frontface culling is on, polygons facing towards camera are not drawn.
- `vtkXMLMaterial = obj.GetMaterial ()` - Get the material representation used for shading. The material will be used only when shading is enabled.

- `string = obj.GetMaterialName ()` - Returns the name of the material currenly loaded, if any.
- `obj.LoadMaterial (string name)` - Load the material. The material can be the name of a built-on material or the filename for a VTK material XML description.
- `obj.LoadMaterialFromString (string materialxml)` - Load the material given the contents of the material file.
- `obj.LoadMaterial (vtkXMLMaterial )` - Load the material given the material representation.
- `obj.SetShading (int )` - Enable/Disable shading. When shading is enabled, the Material must be set.
- `int = obj.GetShading ()` - Enable/Disable shading. When shading is enabled, the Material must be set.
- `obj.ShadingOn ()` - Enable/Disable shading. When shading is enabled, the Material must be set.
- `obj.ShadingOff ()` - Enable/Disable shading. When shading is enabled, the Material must be set.
- `vtkShaderProgram = obj.GetShaderProgram ()` - Get the Shader program. If Material is not set/or not loaded properly, this will return null.
- `obj.AddShaderVariable (string name, int numVars, int x)` - Provide values to initialize shader variables. Useful to initialize shader variables that change over time (animation, GUI widgets inputs, etc.) - name - hardware name of the uniform variable - numVars - number of variables being set - x - values
- `obj.AddShaderVariable (string name, int numVars, float x)` - Provide values to initialize shader variables. Useful to initialize shader variables that change over time (animation, GUI widgets inputs, etc.) - name - hardware name of the uniform variable - numVars - number of variables being set - x - values
- `obj.AddShaderVariable (string name, int numVars, double x)` - Provide values to initialize shader variables. Useful to initialize shader variables that change over time (animation, GUI widgets inputs, etc.) - name - hardware name of the uniform variable - numVars - number of variables being set - x - values
- `obj.AddShaderVariable (string name, int v)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, float v)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, double v)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, int v1, int v2)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, float v1, float v2)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, double v1, double v2)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, int v1, int v2, int v3)` - Methods to provide to add shader variables from tcl.
- `obj.AddShaderVariable (string name, float v1, float v2, float v3)` - Methods to provide to add shader variables from tcl.

- `obj.AddShaderVariable (string name, double v1, double v2, double v3)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. A property does not need to have an associated texture map and multiple properties can share one texture. Textures must be assigned unique names.
- `obj.SetTexture (string name, vtkTexture texture)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. A property does not need to have an associated texture map and multiple properties can share one texture. Textures must be assigned unique names.
- `vtkTexture = obj.GetTexture (string name)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. A property does not need to have an associated texture map and multiple properties can share one texture. Textures must be assigned unique names.
- `obj.SetTexture (int unit, vtkTexture texture)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. A property does not need to have an associated texture map and multiple properties can share one texture. Textures must be assigned unique names.
- `vtkTexture = obj.GetTexture (int unit)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. A property does not need to have an associated texture map and multiple properties can share one texture. Textures must be assigned unique names.
- `obj.RemoveTexture (int unit)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. A property does not need to have an associated texture map and multiple properties can share one texture. Textures must be assigned unique names.
- `obj.RemoveTexture (string name)` - Remove a texture from the collection. Note that the indices of all the subsquent textures, if any, will change.
- `obj.RemoveAllTextures ()` - Remove all the textures.
- `int = obj.GetNumberOfTextures ()` - Returns the number of textures in this property.
- `obj.ReleaseGraphicsResources (vtkWindow win)` - Release any graphics resources that are being consumed by this property. The parameter window could be used to determine which graphic resources to release.

39.149 vtkPropPicker

39.149.1 Usage

vtkPropPicker is used to pick an actor/prop given a selection point (in display coordinates) and a renderer. This class uses graphics hardware/rendering system to pick rapidly (as compared to using ray casting as does vtkCellPicker and vtkPointPicker). This class determines the actor/prop and pick position in world coordinates; point and cell ids are not determined.

To create an instance of class vtkPropPicker, simply invoke its constructor as follows

```
obj = vtkPropPicker
```

39.149.2 Methods

The class vtkPropPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPropPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkPropPicker = obj.NewInstance ()`
- `vtkPropPicker = obj.SafeDownCast (vtkObject o)`
- `int = obj.PickProp (double selectionX, double selectionY, vtkRenderer renderer)` - Perform the pick and set the PickedProp ivar. If something is picked, a 1 is returned, otherwise 0 is returned. Use the GetViewProp() method to get the instance of vtkProp that was picked. Props are picked from the renderers list of pickable Props.
- `int = obj.PickProp (double selectionX, double selectionY, vtkRenderer renderer, vtkPropCollection p` - Perform a pick from the user-provided list of vtkProps and not from the list of vtkProps that the render maintains.
- `int = obj.Pick (double selectionX, double selectionY, double selectionZ, vtkRenderer renderer)` - Overide superclasses' Pick() method.
- `int = obj.Pick (double selectionPt[3], vtkRenderer renderer)` - Overide superclasses' Pick() method.

39.150 vtkQImageToImageSource

39.150.1 Usage

vtkQImageToImageSource produces image data from a QImage.

To create an instance of class vtkQImageToImageSource, simply invoke its constructor as follows

```
obj = vtkQImageToImageSource
```

39.150.2 Methods

The class vtkQImageToImageSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQImageToImageSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQImageToImageSource = obj.NewInstance ()`
- `vtkQImageToImageSource = obj.SafeDownCast (vtkObject o)`

39.151 vtkQtInitialization

39.151.1 Usage

Utility class that initializes Qt by creating an instance of QApplication in its ctor, if one doesn't already exist. This is mainly of use in ParaView with filters that use Qt in their implementation - create an instance of vtkQtInitialization prior to instantiating any filters that require Qt.

To create an instance of class vtkQtInitialization, simply invoke its constructor as follows

```
obj = vtkQtInitialization
```

39.151.2 Methods

The class vtkQtInitialization has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQtInitialization class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQtInitialization = obj.NewInstance ()`
- `vtkQtInitialization = obj.SafeDownCast (vtkObject o)`

39.152 vtkQtLabelRenderStrategy

39.152.1 Usage

This class uses Qt to render labels and compute sizes. The labels are rendered to a QImage, then EndFrame() converts that image to a vtkImageData and textures the image onto a quad spanning the render area.

To create an instance of class vtkQtLabelRenderStrategy, simply invoke its constructor as follows

```
obj = vtkQtLabelRenderStrategy
```

39.152.2 Methods

The class vtkQtLabelRenderStrategy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQtLabelRenderStrategy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQtLabelRenderStrategy = obj.NewInstance ()`
- `vtkQtLabelRenderStrategy = obj.SafeDownCast (vtkObject o)`
- `obj.StartFrame ()` - Start a rendering frame. Renderer must be set.
- `obj.EndFrame ()` - End a rendering frame.
- `obj.ReleaseGraphicsResources (vtkWindow window)` - Release any graphics resources that are being consumed by this strategy. The parameter window could be used to determine which graphic resources to release.

39.153 vtkQtTreeRingLabelMapper

39.153.1 Usage

vtkQtTreeRingLabelMapper is a mapper that renders text on a tree map. A tree map is a vtkTree with an associated 4-tuple array used for storing the boundary rectangle for each vertex in the tree. The user must specify the array name used for storing the rectangles.

The mapper iterates through the tree and attempts and renders a label inside the vertex's rectangle as long as the following conditions hold: 1. The vertex level is within the range of levels specified for labeling. 2. The label can fully fit inside its box. 3. The label does not overlap an ancestor's label.

To create an instance of class vtkQtTreeRingLabelMapper, simply invoke its constructor as follows

```
obj = vtkQtTreeRingLabelMapper
```

39.153.2 Methods

The class vtkQtTreeRingLabelMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQtTreeRingLabelMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQtTreeRingLabelMapper = obj.NewInstance ()`
- `vtkQtTreeRingLabelMapper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOpaqueGeometry (vtkViewport viewport, vtkActor2D actor)` - Draw the text to the screen at each input point.
- `obj.RenderOverlay (vtkViewport viewport, vtkActor2D actor)` - Draw the text to the screen at each input point.
- `vtkTree = obj.GetInputTree ()` - The input to this filter.
- `obj.SetSectorsArrayName (string name)` - The name of the 4-tuple array used for
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the text property. Note that multiple type text properties (set with a second integer parameter) are not currently supported, but are provided to avoid compiler warnings.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the text property. Note that multiple type text properties (set with a second integer parameter) are not currently supported, but are provided to avoid compiler warnings.
- `obj.SetLabelTextProperty (vtkTextProperty p, int type)` - Set/Get the text property. Note that multiple type text properties (set with a second integer parameter) are not currently supported, but are provided to avoid compiler warnings.
- `vtkTextProperty = obj.GetLabelTextProperty (int type)` - Set/Get the name of the text rotation array.
- `obj.SetTextRotationArrayName (string )` - Set/Get the name of the text rotation array.
- `string = obj.GetTextRotationArrayName ()` - Set/Get the name of the text rotation array.
- `long = obj.GetMTime ()` - Return the object's MTime. This is overridden to include the timestamp of its internal class.
- `obj.SetRenderer (vtkRenderer ren)`
- `vtkRenderer = obj.GetRenderer ()`

39.154 vtkQuadricLODActor

39.154.1 Usage

vtkQuadricLODActor implements a specific strategy for level-of-detail using the vtkQuadricClustering decimation algorithm. It supports only two levels of detail: full resolution and a decimated version. The decimated LOD is generated using a tuned strategy to produce output consistent with the requested interactive frame rate (i.e., the vtkRenderWindowInteractor's DesiredUpdateRate). It also makes use of display lists for performance, and adjusts the vtkQuadricClustering algorithm to take into account the dimensionality of

the data (e.g., 2D, x-y surfaces may be binned into n x n x 1 to reduce extra polygons in the z-direction). Finally, the filter may optionally be set in "Static" mode (this works with the vtkMapper::SetStatic() method). 'Enabling Static results in a one time execution of the Mapper's pipeline. After that, the pipeline no longer updated (unless manually forced to do so).

To create an instance of class vtkQuadricLODActor, simply invoke its constructor as follows

```
obj = vtkQuadricLODActor
```

39.154.2 Methods

The class vtkQuadricLODActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadricLODActor class.

- `string = obj.GetClassName ()` - Standard class methods.
- `int = obj.IsA (string name)` - Standard class methods.
- `vtkQuadricLODActor = obj.NewInstance ()` - Standard class methods.
- `vtkQuadricLODActor = obj.SafeDownCast (vtkObject o)` - Standard class methods.
- `obj.SetDeferLODConstruction (int )` - Specify whether to build the LOD immediately (i.e., on the first render) or to wait until the LOD is requested in a subsequent render. By default, LOD construction is not deferred (DeferLODConstruction is false).
- `int = obj.GetDeferLODConstruction ()` - Specify whether to build the LOD immediately (i.e., on the first render) or to wait until the LOD is requested in a subsequent render. By default, LOD construction is not deferred (DeferLODConstruction is false).
- `obj.DeferLODConstructionOn ()` - Specify whether to build the LOD immediately (i.e., on the first render) or to wait until the LOD is requested in a subsequent render. By default, LOD construction is not deferred (DeferLODConstruction is false).
- `obj.DeferLODConstructionOff ()` - Specify whether to build the LOD immediately (i.e., on the first render) or to wait until the LOD is requested in a subsequent render. By default, LOD construction is not deferred (DeferLODConstruction is false).
- `obj.SetStatic (int )` - Turn on/off a flag to control whether the underlying pipeline is static. If static, this means that the data pipeline executes once and then not again until the user manually modifies this class. By default, Static is off because trying to debug this is tricky, and you should only use it when you know what you are doing.
- `int = obj.GetStatic ()` - Turn on/off a flag to control whether the underlying pipeline is static. If static, this means that the data pipeline executes once and then not again until the user manually modifies this class. By default, Static is off because trying to debug this is tricky, and you should only use it when you know what you are doing.
- `obj.StaticOn ()` - Turn on/off a flag to control whether the underlying pipeline is static. If static, this means that the data pipeline executes once and then not again until the user manually modifies this class. By default, Static is off because trying to debug this is tricky, and you should only use it when you know what you are doing.
- `obj.StaticOff ()` - Turn on/off a flag to control whether the underlying pipeline is static. If static, this means that the data pipeline executes once and then not again until the user manually modifies this class. By default, Static is off because trying to debug this is tricky, and you should only use it when you know what you are doing.

- `obj.SetDataConfiguration (int )` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `int = obj.GetDataConfigurationMinValue ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `int = obj.GetDataConfigurationMaxValue ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `int = obj.GetDataConfiguration ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToUnknown ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToXLine ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToYLine ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies

in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToZLine ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToXYPlane ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToYZPlane ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToXZPlane ()` - Force the binning of the quadric clustering according to application knowledge relative to the dimension of the data. For example, if you know your data lies in a 2D x-y plane, the performance of the quadric clustering algorithm can be greatly improved by indicating this (i.e., the number of resulting triangles, and the quality of the decimation version is better). Setting this parameter forces the binning to be configured consistent with the dimnesionality of the data, and the collapse dimension ratio is ignored. Specifying the value of DataConfiguration to UNKNOWN (the default value) means that the class will attempt to figure the dimension of the class automatically using the CollapseDimensionRatio ivar.

- `obj.SetDataConfigurationToXYZVolume ()` - If the data configuration is set to UNKNOWN, this class attempts to figure out the dimensionality of the data using CollapseDimensionRatio. This ivar is the ratio of short edge of the input bounding box to its long edge, which is then used to collapse the data dimension (and set the quadric bin size in that direction to one). By default, this value is 0.05.

- `obj.SetCollapseDimensionRatio (double )` - If the data configuration is set to UNKNOWN, this class attempts to figure out the dimensionality of the data using CollapseDimensionRatio. This ivar is the ratio of short edge of the input bounding box to its long edge, which is then used to collapse the data dimension (and set the quadric bin size in that direction to one). By default, this value is 0.05.

- `double = obj.GetCollapseDimensionRatioMinValue ()` - If the data configuration is set to UNKNOWN, this class attempts to figure out the dimensionality of the data using CollapseDimensionRatio. This ivar is the ratio of short edge of the input bounding box to its long edge, which is then used

to collapse the data dimension (and set the quadric bin size in that direction to one). By default, this value is 0.05.

- `double = obj.GetCollapseDimensionRatioMaxValue ()` - If the data configuration is set to UNKNOWN, this class attempts to figure out the dimensionality of the data using CollapseDimensionRatio. This ivar is the ratio of short edge of the input bounding box to its long edge, which is then used to collapse the data dimension (and set the quadric bin size in that direction to one). By default, this value is 0.05.

- `double = obj.GetCollapseDimensionRatio ()` - If the data configuration is set to UNKNOWN, this class attempts to figure out the dimensionality of the data using CollapseDimensionRatio. This ivar is the ratio of short edge of the input bounding box to its long edge, which is then used to collapse the data dimension (and set the quadric bin size in that direction to one). By default, this value is 0.05.

- `obj.SetLODFilter (vtkQuadricClustering lodFilter)` - This class will create a vtkQuadricClustering algorithm automatically. However, if you would like to specify the filter to use, or to access it and configure it, these method provide access to the filter.

- `vtkQuadricClustering = obj.GetLODFilter ()` - This class will create a vtkQuadricClustering algorithm automatically. However, if you would like to specify the filter to use, or to access it and configure it, these method provide access to the filter.

- `obj.SetMaximumDisplayListSize (int )` - Specify the maximum display list size. This variable is used to determine whether to use display lists (ImmediateModeRenderingOff) or not. Controlling display list size is important to prevent program crashes (i.e., overly large display lists on some graphics hardware will cause faults). The display list size is the length of the vtkCellArray representing the topology of the input vtkPolyData.

- `int = obj.GetMaximumDisplayListSizeMinValue ()` - Specify the maximum display list size. This variable is used to determine whether to use display lists (ImmediateModeRenderingOff) or not. Controlling display list size is important to prevent program crashes (i.e., overly large display lists on some graphics hardware will cause faults). The display list size is the length of the vtkCellArray representing the topology of the input vtkPolyData.

- `int = obj.GetMaximumDisplayListSizeMaxValue ()` - Specify the maximum display list size. This variable is used to determine whether to use display lists (ImmediateModeRenderingOff) or not. Controlling display list size is important to prevent program crashes (i.e., overly large display lists on some graphics hardware will cause faults). The display list size is the length of the vtkCellArray representing the topology of the input vtkPolyData.

- `int = obj.GetMaximumDisplayListSize ()` - Specify the maximum display list size. This variable is used to determine whether to use display lists (ImmediateModeRenderingOff) or not. Controlling display list size is important to prevent program crashes (i.e., overly large display lists on some graphics hardware will cause faults). The display list size is the length of the vtkCellArray representing the topology of the input vtkPolyData.

- `obj.SetPropType (int )` - Indicate that this actor is actually a follower. By default, the prop type is a vtkActor.

- `int = obj.GetPropTypeMinValue ()` - Indicate that this actor is actually a follower. By default, the prop type is a vtkActor.

- `int = obj.GetPropTypeMaxValue ()` - Indicate that this actor is actually a follower. By default, the prop type is a vtkActor.

- `int = obj.GetPropType ()` - Indicate that this actor is actually a follower. By default, the prop type is a vtkActor.

- `obj.SetPropTypeToFollower ()` - Indicate that this actor is actually a follower. By default, the prop type is a vtkActor.
- `obj.SetPropTypeToActor ()` - Set/Get the camera to follow. This method is only applicable when the prop type is set to a vtkFollower.
- `obj.SetCamera (vtkCamera )` - Set/Get the camera to follow. This method is only applicable when the prop type is set to a vtkFollower.
- `vtkCamera = obj.GetCamera ()` - Set/Get the camera to follow. This method is only applicable when the prop type is set to a vtkFollower.
- `obj.Render (vtkRenderer , vtkMapper )` - This causes the actor to be rendered. Depending on the frame rate request, it will use either a full resolution render or an interactive render (i.e., it will use the decimated geometry).
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - This method is used internally by the rendering process. We overide the superclass method to properly set the estimated render time.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of an LOD actor. Overloads the virtual vtkProp method.

39.155 vtkQuaternionInterpolator

39.155.1 Usage

This class is used to interpolate a series of quaternions representing the rotations of a 3D object. The interpolation may be linear in form (using spherical linear interpolation SLERP), or via spline interpolation (using SQUAD). In either case the interpolation is specialized to quaternions since the interpolation occurs on the surface of the unit quaternion sphere.

To use this class, specify at least two pairs of (t,q[4]) with the AddQuaternion() method. Next interpolate the tuples with the InterpolateQuaternion(t,q[4]) method, where "t" must be in the range of (t_min,t_max) parameter values specified by the AddQuaternion() method (t is clamped otherwise), and q[4] is filled in by the method.

There are several important background references. Ken Shoemake described the practical application of quaternions for the interpolation of rotation (K. Shoemake, "Animating rotation with quaternion curves", Computer Graphics (Siggraph '85) 19(3):245–254, 1985). Another fine reference (available on-line) is E. B. Dam, M. Koch, and M. Lillholm, Technical Report DIKU-TR-98/5, Dept. of Computer Science, University of Copenhagen, Denmark.

To create an instance of class vtkQuaternionInterpolator, simply invoke its constructor as follows

```
obj = vtkQuaternionInterpolator
```

39.155.2 Methods

The class vtkQuaternionInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuaternionInterpolator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkQuaternionInterpolator = obj.NewInstance ()`
- `vtkQuaternionInterpolator = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfQuaternions ()` - Return the number of quaternions in the list of quaternions to be interpolated.
- `double = obj.GetMinimumT ()` - Obtain some information about the interpolation range. The numbers returned (corresponding to parameter t, usually thought of as time) are undefined if the list of transforms is empty. This is a convenience method for interpolation.
- `double = obj.GetMaximumT ()` - Obtain some information about the interpolation range. The numbers returned (corresponding to parameter t, usually thought of as time) are undefined if the list of transforms is empty. This is a convenience method for interpolation.
- `obj.Initialize ()` - Reset the class so that it contains no data; i.e., the array of (t,q[4]) information is discarded.
- `obj.AddQuaternion (double t, double q[4])` - Add another quaternion to the list of quaternions to be interpolated. Note that using the same time t value more than once replaces the previous quaternion at t. At least one quaternions must be added to define an interpolation functios.
- `obj.RemoveQuaternion (double t)` - Delete the quaternion at a particular parameter t. If there is no quaternion tuple defined at t, then the method does nothing.
- `obj.InterpolateQuaternion (double t, double q[4])` - Interpolate the list of quaternions and determine a new quaternion (i.e., fill in the quaternion provided). If t is outside the range of (min,max) values, then t is clamped to lie within the range.
- `obj.SetInterpolationType (int )` - Specify which type of function to use for interpolation. By default (SetInterpolationFunctionToSpline()), cubic spline interpolation using a modifed Kochanek basis is employed. Otherwise, if SetInterpolationFunctionToLinear() is invoked, linear spherical interpolation is used between each pair of quaternions.
- `int = obj.GetInterpolationTypeMinValue ()` - Specify which type of function to use for interpolation. By default (SetInterpolationFunctionToSpline()), cubic spline interpolation using a modifed Kochanek basis is employed. Otherwise, if SetInterpolationFunctionToLinear() is invoked, linear spherical interpolation is used between each pair of quaternions.
- `int = obj.GetInterpolationTypeMaxValue ()` - Specify which type of function to use for interpolation. By default (SetInterpolationFunctionToSpline()), cubic spline interpolation using a modifed Kochanek basis is employed. Otherwise, if SetInterpolationFunctionToLinear() is invoked, linear spherical interpolation is used between each pair of quaternions.
- `int = obj.GetInterpolationType ()` - Specify which type of function to use for interpolation. By default (SetInterpolationFunctionToSpline()), cubic spline interpolation using a modifed Kochanek basis is employed. Otherwise, if SetInterpolationFunctionToLinear() is invoked, linear spherical interpolation is used between each pair of quaternions.
- `obj.SetInterpolationTypeToLinear ()` - Specify which type of function to use for interpolation. By default (SetInterpolationFunctionToSpline()), cubic spline interpolation using a modifed Kochanek basis is employed. Otherwise, if SetInterpolationFunctionToLinear() is invoked, linear spherical interpolation is used between each pair of quaternions.
- `obj.SetInterpolationTypeToSpline ()`

39.156 vtkRenderedAreaPicker

39.156.1 Usage

Like vtkAreaPicker, this class picks all props within a selection area on the screen. The difference is in implementation. This class uses graphics hardware to perform the test where the other uses software bounding box/frustum intersection testing.

This picker is more conservative than vtkAreaPicker. It will reject some objects that pass the bounding box test of vtkAreaPicker. This will happen, for instance, when picking through a corner of the bounding box when the data set does not have any visible geometry in that corner.

To create an instance of class vtkRenderedAreaPicker, simply invoke its constructor as follows

```
obj = vtkRenderedAreaPicker
```

39.156.2 Methods

The class vtkRenderedAreaPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderedAreaPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderedAreaPicker = obj.NewInstance ()`
- `vtkRenderedAreaPicker = obj.SafeDownCast (vtkObject o)`
- `int = obj.AreaPick (double x0, double y0, double x1, double y1, vtkRenderer renderer)` - Perform pick operation in volume behind the given screen coordinates. Props intersecting the selection frustum will be accesible via GetProp3D. GetPlanes returns a vtkImplicitFunciton suitable for vtkExtractGeometry.

39.157 vtkRenderer

39.157.1 Usage

vtkRenderer provides an abstract specification for renderers. A renderer is an object that controls the rendering process for objects. Rendering is the process of converting geometry, a specification for lights, and a camera view into an image. vtkRenderer also performs coordinate transformation between world coordinates, view coordinates (the computer graphics rendering coordinate system), and display coordinates (the actual screen coordinates on the display device). Certain advanced rendering features such as two-sided lighting can also be controlled.

To create an instance of class vtkRenderer, simply invoke its constructor as follows

```
obj = vtkRenderer
```

39.157.2 Methods

The class vtkRenderer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkRenderer = obj.NewInstance ()`
- `vtkRenderer = obj.SafeDownCast (vtkObject o)`
- `obj.AddActor (vtkProp p)` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `obj.AddVolume (vtkProp p)` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `obj.RemoveActor (vtkProp p)` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `obj.RemoveVolume (vtkProp p)` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `obj.AddLight (vtkLight )` - Add a light to the list of lights.
- `obj.RemoveLight (vtkLight )` - Remove a light from the list of lights.
- `obj.RemoveAllLights ()` - Remove all lights from the list of lights.
- `vtkLightCollection = obj.GetLights ()` - Return the collection of lights.
- `obj.SetLightCollection (vtkLightCollection lights)` - Set the collection of lights. We cannot name it SetLights because of TestSetGet
- `obj.CreateLight (void )` - Create and add a light to renderer.
- `vtkLight = obj.MakeLight ()` - Create a new Light sutible for use with this type of Renderer. For example, a vtkMesaRenderer should create a vtkMesaLight in this function. The default is to just call vtkLight::New.
- `int = obj.GetTwoSidedLighting ()` - Turn on/off two-sided lighting of surfaces. If two-sided lighting is off, then only the side of the surface facing the light(s) will be lit, and the other side dark. If two-sided lighting on, both sides of the surface will be lit.
- `obj.SetTwoSidedLighting (int )` - Turn on/off two-sided lighting of surfaces. If two-sided lighting is off, then only the side of the surface facing the light(s) will be lit, and the other side dark. If two-sided lighting on, both sides of the surface will be lit.
- `obj.TwoSidedLightingOn ()` - Turn on/off two-sided lighting of surfaces. If two-sided lighting is off, then only the side of the surface facing the light(s) will be lit, and the other side dark. If two-sided lighting on, both sides of the surface will be lit.
- `obj.TwoSidedLightingOff ()` - Turn on/off two-sided lighting of surfaces. If two-sided lighting is off, then only the side of the surface facing the light(s) will be lit, and the other side dark. If two-sided lighting on, both sides of the surface will be lit.
- `obj.SetLightFollowCamera (int )` - Turn on/off the automatic repositioning of lights as the camera moves. If LightFollowCamera is on, lights that are designated as Headlights or CameraLights will be adjusted to move with this renderer's camera. If LightFollowCamera is off, the lights will not be adjusted.

  (Note: In previous versions of vtk, this light-tracking functionality was part of the interactors, not the renderer. For backwards compatibility, the older, more limited interactor behavior is enabled by default. To disable this mode, turn the interactor's LightFollowCamera flag OFF, and leave the renderer's LightFollowCamera flag ON.)

- `int = obj.GetLightFollowCamera ()` - Turn on/off the automatic repositioning of lights as the camera moves. If LightFollowCamera is on, lights that are designated as Headlights or CameraLights will be adjusted to move with this renderer's camera. If LightFollowCamera is off, the lights will not be adjusted.

  (Note: In previous versions of vtk, this light-tracking functionality was part of the interactors, not the renderer. For backwards compatibility, the older, more limited interactor behavior is enabled by default. To disable this mode, turn the interactor's LightFollowCamera flag OFF, and leave the renderer's LightFollowCamera flag ON.)

- `obj.LightFollowCameraOn ()` - Turn on/off the automatic repositioning of lights as the camera moves. If LightFollowCamera is on, lights that are designated as Headlights or CameraLights will be adjusted to move with this renderer's camera. If LightFollowCamera is off, the lights will not be adjusted.

  (Note: In previous versions of vtk, this light-tracking functionality was part of the interactors, not the renderer. For backwards compatibility, the older, more limited interactor behavior is enabled by default. To disable this mode, turn the interactor's LightFollowCamera flag OFF, and leave the renderer's LightFollowCamera flag ON.)

- `obj.LightFollowCameraOff ()` - Turn on/off the automatic repositioning of lights as the camera moves. If LightFollowCamera is on, lights that are designated as Headlights or CameraLights will be adjusted to move with this renderer's camera. If LightFollowCamera is off, the lights will not be adjusted.

  (Note: In previous versions of vtk, this light-tracking functionality was part of the interactors, not the renderer. For backwards compatibility, the older, more limited interactor behavior is enabled by default. To disable this mode, turn the interactor's LightFollowCamera flag OFF, and leave the renderer's LightFollowCamera flag ON.)

- `int = obj.GetAutomaticLightCreation ()` - Turn on/off a flag which disables the automatic light creation capability. Normally in VTK if no lights are associated with the renderer, then a light is automatically created. However, in special circumstances this feature is undesirable, so the following boolean is provided to disable automatic light creation. (Turn AutomaticLightCreation off if you do not want lights to be created.)

- `obj.SetAutomaticLightCreation (int )` - Turn on/off a flag which disables the automatic light creation capability. Normally in VTK if no lights are associated with the renderer, then a light is automatically created. However, in special circumstances this feature is undesirable, so the following boolean is provided to disable automatic light creation. (Turn AutomaticLightCreation off if you do not want lights to be created.)

- `obj.AutomaticLightCreationOn ()` - Turn on/off a flag which disables the automatic light creation capability. Normally in VTK if no lights are associated with the renderer, then a light is automatically created. However, in special circumstances this feature is undesirable, so the following boolean is provided to disable automatic light creation. (Turn AutomaticLightCreation off if you do not want lights to be created.)

- `obj.AutomaticLightCreationOff ()` - Turn on/off a flag which disables the automatic light creation capability. Normally in VTK if no lights are associated with the renderer, then a light is automatically created. However, in special circumstances this feature is undesirable, so the following boolean is provided to disable automatic light creation. (Turn AutomaticLightCreation off if you do not want lights to be created.)

- `int = obj.UpdateLightsGeometryToFollowCamera (void )` - Ask the lights in the scene that are not in world space (for instance, Headlights or CameraLights that are attached to the camera) to update their geometry to match the active camera.

- `vtkVolumeCollection = obj.GetVolumes ()` - Return the collection of volumes.

- `vtkActorCollection = obj.GetActors ()` - Return any actors in this renderer.
- `obj.SetActiveCamera (vtkCamera )` - Specify the camera to use for this renderer.
- `vtkCamera = obj.GetActiveCamera ()` - Get the current camera. If there is not camera assigned to the renderer already, a new one is created automatically. This does *not* reset the camera.
- `vtkCamera = obj.MakeCamera ()` - Create a new Camera sutible for use with this type of Renderer. For example, a vtkMesaRenderer should create a vtkMesaCamera in this function. The default is to just call vtkCamera::New.
- `obj.SetErase (int )` - When this flag is off, the renderer will not erase the background or the Zbuffer. It is used to have overlapping renderers. Both the RenderWindow Erase and Render Erase must be on for the camera to clear the renderer. By default, Erase is on.
- `int = obj.GetErase ()` - When this flag is off, the renderer will not erase the background or the Zbuffer. It is used to have overlapping renderers. Both the RenderWindow Erase and Render Erase must be on for the camera to clear the renderer. By default, Erase is on.
- `obj.EraseOn ()` - When this flag is off, the renderer will not erase the background or the Zbuffer. It is used to have overlapping renderers. Both the RenderWindow Erase and Render Erase must be on for the camera to clear the renderer. By default, Erase is on.
- `obj.EraseOff ()` - When this flag is off, the renderer will not erase the background or the Zbuffer. It is used to have overlapping renderers. Both the RenderWindow Erase and Render Erase must be on for the camera to clear the renderer. By default, Erase is on.
- `obj.SetDraw (int )` - When this flag is off, render commands are ignored. It is used to either multiplex a vtkRenderWindow or render only part of a vtkRenderWindow. By default, Draw is on.
- `int = obj.GetDraw ()` - When this flag is off, render commands are ignored. It is used to either multiplex a vtkRenderWindow or render only part of a vtkRenderWindow. By default, Draw is on.
- `obj.DrawOn ()` - When this flag is off, render commands are ignored. It is used to either multiplex a vtkRenderWindow or render only part of a vtkRenderWindow. By default, Draw is on.
- `obj.DrawOff ()` - When this flag is off, render commands are ignored. It is used to either multiplex a vtkRenderWindow or render only part of a vtkRenderWindow. By default, Draw is on.
- `obj.AddCuller (vtkCuller )` - Add an culler to the list of cullers.
- `obj.RemoveCuller (vtkCuller )` - Remove an actor from the list of cullers.
- `vtkCullerCollection = obj.GetCullers ()` - Return the collection of cullers.
- `obj.SetAmbient (double , double , double )` - Set the intensity of ambient lighting.
- `obj.SetAmbient (double  a[3])` - Set the intensity of ambient lighting.
- `double = obj. GetAmbient ()` - Set the intensity of ambient lighting.
- `obj.SetAllocatedRenderTime (double )` - Set/Get the amount of time this renderer is allowed to spend rendering its scene. This is used by vtkLODActor's.
- `double = obj.GetAllocatedRenderTime ()` - Set/Get the amount of time this renderer is allowed to spend rendering its scene. This is used by vtkLODActor's.
- `double = obj.GetTimeFactor ()` - Get the ratio between allocated time and actual render time. TimeFactor has been taken out of the render process. It is still computed in case someone finds it useful. It may be taken away in the future.

- `obj.Render ()` - CALLED BY vtkRenderWindow ONLY. End-user pass your way and call vtkRenderWindow::Render(). Create an image. This is a superclass method which will in turn call the DeviceRender method of Subclasses of vtkRenderer.
- `obj.DeviceRender ()` - Create an image. Subclasses of vtkRenderer must implement this method.
- `obj.DeviceRenderTranslucentPolygonalGeometry ()` - Render translucent polygonal geometry. Default implementation just call UpdateTranslucentPolygonalGeometry(). Subclasses of vtkRenderer that can deal with depth peeling must override this method. It updates boolean ivar LastRenderingUsedDepthPeeling.
- `obj.Clear ()` - Clear the image to the background color.
- `int = obj.VisibleActorCount ()` - Returns the number of visible actors.
- `int = obj.VisibleVolumeCount ()` - Returns the number of visible volumes.
- `obj.ComputeVisiblePropBounds (double bounds[6])` - Compute the bounding box of all the visible props Used in ResetCamera() and ResetCameraClippingRange()
- `double = obj.ComputeVisiblePropBounds ()` - Wrapper-friendly version of ComputeVisiblePropBounds
- `obj.ResetCameraClippingRange ()` - Reset the camera clipping range based on the bounds of the visible actors. This ensures that no props are cut off
- `obj.ResetCameraClippingRange (double bounds[6])` - Reset the camera clipping range based on a bounding box. This method is called from ResetCameraClippingRange()
- `obj.ResetCameraClippingRange (double xmin, double xmax, double ymin, double ymax, double zmin, doub` - Reset the camera clipping range based on a bounding box. This method is called from ResetCameraClippingRange()
- `obj.SetNearClippingPlaneTolerance (double )` - Specify tolerance for near clipping plane distance to the camera as a percentage of the far clipping plane distance. By default this will be set to 0.01 for 16 bit zbuffers and 0.001 for higher depth z buffers
- `double = obj.GetNearClippingPlaneToleranceMinValue ()` - Specify tolerance for near clipping plane distance to the camera as a percentage of the far clipping plane distance. By default this will be set to 0.01 for 16 bit zbuffers and 0.001 for higher depth z buffers
- `double = obj.GetNearClippingPlaneToleranceMaxValue ()` - Specify tolerance for near clipping plane distance to the camera as a percentage of the far clipping plane distance. By default this will be set to 0.01 for 16 bit zbuffers and 0.001 for higher depth z buffers
- `double = obj.GetNearClippingPlaneTolerance ()` - Specify tolerance for near clipping plane distance to the camera as a percentage of the far clipping plane distance. By default this will be set to 0.01 for 16 bit zbuffers and 0.001 for higher depth z buffers
- `obj.ResetCamera ()` - Automatically set up the camera based on the visible actors. The camera will reposition itself to view the center point of the actors, and move along its initial view plane normal (i.e., vector defined from camera position to focal point) so that all of the actors can be seen.
- `obj.ResetCamera (double bounds[6])` - Automatically set up the camera based on a specified bounding box (xmin,xmax, ymin,ymax, zmin,zmax). Camera will reposition itself so that its focal point is the center of the bounding box, and adjust its distance and position to preserve its initial view plane normal (i.e., vector defined from camera position to focal point). Note: is the view plane is parallel to the view up axis, the view up axis will be reset to one of the three coordinate axes.

- `obj.ResetCamera (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Alternative version of ResetCamera(bounds[6]);
- `obj.SetRenderWindow (vtkRenderWindow )` - Specify the rendering window in which to draw. This is automatically set when the renderer is created by MakeRenderer. The user probably shouldn't ever need to call this method.
- `vtkRenderWindow = obj.GetRenderWindow ()` - Specify the rendering window in which to draw. This is automatically set when the renderer is created by MakeRenderer. The user probably shouldn't ever need to call this method.
- `vtkWindow = obj.GetVTKWindow ()` - Specify the rendering window in which to draw. This is automatically set when the renderer is created by MakeRenderer. The user probably shouldn't ever need to call this method.
- `obj.SetBackingStore (int )` - Turn on/off using backing store. This may cause the re-rendering time to be slightly slower when the view changes. But it is much faster when the image has not changed, such as during an expose event.
- `int = obj.GetBackingStore ()` - Turn on/off using backing store. This may cause the re-rendering time to be slightly slower when the view changes. But it is much faster when the image has not changed, such as during an expose event.
- `obj.BackingStoreOn ()` - Turn on/off using backing store. This may cause the re-rendering time to be slightly slower when the view changes. But it is much faster when the image has not changed, such as during an expose event.
- `obj.BackingStoreOff ()` - Turn on/off using backing store. This may cause the re-rendering time to be slightly slower when the view changes. But it is much faster when the image has not changed, such as during an expose event.
- `obj.SetInteractive (int )` - Turn on/off interactive status. An interactive renderer is one that can receive events from an interactor. Should only be set if there are multiple renderers in the same section of the viewport.
- `int = obj.GetInteractive ()` - Turn on/off interactive status. An interactive renderer is one that can receive events from an interactor. Should only be set if there are multiple renderers in the same section of the viewport.
- `obj.InteractiveOn ()` - Turn on/off interactive status. An interactive renderer is one that can receive events from an interactor. Should only be set if there are multiple renderers in the same section of the viewport.
- `obj.InteractiveOff ()` - Turn on/off interactive status. An interactive renderer is one that can receive events from an interactor. Should only be set if there are multiple renderers in the same section of the viewport.
- `obj.SetLayer (int )` - Set/Get the layer that this renderer belongs to. This is only used if there are layered renderers.
- `int = obj.GetLayer ()` - Set/Get the layer that this renderer belongs to. This is only used if there are layered renderers.
- `obj.SetPreserveDepthBuffer (int )` - Normally a renderer is treated as transparent if Layer ¿ 0. To treat a renderer at Layer 0 as transparent, set this flag to true.
- `int = obj.GetPreserveDepthBuffer ()` - Normally a renderer is treated as transparent if Layer ¿ 0. To treat a renderer at Layer 0 as transparent, set this flag to true.

- `obj.PreserveDepthBufferOn ()` - Normally a renderer is treated as transparent if Layer ¿ 0. To treat a renderer at Layer 0 as transparent, set this flag to true.
- `obj.PreserveDepthBufferOff ()` - Normally a renderer is treated as transparent if Layer ¿ 0. To treat a renderer at Layer 0 as transparent, set this flag to true.
- `int = obj.Transparent ()` - Returns a boolean indicating if this renderer is transparent. It is transparent if it is not in the deepest layer of its render window.
- `obj.WorldToView ()` - Convert world point coordinates to view coordinates.
- `obj.ViewToWorld ()` - Convert view point coordinates to world coordinates.
- `double = obj.GetZ (int x, int y)` - Given a pixel location, return the Z value. The z value is normalized (0,1) between the front and back clipping planes.
- `long = obj.GetMTime ()` - Return the MTime of the renderer also considering its ivars.
- `double = obj.GetLastRenderTimeInSeconds ()` - Get the time required, in seconds, for the last Render call.
- `int = obj.GetNumberOfPropsRendered ()` - Should be used internally only during a render Get the number of props that were rendered using a RenderOpaqueGeometry or RenderTranslucentPolygonalGeometry call. This is used to know if something is in the frame buffer.
- `vtkAssemblyPath = obj.PickProp (double selectionX, double selectionY)` - Return the prop (via a vtkAssemblyPath) that has the highest z value at the given x, y position in the viewport. Basically, the top most prop that renders the pixel at selectionX, selectionY will be returned. If nothing was picked then NULL is returned. This method selects from the renderers Prop list.
- `vtkAssemblyPath = obj.PickProp (double selectionX1, double selectionY1, double selectionX2, double` - Return the prop (via a vtkAssemblyPath) that has the highest z value at the given x, y position in the viewport. Basically, the top most prop that renders the pixel at selectionX, selectionY will be returned. If nothing was picked then NULL is returned. This method selects from the renderers Prop list.
- `obj.StereoMidpoint ()` - Do anything necessary between rendering the left and right viewpoints in a stereo render. Doesn't do anything except in the derived vtkIceTRenderer in ParaView.
- `double = obj.GetTiledAspectRatio ()` - Compute the aspect ratio of this renderer for the current tile. When tiled displays are used the aspect ratio of the renderer for a given tile may be diferent that the aspect ratio of the renderer when rendered in it entirity
- `int = obj.IsActiveCameraCreated ()` - Turn on/off rendering of translucent material with depth peeling technique. The render window must have alpha bits (ie call SetAlphaBitPlanes(1)) and no multisample buffer (ie call SetMultiSamples(0)) to support depth peeling. If UseDepthPeeling is on and the GPU supports it, depth peeling is used for rendering translucent materials. If UseDepthPeeling is off, alpha blending is used. Initial value is off.
- `obj.SetUseDepthPeeling (int )` - Turn on/off rendering of translucent material with depth peeling technique. The render window must have alpha bits (ie call SetAlphaBitPlanes(1)) and no multisample buffer (ie call SetMultiSamples(0)) to support depth peeling. If UseDepthPeeling is on and the GPU supports it, depth peeling is used for rendering translucent materials. If UseDepthPeeling is off, alpha blending is used. Initial value is off.
- `int = obj.GetUseDepthPeeling ()` - Turn on/off rendering of translucent material with depth peeling technique. The render window must have alpha bits (ie call SetAlphaBitPlanes(1)) and no multisample buffer (ie call SetMultiSamples(0)) to support depth peeling. If UseDepthPeeling is on and the GPU supports it, depth peeling is used for rendering translucent materials. If UseDepthPeeling is off, alpha blending is used. Initial value is off.

- `obj.UseDepthPeelingOn ()` - Turn on/off rendering of translucent material with depth peeling technique. The render window must have alpha bits (ie call SetAlphaBitPlanes(1)) and no multisample buffer (ie call SetMultiSamples(0)) to support depth peeling. If UseDepthPeeling is on and the GPU supports it, depth peeling is used for rendering translucent materials. If UseDepthPeeling is off, alpha blending is used. Initial value is off.

- `obj.UseDepthPeelingOff ()` - Turn on/off rendering of translucent material with depth peeling technique. The render window must have alpha bits (ie call SetAlphaBitPlanes(1)) and no multisample buffer (ie call SetMultiSamples(0)) to support depth peeling. If UseDepthPeeling is on and the GPU supports it, depth peeling is used for rendering translucent materials. If UseDepthPeeling is off, alpha blending is used. Initial value is off.

- `obj.SetOcclusionRatio (double )` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.

- `double = obj.GetOcclusionRatioMinValue ()` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.

- `double = obj.GetOcclusionRatioMaxValue ()` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.

- `double = obj.GetOcclusionRatio ()` - In case of use of depth peeling technique for rendering translucent material, define the threshold under which the algorithm stops to iterate over peel layers. This is the ratio of the number of pixels that have been touched by the last layer over the total number of pixels of the viewport area. Initial value is 0.0, meaning rendering have to be exact. Greater values may speed-up the rendering with small impact on the quality.

- `obj.SetMaximumNumberOfPeels (int )` - In case of depth peeling, define the maximum number of peeling layers. Initial value is 4. A special value of 0 means no maximum limit. It has to be a positive value.

- `int = obj.GetMaximumNumberOfPeels ()` - In case of depth peeling, define the maximum number of peeling layers. Initial value is 4. A special value of 0 means no maximum limit. It has to be a positive value.

- `int = obj.GetLastRenderingUsedDepthPeeling ()` - Tells if the last call to DeviceRenderTranslucentPolygonalGeometry() actually used depth peeling. Initial value is false.

- `obj.SetDelegate (vtkRendererDelegate d)` - Set/Get a custom Render call. Allows to hook a Render call from an external project.It will be used in place of vtkRenderer::Render() if it is not NULL and its Used ivar is set to true. Initial value is NULL.

- `vtkRendererDelegate = obj.GetDelegate ()` - Set/Get a custom Render call. Allows to hook a Render call from an external project.It will be used in place of vtkRenderer::Render() if it is not NULL and its Used ivar is set to true. Initial value is NULL.

- `obj.SetPass (vtkRenderPass p)` - Set/Get a custom render pass. Initial value is NULL.

- `vtkRenderPass = obj.GetPass ()` - Set/Get a custom render pass. Initial value is NULL.

- `vtkHardwareSelector = obj.GetSelector ()` - Get the current hardware selector. If the Selector is set, it implies the current render pass is for selection. Mappers/Properties may choose to behave differently when rendering for hardware selection.
- `obj.SetBackgroundTexture (vtkTexture )` - Set/Get the texture to be used for the background. If set and enabled this gets the priority over the gradient background.
- `vtkTexture = obj.GetBackgroundTexture ()` - Set/Get the texture to be used for the background. If set and enabled this gets the priority over the gradient background.
- `obj.SetTexturedBackground (bool )` - Set/Get whether this viewport should have a textured background. Default is off.
- `bool = obj.GetTexturedBackground ()` - Set/Get whether this viewport should have a textured background. Default is off.
- `obj.TexturedBackgroundOn ()` - Set/Get whether this viewport should have a textured background. Default is off.
- `obj.TexturedBackgroundOff ()` - Set/Get whether this viewport should have a textured background. Default is off.

39.158 vtkRendererCollection

39.158.1 Usage

vtkRendererCollection represents and provides methods to manipulate a list of renderers (i.e., vtkRenderer and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkRendererCollection, simply invoke its constructor as follows

```
obj = vtkRendererCollection
```

39.158.2 Methods

The class vtkRendererCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRendererCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRendererCollection = obj.NewInstance ()`
- `vtkRendererCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkRenderer a)` - Get the next Renderer in the list. Return NULL when at the end of the list.
- `vtkRenderer = obj.GetNextItem ()` - Get the next Renderer in the list. Return NULL when at the end of the list.
- `obj.Render ()` - Forward the Render() method to each renderer in the list.
- `vtkRenderer = obj.GetFirstRenderer ()` - Get the first Renderer in the list. Return NULL when at the end of the list.

39.159 vtkRendererDelegate

39.159.1 Usage

vtkRendererDelegate is an abstract class with a pure virtual method Render. This method replaces the Render method of vtkRenderer to allow custom rendering from an external project. A RendererDelegate is connected to a vtkRenderer with method SetDelegate(). An external project just has to provide a concrete implementation of vtkRendererDelegate.

To create an instance of class vtkRendererDelegate, simply invoke its constructor as follows

```
obj = vtkRendererDelegate
```

39.159.2 Methods

The class vtkRendererDelegate has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRendererDelegate class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRendererDelegate = obj.NewInstance ()`
- `vtkRendererDelegate = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer r)` - Render the props of vtkRenderer if Used is on.
- `obj.SetUsed (bool )` - Tells if the delegate has to be used by the renderer or not. Initial value is off.
- `bool = obj.GetUsed ()` - Tells if the delegate has to be used by the renderer or not. Initial value is off.
- `obj.UsedOn ()` - Tells if the delegate has to be used by the renderer or not. Initial value is off.
- `obj.UsedOff ()` - Tells if the delegate has to be used by the renderer or not. Initial value is off.

39.160 vtkRendererSource

39.160.1 Usage

vtkRendererSource is a source object that gets its input from a renderer and converts it to structured points. This can then be used in a visualization pipeline. You must explicitly send a Modify() to this object to get it to reload its data from the renderer. Consider using vtkWindowToImageFilter instead of this class.

The data placed into the output is the renderer's image rgb values. Optionally, you can also grab the image depth (e.g., z-buffer) values, and place then into the output (point) field data.

To create an instance of class vtkRendererSource, simply invoke its constructor as follows

```
obj = vtkRendererSource
```

39.160.2 Methods

The class vtkRendererSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRendererSource class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkRendererSource = obj.NewInstance ()`
- `vtkRendererSource = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime also considering the Renderer.
- `obj.SetInput (vtkRenderer )` - Indicates what renderer to get the pixel data from.
- `vtkRenderer = obj.GetInput ()` - Returns which renderer is being used as the source for the pixel data.
- `obj.SetWholeWindow (int )` - Use the entire RenderWindow as a data source or just the Renderer. The default is zero, just the Renderer.
- `int = obj.GetWholeWindow ()` - Use the entire RenderWindow as a data source or just the Renderer. The default is zero, just the Renderer.
- `obj.WholeWindowOn ()` - Use the entire RenderWindow as a data source or just the Renderer. The default is zero, just the Renderer.
- `obj.WholeWindowOff ()` - Use the entire RenderWindow as a data source or just the Renderer. The default is zero, just the Renderer.
- `obj.SetRenderFlag (int )` - If this flag is on, the Executing causes a render first.
- `int = obj.GetRenderFlag ()` - If this flag is on, the Executing causes a render first.
- `obj.RenderFlagOn ()` - If this flag is on, the Executing causes a render first.
- `obj.RenderFlagOff ()` - If this flag is on, the Executing causes a render first.
- `obj.SetDepthValues (int )` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed into a field data attributes named "ZBuffer" .
- `int = obj.GetDepthValues ()` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed into a field data attributes named "ZBuffer" .
- `obj.DepthValuesOn ()` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed into a field data attributes named "ZBuffer" .
- `obj.DepthValuesOff ()` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed into a field data attributes named "ZBuffer" .
- `obj.SetDepthValuesInScalars (int )` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed in the scalars as a fourth Z component (shift and scaled to map the full 0..255 range).
- `int = obj.GetDepthValuesInScalars ()` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed in the scalars as a fourth Z component (shift and scaled to map the full 0..255 range).
- `obj.DepthValuesInScalarsOn ()` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed in the scalars as a fourth Z component (shift and scaled to map the full 0..255 range).
- `obj.DepthValuesInScalarsOff ()` - A boolean value to control whether to grab z-buffer (i.e., depth values) along with the image data. The z-buffer data is placed in the scalars as a fourth Z component (shift and scaled to map the full 0..255 range).
- `vtkImageData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.

39.161 vtkRenderPass

39.161.1 Usage

vtkRenderPass is a deferred class with a simple deferred method Render. This method performs a rendering pass of the scene described in vtkRenderState. Subclasses define what really happens during rendering.

Directions to write a subclass of vtkRenderPass: It is up to the subclass to decide if it needs to delegate part of its job to some other vtkRenderPass objects ("delegates"). - The subclass has to define ivar to set/get its delegates. - The documentation of the subclass has to describe: - what each delegate is supposed to perform - if a delegate is supposed to be used once or multiple times - what it expects to have in the framebuffer before starting (status of colorbuffers, depth buffer, stencil buffer) - what it will change in the framebuffer. - A pass cannot modify the vtkRenderState where it will perform but it can build a new vtkRenderState (it can change the FrameBuffer, change the prop array, changed the required prop properties keys (usually adding some to a copy of the existing list) but it has to keep the same vtkRenderer object), make it current and pass it to its delegate. - at the end of the execution of Render, the pass has to ensure the current vtkRenderState is the one it has in argument.

To create an instance of class vtkRenderPass, simply invoke its constructor as follows

```
obj = vtkRenderPass
```

39.161.2 Methods

The class vtkRenderPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderPass = obj.NewInstance ()`
- `vtkRenderPass = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfRenderedProps ()` - Number of props rendered at the last Render call.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources. Default implementation is empty.

39.162 vtkRenderPassCollection

39.162.1 Usage

vtkRenderPassCollection represents a list of RenderPasses (i.e., vtkRenderPass and subclasses) and provides methods to manipulate the list. The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkRenderPassCollection, simply invoke its constructor as follows

```
obj = vtkRenderPassCollection
```

39.162.2 Methods

The class vtkRenderPassCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderPassCollection class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkRenderPassCollection = obj.NewInstance ()`
- `vtkRenderPassCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkRenderPass pass)` - Add an RenderPass to the list.
- `vtkRenderPass = obj.GetNextRenderPass ()` - Get the next RenderPass in the list.
- `vtkRenderPass = obj.GetLastRenderPass ()` - Get the last RenderPass in the list.

39.163 vtkRenderWindow

39.163.1 Usage

vtkRenderWindow is an abstract object to specify the behavior of a rendering window. A rendering window is a window in a graphical user interface where renderers draw their images. Methods are provided to synchronize the rendering process, set window size, and control double buffering. The window also allows rendering in stereo. The interlaced render stereo type is for output to a VRex stereo projector. All of the odd horizontal lines are from the left eye, and the even lines are from the right eye. The user has to make the render window aligned with the VRex projector, or the eye will be swapped.

To create an instance of class vtkRenderWindow, simply invoke its constructor as follows

```
obj = vtkRenderWindow
```

39.163.2 Methods

The class vtkRenderWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderWindow class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderWindow = obj.NewInstance ()`
- `vtkRenderWindow = obj.SafeDownCast (vtkObject o)`
- `obj.AddRenderer (vtkRenderer )` - Add a renderer to the list of renderers.
- `obj.RemoveRenderer (vtkRenderer )` - Remove a renderer from the list of renderers.
- `int = obj.HasRenderer (vtkRenderer )` - Query if a renderer is in the list of renderers.
- `vtkRendererCollection = obj.GetRenderers ()` - Return the collection of renderers in the render window.
- `obj.Render ()` - Ask each renderer owned by this RenderWindow to render its image and synchronize this process.
- `obj.Start ()` - Initialize the rendering process.
- `obj.Finalize ()` - Finalize the rendering process.
- `obj.Frame ()` - A termination method performed at the end of the rendering process to do things like swapping buffers (if necessary) or similar actions.

- `obj.WaitForCompletion ()` - Block the thread until the actual rendering is finished(). Useful for measurement only.
- `obj.CopyResultFrame ()` - Performed at the end of the rendering process to generate image. This is typically done right before swapping buffers.
- `vtkRenderWindowInteractor = obj.MakeRenderWindowInteractor ()` - Create an interactor to control renderers in this window. We need to know what type of interactor to create, because we might be in X Windows or MS Windows.
- `obj.HideCursor ()` - Hide or Show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead. Set cursor position in window (note that (0,0) is the lower left corner).
- `obj.ShowCursor ()` - Hide or Show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead. Set cursor position in window (note that (0,0) is the lower left corner).
- `obj.SetCursorPosition (int , int )` - Hide or Show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead. Set cursor position in window (note that (0,0) is the lower left corner).
- `obj.SetCurrentCursor (int )` - Change the shape of the cursor.
- `int = obj.GetCurrentCursor ()` - Change the shape of the cursor.
- `obj.SetFullScreen (int )` - Turn on/off rendering full screen window size.
- `int = obj.GetFullScreen ()` - Turn on/off rendering full screen window size.
- `obj.FullScreenOn ()` - Turn on/off rendering full screen window size.
- `obj.FullScreenOff ()` - Turn on/off rendering full screen window size.
- `obj.SetBorders (int )` - Turn on/off window manager borders. Typically, you shouldn't turn the borders off, because that bypasses the window manager and can cause undesirable behavior.
- `int = obj.GetBorders ()` - Turn on/off window manager borders. Typically, you shouldn't turn the borders off, because that bypasses the window manager and can cause undesirable behavior.
- `obj.BordersOn ()` - Turn on/off window manager borders. Typically, you shouldn't turn the borders off, because that bypasses the window manager and can cause undesirable behavior.
- `obj.BordersOff ()` - Turn on/off window manager borders. Typically, you shouldn't turn the borders off, because that bypasses the window manager and can cause undesirable behavior.
- `int = obj.GetStereoCapableWindow ()` - Prescribe that the window be created in a stereo-capable mode. This method must be called before the window is realized. Default is off.
- `obj.StereoCapableWindowOn ()` - Prescribe that the window be created in a stereo-capable mode. This method must be called before the window is realized. Default is off.
- `obj.StereoCapableWindowOff ()` - Prescribe that the window be created in a stereo-capable mode. This method must be called before the window is realized. Default is off.
- `obj.SetStereoCapableWindow (int capable)` - Prescribe that the window be created in a stereo-capable mode. This method must be called before the window is realized. Default is off.
- `int = obj.GetStereoRender ()` - Turn on/off stereo rendering.
- `obj.SetStereoRender (int stereo)` - Turn on/off stereo rendering.

- `obj.StereoRenderOn ()` - Turn on/off stereo rendering.
- `obj.StereoRenderOff ()` - Turn on/off stereo rendering.
- `obj.SetAlphaBitPlanes (int )` - Turn on/off the use of alpha bitplanes.
- `int = obj.GetAlphaBitPlanes ()` - Turn on/off the use of alpha bitplanes.
- `obj.AlphaBitPlanesOn ()` - Turn on/off the use of alpha bitplanes.
- `obj.AlphaBitPlanesOff ()` - Turn on/off the use of alpha bitplanes.
- `obj.SetPointSmoothing (int )` - Turn on/off point smoothing. Default is off. This must be applied before the first Render.
- `int = obj.GetPointSmoothing ()` - Turn on/off point smoothing. Default is off. This must be applied before the first Render.
- `obj.PointSmoothingOn ()` - Turn on/off point smoothing. Default is off. This must be applied before the first Render.
- `obj.PointSmoothingOff ()` - Turn on/off point smoothing. Default is off. This must be applied before the first Render.
- `obj.SetLineSmoothing (int )` - Turn on/off line smoothing. Default is off. This must be applied before the first Render.
- `int = obj.GetLineSmoothing ()` - Turn on/off line smoothing. Default is off. This must be applied before the first Render.
- `obj.LineSmoothingOn ()` - Turn on/off line smoothing. Default is off. This must be applied before the first Render.
- `obj.LineSmoothingOff ()` - Turn on/off line smoothing. Default is off. This must be applied before the first Render.
- `obj.SetPolygonSmoothing (int )` - Turn on/off polygon smoothing. Default is off. This must be applied before the first Render.
- `int = obj.GetPolygonSmoothing ()` - Turn on/off polygon smoothing. Default is off. This must be applied before the first Render.
- `obj.PolygonSmoothingOn ()` - Turn on/off polygon smoothing. Default is off. This must be applied before the first Render.
- `obj.PolygonSmoothingOff ()` - Turn on/off polygon smoothing. Default is off. This must be applied before the first Render.
- `int = obj.GetStereoType ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.

- `obj.SetStereoType (int )` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToCrystalEyes ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToRedBlue ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToInterlaced ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToLeft ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToRight ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToDresden ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset

of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.

- `obj.SetStereoTypeToAnaglyph ()` - Set/Get what type of stereo rendering to use. CrystalEyes mode uses frame-sequential capabilities available in OpenGL to drive LCD shutter glasses and stereo projectors. RedBlue mode is a simple type of stereo for use with red-blue glasses. Anaglyph mode is a superset of RedBlue mode, but the color output channels can be configured using the AnaglyphColorMask and the color of the original image can be (somewhat) maintained using AnaglyphColorSaturation; the default colors for Anaglyph mode is red-cyan. Interlaced stereo mode produces a composite image where horizontal lines alternate between left and right views. StereoLeft and StereoRight modes choose one or the other stereo view. Dresden mode is yet another stereoscopic interleaving.
- `obj.SetStereoTypeToCheckerboard ()`
- `string = obj.GetStereoTypeAsString ()`
- `obj.StereoUpdate ()` - Update the system, if needed, due to stereo rendering. For some stereo methods, subclasses might need to switch some hardware settings here.
- `obj.StereoMidpoint ()` - Intermediate method performs operations required between the rendering of the left and right eye.
- `obj.StereoRenderComplete ()` - Handles work required once both views have been rendered when using stereo rendering.
- `obj.SetAnaglyphColorSaturation (float )`
- `float = obj.GetAnaglyphColorSaturationMinValue ()`
- `float = obj.GetAnaglyphColorSaturationMaxValue ()`
- `float = obj.GetAnaglyphColorSaturation ()`
- `obj.SetAnaglyphColorMask (int , int )`
- `obj.SetAnaglyphColorMask (int  a[2])`
- `int = obj. GetAnaglyphColorMask ()`
- `obj.WindowRemap ()` - Remap the rendering window. This probably only works on UNIX right now. It is useful for changing properties that can't normally be changed once the window is up.
- `obj.SetSwapBuffers (int )` - Turn on/off buffer swapping between images.
- `int = obj.GetSwapBuffers ()` - Turn on/off buffer swapping between images.
- `obj.SwapBuffersOn ()` - Turn on/off buffer swapping between images.
- `obj.SwapBuffersOff ()` - Turn on/off buffer swapping between images.
- `int = obj.SetPixelData (int x, int y, int x2, int y2, string data, int front)` - Set/Get the pixel data of an image, transmitted as RGBRGBRGB. The front argument indicates if the front buffer should be used or the back buffer. It is the caller's responsibility to delete the resulting array. It is very important to realize that the memory in this array is organized from the bottom of the window to the top. The origin of the screen is in the lower left corner. The y axis increases as you go up the screen. So the storage of pixels is from left to right and from bottom to top. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.

- `int = obj.SetPixelData (int x, int y, int x2, int y2, vtkUnsignedCharArray data, int front)` - Set/Get the pixel data of an image, transmitted as RGBRGBRGB. The front argument indicates if the front buffer should be used or the back buffer. It is the caller's responsibility to delete the resulting array. It is very important to realize that the memory in this array is organized from the bottom of the window to the top. The origin of the screen is in the lower left corner. The y axis increases as you go up the screen. So the storage of pixels is from left to right and from bottom to top. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.

- `int = obj.GetRGBAPixelData (int x, int y, int x2, int y2, int front, vtkFloatArray data)` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `int = obj.SetRGBAPixelData (int x, int y, int x2, int y2, float , int front, int blend)` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `int = obj.SetRGBAPixelData (int , int , int , int , vtkFloatArray , int , int blend)` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `obj.ReleaseRGBAPixelData (float data)` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `int = obj.GetRGBACharPixelData (int x, int y, int x2, int y2, int front, vtkUnsignedCharArray data)` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `int = obj.SetRGBACharPixelData (int x, int y, int x2, int y2, string data, int front, int blend)` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `int = obj.SetRGBACharPixelData (int x, int y, int x2, int y2, vtkUnsignedCharArray data, int front,` - Same as Get/SetPixelData except that the image also contains an alpha component. The image is transmitted as RGBARGBARGBA... each of which is a float value. The "blend" parameter controls whether the SetRGBAPixelData method blends the data with the previous contents of the frame buffer or completely replaces the frame buffer data.

- `int = obj.GetZbufferData (int x, int y, int x2, int y2, float z)` - Set/Get the zbuffer data from the frame buffer. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.

- `int = obj.GetZbufferData (int x, int y, int x2, int y2, vtkFloatArray z)` - Set/Get the zbuffer data from the frame buffer. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.

- `int = obj.SetZbufferData (int x, int y, int x2, int y2, float z)` - Set/Get the zbuffer data from the frame buffer. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.

- `int = obj.SetZbufferData (int x, int y, int x2, int y2, vtkFloatArray z)` - Set/Get the zbuffer data from the frame buffer. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.
- `float = obj.GetZbufferDataAtPoint (int x, int y)` - Set the number of frames for doing antialiasing. The default is zero. Typically five or six will yield reasonable results without taking too long.
- `int = obj.GetAAFrames ()` - Set the number of frames for doing antialiasing. The default is zero. Typically five or six will yield reasonable results without taking too long.
- `obj.SetAAFrames (int )` - Set the number of frames for doing antialiasing. The default is zero. Typically five or six will yield reasonable results without taking too long.
- `int = obj.GetFDFrames ()` - Set the number of frames for doing focal depth. The default is zero. Depending on how your scene is organized you can get away with as few as four frames for focal depth or you might need thirty. One thing to note is that if you are using focal depth frames, then you will not need many (if any) frames for antialiasing.
- `obj.SetFDFrames (int )` - Set the number of frames for doing focal depth. The default is zero. Depending on how your scene is organized you can get away with as few as four frames for focal depth or you might need thirty. One thing to note is that if you are using focal depth frames, then you will not need many (if any) frames for antialiasing.
- `int = obj.GetSubFrames ()` - Set the number of sub frames for doing motion blur. The default is zero. Once this is set greater than one, you will no longer see a new frame for every Render(). If you set this to five, you will need to do five Render() invocations before seeing the result. This isn't very impressive unless something is changing between the Renders. Changing this value may reset the current subframe count.
- `obj.SetSubFrames (int subFrames)` - Set the number of sub frames for doing motion blur. The default is zero. Once this is set greater than one, you will no longer see a new frame for every Render(). If you set this to five, you will need to do five Render() invocations before seeing the result. This isn't very impressive unless something is changing between the Renders. Changing this value may reset the current subframe count.
- `int = obj.GetNeverRendered ()` - This flag is set if the window hasn't rendered since it was created
- `int = obj.GetAbortRender ()` - This is a flag that can be set to interrupt a rendering that is in progress.
- `obj.SetAbortRender (int )` - This is a flag that can be set to interrupt a rendering that is in progress.
- `int = obj.GetInAbortCheck ()` - This is a flag that can be set to interrupt a rendering that is in progress.
- `obj.SetInAbortCheck (int )` - This is a flag that can be set to interrupt a rendering that is in progress.
- `int = obj.CheckAbortStatus ()` - This is a flag that can be set to interrupt a rendering that is in progress.
- `int = obj.GetIsPicking ()`
- `obj.SetIsPicking (int )`
- `obj.IsPickingOn ()`
- `obj.IsPickingOff ()`

- `int = obj.GetEventPending ()` - Check to see if a mouse button has been pressed. All other events are ignored by this method. Ideally, you want to abort the render on any event which causes the DesiredUpdateRate to switch from a high-quality rate to a more interactive rate.
- `int = obj.CheckInRenderStatus ()` - Clear status (after an exception was thrown for example)
- `obj.ClearInRenderStatus ()` - Set/Get the desired update rate. This is used with the vtkLODActor class. When using level of detail actors you need to specify what update rate you require. The LODActors then will pick the correct resolution to meet your desired update rate in frames per second. A value of zero indicates that they can use all the time they want to.
- `obj.SetDesiredUpdateRate (double )` - Set/Get the desired update rate. This is used with the vtkLODActor class. When using level of detail actors you need to specify what update rate you require. The LODActors then will pick the correct resolution to meet your desired update rate in frames per second. A value of zero indicates that they can use all the time they want to.
- `double = obj.GetDesiredUpdateRate ()` - Set/Get the desired update rate. This is used with the vtkLODActor class. When using level of detail actors you need to specify what update rate you require. The LODActors then will pick the correct resolution to meet your desired update rate in frames per second. A value of zero indicates that they can use all the time they want to.
- `int = obj.GetNumberOfLayers ()` - Get the number of layers for renderers. Each renderer should have its layer set individually. Some algorithms iterate through all layers, so it is not wise to set the number of layers to be exorbitantly large (say bigger than 100).
- `obj.SetNumberOfLayers (int )` - Get the number of layers for renderers. Each renderer should have its layer set individually. Some algorithms iterate through all layers, so it is not wise to set the number of layers to be exorbitantly large (say bigger than 100).
- `int = obj.GetNumberOfLayersMinValue ()` - Get the number of layers for renderers. Each renderer should have its layer set individually. Some algorithms iterate through all layers, so it is not wise to set the number of layers to be exorbitantly large (say bigger than 100).
- `int = obj.GetNumberOfLayersMaxValue ()` - Get the number of layers for renderers. Each renderer should have its layer set individually. Some algorithms iterate through all layers, so it is not wise to set the number of layers to be exorbitantly large (say bigger than 100).
- `vtkRenderWindowInteractor = obj.GetInteractor ()` - Get the interactor associated with this render window
- `obj.SetInteractor (vtkRenderWindowInteractor )` - Set the interactor to the render window
- `obj.UnRegister (vtkObjectBase o)` - This Method detects loops of RenderWindow¡-¿Interactor, so objects are freed properly.
- `obj.SetWindowInfo (string )` - Dummy stubs for vtkWindow API.
- `obj.SetNextWindowInfo (string )` - Dummy stubs for vtkWindow API.
- `obj.SetParentInfo (string )` - Dummy stubs for vtkWindow API.
- `obj.MakeCurrent ()` - Attempt to make this window the current graphics context for the calling thread.
- `bool = obj.IsCurrent ()` - Tells if this window is the current graphics context for the calling thread.
- `obj.SetForceMakeCurrent ()` - If called, allow MakeCurrent() to skip cache-check when called. MakeCurrent() reverts to original behavior of cache-checking on the next render.
- `string = obj.ReportCapabilities ()` - Get report of capabilities for the render window

- `int = obj.SupportsOpenGL ()` - Does this render window support OpenGL? 0-false, 1-true
- `int = obj.IsDirect ()` - Is this render window using hardware acceleration? 0-false, 1-true
- `int = obj.GetDepthBufferSize ()` - This method should be defined by the subclass. How many bits of precision are there in the zbuffer?
- `int = obj.GetColorBufferSizes (int rgba)` - Get the size of the color buffer. Returns 0 if not able to determine otherwise sets R G B and A into buffer.
- `vtkPainterDeviceAdapter = obj.GetPainterDeviceAdapter ()` - Get the vtkPainterDeviceAdapter which can be used to paint on this render window.
- `obj.SetMultiSamples (int )` - Set / Get the number of multisamples to use for hardware antialiasing.
- `int = obj.GetMultiSamples ()` - Set / Get the number of multisamples to use for hardware antialiasing.
- `obj.SetStencilCapable (int )` - Set / Get the availability of the stencil buffer.
- `int = obj.GetStencilCapable ()` - Set / Get the availability of the stencil buffer.
- `obj.StencilCapableOn ()` - Set / Get the availability of the stencil buffer.
- `obj.StencilCapableOff ()` - Set / Get the availability of the stencil buffer.
- `obj.SetReportGraphicErrors (int )` - Turn on/off report of graphic errors. Initial value is false (off). This flag is used by vtkGraphicErrorMacro.
- `int = obj.GetReportGraphicErrors ()` - Turn on/off report of graphic errors. Initial value is false (off). This flag is used by vtkGraphicErrorMacro.
- `obj.ReportGraphicErrorsOn ()` - Turn on/off report of graphic errors. Initial value is false (off). This flag is used by vtkGraphicErrorMacro.
- `obj.ReportGraphicErrorsOff ()` - Turn on/off report of graphic errors. Initial value is false (off). This flag is used by vtkGraphicErrorMacro.
- `obj.CheckGraphicError ()` - Update graphic error status, regardless of ReportGraphicErrors flag. It means this method can be used in any context and is not restricted to debug mode.
- `int = obj.HasGraphicError ()` - Return the last graphic error status. Initial value is false.
- `string = obj.GetLastGraphicErrorString ()` - Return a string matching the last graphic error status.

39.164 vtkRenderWindowCollection

39.164.1 Usage

vtkRenderWindowCollection represents and provides methods to manipulate a list of RenderWindows. The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkRenderWindowCollection, simply invoke its constructor as follows

```
obj = vtkRenderWindowCollection
```

39.164.2 Methods

The class vtkRenderWindowCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderWindowCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderWindowCollection = obj.NewInstance ()`
- `vtkRenderWindowCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkRenderWindow a)` - Get the next RenderWindow in the list. Return NULL when at the end of the list.
- `vtkRenderWindow = obj.GetNextItem ()`

39.165 vtkRenderWindowInteractor

39.165.1 Usage

vtkRenderWindowInteractor provides a platform-independent interaction mechanism for mouse/key/time events. It serves as a base class for platform-dependent implementations that handle routing of mouse/key/timer messages to vtkInteractorObserver and its subclasses. vtkRenderWindowInteractor also provides controls for picking, rendering frame rate, and headlights.

vtkRenderWindowInteractor has changed from previous implementations and now serves only as a shell to hold user preferences and route messages to vtkInteractorStyle. Callbacks are available for many events. Platform specific subclasses should provide methods for manipulating timers, TerminateApp, and an event loop if required via Initialize/Start/Enable/Disable.

To create an instance of class vtkRenderWindowInteractor, simply invoke its constructor as follows

```
obj = vtkRenderWindowInteractor
```

39.165.2 Methods

The class vtkRenderWindowInteractor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderWindowInteractor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderWindowInteractor = obj.NewInstance ()`
- `vtkRenderWindowInteractor = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Prepare for handling events. This must be called before the interactor will work.
- `obj.ReInitialize ()` - This Method detects loops of RenderWindow-Interactor, so objects are freed properly.
- `obj.UnRegister (vtkObjectBase o)` - This Method detects loops of RenderWindow-Interactor, so objects are freed properly.

- `obj.Start ()` - Enable/Disable interactions. By default interactors are enabled when initialized. Initialize() must be called prior to enabling/disabling interaction. These methods are used when a window/widget is being shared by multiple renderers and interactors. This allows a "modal" display where one interactor is active when its data is to be displayed and all other interactors associated with the widget are disabled when their data is not displayed.

- `obj.Enable ()` - Enable/Disable interactions. By default interactors are enabled when initialized. Initialize() must be called prior to enabling/disabling interaction. These methods are used when a window/widget is being shared by multiple renderers and interactors. This allows a "modal" display where one interactor is active when its data is to be displayed and all other interactors associated with the widget are disabled when their data is not displayed.

- `obj.Disable ()` - Enable/Disable interactions. By default interactors are enabled when initialized. Initialize() must be called prior to enabling/disabling interaction. These methods are used when a window/widget is being shared by multiple renderers and interactors. This allows a "modal" display where one interactor is active when its data is to be displayed and all other interactors associated with the widget are disabled when their data is not displayed.

- `int = obj.GetEnabled ()` - Enable/Disable interactions. By default interactors are enabled when initialized. Initialize() must be called prior to enabling/disabling interaction. These methods are used when a window/widget is being shared by multiple renderers and interactors. This allows a "modal" display where one interactor is active when its data is to be displayed and all other interactors associated with the widget are disabled when their data is not displayed.

- `obj.EnableRenderOn ()` - Enable/Disable whether vtkRenderWindowInteractor::Render() calls this-¿RenderWindow-¿Render().

- `obj.EnableRenderOff ()` - Enable/Disable whether vtkRenderWindowInteractor::Render() calls this-¿RenderWindow-¿Render().

- `obj.SetEnableRender (bool )` - Enable/Disable whether vtkRenderWindowInteractor::Render() calls this-¿RenderWindow-¿Render().

- `bool = obj.GetEnableRender ()` - Enable/Disable whether vtkRenderWindowInteractor::Render() calls this-¿RenderWindow-¿Render().

- `obj.SetRenderWindow (vtkRenderWindow aren)` - Set/Get the rendering window being controlled by this object.

- `vtkRenderWindow = obj.GetRenderWindow ()` - Set/Get the rendering window being controlled by this object.

- `obj.UpdateSize (int x, int y)` - Event loop notification member for window size change. Window size is measured in pixels.

- `int = obj.CreateTimer (int timerType)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.DestroyTimer ()` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.CreateRepeatingTimer (long duration)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.CreateOneShotTimer (long duration)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.IsOneShotTimer (int timerId)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `long = obj.GetTimerDuration (int timerId)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and

DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.ResetTimer (int timerId)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.DestroyTimer (int timerId)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `int = obj.GetVTKTimerId (int platformTimerId)` - This class provides two groups of methods for manipulating timers. The first group (CreateTimer(timerType) and DestroyTimer()) implicitly use an internal timer id (and are present for backward compatibility). The second group (CreateRepeatingTimer(long),CreateOneShotTimer(long), ResetTimer(int),DestroyTimer(int)) use timer ids so multiple timers can be independently managed. In the first group, the CreateTimer() method takes an argument indicating whether the timer is created the first time (timerType==VTKI_TIMER_FIRST) or whether it is being reset (timerType==VTKI_TIMER_UPDATE). (In initial implementations of VTK this was how one shot and repeating timers were managed.) In the second group, the create methods take a timer duration argument (in milliseconds) and return a timer id. Thus the ResetTimer(timerId) and DestroyTimer(timerId) methods take this timer id and operate on the timer as appropriate. Methods are also available for determining

- `obj.SetTimerDuration (long )` - Specify the default timer interval (in milliseconds). (This is used in conjunction with the timer methods described previously, e.g., CreateTimer() uses this value; and CreateRepeatingTimer(duration) and CreateOneShotTimer(duration) use the default value if the parameter "duration" is less than or equal to zero.) Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `GetTimerDurationMinValue = obj.()` - Specify the default timer interval (in milliseconds). (This is used in conjunction with the timer methods described previously, e.g., CreateTimer() uses this value; and CreateRepeatingTimer(duration) and CreateOneShotTimer(duration) use the default value if the parameter "duration" is less than or equal to zero.) Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `GetTimerDurationMaxValue = obj.()` - Specify the default timer interval (in milliseconds). (This is used in conjunction with the timer methods described previously, e.g., CreateTimer() uses this value; and CreateRepeatingTimer(duration) and CreateOneShotTimer(duration) use the default value if the parameter "duration" is less than or equal to zero.) Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `long = obj.GetTimerDuration ()` - Specify the default timer interval (in milliseconds). (This is used in conjunction with the timer methods described previously, e.g., CreateTimer() uses this value; and CreateRepeatingTimer(duration) and CreateOneShotTimer(duration) use the default value if the parameter "duration" is less than or equal to zero.) Care must be taken when adjusting the timer interval from the default value of 10 milliseconds–it may adversely affect the interactors.

- `obj.SetTimerEventId (int )` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `int = obj.GetTimerEventId ()` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `obj.SetTimerEventType (int )` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `int = obj.GetTimerEventType ()` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `obj.SetTimerEventDuration (int )` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `int = obj.GetTimerEventDuration ()` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `obj.SetTimerEventPlatformId (int )` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should

set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `int = obj.GetTimerEventPlatformId ()` - These methods are used to communicate information about the currently firing CreateTimerEvent or DestroyTimerEvent. The caller of CreateTimerEvent sets up TimerEventId, TimerEventType and TimerEventDuration. The observer of CreateTimerEvent should set up an appropriate platform specific timer based on those values and set the TimerEventPlatformId before returning. The caller of DestroyTimerEvent sets up TimerEventPlatformId. The observer of DestroyTimerEvent should simply destroy the platform specific timer created by CreateTimerEvent. See vtkGenericRenderWindowInteractor's InternalCreateTimer and InternalDestroyTimer for an example.

- `obj.TerminateApp (void )` - External switching between joystick/trackball/new? modes. Initial value is a vtkInteractorStyleSwitch object.

- `obj.SetInteractorStyle (vtkInteractorObserver )` - External switching between joystick/trackball/new? modes. Initial value is a vtkInteractorStyleSwitch object.

- `vtkInteractorObserver = obj.GetInteractorStyle ()` - External switching between joystick/trackball/new? modes. Initial value is a vtkInteractorStyleSwitch object.

- `obj.SetLightFollowCamera (int )` - Turn on/off the automatic repositioning of lights as the camera moves. Default is On.

- `int = obj.GetLightFollowCamera ()` - Turn on/off the automatic repositioning of lights as the camera moves. Default is On.

- `obj.LightFollowCameraOn ()` - Turn on/off the automatic repositioning of lights as the camera moves. Default is On.

- `obj.LightFollowCameraOff ()` - Turn on/off the automatic repositioning of lights as the camera moves. Default is On.

- `obj.SetDesiredUpdateRate (double )` - Set/Get the desired update rate. This is used by vtkLODActor's to tell them how quickly they need to render. This update is in effect only when the camera is being rotated, or zoomed. When the interactor is still, the StillUpdateRate is used instead. The default is 15.

- `double = obj.GetDesiredUpdateRateMinValue ()` - Set/Get the desired update rate. This is used by vtkLODActor's to tell them how quickly they need to render. This update is in effect only when the camera is being rotated, or zoomed. When the interactor is still, the StillUpdateRate is used instead. The default is 15.

- `double = obj.GetDesiredUpdateRateMaxValue ()` - Set/Get the desired update rate. This is used by vtkLODActor's to tell them how quickly they need to render. This update is in effect only when the camera is being rotated, or zoomed. When the interactor is still, the StillUpdateRate is used instead. The default is 15.

- `double = obj.GetDesiredUpdateRate ()` - Set/Get the desired update rate. This is used by vtkLODActor's to tell them how quickly they need to render. This update is in effect only when the camera is being rotated, or zoomed. When the interactor is still, the StillUpdateRate is used instead. The default is 15.

- `obj.SetStillUpdateRate (double )` - Set/Get the desired update rate when movement has stopped. For the non-still update rate, see the SetDesiredUpdateRate method. The default is 0.0001

- `double = obj.GetStillUpdateRateMinValue ()` - Set/Get the desired update rate when movement has stopped. For the non-still update rate, see the SetDesiredUpdateRate method. The default is 0.0001
- `double = obj.GetStillUpdateRateMaxValue ()` - Set/Get the desired update rate when movement has stopped. For the non-still update rate, see the SetDesiredUpdateRate method. The default is 0.0001
- `double = obj.GetStillUpdateRate ()` - Set/Get the desired update rate when movement has stopped. For the non-still update rate, see the SetDesiredUpdateRate method. The default is 0.0001
- `int = obj.GetInitialized ()` - See whether interactor has been initialized yet. Default is 0.
- `obj.SetPicker (vtkAbstractPicker )` - Set/Get the object used to perform pick operations. In order to pick instances of vtkProp, the picker must be a subclass of vtkAbstractPropPicker, meaning that it can identify a particular instance of vtkProp.
- `vtkAbstractPicker = obj.GetPicker ()` - Set/Get the object used to perform pick operations. In order to pick instances of vtkProp, the picker must be a subclass of vtkAbstractPropPicker, meaning that it can identify a particular instance of vtkProp.
- `vtkAbstractPropPicker = obj.CreateDefaultPicker ()` - Create default picker. Used to create one when none is specified. Default is an instance of vtkPropPicker.
- `obj.ExitCallback ()` - These methods correspond to the the Exit, User and Pick callbacks. They allow for the Style to invoke them.
- `obj.UserCallback ()` - These methods correspond to the the Exit, User and Pick callbacks. They allow for the Style to invoke them.
- `obj.StartPickCallback ()` - These methods correspond to the the Exit, User and Pick callbacks. They allow for the Style to invoke them.
- `obj.EndPickCallback ()` - These methods correspond to the the Exit, User and Pick callbacks. They allow for the Style to invoke them.
- `obj.GetMousePosition (int x, int y)` - Hide or show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead.
- `obj.HideCursor ()` - Hide or show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead.
- `obj.ShowCursor ()` - Hide or show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead.
- `obj.Render ()` - Render the scene. Just pass the render call on to the associated vtkRenderWindow.
- `obj.FlyTo (vtkRenderer ren, double x, double y, double z)` - Given a position x, move the current camera's focal point to x. The movement is animated over the number of frames specified in NumberOfFlyFrames. The LOD desired frame rate is used.
- `obj.FlyTo (vtkRenderer ren, double x)` - Given a position x, move the current camera's focal point to x. The movement is animated over the number of frames specified in NumberOfFlyFrames. The LOD desired frame rate is used.
- `obj.FlyToImage (vtkRenderer ren, double x, double y)` - Given a position x, move the current camera's focal point to x. The movement is animated over the number of frames specified in NumberOfFlyFrames. The LOD desired frame rate is used.
- `obj.FlyToImage (vtkRenderer ren, double x)` - Set the number of frames to fly to when FlyTo is invoked.

- `obj.SetNumberOfFlyFrames (int )` - Set the number of frames to fly to when FlyTo is invoked.
- `int = obj.GetNumberOfFlyFramesMinValue ()` - Set the number of frames to fly to when FlyTo is invoked.
- `int = obj.GetNumberOfFlyFramesMaxValue ()` - Set the number of frames to fly to when FlyTo is invoked.
- `int = obj.GetNumberOfFlyFrames ()` - Set the number of frames to fly to when FlyTo is invoked.
- `obj.SetDolly (double )` - Set the total Dolly value to use when flying to (FlyTo()) a specified point. Negative values fly away from the point.
- `double = obj.GetDolly ()` - Set the total Dolly value to use when flying to (FlyTo()) a specified point. Negative values fly away from the point.
- `int = obj. GetEventPosition ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `int = obj. GetLastEventPosition ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetLastEventPosition (int , int )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetLastEventPosition (int  a[2])` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetEventPosition (int x, int y)` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetEventPosition (int pos[2])` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetEventPositionFlipY (int x, int y)` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetEventPositionFlipY (int pos[2])` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetAltKey (int )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.

- `int = obj.GetAltKey ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetControlKey (int )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `int = obj.GetControlKey ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetShiftKey (int )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `int = obj.GetShiftKey ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetKeyCode (char )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `char = obj.GetKeyCode ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetRepeatCount (int )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `int = obj.GetRepeatCount ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetKeySym (string )` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `string = obj.GetKeySym ()` - Set/Get information about the current event. The current x,y position is in the EventPosition, and the previous event position is in LastEventPosition, updated automatically each time EventPosition is set using its Set() method. Mouse positions are measured in pixels. The other information is about key board input.
- `obj.SetEventInformation (int x, int y, int ctrl, int shift, char keycode, int repeatcount, string k` - Calls SetEventInformation, but flips the Y based on the current Size[1] value (i.e. y = this-¿Size[1] - y - 1).

- `obj.SetEventInformationFlipY (int x, int y, int ctrl, int shift, char keycode, int repeatcount, str` - Set all the keyboard-related event information in one call.

- `obj.SetKeyEventInformation (int ctrl, int shift, char keycode, int repeatcount, string keysym)` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `obj.SetSize (int , int )` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `obj.SetSize (int a[2])` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `int = obj. GetSize ()` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `obj.SetEventSize (int , int )` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `obj.SetEventSize (int a[2])` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `int = obj. GetEventSize ()` - This methods sets the Size ivar of the interactor without actually changing the size of the window. Normally application programmers would use UpdateSize if anything. This is useful for letting someone else change the size of the rendering window and just letting the interactor know about the change. The current event width/height (if any) is in EventSize (Expose event, for example). Window size is measured in pixels.

- `vtkRenderer = obj.FindPokedRenderer (int , int )` - When an event occurs, we must determine which Renderer the event occurred within, since one RenderWindow may contain multiple renderers.

- `vtkObserverMediator = obj.GetObserverMediator ()` - Return the object used to mediate between vtkInteractorObservers contending for resources. Multiple interactor observers will often request different resources (e.g., cursor shape); the mediator uses a strategy to provide the resource based on priority of the observer plus the particular request (default versus non-default cursor shape).

- `obj.SetUseTDx (bool )` - Use a 3DConnexion device. Initial value is false. If VTK is not build with the TDx option, this is no-op. If VTK is build with the TDx option, and a device is not connected, a warning is emitted. It is must be called before the first Render to be effective, otherwise it is ignored.

- `bool = obj.GetUseTDx ()` - Use a 3DConnexion device. Initial value is false. If VTK is not build with the TDx option, this is no-op. If VTK is build with the TDx option, and a device is not connected, a warning is emitted. It is must be called before the first Render to be effective, otherwise it is ignored.

39.166 vtkRepresentationPainter

39.166.1 Usage

This painter merely defines the interface. Subclasses will change the polygon rendering mode dependent on the graphics library.

To create an instance of class vtkRepresentationPainter, simply invoke its constructor as follows

```
obj = vtkRepresentationPainter
```

39.166.2 Methods

The class vtkRepresentationPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRepresentationPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRepresentationPainter = obj.NewInstance ()`
- `vtkRepresentationPainter = obj.SafeDownCast (vtkObject o)`

39.167 vtkScalarBarActor

39.167.1 Usage

vtkScalarBarActor creates a scalar bar with annotation text. A scalar bar is a legend that indicates to the viewer the correspondence between color value and data value. The legend consists of a rectangular bar made of rectangular pieces each colored a constant value. Since vtkScalarBarActor is a subclass of vtkActor2D, it is drawn in the image plane (i.e., in the renderer's viewport) on top of the 3D graphics window.

To use vtkScalarBarActor you must associate a vtkScalarsToColors (or subclass) with it. The lookup table defines the colors and the range of scalar values used to map scalar data. Typically, the number of colors shown in the scalar bar is not equal to the number of colors in the lookup table, in which case sampling of the lookup table is performed.

Other optional capabilities include specifying the fraction of the viewport size (both x and y directions) which will control the size of the scalar bar and the number of annotation labels. The actual position of the scalar bar on the screen is controlled by using the vtkActor2D::SetPosition() method (by default the scalar bar is centered in the viewport). Other features include the ability to orient the scalar bar horizontally of vertically and controlling the format (printf style) with which to print the labels on the scalar bar. Also, the vtkScalarBarActor's property is applied to the scalar bar and annotation (including layer, and compositing operator).

Set the text property/attributes of the title and the labels through the vtkTextProperty objects associated to this actor.

To create an instance of class vtkScalarBarActor, simply invoke its constructor as follows

```
obj = vtkScalarBarActor
```

39.167.2 Methods

The class vtkScalarBarActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScalarBarActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScalarBarActor = obj.NewInstance ()`
- `vtkScalarBarActor = obj.SafeDownCast (vtkObject o)`
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Draw the scalar bar and annotation text to the screen.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Draw the scalar bar and annotation text to the screen.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Draw the scalar bar and annotation text to the screen.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.SetLookupTable (vtkScalarsToColors )` - Set/Get the vtkLookupTable to use. The lookup table specifies the number of colors to use in the table (if not overridden), as well as the scalar range.
- `vtkScalarsToColors = obj.GetLookupTable ()` - Set/Get the vtkLookupTable to use. The lookup table specifies the number of colors to use in the table (if not overridden), as well as the scalar range.
- `obj.SetUseOpacity (int )` - Should be display the opacity as well. This is displayed by changing the opacity of the scalar bar in accordance with the opacity of the given color. For clarity, a texture grid is placed in the background if Opacity is ON. You might also want to play with SetTextureGridWith in that case. [Default: off]
- `int = obj.GetUseOpacity ()` - Should be display the opacity as well. This is displayed by changing the opacity of the scalar bar in accordance with the opacity of the given color. For clarity, a texture grid is placed in the background if Opacity is ON. You might also want to play with SetTextureGridWith in that case. [Default: off]
- `obj.UseOpacityOn ()` - Should be display the opacity as well. This is displayed by changing the opacity of the scalar bar in accordance with the opacity of the given color. For clarity, a texture grid is placed in the background if Opacity is ON. You might also want to play with SetTextureGridWith in that case. [Default: off]
- `obj.UseOpacityOff ()` - Should be display the opacity as well. This is displayed by changing the opacity of the scalar bar in accordance with the opacity of the given color. For clarity, a texture grid is placed in the background if Opacity is ON. You might also want to play with SetTextureGridWith in that case. [Default: off]
- `obj.SetMaximumNumberOfColors (int )` - Set/Get the maximum number of scalar bar segments to show. This may differ from the number of colors in the lookup table, in which case the colors are samples from the lookup table.

- `int = obj.GetMaximumNumberOfColorsMinValue ()` - Set/Get the maximum number of scalar bar segments to show. This may differ from the number of colors in the lookup table, in which case the colors are samples from the lookup table.
- `int = obj.GetMaximumNumberOfColorsMaxValue ()` - Set/Get the maximum number of scalar bar segments to show. This may differ from the number of colors in the lookup table, in which case the colors are samples from the lookup table.
- `int = obj.GetMaximumNumberOfColors ()` - Set/Get the maximum number of scalar bar segments to show. This may differ from the number of colors in the lookup table, in which case the colors are samples from the lookup table.
- `obj.SetNumberOfLabels (int )` - Set/Get the number of annotation labels to show.
- `int = obj.GetNumberOfLabelsMinValue ()` - Set/Get the number of annotation labels to show.
- `int = obj.GetNumberOfLabelsMaxValue ()` - Set/Get the number of annotation labels to show.
- `int = obj.GetNumberOfLabels ()` - Set/Get the number of annotation labels to show.
- `obj.SetOrientation (int )` - Control the orientation of the scalar bar.
- `int = obj.GetOrientationMinValue ()` - Control the orientation of the scalar bar.
- `int = obj.GetOrientationMaxValue ()` - Control the orientation of the scalar bar.
- `int = obj.GetOrientation ()` - Control the orientation of the scalar bar.
- `obj.SetOrientationToHorizontal ()` - Control the orientation of the scalar bar.
- `obj.SetOrientationToVertical ()` - Control the orientation of the scalar bar.
- `obj.SetTitleTextProperty (vtkTextProperty p)` - Set/Get the title text property.
- `vtkTextProperty = obj.GetTitleTextProperty ()` - Set/Get the title text property.
- `obj.SetLabelTextProperty (vtkTextProperty p)` - Set/Get the labels text property.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - Set/Get the labels text property.
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the labels on the scalar bar.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the labels on the scalar bar.
- `obj.SetTitle (string )` - Set/Get the title of the scalar bar actor,
- `string = obj.GetTitle ()` - Set/Get the title of the scalar bar actor,
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of a scalar bar actor. Overloads the virtual vtkProp method.
- `obj.SetTextureGridWidth (double )` - Set the width of the texture grid. Used only if UseOpacity is ON.
- `double = obj.GetTextureGridWidth ()` - Set the width of the texture grid. Used only if UseOpacity is ON.
- `vtkActor2D = obj.GetTextureActor ()` - Get the texture actor.. you may want to change some properties on it

- `obj.SetTextPosition (int )` - Have the text preceding the scalar bar or suceeding it ? Succeed implies the that the text is Above scalar bar if orientation is horizontal or Right of scalar bar if orientation is vertical. Precede is the opposite

- `int = obj.GetTextPositionMinValue ()` - Have the text preceding the scalar bar or suceeding it ? Succeed implies the that the text is Above scalar bar if orientation is horizontal or Right of scalar bar if orientation is vertical. Precede is the opposite

- `int = obj.GetTextPositionMaxValue ()` - Have the text preceding the scalar bar or suceeding it ? Succeed implies the that the text is Above scalar bar if orientation is horizontal or Right of scalar bar if orientation is vertical. Precede is the opposite

- `int = obj.GetTextPosition ()` - Have the text preceding the scalar bar or suceeding it ? Succeed implies the that the text is Above scalar bar if orientation is horizontal or Right of scalar bar if orientation is vertical. Precede is the opposite

- `obj.SetTextPositionToPrecedeScalarBar ()` - Have the text preceding the scalar bar or suceeding it ? Succeed implies the that the text is Above scalar bar if orientation is horizontal or Right of scalar bar if orientation is vertical. Precede is the opposite

- `obj.SetTextPositionToSucceedScalarBar ()` - Set/Get the maximum width and height in pixels. Specifying the size as a relative fraction of the viewport can sometimes undersirably strech the size of the actor too much. These methods allow the user to set bounds on the maximum size of the scalar bar in pixels along any direction. Defaults to unbounded.

- `obj.SetMaximumWidthInPixels (int )` - Set/Get the maximum width and height in pixels. Specifying the size as a relative fraction of the viewport can sometimes undersirably strech the size of the actor too much. These methods allow the user to set bounds on the maximum size of the scalar bar in pixels along any direction. Defaults to unbounded.

- `int = obj.GetMaximumWidthInPixels ()` - Set/Get the maximum width and height in pixels. Specifying the size as a relative fraction of the viewport can sometimes undersirably strech the size of the actor too much. These methods allow the user to set bounds on the maximum size of the scalar bar in pixels along any direction. Defaults to unbounded.

- `obj.SetMaximumHeightInPixels (int )` - Set/Get the maximum width and height in pixels. Specifying the size as a relative fraction of the viewport can sometimes undersirably strech the size of the actor too much. These methods allow the user to set bounds on the maximum size of the scalar bar in pixels along any direction. Defaults to unbounded.

- `int = obj.GetMaximumHeightInPixels ()` - Set/Get the maximum width and height in pixels. Specifying the size as a relative fraction of the viewport can sometimes undersirably strech the size of the actor too much. These methods allow the user to set bounds on the maximum size of the scalar bar in pixels along any direction. Defaults to unbounded.

39.168 vtkScalarsToColorsPainter

39.168.1 Usage

This is a painter that converts scalars to colors. It enable/disables coloring state depending on the ScalarMode. This painter is composite dataset enabled.

To create an instance of class vtkScalarsToColorsPainter, simply invoke its constructor as follows

```
obj = vtkScalarsToColorsPainter
```

39.168.2 Methods

The class vtkScalarsToColorsPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScalarsToColorsPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScalarsToColorsPainter = obj.NewInstance ()`
- `vtkScalarsToColorsPainter = obj.SafeDownCast (vtkObject o)`
- `obj.SetLookupTable (vtkScalarsToColors lut)` - Specify a lookup table for the mapper to use.
- `vtkScalarsToColors = obj.GetLookupTable ()` - Specify a lookup table for the mapper to use.
- `obj.CreateDefaultLookupTable ()` - Create default lookup table. Generally used to create one when none is available with the scalar data.
- `int = obj.GetPremultiplyColorsWithAlpha (vtkActor actor)` - For alpha blending, we sometime premultiply the colors with alpha and change the alpha blending function. This call returns whether we are premultiplying or using the default blending function. Currently this checks if the actor has a texture, if not it returns true. TODO: It is possible to make this decision dependent on key passed down from a painter upstream that makes a more informed decision for alpha blending depending on extensions available, for example.
- `vtkDataObject = obj.GetOutput ()` - Subclasses need to override this to return the output of the pipeline.

39.169 vtkScaledTextActor

39.169.1 Usage

vtkScaledTextActor is deprecated. New code should use vtkTextActor with the Scaled = true option.

To create an instance of class vtkScaledTextActor, simply invoke its constructor as follows

```
obj = vtkScaledTextActor
```

39.169.2 Methods

The class vtkScaledTextActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScaledTextActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScaledTextActor = obj.NewInstance ()`
- `vtkScaledTextActor = obj.SafeDownCast (vtkObject o)`

39.170 vtkScenePicker

39.170.1 Usage

The Scene picker, unline conventional pickers picks an entire viewport at one shot and caches the result, which can be retrieved later. The utility of the class arises during ¡b¿Actor Selection¡/b¿. Let's say you have a couple of polygonal objects in your scene and you wish to have a status bar that indicates the object your mouse is over. Picking repeatedly every time your mouse moves would be very slow. The scene picker automatically picks your viewport every time the camera is changed and caches the information. Additionally, it observes the vtkRenderWindowInteractor to avoid picking during interaction, so that you still maintain your interactivity. In effect, the picker does an additional pick-render of your scene every time you stop interacting with your scene. As an example, see Rendering/TestScenePicker.

To create an instance of class vtkScenePicker, simply invoke its constructor as follows

```
obj = vtkScenePicker
```

39.170.2 Methods

The class vtkScenePicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScenePicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScenePicker = obj.NewInstance ()`
- `vtkScenePicker = obj.SafeDownCast (vtkObject o)`
- `obj.SetRenderer (vtkRenderer )` - Set the renderer. Scene picks are restricted to the viewport.
- `vtkRenderer = obj.GetRenderer ()` - Set the renderer. Scene picks are restricted to the viewport.
- `vtkIdType = obj.GetCellId (int displayPos[2])` - Get cell id at the pick position. Returns -1 if no cell was picked. Makes sense only after Pick has been called.
- `vtkIdType = obj.GetVertexId (int displayPos[2])` - Get cell id at the pick position. Returns -1 if no cell was picked. Makes sense only after Pick has been called.
- `vtkProp = obj.GetViewProp (int displayPos[2])` - Get actor at the pick position. Returns NULL if none. Makes sense only after Pick has been called.
- `obj.SetEnableVertexPicking (int )` - Vertex picking (using the method GetVertexId()), required additional resources and can slow down still render time by 5-10
- `int = obj.GetEnableVertexPicking ()` - Vertex picking (using the method GetVertexId()), required additional resources and can slow down still render time by 5-10
- `obj.EnableVertexPickingOn ()` - Vertex picking (using the method GetVertexId()), required additional resources and can slow down still render time by 5-10
- `obj.EnableVertexPickingOff ()` - Vertex picking (using the method GetVertexId()), required additional resources and can slow down still render time by 5-10

39.171 vtkSelectVisiblePoints

39.171.1 Usage

vtkSelectVisiblePoints is a filter that selects points based on whether they are visible or not. Visibility is determined by accessing the z-buffer of a rendering window. (The position of each input point is converted into display coordinates, and then the z-value at that point is obtained. If within the user-specified tolerance, the point is considered visible.)

Points that are visible (or if the ivar SelectInvisible is on, invisible points) are passed to the output. Associated data attributes are passed to the output as well.

This filter also allows you to specify a rectangular window in display (pixel) coordinates in which the visible points must lie. This can be used as a sort of local "brushing" operation to select just data within a window.

To create an instance of class vtkSelectVisiblePoints, simply invoke its constructor as follows

```
obj = vtkSelectVisiblePoints
```

39.171.2 Methods

The class vtkSelectVisiblePoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSelectVisiblePoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSelectVisiblePoints = obj.NewInstance ()`
- `vtkSelectVisiblePoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetRenderer (vtkRenderer ren)` - Specify the renderer in which the visibility computation is to be performed.
- `vtkRenderer = obj.GetRenderer ()` - Set/Get the flag which enables selection in a rectangular display region.
- `obj.SetSelectionWindow (int )` - Set/Get the flag which enables selection in a rectangular display region.
- `int = obj.GetSelectionWindow ()` - Set/Get the flag which enables selection in a rectangular display region.
- `obj.SelectionWindowOn ()` - Set/Get the flag which enables selection in a rectangular display region.
- `obj.SelectionWindowOff ()` - Set/Get the flag which enables selection in a rectangular display region.
- `obj.SetSelection (int , int , int , int )` - Specify the selection window in display coordinates. You must specify a rectangular region using (xmin,xmax,ymin,ymax).
- `obj.SetSelection (int  a[4])` - Specify the selection window in display coordinates. You must specify a rectangular region using (xmin,xmax,ymin,ymax).
- `int = obj. GetSelection ()` - Specify the selection window in display coordinates. You must specify a rectangular region using (xmin,xmax,ymin,ymax).
- `obj.SetSelectInvisible (int )` - Set/Get the flag which enables inverse selection; i.e., invisible points are selected.

- `int = obj.GetSelectInvisible ()` - Set/Get the flag which enables inverse selection; i.e., invisible points are selected.
- `obj.SelectInvisibleOn ()` - Set/Get the flag which enables inverse selection; i.e., invisible points are selected.
- `obj.SelectInvisibleOff ()` - Set/Get the flag which enables inverse selection; i.e., invisible points are selected.
- `obj.SetTolerance (double )` - Set/Get a tolerance to use to determine whether a point is visible. A tolerance is usually required because the conversion from world space to display space during rendering introduces numerical round-off.
- `double = obj.GetToleranceMinValue ()` - Set/Get a tolerance to use to determine whether a point is visible. A tolerance is usually required because the conversion from world space to display space during rendering introduces numerical round-off.
- `double = obj.GetToleranceMaxValue ()` - Set/Get a tolerance to use to determine whether a point is visible. A tolerance is usually required because the conversion from world space to display space during rendering introduces numerical round-off.
- `double = obj.GetTolerance ()` - Set/Get a tolerance to use to determine whether a point is visible. A tolerance is usually required because the conversion from world space to display space during rendering introduces numerical round-off.
- `bool = obj.IsPointOccluded (double x[], float zPtr)` - Tests if a point x is being occluded or not against the Z-Buffer array passed in by zPtr. Call Initialize before calling this method.
- `long = obj.GetMTime ()` - Return MTime also considering the renderer.

39.172 vtkSequencePass

39.172.1 Usage

vtkSequencePass executes a list of render passes sequentially. This class allows to define a sequence of render passes at run time. The other solution to write a sequence of render passes is to write an effective subclass of vtkRenderPass.

As vtkSequencePass is a vtkRenderPass itself, it is possible to have a hierarchy of render passes built at runtime.

To create an instance of class vtkSequencePass, simply invoke its constructor as follows

```
obj = vtkSequencePass
```

39.172.2 Methods

The class vtkSequencePass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSequencePass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSequencePass = obj.NewInstance ()`
- `vtkSequencePass = obj.SafeDownCast (vtkObject o)`

- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.
- `vtkRenderPassCollection = obj.GetPasses ()` - The ordered list of render passes to execute sequentially. If the pointer is NULL or the list is empty, it is silently ignored. There is no warning. Initial value is a NULL pointer.
- `obj.SetPasses (vtkRenderPassCollection passes)` - The ordered list of render passes to execute sequentially. If the pointer is NULL or the list is empty, it is silently ignored. There is no warning. Initial value is a NULL pointer.

39.173 vtkShader

39.173.1 Usage

vtkShader is a base class for interfacing VTK to hardware shader libraries. vtkShader interprets a vtkXMLDataElement that describes a particular shader. Descendants of this class inherit this functionality and additionally interface to specific shader libraries like NVidia's Cg and OpenGL2.0 (GLSL) to perform operations, on individual shaders.

During each render, the vtkShaderProgram calls Compile(), PassShaderVariables(), Bind() and after the actor has been rendered, calls Unbind(), in that order.

To create an instance of class vtkShader, simply invoke its constructor as follows

```
obj = vtkShader
```

39.173.2 Methods

The class vtkShader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShader = obj.NewInstance ()`
- `vtkShader = obj.SafeDownCast (vtkObject o)`
- `int = obj.Compile ()` - Called to compile the shader code. The subclasses must only compile the code in this method. Returns if the compile was successful. Subclasses should compile the code only if it was not already compiled.
- `obj.PassShaderVariables (vtkActor actor, vtkRenderer ren)` - Called to pass VTK actor/property/light values and other Shader variables over to the shader. This is called by the ShaderProgram during each render.
- `obj.Bind ()` - Called to unbind the shader. As with Bind(), this is only applicable to Cg.
- `obj.Unbind ()` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Get/Set the XMLShader representation for this shader. A shader is not valid without a XMLShader.
- `obj.SetXMLShader (vtkXMLShader )` - Get/Set the XMLShader representation for this shader. A shader is not valid without a XMLShader.

- `vtkXMLShader = obj.GetXMLShader ()` - Get/Set the XMLShader representation for this shader. A shader is not valid without a XMLShader.
- `int = obj.HasShaderVariable (string name)` - Indicates if a variable by the given name exists.
- `obj.AddShaderVariable (string name, int num\_of\_elements, int values)` - Methods to add shader variables to this shader. The shader variable type must match with that declared in the Material xml, otherwise, the variable is not made available to the shader.
- `obj.AddShaderVariable (string name, int num\_of\_elements, float values)` - Methods to add shader variables to this shader. The shader variable type must match with that declared in the Material xml, otherwise, the variable is not made available to the shader.
- `obj.AddShaderVariable (string name, int num\_of\_elements, double values)` - Methods to add shader variables to this shader. The shader variable type must match with that declared in the Material xml, otherwise, the variable is not made available to the shader.
- `int = obj.GetShaderVariableSize (string name)` - Get number of elements in a Shader variable. Return 0 if failed to find the shader variable.
- `int = obj.GetShaderVariableType (string name)` - Returns the type of a Shader variable with the given name. Return 0 on error.
- `int = obj.GetShaderVariable (string name, int values)` - Methods to get the value of shader variables with the given name. Values must be at least the size of the shader variable (obtained by GetShaderVariableSize(). Returns if the operation was successful.
- `int = obj.GetShaderVariable (string name, float values)` - Methods to get the value of shader variables with the given name. Values must be at least the size of the shader variable (obtained by GetShaderVariableSize(). Returns if the operation was successful.
- `int = obj.GetShaderVariable (string name, double values)` - Methods to get the value of shader variables with the given name. Values must be at least the size of the shader variable (obtained by GetShaderVariableSize(). Returns if the operation was successful.
- `int = obj.GetScope ()` - Returns the scope of the shader i.e. if it's a vertex or fragment shader. (vtkXMLShader::SCOPE_VERTEX or vtkXMLShader::SCOPE_FRAGMENT).

39.174 vtkShaderProgram

39.174.1 Usage

vtkShaderProgram is a superclass for managing Hardware Shaders defined in the XML Material file and interfacing VTK to those shaders. It's concrete descendants are responsible for installing vertex and fragment programs to the graphics hardware.

.SECTION Shader Operations are shader library operations that are performed on individual shaders, that is, without consideration of the partner shader.

.SECTION Program Operations are shader library operations that treat the vertex and fragment shader as a single unit.

.SECTION Design This class is a Strategy pattern for 'Program' operations, which treat vertex/fragment shader pairs as a single 'Program', as required by some shader libraries (GLSL). Typically, 'Shader' operations are delegated to instances of vtkShader (managed by descendants of this class) while 'Program' operations are handled by descendants of this class, vtkCgShaderProgram, vtkGLSLShaderProgram.

To create an instance of class vtkShaderProgram, simply invoke its constructor as follows

```
obj = vtkShaderProgram
```

39.174.2 Methods

The class vtkShaderProgram has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShaderProgram class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShaderProgram = obj.NewInstance ()`
- `vtkShaderProgram = obj.SafeDownCast (vtkObject o)`
- `vtkXMLMaterial = obj.GetMaterial ()`
- `obj.SetMaterial (vtkXMLMaterial )`
- `int = obj.AddShader (vtkShader shader)`
- `obj.RemoveShader (int index)` - Remove a shader at the given index.
- `obj.RemoveShader (vtkShader shader)` - Removes the given shader.
- `vtkCollectionIterator = obj.NewShaderIterator ()` - Returns a new iterator to iterate over the shaders.
- `int = obj.GetNumberOfShaders ()` - Returns the number of shaders available in this shader program.
- `obj.ReadMaterial ()`
- `obj.Render (vtkActor , vtkRenderer )`
- `obj.AddShaderVariable (string name, int numVars, int x)`
- `obj.AddShaderVariable (string name, int numVars, float x)`
- `obj.AddShaderVariable (string name, int numVars, double x)`
- `obj.PostRender (vtkActor , vtkRenderer )` - Called to unload the shaders after the actor has been rendered.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `vtkShaderDeviceAdapter = obj.GetShaderDeviceAdapter ()` - Get the vtkShaderDeviceAdapter which can be used to execute this shader program.

39.175 vtkShadowMapPass

39.175.1 Usage

Render the opaque polygonal geometry of a scene with shadow maps (a technique to render hard shadows in hardware).

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color. An opaque pass may have been performed right after the initialization.

Its delegate is usually set to a vtkOpaquePass.

.SECTION Implementation The first pass of the algorithm is to generate a shadow map per light (depth map from the light point of view) by rendering the opaque objects with the OCCLUDER property keys. The second pass is to render the opaque objects with the RECEIVER keys.

To create an instance of class vtkShadowMapPass, simply invoke its constructor as follows

```
obj = vtkShadowMapPass
```

39.175.2 Methods

The class vtkShadowMapPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShadowMapPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShadowMapPass = obj.NewInstance ()`
- `vtkShadowMapPass = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.
- `vtkRenderPass = obj.GetOpaquePass ()` - Delegate for rendering the opaque polygonal geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkTranslucentPass. Initial value is a NULL pointer.
- `obj.SetOpaquePass (vtkRenderPass opaquePass)` - Delegate for rendering the opaque polygonal geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkTranslucentPass. Initial value is a NULL pointer.
- `vtkRenderPass = obj.GetCompositeZPass ()` - Delegate for rendering the opaque polygonal geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkTranslucentPass. Initial value is a NULL pointer.
- `obj.SetCompositeZPass (vtkRenderPass opaquePass)` - Delegate for rendering the opaque polygonal geometry. If it is NULL, nothing will be rendered and a warning will be emitted. It is usually set to a vtkTranslucentPass. Initial value is a NULL pointer.
- `obj.SetResolution (int )` - Set/Get the number of pixels in each dimension of the shadow maps (shadow maps are square). Initial value is 256. The greater the better. Resolution does not have to be a power-of-two value.
- `int = obj.GetResolution ()` - Set/Get the number of pixels in each dimension of the shadow maps (shadow maps are square). Initial value is 256. The greater the better. Resolution does not have to be a power-of-two value.
- `obj.SetPolygonOffsetFactor (float )` - Factor used to scale the maximum depth slope of a polygon (definition from OpenGL 2.1 spec section 3.5.5 "Depth Offset" page 112). This is used during the creation the shadow maps (not during mapping of the shadow maps onto the geometry) Play with this value and PolygonOffsetUnits to solve self-shadowing. Valid values can be either positive or negative. Initial value is 1.1f (recommended by the nVidia presentation about Shadow Mapping by Cass Everitt). 3.1f works well with the regression test.

- `float = obj.GetPolygonOffsetFactor ()` - Factor used to scale the maximum depth slope of a polygon (definition from OpenGL 2.1 spec section 3.5.5 "Depth Offset" page 112). This is used during the creation the shadow maps (not during mapping of the shadow maps onto the geometry) Play with this value and PolygonOffsetUnits to solve self-shadowing. Valid values can be either positive or negative. Initial value is 1.1f (recommended by the nVidia presentation about Shadow Mapping by Cass Everitt). 3.1f works well with the regression test.

- `obj.SetPolygonOffsetUnits (float )` - Factor used to scale an implementation dependent constant that relates to the usable resolution of the depth buffer (definition from OpenGL 2.1 spec section 3.5.5 "Depth Offset" page 112). This is used during the creation the shadow maps (not during mapping of the shadow maps onto the geometry) Play with this value and PolygonOffsetFactor to solve self-shadowing. Valid values can be either positive or negative. Initial value is 4.0f (recommended by the nVidia presentation about Shadow Mapping by Cass Everitt). 10.0f works well with the regression test.

- `float = obj.GetPolygonOffsetUnits ()` - Factor used to scale an implementation dependent constant that relates to the usable resolution of the depth buffer (definition from OpenGL 2.1 spec section 3.5.5 "Depth Offset" page 112). This is used during the creation the shadow maps (not during mapping of the shadow maps onto the geometry) Play with this value and PolygonOffsetFactor to solve self-shadowing. Valid values can be either positive or negative. Initial value is 4.0f (recommended by the nVidia presentation about Shadow Mapping by Cass Everitt). 10.0f works well with the regression test.

39.176 vtkSobelGradientMagnitudePass

39.176.1 Usage

Detect the edges of the image renderered by its delegate. Edge-detection uses a Sobel high-pass filter (3x3 kernel).

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color. An opaque pass may have been performed right after the initialization.

The delegate is used once.

Its delegate is usually set to a vtkCameraPass or to a post-processing pass.

This pass requires a OpenGL context that supports texture objects (TO), framebuffer objects (FBO) and GLSL. If not, it will emit an error message and will render its delegate and return.

.SECTION Implementation To compute the gradient magnitude, the x and y components of the gradient (Gx and Gy) have to be computed first. Each computation of Gx and Gy uses a separable filter. The first pass takes the image from the delegate as the single input texture. The first pass has two outputs, one for the first part of Gx, Gx1, result of a convolution with (-1 0 1), one for the first part of Gy, Gy1, result of a convolution with (1 2 1). The second pass has two inputs, Gx1 and Gy1. Kernel (1 2 1)$\hat{\text{T}}$ is applied to Gx1 and kernel (-1 0 1)$\hat{\text{T}}$ is applied to Gx2. It gives the values for Gx and Gy. Thoses values are then used to compute the magnitude of the gradient which is stored in the render target. The gradient computation happens per component (R,G,B). A is arbitrarly set to 1 (full opacity).

To create an instance of class vtkSobelGradientMagnitudePass, simply invoke its constructor as follows

```
obj = vtkSobelGradientMagnitudePass
```

39.176.2 Methods

The class vtkSobelGradientMagnitudePass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSobelGradientMagnitudePass class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkSobelGradientMagnitudePass = obj.NewInstance ()`
- `vtkSobelGradientMagnitudePass = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Release graphics resources and ask components to release their own resources.

39.177 vtkStandardPolyDataPainter

39.177.1 Usage

vtkStandardPolyDataPainter is a catch-all painter. It should work with pretty much any vtkPolyData, and attributes, and vtkPolyDataPainterDeviceAdapter. On the flip side, the vtkStandardPolyDataPainter will be slower than the more special purpose painters.

To create an instance of class vtkStandardPolyDataPainter, simply invoke its constructor as follows

```
obj = vtkStandardPolyDataPainter
```

39.177.2 Methods

The class vtkStandardPolyDataPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStandardPolyDataPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStandardPolyDataPainter = obj.NewInstance ()`
- `vtkStandardPolyDataPainter = obj.SafeDownCast (vtkObject o)`
- `obj.AddMultiTextureCoordsArray (vtkDataArray array)`

39.178 vtkSurfaceLICDefaultPainter

39.178.1 Usage

vtkSurfaceLICDefaultPainter is a vtkDefaultPainter replacement that inserts the vtkSurfaceLICPainter at the correct position in the painter chain.

To create an instance of class vtkSurfaceLICDefaultPainter, simply invoke its constructor as follows

```
obj = vtkSurfaceLICDefaultPainter
```

39.178.2 Methods

The class vtkSurfaceLICDefaultPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSurfaceLICDefaultPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkSurfaceLICDefaultPainter = obj.NewInstance ()`
- `vtkSurfaceLICDefaultPainter = obj.SafeDownCast (vtkObject o)`
- `obj.SetSurfaceLICPainter (vtkSurfaceLICPainter )` - Get/Set the Surface LIC painter.
- `vtkSurfaceLICPainter = obj.GetSurfaceLICPainter ()` - Get/Set the Surface LIC painter.

39.179 vtkSurfaceLICPainter

39.179.1 Usage

vtkSurfaceLICPainter painter performs LIC on the surface of arbitrary geometry. Point vectors are used as the vector field for generating the LIC. The implementation is based on "Image Space Based Visualization on Unstread Flow on Surfaces" by Laramee, Jobard and Hauser appered in proceedings of IEEE Visualization '03, pages 131-138.

To create an instance of class vtkSurfaceLICPainter, simply invoke its constructor as follows

```
obj = vtkSurfaceLICPainter
```

39.179.2 Methods

The class vtkSurfaceLICPainter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSurfaceLICPainter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSurfaceLICPainter = obj.NewInstance ()`
- `vtkSurfaceLICPainter = obj.SafeDownCast (vtkObject o)`
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release. In this case, releases the display lists.
- `vtkDataObject = obj.GetOutput ()` - Get the output data object from this painter. Overridden to pass the input points (or cells) vectors as the tcoords to the deletage painters. This is required by the internal GLSL shader programs used for generating LIC.
- `obj.SetEnable (int )` - Enable/Disable this painter.
- `int = obj.GetEnable ()` - Enable/Disable this painter.
- `obj.EnableOn ()` - Enable/Disable this painter.
- `obj.EnableOff ()` - Enable/Disable this painter.
- `obj.SetInputArrayToProcess (int fieldAssociation, string name)` - Set the vectors to used for applying LIC. By default point vectors are used. Arguments are same as those passed to vtkAlgorithm::SetInputArrayToProcess except the first 3 arguments i.e. idx, port, connection.
- `obj.SetInputArrayToProcess (int fieldAssociation, int fieldAttributeType)` - Set the vectors to used for applying LIC. By default point vectors are used. Arguments are same as those passed to vtkAlgorithm::SetInputArrayToProcess except the first 3 arguments i.e. idx, port, connection.

- `obj.SetEnhancedLIC (int )` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `int = obj.GetEnhancedLIC ()` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `obj.EnhancedLICOn ()` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `obj.EnhancedLICOff ()` - Enable/Disable enhanced LIC that improves image quality by increasing inter-streamline contrast while suppressing artifacts. Enhanced LIC performs two passes of LIC, with a 3x3 Laplacian high-pass filter in between that processes the output of pass #1 LIC and forwards the result as the input 'noise' to pass #2 LIC. This flag is automatically turned off during user interaction.
- `obj.SetNumberOfSteps (int )` - Get/Set the number of integration steps in each direction.
- `int = obj.GetNumberOfSteps ()` - Get/Set the number of integration steps in each direction.
- `obj.SetStepSize (double )` - Get/Set the step size (in pixels).
- `double = obj.GetStepSize ()` - Get/Set the step size (in pixels).
- `obj.SetLICIntensity (double )` - Control the contribution of the LIC in the final output image. 0.0 produces same result as disabling LIC alltogether, while 1.0 implies show LIC result alone.
- `double = obj.GetLICIntensityMinValue ()` - Control the contribution of the LIC in the final output image. 0.0 produces same result as disabling LIC alltogether, while 1.0 implies show LIC result alone.
- `double = obj.GetLICIntensityMaxValue ()` - Control the contribution of the LIC in the final output image. 0.0 produces same result as disabling LIC alltogether, while 1.0 implies show LIC result alone.
- `double = obj.GetLICIntensity ()` - Control the contribution of the LIC in the final output image. 0.0 produces same result as disabling LIC alltogether, while 1.0 implies show LIC result alone.
- `int = obj.GetRenderingPreparationSuccess ()` - Check if the LIC process runs properly.
- `int = obj.GetLICSuccess ()` - Returns true is the rendering context supports extensions needed by this painter.

39.180 vtkTDxInteractorStyle

39.180.1 Usage

vtkTDxInteractorStyle is an abstract class defining an event-driven interface to support 3DConnexion device events send by vtkRenderWindowInteractor. vtkRenderWindowInteractor forwards events in a platform independent form to vtkInteractorStyle which can then delegate some processing to vtkTDxInteractorStyle.

To create an instance of class vtkTDxInteractorStyle, simply invoke its constructor as follows

```
obj = vtkTDxInteractorStyle
```

39.180.2 Methods

The class vtkTDxInteractorStyle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTDxInteractorStyle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTDxInteractorStyle = obj.NewInstance ()`
- `vtkTDxInteractorStyle = obj.SafeDownCast (vtkObject o)`
- `vtkTDxInteractorStyleSettings = obj.GetSettings ()` - 3Dconnexion device settings. (sensitivity, individual axis filters). Initial object is not null.
- `obj.SetSettings (vtkTDxInteractorStyleSettings settings)` - 3Dconnexion device settings. (sensitivity, individual axis filters). Initial object is not null.

39.181 vtkTDxInteractorStyleCamera

39.181.1 Usage

vtkTDxInteractorStyleCamera allows the end-user to manipulate tha camera with a 3DConnexion device.
To create an instance of class vtkTDxInteractorStyleCamera, simply invoke its constructor as follows

```
obj = vtkTDxInteractorStyleCamera
```

39.181.2 Methods

The class vtkTDxInteractorStyleCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTDxInteractorStyleCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTDxInteractorStyleCamera = obj.NewInstance ()`
- `vtkTDxInteractorStyleCamera = obj.SafeDownCast (vtkObject o)`

39.182 vtkTDxInteractorStyleSettings

39.182.1 Usage

vtkTDxInteractorStyleSettings defines settings for 3DConnexion device such as sensitivity, axis filters
To create an instance of class vtkTDxInteractorStyleSettings, simply invoke its constructor as follows

```
obj = vtkTDxInteractorStyleSettings
```

39.182.2 Methods

The class vtkTDxInteractorStyleSettings has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTDxInteractorStyleSettings class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTDxInteractorStyleSettings = obj.NewInstance ()`
- `vtkTDxInteractorStyleSettings = obj.SafeDownCast (vtkObject o)`
- `obj.SetAngleSensitivity (double )` - Sensitivity of the rotation angle. This can be any value: positive, negative, null. - x¡-1.0: faster reversed - x=-1.0: reversed neutral - -1.0¡x¡0.0: reversed slower - x=0.0: no rotation - 0.0¡x¡1.0: slower - x=1.0: neutral - x¿1.0: faster
- `double = obj.GetAngleSensitivity ()` - Sensitivity of the rotation angle. This can be any value: positive, negative, null. - x¡-1.0: faster reversed - x=-1.0: reversed neutral - -1.0¡x¡0.0: reversed slower - x=0.0: no rotation - 0.0¡x¡1.0: slower - x=1.0: neutral - x¿1.0: faster
- `obj.SetUseRotationX (bool )` - Use or mask the rotation component around the X-axis. Initial value is true.
- `bool = obj.GetUseRotationX ()` - Use or mask the rotation component around the X-axis. Initial value is true.
- `obj.SetUseRotationY (bool )` - Use or mask the rotation component around the Y-axis. Initial value is true.
- `bool = obj.GetUseRotationY ()` - Use or mask the rotation component around the Y-axis. Initial value is true.
- `obj.SetUseRotationZ (bool )` - Use or mask the rotation component around the Z-axis. Initial value is true.
- `bool = obj.GetUseRotationZ ()` - Use or mask the rotation component around the Z-axis. Initial value is true.
- `obj.SetTranslationXSensitivity (double )` - Sensitivity of the translation along the X-axis. This can be any value: positive, negative, null. - x¡-1.0: faster reversed - x=-1.0: reversed neutral - -1.0¡x¡0.0: reversed slower - x=0.0: no translation - 0.0¡x¡1.0: slower - x=1.0: neutral - x¿1.0: faster Initial value is 1.0
- `double = obj.GetTranslationXSensitivity ()` - Sensitivity of the translation along the X-axis. This can be any value: positive, negative, null. - x¡-1.0: faster reversed - x=-1.0: reversed neutral - -1.0¡x¡0.0: reversed slower - x=0.0: no translation - 0.0¡x¡1.0: slower - x=1.0: neutral - x¿1.0: faster Initial value is 1.0
- `obj.SetTranslationYSensitivity (double )` - Sensitivity of the translation along the Y-axis. See comment of SetTranslationXSensitivity().
- `double = obj.GetTranslationYSensitivity ()` - Sensitivity of the translation along the Y-axis. See comment of SetTranslationXSensitivity().
- `obj.SetTranslationZSensitivity (double )` - Sensitivity of the translation along the Z-axis. See comment of SetTranslationXSensitivity().
- `double = obj.GetTranslationZSensitivity ()` - Sensitivity of the translation along the Z-axis. See comment of SetTranslationXSensitivity().

39.183 vtkTesting

39.183.1 Usage

This is a VTK regression testing framework. Looks like this:
vtkTesting* t = vtkTesting::New();
Two options for setting arguments
Option 1: for (cc = 1; cc ¡ argc; cc ++) t-¿AddArgument(argv[cc]);
Option 2: t-¿AddArgument("-D"); t-¿AddArgument(my_data_dir); t-¿AddArgument("-V"); t-¿AddArgument(my_valid_in
...
Two options of doing testing:
Option 1: t-¿SetRenderWindow(renWin); int res = t-¿RegressionTest(threshold);
Option 2: int res = t-¿RegressionTest(test_image, threshold);
...
if (res == vtkTesting::PASSED) Test passed else Test failed
To create an instance of class vtkTesting, simply invoke its constructor as follows

```
obj = vtkTesting
```

39.183.2 Methods

The class vtkTesting has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTesting class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTesting = obj.NewInstance ()`
- `vtkTesting = obj.SafeDownCast (vtkObject o)`
- `obj.SetFrontBuffer (int )` - Use front buffer for tests. By default use back buffer.
- `int = obj.GetFrontBufferMinValue ()` - Use front buffer for tests. By default use back buffer.
- `int = obj.GetFrontBufferMaxValue ()` - Use front buffer for tests. By default use back buffer.
- `obj.FrontBufferOn ()` - Use front buffer for tests. By default use back buffer.
- `obj.FrontBufferOff ()` - Use front buffer for tests. By default use back buffer.
- `int = obj.GetFrontBuffer ()` - Use front buffer for tests. By default use back buffer.
- `int = obj.RegressionTest (double thresh)` - Perform the test and return result. At the same time the output will be written cout
- `int = obj.RegressionTest (vtkImageData image, double thresh)` - Compare the image with the valid image.
- `int = obj.CompareAverageOfL2Norm (vtkDataSet pdA, vtkDataSet pdB, double tol)` - Compute the average L2 norm between all point data data arrays of types float and double present in the data sets "dsA" and "dsB" (this includes instances of vtkPoints) Compare the result of each L2 comutation to "tol".
- `int = obj.CompareAverageOfL2Norm (vtkDataArray daA, vtkDataArray daB, double tol)` - Compute the average L2 norm between two data arrays "daA" and "daB" and compare against "tol".
- `obj.SetRenderWindow (vtkRenderWindow rw)` - Set and get the render window that will be used for regression testing.

- `vtkRenderWindow = obj.GetRenderWindow ()` - Set and get the render window that will be used for regression testing.
- `obj.SetValidImageFileName (string )` - Set/Get the name of the valid image file
- `string = obj.GetValidImageFileName ()` - Set/Get the name of the valid image file
- `double = obj.GetImageDifference ()` - Get the image difference.
- `obj.AddArgument (string argv)` - Pass the command line arguments into this class to be processed. Many of the Get methods such as GetValidImage and GetBaselineRoot rely on the arguments to be passed in prior to retrieving these values. Just call AddArgument for each argument that was passed into the command line
- `obj.CleanArguments ()`
- `string = obj.GetDataRoot ()` - Get some paramters from the command line arguments, env, or defaults
- `obj.SetDataRoot (string )` - Get some paramters from the command line arguments, env, or defaults
- `string = obj.GetTempDirectory ()` - Get some paramters from the command line arguments, env, or defaults
- `obj.SetTempDirectory (string )` - Get some paramters from the command line arguments, env, or defaults
- `int = obj.IsValidImageSpecified ()` - Is a valid image specified on the command line areguments?
- `int = obj.IsInteractiveModeSpecified ()` - Is the interactive mode specified?
- `int = obj.IsFlagSpecified (string flag)` - Is some arbitrary user flag ("-X", "-Z" etc) specified
- `obj.SetBorderOffset (int )` - Number of pixels added as borders to avoid problems with window decorations added by some window managers.
- `int = obj.GetBorderOffset ()` - Number of pixels added as borders to avoid problems with window decorations added by some window managers.
- `obj.SetVerbose (int )` - Get/Set verbosity level. A level of 0 is quiet.
- `int = obj.GetVerbose ()` - Get/Set verbosity level. A level of 0 is quiet.

39.184 vtkTextActor

39.184.1 Usage

vtkTextActor can be used to place text annotation into a window. When TextScaleMode is NONE, the text is fixed font and operation is the same as a vtkPolyDataMapper2D/vtkActor2D pair. When TextScaleMode is VIEWPORT, the font resizes such that it maintains a consistent size relative to the viewport in which it is rendered. When TextScaleMode is PROP, the font resizes such that the text fits inside the box defined by the position 1 & 2 coordinates. This class replaces the deprecated vtkScaledTextActor and acts as a convenient wrapper for a vtkTextMapper/vtkActor2D pair. Set the text property/attributes through the vtkTextProperty associated to this actor.

To create an instance of class vtkTextActor, simply invoke its constructor as follows

```
obj = vtkTextActor
```

39.184.2 Methods

The class vtkTextActor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextActor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextActor = obj.NewInstance ()`
- `vtkTextActor = obj.SafeDownCast (vtkObject o)`
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this text actor. Overloads the virtual vtkProp method.
- `obj.SetMapper (vtkPolyDataMapper2D mapper)` - Override the vtkPolyDataMapper2D that defines the text to be drawn. One will be created by default if none is supplied
- `obj.SetInput (string inputString)` - Set the text string to be displayed. "
n" is recognized as a carriage return/linefeed (line separator). Only 7-bit ASCII is allowed (anything else, such as Latin1 or UTF8, is not acceptable). Convenience method to the underlying mapper
- `string = obj.GetInput ()` - Set the text string to be displayed. "
n" is recognized as a carriage return/linefeed (line separator). Only 7-bit ASCII is allowed (anything else, such as Latin1 or UTF8, is not acceptable). Convenience method to the underlying mapper
- `obj.SetMinimumSize (int , int )` - Set/Get the minimum size in pixels for this actor. Defaults to 10,10. Only valid when TextScaleMode is PROP.
- `obj.SetMinimumSize (int  a[2])` - Set/Get the minimum size in pixels for this actor. Defaults to 10,10. Only valid when TextScaleMode is PROP.
- `int = obj. GetMinimumSize ()` - Set/Get the minimum size in pixels for this actor. Defaults to 10,10. Only valid when TextScaleMode is PROP.
- `obj.SetMaximumLineHeight (float )` - Set/Get the maximum height of a line of text as a percentage of the vertical area allocated to this scaled text actor. Defaults to 1.0. Only valid when TextScaleMode is PROP.
- `float = obj.GetMaximumLineHeight ()` - Set/Get the maximum height of a line of text as a percentage of the vertical area allocated to this scaled text actor. Defaults to 1.0. Only valid when TextScaleMode is PROP.
- `obj.SetTextScaleMode (int )` - Set how text should be scaled. If set to vtkTextActor::TEXT_SCALE_MODE_NONE, the the font size will be fixed by the size given in TextProperty. If set to vtkTextActor::TEXT_SCALE_MODE_PROP, the text will be scaled to fit exactly in the prop as specified by the position 1 & 2 coordinates. If set to vtkTextActor::TEXT_SCALE_MODE_VIEWPORT, the text will be scaled based on the size of the viewport it is displayed in.
- `int = obj.GetTextScaleModeMinValue ()` - Set how text should be scaled. If set to vtkTextActor::TEXT_SCALE_MODE_NONE, the the font size will be fixed by the size given in TextProperty. If set to vtkTextActor::TEXT_SCALE_MODE_PROP, the text will be scaled to fit exactly in the prop as specified by the position 1 & 2 coordinates. If set to vtkTextActor::TEXT_SCALE_MODE_VIEWPORT, the text will be scaled based on the size of the viewport it is displayed in.

- `int = obj.GetTextScaleModeMaxValue ()` - Set how text should be scaled. If set to vtkTextActor::TEXT_SCALE_MODE_NONE, the the font size will be fixed by the size given in TextProperty. If set to vtkTextActor::TEXT_SCALE_MODE_PROP, the text will be scaled to fit exactly in the prop as specified by the position 1 & 2 coordinates. If set to vtkTextActor::TEXT_SCALE_MODE_VIEWPORT, the text will be scaled based on the size of the viewport it is displayed in.
- `int = obj.GetTextScaleMode ()` - Set how text should be scaled. If set to vtkTextActor::TEXT_SCALE_MODE_NON the the font size will be fixed by the size given in TextProperty. If set to vtkTextActor::TEXT_SCALE_MODE_PROP, the text will be scaled to fit exactly in the prop as specified by the position 1 & 2 coordinates. If set to vtkTextActor::TEXT_SCALE_MODE_VIEWPORT, the text will be scaled based on the size of the viewport it is displayed in.
- `obj.SetTextScaleModeToNone ()` - Set how text should be scaled. If set to vtkTextActor::TEXT_SCALE_MODE_NON the the font size will be fixed by the size given in TextProperty. If set to vtkTextActor::TEXT_SCALE_MODE_PROP, the text will be scaled to fit exactly in the prop as specified by the position 1 & 2 coordinates. If set to vtkTextActor::TEXT_SCALE_MODE_VIEWPORT, the text will be scaled based on the size of the viewport it is displayed in.
- `obj.SetTextScaleModeToProp ()` - Set how text should be scaled. If set to vtkTextActor::TEXT_SCALE_MODE_NON the the font size will be fixed by the size given in TextProperty. If set to vtkTextActor::TEXT_SCALE_MODE_PROP, the text will be scaled to fit exactly in the prop as specified by the position 1 & 2 coordinates. If set to vtkTextActor::TEXT_SCALE_MODE_VIEWPORT, the text will be scaled based on the size of the viewport it is displayed in.
- `obj.SetTextScaleModeToViewport ()` - DO NOT CALL. Deprecated in VTK 5.4. Use SetTextScaleMode or GetTextScaleMode instead.
- `obj.SetScaledText (int )` - DO NOT CALL. Deprecated in VTK 5.4. Use SetTextScaleMode or GetTextScaleMode instead.
- `int = obj.GetScaledText ()` - DO NOT CALL. Deprecated in VTK 5.4. Use SetTextScaleMode or GetTextScaleMode instead.
- `obj.ScaledTextOn ()` - DO NOT CALL. Deprecated in VTK 5.4. Use SetTextScaleMode or GetTextScaleMode instead.
- `obj.ScaledTextOff ()` - DO NOT CALL. Deprecated in VTK 5.4. Use SetTextScaleMode or GetTextScaleMode instead.
- `obj.SetUseBorderAlign (int )` - Turn on or off the UseBorderAlign option. When UseBorderAlign is on, the bounding rectangle is used to align the text, which is the proper behavior when using vtkTextRepresentation
- `int = obj.GetUseBorderAlign ()` - Turn on or off the UseBorderAlign option. When UseBorderAlign is on, the bounding rectangle is used to align the text, which is the proper behavior when using vtkTextRepresentation
- `obj.UseBorderAlignOn ()` - Turn on or off the UseBorderAlign option. When UseBorderAlign is on, the bounding rectangle is used to align the text, which is the proper behavior when using vtkTextRepresentation
- `obj.UseBorderAlignOff ()` - Turn on or off the UseBorderAlign option. When UseBorderAlign is on, the bounding rectangle is used to align the text, which is the proper behavior when using vtkTextRepresentation
- `obj.SetAlignmentPoint (int point)` - This method is being depricated. Use SetJustification and SetVerticalJustification in text property instead. Set/Get the Alignment point if zero (default), the text aligns itself to the bottom left corner (which is defined by the PositionCoordinate) otherwise the text aligns itself to corner/midpoint or centre @verbatim 6 7 8 3 4 5 0 1 2 @endverbatim This is

the same as setting the TextProperty's justification. Currently TextActor is not oriented around its AlignmentPoint.

- `int = obj.GetAlignmentPoint ()` - This method is being depricated. Use SetJustification and SetVerticalJustification in text property instead. Set/Get the Alignment point if zero (default), the text aligns itself to the bottom left corner (which is defined by the PositionCoordinate) otherwise the text aligns itself to corner/midpoint or centre @verbatim 6 7 8 3 4 5 0 1 2 @endverbatim This is the same as setting the TextProperty's justification. Currently TextActor is not oriented around its AlignmentPoint.

- `obj.SetOrientation (float orientation)` - Counterclockwise rotation around the Alignment point. Units are in degrees and defaults to 0. The orientation in the text property rotates the text in the texture map. It will proba ly not give you the effect you desire.

- `float = obj.GetOrientation ()` - Counterclockwise rotation around the Alignment point. Units are in degrees and defaults to 0. The orientation in the text property rotates the text in the texture map. It will proba ly not give you the effect you desire.

- `obj.SetTextProperty (vtkTextProperty p)` - Set/Get the text property.

- `vtkTextProperty = obj.GetTextProperty ()` - Set/Get the text property.

- `obj.SetNonLinearFontScale (double exponent, int target)` - Enable non-linear scaling of font sizes. This is useful in combination with scaled text. With small windows you want to use the entire scaled text area. With larger windows you want to reduce the font size some so that the entire area is not used. These values modify the computed font size as follows: newFontSize = pow(FontSize,exponent)*pow(target,1.0 - exponent) typically exponent should be around 0.7 and target should be around 10

- `obj.SpecifiedToDisplay (double pos, vtkViewport vport, int specified)` - This is just a simple coordinate conversion method used in the render process.

- `obj.DisplayToSpecified (double pos, vtkViewport vport, int specified)` - This is just a simple coordinate conversion method used in the render process.

- `obj.ComputeScaledFont (vtkViewport viewport)` - Compute the scale the font should be given the viewport. The result is placed in the ScaledTextProperty ivar.

- `vtkTextProperty = obj.GetScaledTextProperty ()` - Get the scaled font. Use ComputeScaledFont to set the scale for a given viewport.

39.185 vtkTextActor3D

39.185.1 Usage

The input text is rendered into a buffer, which in turn is used as a texture applied onto a quad (a vtkImageActor is used under the hood). .SECTION Warning This class is experimental at the moment. - The orientation is not optimized, the quad should be oriented, not the text itself when it is rendered in the buffer (we end up with excessively big textures for 45 degrees angles). This will be fixed first. - No checking is done at the moment regarding hardware texture size limits. - Alignment is not supported (soon). - Multiline is not supported. - Need to fix angle out of 0¡-¿360

To create an instance of class vtkTextActor3D, simply invoke its constructor as follows

```
obj = vtkTextActor3D
```

39.185.2 Methods

The class vtkTextActor3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextActor3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextActor3D = obj.NewInstance ()`
- `vtkTextActor3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (string )` - Set the text string to be displayed.
- `string = obj.GetInput ()` - Set the text string to be displayed.
- `obj.SetTextProperty (vtkTextProperty p)` - Set/Get the text property.
- `vtkTextProperty = obj.GetTextProperty ()` - Set/Get the text property.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this text actor. Overloads the virtual vtkProp method.
- `double = obj.GetBounds ()` - Get the bounds for this Prop3D as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). These are the padded-to-power-of-two texture bounds.
- `int = obj.GetBoundingBox (int bbox[4])` - Get the Freetype-derived real bounding box for the given vtkTextProperty and text string str. Results are returned in the four element bbox int array. This call can be used for sizing other elements.

39.186 vtkTextMapper

39.186.1 Usage

vtkTextMapper provides 2D text annotation support for VTK. It is a vtkMapper2D that can be associated with a vtkActor2D and placed into a vtkRenderer.

To use vtkTextMapper, specify an input text string.

To create an instance of class vtkTextMapper, simply invoke its constructor as follows

```
obj = vtkTextMapper
```

39.186.2 Methods

The class vtkTextMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextMapper = obj.NewInstance ()`
- `vtkTextMapper = obj.SafeDownCast (vtkObject o)`
- `obj.GetSize (vtkViewport , int size[2])` - Return the size[2]/width/height of the rectangle required to draw this mapper (in pixels).

- `int = obj.GetWidth (vtkViewport v)` - Return the size[2]/width/height of the rectangle required to draw this mapper (in pixels).
- `int = obj.GetHeight (vtkViewport v)` - Return the size[2]/width/height of the rectangle required to draw this mapper (in pixels).
- `obj.SetInput (string inputString)` - Set the input text string to the mapper. The mapper recognizes ”
n” as a carriage return/linefeed (line separator).
- `string = obj.GetInput ()` - Set the input text string to the mapper. The mapper recognizes ”
n” as a carriage return/linefeed (line separator).
- `obj.SetTextProperty (vtkTextProperty p)` - Set/Get the text property.
- `vtkTextProperty = obj.GetTextProperty ()` - Set/Get the text property.
- `obj.ShallowCopy (vtkTextMapper tm)` - Shallow copy of an actor.
- `int = obj.GetNumberOfLines (string input)` - Determine the number of lines in the input string (delimited by ”
n”).
- `int = obj.GetNumberOfLines ()` - Get the number of lines in the input string (the method GetNumberOfLines(char*) must have been previously called for the return value to be valid).
- `int = obj.SetConstrainedFontSize (vtkViewport , int targetWidth, int targetHeight)` - Set and return the font size required to make this mapper fit in a given target rectangle (width x height, in pixels). A static version of the method is also available for convenience to other classes (e.g., widgets).
- `int = obj.GetSystemFontSize (int size)`

39.187 vtkTextProperty

39.187.1 Usage

vtkTextProperty is an object that represents text properties. The primary properties that can be set are color, opacity, font size, font family horizontal and vertical justification, bold/italic/shadow styles.

To create an instance of class vtkTextProperty, simply invoke its constructor as follows

```
obj = vtkTextProperty
```

39.187.2 Methods

The class vtkTextProperty has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextProperty class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextProperty = obj.NewInstance ()`
- `vtkTextProperty = obj.SafeDownCast (vtkObject o)`
- `obj.SetColor (double , double , double )` - Set the color of the text.
- `obj.SetColor (double  a[3])` - Set the color of the text.

- `double = obj. GetColor ()` - Set the color of the text.
- `obj.SetOpacity (double )` - Set/Get the text's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `double = obj.GetOpacity ()` - Set/Get the text's opacity. 1.0 is totally opaque and 0.0 is completely transparent.
- `string = obj.GetFontFamilyAsString ()` - Set/Get the font family. Supports legacy three font family system.
- `obj.SetFontFamilyAsString (string )` - Set/Get the font family. Supports legacy three font family system.
- `obj.SetFontFamily (int t)` - Set/Get the font family. Supports legacy three font family system.
- `int = obj.GetFontFamily ()` - Set/Get the font family. Supports legacy three font family system.
- `int = obj.GetFontFamilyMinValue ()` - Set/Get the font family. Supports legacy three font family system.
- `obj.SetFontFamilyToArial ()` - Set/Get the font family. Supports legacy three font family system.
- `obj.SetFontFamilyToCourier ()` - Set/Get the font family. Supports legacy three font family system.
- `obj.SetFontFamilyToTimes ()` - Set/Get the font family. Supports legacy three font family system.
- `obj.SetFontSize (int )` - Set/Get the font size (in points).
- `int = obj.GetFontSizeMinValue ()` - Set/Get the font size (in points).
- `int = obj.GetFontSizeMaxValue ()` - Set/Get the font size (in points).
- `int = obj.GetFontSize ()` - Set/Get the font size (in points).
- `obj.SetBold (int )` - Enable/disable text bolding.
- `int = obj.GetBold ()` - Enable/disable text bolding.
- `obj.BoldOn ()` - Enable/disable text bolding.
- `obj.BoldOff ()` - Enable/disable text bolding.
- `obj.SetItalic (int )` - Enable/disable text italic.
- `int = obj.GetItalic ()` - Enable/disable text italic.
- `obj.ItalicOn ()` - Enable/disable text italic.
- `obj.ItalicOff ()` - Enable/disable text italic.
- `obj.SetShadow (int )` - Enable/disable text shadow.
- `int = obj.GetShadow ()` - Enable/disable text shadow.
- `obj.ShadowOn ()` - Enable/disable text shadow.
- `obj.ShadowOff ()` - Enable/disable text shadow.
- `obj.SetShadowOffset (int , int )` - Set/Get the shadow offset, i.e. the distance from the text to its shadow, in the same unit as FontSize.
- `obj.SetShadowOffset (int  a[2])` - Set/Get the shadow offset, i.e. the distance from the text to its shadow, in the same unit as FontSize.

- `int = obj. GetShadowOffset ()` - Set/Get the shadow offset, i.e. the distance from the text to its shadow, in the same unit as FontSize.
- `obj.GetShadowColor (double color[3])` - Get the shadow color. It is computed from the Color ivar
- `obj.SetJustification (int )` - Set/Get the horizontal justification to left (default), centered, or right.
- `int = obj.GetJustificationMinValue ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `int = obj.GetJustificationMaxValue ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `int = obj.GetJustification ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `obj.SetJustificationToLeft ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `obj.SetJustificationToCentered ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `obj.SetJustificationToRight ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `string = obj.GetJustificationAsString ()` - Set/Get the horizontal justification to left (default), centered, or right.
- `obj.SetVerticalJustification (int )` - Set/Get the vertical justification to bottom (default), middle, or top.
- `int = obj.GetVerticalJustificationMinValue ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `int = obj.GetVerticalJustificationMaxValue ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `int = obj.GetVerticalJustification ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `obj.SetVerticalJustificationToBottom ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `obj.SetVerticalJustificationToCentered ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `obj.SetVerticalJustificationToTop ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `string = obj.GetVerticalJustificationAsString ()` - Set/Get the vertical justification to bottom (default), middle, or top.
- `obj.SetOrientation (double )` - Set/Get the text's orientation (in degrees).
- `double = obj.GetOrientation ()` - Set/Get the text's orientation (in degrees).
- `obj.SetLineSpacing (double )` - Set/Get the (extra) spacing between lines, expressed as a text height multiplication factor.
- `double = obj.GetLineSpacing ()` - Set/Get the (extra) spacing between lines, expressed as a text height multiplication factor.

- `obj.SetLineOffset (double )` - Set/Get the vertical offset (measured in pixels).
- `double = obj.GetLineOffset ()` - Set/Get the vertical offset (measured in pixels).
- `obj.ShallowCopy (vtkTextProperty tprop)` - Shallow copy of a text property.

39.188 vtkTexture

39.188.1 Usage

vtkTexture is an object that handles loading and binding of texture maps. It obtains its data from an input image data dataset type. Thus you can create visualization pipelines to read, process, and construct textures. Note that textures will only work if texture coordinates are also defined, and if the rendering system supports texture.

Instances of vtkTexture are associated with actors via the actor's SetTexture() method. Actors can share texture maps (this is encouraged to save memory resources.)

To create an instance of class vtkTexture, simply invoke its constructor as follows

```
obj = vtkTexture
```

39.188.2 Methods

The class vtkTexture has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTexture class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTexture = obj.NewInstance ()`
- `vtkTexture = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren)` - Renders a texture map. It first checks the object's modified time to make sure the texture maps Input is valid, then it invokes the Load() method.
- `obj.PostRender (vtkRenderer )` - Cleans up after the texture rendering to restore the state of the graphics context.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this texture. The parameter window could be used to determine which graphic resources to release.
- `obj.Load (vtkRenderer )` - Abstract interface to renderer. Each concrete subclass of vtkTexture will load its data into graphics system in response to this method invocation.
- `int = obj.GetRepeat ()` - Turn on/off the repetition of the texture map when the texture coords extend beyond the [0,1] range.
- `obj.SetRepeat (int )` - Turn on/off the repetition of the texture map when the texture coords extend beyond the [0,1] range.
- `obj.RepeatOn ()` - Turn on/off the repetition of the texture map when the texture coords extend beyond the [0,1] range.
- `obj.RepeatOff ()` - Turn on/off the repetition of the texture map when the texture coords extend beyond the [0,1] range.

- `int = obj.GetEdgeClamp ()` - Turn on/off the clamping of the texture map when the texture coords extend beyond the [0,1] range. Only used when Repeat is off, and edge clamping is supported by the graphics card.

- `obj.SetEdgeClamp (int )` - Turn on/off the clamping of the texture map when the texture coords extend beyond the [0,1] range. Only used when Repeat is off, and edge clamping is supported by the graphics card.

- `obj.EdgeClampOn ()` - Turn on/off the clamping of the texture map when the texture coords extend beyond the [0,1] range. Only used when Repeat is off, and edge clamping is supported by the graphics card.

- `obj.EdgeClampOff ()` - Turn on/off the clamping of the texture map when the texture coords extend beyond the [0,1] range. Only used when Repeat is off, and edge clamping is supported by the graphics card.

- `int = obj.GetInterpolate ()` - Turn on/off linear interpolation of the texture map when rendering.

- `obj.SetInterpolate (int )` - Turn on/off linear interpolation of the texture map when rendering.

- `obj.InterpolateOn ()` - Turn on/off linear interpolation of the texture map when rendering.

- `obj.InterpolateOff ()` - Turn on/off linear interpolation of the texture map when rendering.

- `obj.SetQuality (int )` - Force texture quality to 16-bit or 32-bit. This might not be supported on all machines.

- `int = obj.GetQuality ()` - Force texture quality to 16-bit or 32-bit. This might not be supported on all machines.

- `obj.SetQualityToDefault ()` - Force texture quality to 16-bit or 32-bit. This might not be supported on all machines.

- `obj.SetQualityTo16Bit ()` - Force texture quality to 16-bit or 32-bit. This might not be supported on all machines.

- `obj.SetQualityTo32Bit ()` - Force texture quality to 16-bit or 32-bit. This might not be supported on all machines.

- `int = obj.GetMapColorScalarsThroughLookupTable ()` - Turn on/off the mapping of color scalars through the lookup table. The default is Off. If Off, unsigned char scalars will be used directly as texture. If On, scalars will be mapped through the lookup table to generate 4-component unsigned char scalars. This ivar does not affect other scalars like unsigned short, float, etc. These scalars are always mapped through lookup tables.

- `obj.SetMapColorScalarsThroughLookupTable (int )` - Turn on/off the mapping of color scalars through the lookup table. The default is Off. If Off, unsigned char scalars will be used directly as texture. If On, scalars will be mapped through the lookup table to generate 4-component unsigned char scalars. This ivar does not affect other scalars like unsigned short, float, etc. These scalars are always mapped through lookup tables.

- `obj.MapColorScalarsThroughLookupTableOn ()` - Turn on/off the mapping of color scalars through the lookup table. The default is Off. If Off, unsigned char scalars will be used directly as texture. If On, scalars will be mapped through the lookup table to generate 4-component unsigned char scalars. This ivar does not affect other scalars like unsigned short, float, etc. These scalars are always mapped through lookup tables.

- `obj.MapColorScalarsThroughLookupTableOff ()` - Turn on/off the mapping of color scalars through the lookup table. The default is Off. If Off, unsigned char scalars will be used directly as texture. If On, scalars will be mapped through the lookup table to generate 4-component unsigned char scalars. This ivar does not affect other scalars like unsigned short, float, etc. These scalars are always mapped through lookup tables.

- `obj.SetLookupTable (vtkScalarsToColors )` - Specify the lookup table to convert scalars if necessary

- `vtkScalarsToColors = obj.GetLookupTable ()` - Specify the lookup table to convert scalars if necessary

- `vtkUnsignedCharArray = obj.GetMappedScalars ()` - Get Mapped Scalars

- `obj.SetTransform (vtkTransform transform)` - Set a transform on the texture which allows one to scale, rotate and translate the texture.

- `vtkTransform = obj.GetTransform ()` - Set a transform on the texture which allows one to scale, rotate and translate the texture.

- `int = obj.GetBlendingMode ()` - Used to specify how the texture will blend its RGB and Alpha values with other textures and the fragment the texture is rendered upon.

- `obj.SetBlendingMode (int )` - Used to specify how the texture will blend its RGB and Alpha values with other textures and the fragment the texture is rendered upon.

- `bool = obj.GetPremultipliedAlpha ()` - Whether the texture colors are premultiplied by alpha. Initial value is false.

- `obj.SetPremultipliedAlpha (bool )` - Whether the texture colors are premultiplied by alpha. Initial value is false.

- `obj.PremultipliedAlphaOn ()` - Whether the texture colors are premultiplied by alpha. Initial value is false.

- `obj.PremultipliedAlphaOff ()` - Whether the texture colors are premultiplied by alpha. Initial value is false.

- `int = obj.GetRestrictPowerOf2ImageSmaller ()` - When the texture is forced to be a power of 2, the default behavior is for the "new" image's dimensions to be greater than or equal to with respects to the original. Setting RestrictPowerOf2ImageSmaller to be 1 (or ON) with force the new image's dimensions to be less than or equal to with respects to the original.

- `obj.SetRestrictPowerOf2ImageSmaller (int )` - When the texture is forced to be a power of 2, the default behavior is for the "new" image's dimensions to be greater than or equal to with respects to the original. Setting RestrictPowerOf2ImageSmaller to be 1 (or ON) with force the new image's dimensions to be less than or equal to with respects to the original.

- `obj.RestrictPowerOf2ImageSmallerOn ()` - When the texture is forced to be a power of 2, the default behavior is for the "new" image's dimensions to be greater than or equal to with respects to the original. Setting RestrictPowerOf2ImageSmaller to be 1 (or ON) with force the new image's dimensions to be less than or equal to with respects to the original.

- `obj.RestrictPowerOf2ImageSmallerOff ()` - When the texture is forced to be a power of 2, the default behavior is for the "new" image's dimensions to be greater than or equal to with respects to the original. Setting RestrictPowerOf2ImageSmaller to be 1 (or ON) with force the new image's dimensions to be less than or equal to with respects to the original.

39.189 vtkTexturedActor2D

39.189.1 Usage

vtkTexturedActor2D is an Actor2D which has additional support for textures, just like vtkActor. To use textures, the geometry must have texture coordinates, and the texture must be set with SetTexture().

To create an instance of class vtkTexturedActor2D, simply invoke its constructor as follows

```
obj = vtkTexturedActor2D
```

39.189.2 Methods

The class vtkTexturedActor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTexturedActor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTexturedActor2D = obj.NewInstance ()`
- `vtkTexturedActor2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetTexture (vtkTexture texture)` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. An actor does not need to have an associated texture map and multiple actors can share one texture.
- `vtkTexture = obj.GetTexture ()` - Set/Get the texture object to control rendering texture maps. This will be a vtkTexture object. An actor does not need to have an associated texture map and multiple actors can share one texture.
- `obj.ReleaseGraphicsResources (vtkWindow win)` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Support the standard render methods.
- `long = obj.GetMTime ()` - Return this object's modified time.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this vtkTexturedActor2D. Overrides vtkActor2D method.

39.190 vtkTextureObject

39.190.1 Usage

vtkTextureObject represents an OpenGL texture object. It provides API to create textures using data already loaded into pixel buffer objects. It can also be used to create textures without uploading any data.

To create an instance of class vtkTextureObject, simply invoke its constructor as follows

```
obj = vtkTextureObject
```

39.190.2 Methods

The class vtkTextureObject has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextureObject class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTextureObject = obj.NewInstance ()`
- `vtkTextureObject = obj.SafeDownCast (vtkObject o)`
- `obj.SetContext (vtkRenderWindow )` - Get/Set the context. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.
- `vtkRenderWindow = obj.GetContext ()` - Get/Set the context. This does not increase the reference count of the context to avoid reference loops. SetContext() may raise an error is the OpenGL context does not support the required OpenGL extensions.
- `int = obj.GetWidth ()` - Get the texture dimensions. These are the properties of the OpenGL texture this instance represents.
- `int = obj.GetHeight ()` - Get the texture dimensions. These are the properties of the OpenGL texture this instance represents.
- `int = obj.GetDepth ()` - Get the texture dimensions. These are the properties of the OpenGL texture this instance represents.
- `int = obj.GetComponents ()` - Get the texture dimensions. These are the properties of the OpenGL texture this instance represents.
- `int = obj.GetNumberOfDimensions ()`
- `int = obj.GetTarget ()` - Returns OpenGL texture target to which the texture is/can be bound.
- `int = obj.GetHandle ()` - Returns the OpenGL handle.
- `obj.Bind ()` - Activate the texture. The texture must have been created using Create(). RenderWindow must be set before calling this.
- `obj.UnBind ()` - Activate the texture. The texture must have been created using Create(). RenderWindow must be set before calling this.
- `bool = obj.IsBound ()` - Tells if the texture object is bound to the active texture image unit. (a texture object can be bound to multiple texture image unit).
- `obj.SendParameters ()` - Send all the texture object parameters to the hardware if not done yet.
- `bool = obj.Create1D (int numComps, vtkPixelBufferObject pbo, bool shaderSupportsTextureInt)` - Create a 1D texture using the PBO. Eventually we may start supporting creating a texture from subset of data in the PBO, but for simplicity we'll begin with entire PBO data. numComps must be in [1-4]. shaderSupportsTextureInt is true if the shader has an alternate implementation supporting sampler with integer values. Even if the card supports texture int, it does not mean that the implementor of the shader made a version that supports texture int.

- `bool = obj.Create2D (int width, int height, int numComps, vtkPixelBufferObject pbo, bool shaderSupp` - Create a 2D texture using the PBO. Eventually we may start supporting creating a texture from subset of data in the PBO, but for simplicity we'll begin with entire PBO data. numComps must be in [1-4].

- `bool = obj.CreateDepth (int width, int height, int internalFormat, vtkPixelBufferObject pbo)` - Create a 2D depth texture using a PBO. re: valid_internalFormat: internalFormat¿=0 && internalFormat¡NumberOfDepthFormats

- `bool = obj.AllocateDepth (int width, int height, int internalFormat)` - Create a 2D depth texture but does not initialize its values.

- `bool = obj.Allocate1D (int width, int numComps, int vtkType)` - Create a 1D color texture but does not initialize its values. Internal format is deduced from numComps and vtkType.

- `bool = obj.Allocate2D (int width, int height, int numComps, int vtkType)` - Create a 2D color texture but does not initialize its values. Internal format is deduced from numComps and vtkType.

- `bool = obj.Allocate3D (int width, int height, int depth, int numComps, int vtkType)` - Create a 3D color texture but does not initialize its values. Internal format is deduced from numComps and vtkType.

- `bool = obj.Create3D (int width, int height, int depth, int numComps, vtkPixelBufferObject pbo, bool` - Create a 3D texture using the PBO. Eventually we may start supporting creating a texture from subset of data in the PBO, but for simplicity we'll begin with entire PBO data. numComps must be in [1-4].

- `bool = obj.Create2D (int width, int height, int numComps, int vtktype, bool shaderSupportsTextureIn` - Create texture without uploading any data. To create a DEPTH_COMPONENT texture, vtktype must be set to VTK_VOID and numComps must be 1.

- `bool = obj.Create3D (int width, int height, int depth, int numComps, int vtktype, bool shaderSuppor` - Create texture without uploading any data. To create a DEPTH_COMPONENT texture, vtktype must be set to VTK_VOID and numComps must be 1.

- `vtkPixelBufferObject = obj.Download ()` - This is used to download raw data from the texture into a pixel bufer. The pixel buffer API can then be used to download the pixel buffer data to CPU arrays. The caller takes on the responsibility of deleting the returns vtkPixelBufferObject once it done with it.

- `int = obj.GetDataType ()` - Get the data type for the texture as a vtk type int i.e. VTK_INT etc.

- `int = obj.GetInternalFormat (int vtktype, int numComps, bool shaderSupportsTextureInt)`

- `int = obj.GetFormat (int vtktype, int numComps, bool shaderSupportsTextureInt)`

- `int = obj.GetWrapS ()` - Wrap mode for the first texture coordinate "s" Valid values are: - Clamp - ClampToEdge - Repeat - ClampToBorder - MirroredRepeat Initial value is Repeat (as in OpenGL spec)

- `obj.SetWrapS (int )` - Wrap mode for the first texture coordinate "s" Valid values are: - Clamp - ClampToEdge - Repeat - ClampToBorder - MirroredRepeat Initial value is Repeat (as in OpenGL spec)

- `int = obj.GetWrapT ()` - Wrap mode for the first texture coordinate "t" Valid values are: - Clamp - ClampToEdge - Repeat - ClampToBorder - MirroredRepeat Initial value is Repeat (as in OpenGL spec)

- `obj.SetWrapT (int )` - Wrap mode for the first texture coordinate "t" Valid values are: - Clamp - ClampToEdge - Repeat - ClampToBorder - MirroredRepeat Initial value is Repeat (as in OpenGL spec)
- `int = obj.GetWrapR ()` - Wrap mode for the first texture coordinate "r" Valid values are: - Clamp - ClampToEdge - Repeat - ClampToBorder - MirroredRepeat Initial value is Repeat (as in OpenGL spec)
- `obj.SetWrapR (int )` - Wrap mode for the first texture coordinate "r" Valid values are: - Clamp - ClampToEdge - Repeat - ClampToBorder - MirroredRepeat Initial value is Repeat (as in OpenGL spec)
- `int = obj.GetMinificationFilter ()` - Minification filter mode. Valid values are: - Nearest - Linear - NearestMipmapNearest - NearestMipmapLinear - LinearMipmapNearest - LinearMipmapLinear Initial value is Nearest (note initial value in OpenGL spec is NearestMipMapLinear but this is error-prone because it makes the texture object incomplete.).
- `obj.SetMinificationFilter (int )` - Minification filter mode. Valid values are: - Nearest - Linear - NearestMipmapNearest - NearestMipmapLinear - LinearMipmapNearest - LinearMipmapLinear Initial value is Nearest (note initial value in OpenGL spec is NearestMipMapLinear but this is error-prone because it makes the texture object incomplete.).
- `bool = obj.GetLinearMagnification ()` - Tells if the magnification mode is linear (true) or nearest (false). Initial value is false (initial value in OpenGL spec is true).
- `obj.SetLinearMagnification (bool )` - Tells if the magnification mode is linear (true) or nearest (false). Initial value is false (initial value in OpenGL spec is true).
- `obj.SetBorderColor (float , float , float , float )` - Border Color (RGBA). Each component is in [0.0f,1.0f]. Initial value is (0.0f,0.0f,0.0f,0.0f), as in OpenGL spec.
- `obj.SetBorderColor (float a[4])` - Border Color (RGBA). Each component is in [0.0f,1.0f]. Initial value is (0.0f,0.0f,0.0f,0.0f), as in OpenGL spec.
- `float = obj. GetBorderColor ()` - Border Color (RGBA). Each component is in [0.0f,1.0f]. Initial value is (0.0f,0.0f,0.0f,0.0f), as in OpenGL spec.
- `obj.SetPriority (float )` - Priority of the texture object to be resident on the card for higher performance in the range [0.0f,1.0f]. Initial value is 1.0f, as in OpenGL spec.
- `float = obj.GetPriority ()` - Priority of the texture object to be resident on the card for higher performance in the range [0.0f,1.0f]. Initial value is 1.0f, as in OpenGL spec.
- `obj.SetMinLOD (float )` - Lower-clamp the computed LOD against this value. Any float value is valid. Initial value is -1000.0f, as in OpenGL spec.
- `float = obj.GetMinLOD ()` - Lower-clamp the computed LOD against this value. Any float value is valid. Initial value is -1000.0f, as in OpenGL spec.
- `obj.SetMaxLOD (float )` - Upper-clamp the computed LOD against this value. Any float value is valid. Initial value is 1000.0f, as in OpenGL spec.
- `float = obj.GetMaxLOD ()` - Upper-clamp the computed LOD against this value. Any float value is valid. Initial value is 1000.0f, as in OpenGL spec.
- `obj.SetBaseLevel (int )` - Level of detail of the first texture image. A texture object is a list of texture images. It is a non-negative integer value. Initial value is 0, as in OpenGL spec.
- `int = obj.GetBaseLevel ()` - Level of detail of the first texture image. A texture object is a list of texture images. It is a non-negative integer value. Initial value is 0, as in OpenGL spec.

- `obj.SetMaxLevel (int )` - Level of detail of the first texture image. A texture object is a list of texture images. It is a non-negative integer value. Initial value is 1000, as in OpenGL spec.

- `int = obj.GetMaxLevel ()` - Level of detail of the first texture image. A texture object is a list of texture images. It is a non-negative integer value. Initial value is 1000, as in OpenGL spec.

- `bool = obj.GetDepthTextureCompare ()` - Tells if the output of a texture unit with a depth texture uses comparison or not. Comparison happens between D_t the depth texture value in the range [0,1] and with R the interpolated third texture coordinate clamped to range [0,1]. The result of the comparison is noted 'r'. If this flag is false, r=D_t. Initial value is false, as in OpenGL spec. Ignored if the texture object is not a depth texture.

- `obj.SetDepthTextureCompare (bool )` - Tells if the output of a texture unit with a depth texture uses comparison or not. Comparison happens between D_t the depth texture value in the range [0,1] and with R the interpolated third texture coordinate clamped to range [0,1]. The result of the comparison is noted 'r'. If this flag is false, r=D_t. Initial value is false, as in OpenGL spec. Ignored if the texture object is not a depth texture.

- `int = obj.GetDepthTextureCompareFunction ()` - In case DepthTextureCompare is true, specify the comparison function in use. The result of the comparison is noted 'r'. Valid values are: - Value - Lequal: r=R¡=Dt ? 1.0 : 0.0 - Gequal: r=R¿=Dt ? 1.0 : 0.0 - Less: r=R¡D_t ? 1.0 : 0.0 - Greater: r=R¿Dt ? 1.0 : 0.0 - Equal: r=R==Dt ? 1.0 : 0.0 - NotEqual: r=R!=Dt ? 1.0 : 0.0 - AlwaysTrue: r=1.0 - Never: r=0.0 If the magnification of minification factor are not nearest, percentage closer filtering (PCF) is used: R is compared to several D_t and r is the average of the comparisons (it is NOT the average of D_t compared once to R). Initial value is Lequal, as in OpenGL spec. Ignored if the texture object is not a depth texture.

- `obj.SetDepthTextureCompareFunction (int )` - In case DepthTextureCompare is true, specify the comparison function in use. The result of the comparison is noted 'r'. Valid values are: - Value - Lequal: r=R¡=Dt ? 1.0 : 0.0 - Gequal: r=R¿=Dt ? 1.0 : 0.0 - Less: r=R¡D_t ? 1.0 : 0.0 - Greater: r=R¿Dt ? 1.0 : 0.0 - Equal: r=R==Dt ? 1.0 : 0.0 - NotEqual: r=R!=Dt ? 1.0 : 0.0 - AlwaysTrue: r=1.0 - Never: r=0.0 If the magnification of minification factor are not nearest, percentage closer filtering (PCF) is used: R is compared to several D_t and r is the average of the comparisons (it is NOT the average of D_t compared once to R). Initial value is Lequal, as in OpenGL spec. Ignored if the texture object is not a depth texture.

- `int = obj.GetDepthTextureMode ()` - Defines the mapping from depth component 'r' to RGBA components. Ignored if the texture object is not a depth texture. Valid modes are: - Luminance: (R,G,B,A)=(r,r,r,1) - Intensity: (R,G,B,A)=(r,r,r,r) - Alpha: (R.G.B.A)=(0,0,0,r) Initial value is Luminance, as in OpenGL spec.

- `obj.SetDepthTextureMode (int )` - Defines the mapping from depth component 'r' to RGBA components. Ignored if the texture object is not a depth texture. Valid modes are: - Luminance: (R,G,B,A)=(r,r,r,1) - Intensity: (R,G,B,A)=(r,r,r,r) - Alpha: (R.G.B.A)=(0,0,0,r) Initial value is Luminance, as in OpenGL spec.

- `bool = obj.GetGenerateMipmap ()` - Tells the hardware to generate mipmap textures from the first texture image at BaseLevel. Initial value is false, as in OpenGL spec.

- `obj.SetGenerateMipmap (bool )` - Tells the hardware to generate mipmap textures from the first texture image at BaseLevel. Initial value is false, as in OpenGL spec.

- `obj.CopyToFrameBuffer (int srcXmin, int srcYmin, int srcXmax, int srcYmax, int dstXmin, int dstYmin` - Copy a sub-part of the texture (src) in the current framebuffer at location (dstXmin,dstYmin). (dstXmin,dstYmin) is the location of the lower left corner of the rectangle. width and height are the dimensions of the framebuffer. - texture coordinates are sent on texture coordinate processing unit 0. - if the fixed-pipeline fragment shader is used, texturing has to be set on texture image unit 0 and the texture object has to be bound on texture image unit 0. - if a customized fragment shader is used, you

are free to pick the texture image unit you want. You can even have multiple texture objects attached on multiple texture image units. In this case, you call this method only on one of them.

- `obj.CopyFromFrameBuffer (int srcXmin, int srcYmin, int dstXmin, int dstYmin, int width, int height)` - Copy a sub-part of a logical buffer of the framebuffer (color or depth) to the texture object. src is the framebuffer, dst is the texture. (srcXmin,srcYmin) is the location of the lower left corner of the rectangle in the framebuffer. (dstXmin,dstYmin) is the location of the lower left corner of the rectangle in the texture. width and height specifies the size of the rectangle in pixels. If the logical buffer is a color buffer, it has to be selected first with glReadBuffer().

39.191 vtkTransformInterpolator

39.191.1 Usage

This class is used to interpolate a series of 4x4 transformation matrices. Position, scale and orientation (i.e., rotations) are interpolated separately, and can be interpolated linearly or with a spline function. Note that orientation is interpolated using quaternions via SLERP (spherical linear interpolation) or the special vtkQuaternionSpline class.

To use this class, specify at least two pairs of (t,transformation matrix) with the AddTransform() method. Then interpolated the transforms with the InterpolateTransform(t,transform) method, where "t" must be in the range of (min,max) times specified by the AddTransform() method.

By default, spline interpolation is used for the interpolation of the transformation matrices. The position, scale and orientation of the matrices are interpolated with instances of the classes vtkTupleInterpolator (position,scale) and vtkQuaternionInterpolator (rotation). The user can override the interpolation behavior by gaining access to these separate interpolation classes. These interpolator classes (vtkTupleInterpolator and vtkQuaternionInterpolator) can be modified to perform linear versus spline interpolation, and/or different spline basis functions can be specified.

To create an instance of class vtkTransformInterpolator, simply invoke its constructor as follows

```
obj = vtkTransformInterpolator
```

39.191.2 Methods

The class vtkTransformInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformInterpolator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransformInterpolator = obj.NewInstance ()`
- `vtkTransformInterpolator = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfTransforms ()` - Return the number of transforms in the list of transforms.
- `double = obj.GetMinimumT ()` - Obtain some information about the interpolation range. The numbers returned (corresponding to parameter t, usually thought of as time) are undefined if the list of transforms is empty.
- `double = obj.GetMaximumT ()` - Obtain some information about the interpolation range. The numbers returned (corresponding to parameter t, usually thought of as time) are undefined if the list of transforms is empty.
- `obj.Initialize ()` - Clear the list of transforms.

- `obj.AddTransform (double t, vtkTransform xform)` - Add another transform to the list of transformations defining the transform function. Note that using the same time t value more than once replaces the previous transform value at t. At least two transforms must be added to define a function. There are variants to this method depending on whether you are adding a vtkTransform, vtkMaxtirx4x4, and/or vtkProp3D.

- `obj.AddTransform (double t, vtkMatrix4x4 matrix)` - Add another transform to the list of transformations defining the transform function. Note that using the same time t value more than once replaces the previous transform value at t. At least two transforms must be added to define a function. There are variants to this method depending on whether you are adding a vtkTransform, vtkMaxtirx4x4, and/or vtkProp3D.

- `obj.AddTransform (double t, vtkProp3D prop3D)` - Add another transform to the list of transformations defining the transform function. Note that using the same time t value more than once replaces the previous transform value at t. At least two transforms must be added to define a function. There are variants to this method depending on whether you are adding a vtkTransform, vtkMaxtirx4x4, and/or vtkProp3D.

- `obj.RemoveTransform (double t)` - Delete the transform at a particular parameter t. If there is no transform defined at location t, then the method does nothing.

- `obj.InterpolateTransform (double t, vtkTransform xform)` - Interpolate the list of transforms and determine a new transform (i.e., fill in the transformation provided). If t is outside the range of (min,max) values, then t is clamped.

- `obj.SetInterpolationType (int )` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the position, scale and orientation interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `int = obj.GetInterpolationTypeMinValue ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the position, scale and orientation interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `int = obj.GetInterpolationTypeMaxValue ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the position, scale and orientation interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `int = obj.GetInterpolationType ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the position, scale and orientation interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `obj.SetInterpolationTypeToLinear ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the position, scale and orientation interpolators. Note that if the InterpolationType is set to "Manual", then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `obj.SetInterpolationTypeToSpline ()` - These are convenience methods to switch between linear and spline interpolation. The methods simply forward the request for linear or spline interpolation to the position, scale and orientation interpolators. Note that if the InterpolationType is set to "Manual",

then the interpolators are expected to be directly manipulated and this class does not forward the request for interpolation type to its interpolators.

- `obj.SetInterpolationTypeToManual ()` - Set/Get the tuple interpolator used to interpolate the position portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `obj.SetPositionInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the position portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `vtkTupleInterpolator = obj.GetPositionInterpolator ()` - Set/Get the tuple interpolator used to interpolate the position portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `obj.SetScaleInterpolator (vtkTupleInterpolator )` - Set/Get the tuple interpolator used to interpolate the scale portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `vtkTupleInterpolator = obj.GetScaleInterpolator ()` - Set/Get the tuple interpolator used to interpolate the scale portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `obj.SetRotationInterpolator (vtkQuaternionInterpolator )` - Set/Get the tuple interpolator used to interpolate the orientation portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `vtkQuaternionInterpolator = obj.GetRotationInterpolator ()` - Set/Get the tuple interpolator used to interpolate the orientation portion of the transformation matrix. Note that you can modify the behavior of the interpolator (linear vs spline interpolation; change spline basis) by manipulating the interpolator instances.
- `long = obj.GetMTime ()` - Override GetMTime() because we depend on the interpolators which may be modified outside of this class.

39.192 vtkTranslucentPass

39.192.1 Usage

vtkTranslucentPass renders the translucent polygonal geometry of all the props that have the keys contained in vtkRenderState.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color.

To create an instance of class vtkTranslucentPass, simply invoke its constructor as follows

```
obj = vtkTranslucentPass
```

39.192.2 Methods

The class vtkTranslucentPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTranslucentPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTranslucentPass = obj.NewInstance ()`
- `vtkTranslucentPass = obj.SafeDownCast (vtkObject o)`

39.193 vtkTupleInterpolator

39.193.1 Usage

This class is used to interpolate a tuple which may have an arbitrary number of components (but at least one component). The interpolation may be linear in form, or via a subclasses of vtkSpline.

To use this class, begin by specifying the number of components of the tuple and the interpolation function to use. Then specify at least one pair of (t,tuple) with the AddTuple() method. Next interpolate the tuples with the InterpolateTuple(t,tuple) method, where "t" must be in the range of (t_min,t_max) parameter values specified by the AddTuple() method (if not then t is clamped), and tuple[] is filled in by the method (make sure that tuple [] is long enough to hold the interpolated data).

You can control the type of interpolation to use. By default, the interpolation is based on a Kochanek spline. However, other types of splines can be specified. You can also set the interpolation method to linear, in which case the specified spline has no effect on the interpolation.

To create an instance of class vtkTupleInterpolator, simply invoke its constructor as follows

```
obj = vtkTupleInterpolator
```

39.193.2 Methods

The class vtkTupleInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTupleInterpolator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTupleInterpolator = obj.NewInstance ()`
- `vtkTupleInterpolator = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfComponents (int numComp)` - Specify the number of tuple components to interpolate. Note that setting this value discards any previously inserted data.
- `int = obj.GetNumberOfComponents ()` - Specify the number of tuple components to interpolate. Note that setting this value discards any previously inserted data.
- `int = obj.GetNumberOfTuples ()` - Return the number of tuples in the list of tuples to be interpolated.
- `double = obj.GetMinimumT ()` - Obtain some information about the interpolation range. The numbers returned (corresponding to parameter t, usually thought of as time) are undefined if the list of transforms is empty. This is a convenience method for interpolation.
- `double = obj.GetMaximumT ()` - Obtain some information about the interpolation range. The numbers returned (corresponding to parameter t, usually thought of as time) are undefined if the list of transforms is empty. This is a convenience method for interpolation.
- `obj.Initialize ()` - Reset the class so that it contains no (t,tuple) information.

- `obj.AddTuple (double t, double tuple[])` - Add another tuple to the list of tuples to be interpolated. Note that using the same time t value more than once replaces the previous tuple value at t. At least two tuples must be added to define an interpolation function.

- `obj.RemoveTuple (double t)` - Delete the tuple at a particular parameter t. If there is no tuple defined at t, then the method does nothing.

- `obj.InterpolateTuple (double t, double tuple[])` - Interpolate the list of tuples and determine a new tuple (i.e., fill in the tuple provided). If t is outside the range of (min,max) values, then t is clamped. Note that each component of tuple[] is interpolated independently.

- `obj.SetInterpolationType (int type)` - Specify which type of function to use for interpolation. By default spline interpolation (SetInterpolationFunctionToSpline()) is used (i.e., a Kochanek spline) and the InterpolatingSpline instance variable is used to birth the actual interpolation splines via a combination of NewInstance() and DeepCopy(). You may also choose to use linear interpolation by invoking SetInterpolationFunctionToLinear(). Note that changing the type of interpolation causes previously inserted data to be discarded.

- `int = obj.GetInterpolationType ()` - Specify which type of function to use for interpolation. By default spline interpolation (SetInterpolationFunctionToSpline()) is used (i.e., a Kochanek spline) and the InterpolatingSpline instance variable is used to birth the actual interpolation splines via a combination of NewInstance() and DeepCopy(). You may also choose to use linear interpolation by invoking SetInterpolationFunctionToLinear(). Note that changing the type of interpolation causes previously inserted data to be discarded.

- `obj.SetInterpolationTypeToLinear ()` - Specify which type of function to use for interpolation. By default spline interpolation (SetInterpolationFunctionToSpline()) is used (i.e., a Kochanek spline) and the InterpolatingSpline instance variable is used to birth the actual interpolation splines via a combination of NewInstance() and DeepCopy(). You may also choose to use linear interpolation by invoking SetInterpolationFunctionToLinear(). Note that changing the type of interpolation causes previously inserted data to be discarded.

- `obj.SetInterpolationTypeToSpline ()` - If the InterpolationType is set to spline, then this method applies. By default Kochanek interpolation is used, but you can specify any instance of vtkSpline to use. Note that the actual interpolating splines are created by invoking NewInstance() followed by DeepCopy() on the interpolating spline specified here, for each tuple component to interpolate.

- `obj.SetInterpolatingSpline (vtkSpline )` - If the InterpolationType is set to spline, then this method applies. By default Kochanek interpolation is used, but you can specify any instance of vtkSpline to use. Note that the actual interpolating splines are created by invoking NewInstance() followed by DeepCopy() on the interpolating spline specified here, for each tuple component to interpolate.

- `vtkSpline = obj.GetInterpolatingSpline ()` - If the InterpolationType is set to spline, then this method applies. By default Kochanek interpolation is used, but you can specify any instance of vtkSpline to use. Note that the actual interpolating splines are created by invoking NewInstance() followed by DeepCopy() on the interpolating spline specified here, for each tuple component to interpolate.

39.194 vtkUniformVariables

39.194.1 Usage

vtkUniformVariables is a list of uniform variables attached to either a vtkShader2 object or to a vtkShaderProgram2. Uniform variables on a vtkShaderProgram2 override values of uniform variables on a vtkShader2.

To create an instance of class vtkUniformVariables, simply invoke its constructor as follows

```
obj = vtkUniformVariables
```

39.194.2 Methods

The class vtkUniformVariables has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUniformVariables class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUniformVariables = obj.NewInstance ()`
- `vtkUniformVariables = obj.SafeDownCast (vtkObject o)`
- `obj.SetUniformi (string name, int numberOfComponents, int value)` - Set an integer uniform variable.
- `obj.SetUniformf (string name, int numberOfComponents, float value)` - Set an float uniform variable.
- `obj.SetUniformiv (string name, int numberOfComponents, int numberOfElements, int value)` - Set an array of integer uniform variables. The array 'value' is of size 'numberOfElements'*'numberOfComponents.'.
- `obj.SetUniformfv (string name, int numberOfComponents, int numberOfElements, float value)` - Set an array of float uniform variables. The array 'value' is of size 'numberOfElements'*'numberOfComponents.'.
- `obj.SetUniformMatrix (string name, int rows, int columns, float value)` - Set a matrix uniform variable.
- `obj.RemoveUniform (string name)` - Remove uniform 'name' from the list.
- `obj.RemoveAllUniforms ()` - Remove all uniforms from the list.
- `obj.Send (string name, int uniformIndex)` -
- `obj.Start ()` - Place the internal cursor on the first uniform.
- `bool = obj.IsAtEnd ()` - Is the iteration done?
- `string = obj.GetCurrentName ()` - Name of the uniform at the current cursor position.
- `obj.SendCurrentUniform (int uniformIndex)` -
- `obj.Next ()` - Move the cursor to the next uniform.
- `obj.DeepCopy (vtkUniformVariables other)` - Copy all the variables from 'other'. Any existing variable will be deleted first.
- `obj.Merge (vtkUniformVariables other)` - Copy all the variables from 'other'. Any existing variable will be overwritten.

39.195 vtkViewTheme

39.195.1 Usage

This may be set on any subclass of vtkView. The view class will attempt to use the values set in the theme to customize the view. Views will not generally use every aspect of the theme. NOTICE: This class will be deprecated in favor of a more robust solution based on style sheets. Do not become overly-dependent on the functionality of themes.

To create an instance of class vtkViewTheme, simply invoke its constructor as follows

```
obj = vtkViewTheme
```

39.195.2 Methods

The class vtkViewTheme has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkViewTheme class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkViewTheme = obj.NewInstance ()`
- `vtkViewTheme = obj.SafeDownCast (vtkObject o)`
- `obj.SetPointSize (double )` - The size of points or vertices
- `double = obj.GetPointSize ()` - The size of points or vertices
- `obj.SetLineWidth (double )` - The width of lines or edges
- `double = obj.GetLineWidth ()` - The width of lines or edges
- `obj.SetPointColor (double , double , double )` - The color and opacity of points or vertices when not mapped through a lookup table.
- `obj.SetPointColor (double  a[3])` - The color and opacity of points or vertices when not mapped through a lookup table.
- `double = obj. GetPointColor ()` - The color and opacity of points or vertices when not mapped through a lookup table.
- `obj.SetPointOpacity (double )` - The color and opacity of points or vertices when not mapped through a lookup table.
- `double = obj.GetPointOpacity ()` - The color and opacity of points or vertices when not mapped through a lookup table.
- `obj.SetPointHueRange (double mn, double mx)` - The ranges to use in the point lookup table. You may also do this by accessing the point lookup table directly with GetPointLookupTable() and calling these methods.
- `obj.SetPointHueRange (double rng[2])` - The ranges to use in the point lookup table. You may also do this by accessing the point lookup table directly with GetPointLookupTable() and calling these methods.
- `obj.GetPointHueRange (double rng[2])` - The ranges to use in the point lookup table. You may also do this by accessing the point lookup table directly with GetPointLookupTable() and calling these methods.
- `obj.SetPointSaturationRange (double mn, double mx)`
- `obj.SetPointSaturationRange (double rng[2])`
- `obj.GetPointSaturationRange (double rng[2])`
- `obj.SetPointValueRange (double mn, double mx)`
- `obj.SetPointValueRange (double rng[2])`
- `obj.GetPointValueRange (double rng[2])`
- `obj.SetPointAlphaRange (double mn, double mx)`

- `obj.SetPointAlphaRange (double rng[2])`
- `obj.GetPointAlphaRange (double rng[2])`
- `vtkScalarsToColors = obj.GetPointLookupTable ()` - Set/Get the point lookup table.
- `obj.SetPointLookupTable (vtkScalarsToColors lut)` - Set/Get the point lookup table.
- `obj.SetScalePointLookupTable (bool )` - Whether to scale the lookup table to fit the range of the data.
- `bool = obj.GetScalePointLookupTable ()` - Whether to scale the lookup table to fit the range of the data.
- `obj.ScalePointLookupTableOn ()` - Whether to scale the lookup table to fit the range of the data.
- `obj.ScalePointLookupTableOff ()` - Whether to scale the lookup table to fit the range of the data.
- `obj.SetCellColor (double , double , double )` - The color and opacity of cells or edges when not mapped through a lookup table.
- `obj.SetCellColor (double  a[3])` - The color and opacity of cells or edges when not mapped through a lookup table.
- `double = obj. GetCellColor ()` - The color and opacity of cells or edges when not mapped through a lookup table.
- `obj.SetCellOpacity (double )` - The color and opacity of cells or edges when not mapped through a lookup table.
- `double = obj.GetCellOpacity ()` - The color and opacity of cells or edges when not mapped through a lookup table.
- `obj.SetCellHueRange (double mn, double mx)` - The ranges to use in the cell lookup table. You may also do this by accessing the cell lookup table directly with GetCellLookupTable() and calling these methods.
- `obj.SetCellHueRange (double rng[2])` - The ranges to use in the cell lookup table. You may also do this by accessing the cell lookup table directly with GetCellLookupTable() and calling these methods.
- `obj.GetCellHueRange (double rng[2])` - The ranges to use in the cell lookup table. You may also do this by accessing the cell lookup table directly with GetCellLookupTable() and calling these methods.
- `obj.SetCellSaturationRange (double mn, double mx)`
- `obj.SetCellSaturationRange (double rng[2])`
- `obj.GetCellSaturationRange (double rng[2])`
- `obj.SetCellValueRange (double mn, double mx)`
- `obj.SetCellValueRange (double rng[2])`
- `obj.GetCellValueRange (double rng[2])`
- `obj.SetCellAlphaRange (double mn, double mx)`
- `obj.SetCellAlphaRange (double rng[2])`
- `obj.GetCellAlphaRange (double rng[2])`
- `vtkScalarsToColors = obj.GetCellLookupTable ()` - Set/Get the cell lookup table.

- `obj.SetCellLookupTable (vtkScalarsToColors lut)` - Set/Get the cell lookup table.
- `obj.SetScaleCellLookupTable (bool )` - Whether to scale the lookup table to fit the range of the data.
- `bool = obj.GetScaleCellLookupTable ()` - Whether to scale the lookup table to fit the range of the data.
- `obj.ScaleCellLookupTableOn ()` - Whether to scale the lookup table to fit the range of the data.
- `obj.ScaleCellLookupTableOff ()` - Whether to scale the lookup table to fit the range of the data.
- `obj.SetOutlineColor (double , double , double )` - The color of any outlines in the view.
- `obj.SetOutlineColor (double a[3])` - The color of any outlines in the view.
- `double = obj. GetOutlineColor ()` - The color of any outlines in the view.
- `obj.SetSelectedPointColor (double , double , double )` - The color of selected points or vertices.
- `obj.SetSelectedPointColor (double a[3])` - The color of selected points or vertices.
- `double = obj. GetSelectedPointColor ()` - The color of selected points or vertices.
- `obj.SetSelectedPointOpacity (double )` - The color of selected points or vertices.
- `double = obj.GetSelectedPointOpacity ()` - The color of selected points or vertices.
- `obj.SetSelectedCellColor (double , double , double )` - The color of selected cells or edges.
- `obj.SetSelectedCellColor (double a[3])` - The color of selected cells or edges.
- `double = obj. GetSelectedCellColor ()` - The color of selected cells or edges.
- `obj.SetSelectedCellOpacity (double )` - The color of selected cells or edges.
- `double = obj.GetSelectedCellOpacity ()` - The color of selected cells or edges.
- `obj.SetBackgroundColor (double , double , double )` - The view background color.
- `obj.SetBackgroundColor (double a[3])` - The view background color.
- `double = obj. GetBackgroundColor ()` - The view background color.
- `obj.SetBackgroundColor2 (double , double , double )` - The second background color (for gradients).
- `obj.SetBackgroundColor2 (double a[3])` - The second background color (for gradients).
- `double = obj. GetBackgroundColor2 ()` - The second background color (for gradients).
- `obj.SetPointTextProperty (vtkTextProperty tprop)` - The text property to use for labelling points/vertices.
- `vtkTextProperty = obj.GetPointTextProperty ()` - The text property to use for labelling points/vertices.
- `obj.SetCellTextProperty (vtkTextProperty tprop)` - The text property to use for labelling edges/cells.
- `vtkTextProperty = obj.GetCellTextProperty ()` - The text property to use for labelling edges/cells.
- `obj.SetVertexLabelColor (double r, double g, double b)` - The color to use for labelling graph vertices. This is deprecated. Use GetPointTextProperty()-¿SetColor() instead.
- `obj.SetVertexLabelColor (double c[3])` - The color to use for labelling graph vertices. This is deprecated. Use GetPointTextProperty()-¿SetColor() instead.

- `obj.GetVertexLabelColor (double c[3])` - The color to use for labelling graph edges. This is deprecated. Use GetCellTextProperty()-¿SetColor() instead.

- `obj.SetEdgeLabelColor (double r, double g, double b)` - The color to use for labelling graph edges. This is deprecated. Use GetCellTextProperty()-¿SetColor() instead.

- `obj.SetEdgeLabelColor (double c[3])` - The color to use for labelling graph edges. This is deprecated. Use GetCellTextProperty()-¿SetColor() instead.

- `obj.GetEdgeLabelColor (double c[3])` - Convenience methods for creating some default view themes. The return reference is reference-counted, so you will have to call Delete() on the reference when you are finished with it.

- `bool = obj.LookupMatchesPointTheme (vtkScalarsToColors s2c)` - Whether a given lookup table matches the point or cell theme of this theme.

- `bool = obj.LookupMatchesCellTheme (vtkScalarsToColors s2c)` - Whether a given lookup table matches the point or cell theme of this theme.

39.196 vtkVisibilitySort

39.196.1 Usage

vtkVisibilitySort encapsulates a method for depth sorting the cells of a vtkDataSet for a given viewpoint. It should be noted that subclasses are not required to give an absolutely correct sorting. Many types of unstructured grids may have sorting cycles, meaning that there is no possible correct sorting. Some subclasses also only give an approximate sorting in the interest of speed.

.SECTION Note The Input field of this class tends to causes reference cycles. To help break these cycles, garbage collection is enabled on this object and the input parameter is traced. For this to work, though, an object in the loop holding the visibility sort should also report that to the garbage collector.

To create an instance of class vtkVisibilitySort, simply invoke its constructor as follows

```
obj = vtkVisibilitySort
```

39.196.2 Methods

The class vtkVisibilitySort has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVisibilitySort class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkVisibilitySort = obj.NewInstance ()`

- `vtkVisibilitySort = obj.SafeDownCast (vtkObject o)`

- `obj.InitTraversal ()` - To facilitate incremental sorting algorithms, the cells are retrieved in an iteration process. That is, call InitTraversal to start the iteration and call GetNextCells to get the cell IDs in order. However, for efficiencies sake, GetNextCells returns an ordered list of several id's in once call (but not necessarily all). GetNextCells will return NULL once the entire sorted list is output. The vtkIdTypeArray returned from GetNextCells is a cached array, so do not delete it. At the same note, do not expect the array to be valid after subsequent calls to GetNextCells.

- `vtkIdTypeArray = obj.GetNextCells ()` - To facilitate incremental sorting algorithms, the cells are retrieved in an iteration process. That is, call InitTraversal to start the iteration and call GetNextCells to get the cell IDs in order. However, for efficiencies sake, GetNextCells returns an ordered list of several id's in once call (but not necessarily all). GetNextCells will return NULL once the entire sorted list is output. The vtkIdTypeArray returned from GetNextCells is a cached array, so do not delete it. At the same note, do not expect the array to be valid after subsequent calls to GetNextCells.
- `obj.SetMaxCellsReturned (int )` - Set/Get the maximum number of cells that GetNextCells will return in one invocation.
- `int = obj.GetMaxCellsReturnedMinValue ()` - Set/Get the maximum number of cells that GetNextCells will return in one invocation.
- `int = obj.GetMaxCellsReturnedMaxValue ()` - Set/Get the maximum number of cells that GetNextCells will return in one invocation.
- `int = obj.GetMaxCellsReturned ()` - Set/Get the maximum number of cells that GetNextCells will return in one invocation.
- `obj.SetModelTransform (vtkMatrix4x4 mat)` - Set/Get the matrix that transforms from object space to world space. Generally, you get this matrix from a call to GetMatrix of a vtkProp3D (vtkActor).
- `vtkMatrix4x4 = obj.GetModelTransform ()` - Set/Get the matrix that transforms from object space to world space. Generally, you get this matrix from a call to GetMatrix of a vtkProp3D (vtkActor).
- `vtkMatrix4x4 = obj.GetInverseModelTransform ()`
- `obj.SetCamera (vtkCamera camera)` - Set/Get the camera that specifies the viewing parameters.
- `vtkCamera = obj.GetCamera ()` - Set/Get the camera that specifies the viewing parameters.
- `obj.SetInput (vtkDataSet data)` - Set/Get the data set containing the cells to sort.
- `vtkDataSet = obj.GetInput ()` - Set/Get the data set containing the cells to sort.
- `int = obj.GetDirection ()` - Set/Get the sorting direction. Be default, the direction is set to back to front.
- `obj.SetDirection (int )` - Set/Get the sorting direction. Be default, the direction is set to back to front.
- `obj.SetDirectionToBackToFront ()` - Set/Get the sorting direction. Be default, the direction is set to back to front.
- `obj.SetDirectionToFrontToBack ()` - Overwritten to enable garbage collection.
- `obj.Register (vtkObjectBase o)` - Overwritten to enable garbage collection.
- `obj.UnRegister (vtkObjectBase o)` - Overwritten to enable garbage collection.

39.197 vtkVisibleCellSelector

39.197.1 Usage

DEPRECATED: Please refer to vtkHardwareSelector instead. This class can be used to determine what cells are visible within a given rectangle of the RenderWindow. To use it, call in order, SetRenderer(), SetArea(), SetProcessorId(), SetRenderPasses(), and then Select(). Select will cause the attached vtkRenderer to render in a special color mode, where each cell is given it own color so that later inspection of the Rendered Pixels can determine what cells are visible. In practice up to five different rendering passes may occur depending

on your choices in SetRenderPasses. After Select(), a list of the visible cells can be obtained by calling GetSelectedIds().

Limitations: Antialiasing will break this class. If your graphics card settings force their use this class will return invalid results.

Currently only cells from PolyDataMappers can be selected from. When vtkRenderer is put into a SelectMode, it temporarily swaps in a new vtkIdentColoredPainter to do the color index rendering of each cell in each vtkProp that it renders. Until alternatives to vtkIdentColoredPainter exist that can do a similar coloration of other vtkDataSet types, only polygonal data can be selected. If you need to select other data types, consider using vtkDataSetMapper and turning on it's PassThroughCellIds feature, or using vtkFrustumExtractor.

Only Opaque geometry in Actors is selected from. Assemblies and LODMappers are not currently supported.

During selection, visible datasets that can not be selected from are temporarily hidden so as not to produce invalid indices from their colors.

To create an instance of class vtkVisibleCellSelector, simply invoke its constructor as follows

```
obj = vtkVisibleCellSelector
```

39.197.2 Methods

The class vtkVisibleCellSelector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVisibleCellSelector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVisibleCellSelector = obj.NewInstance ()`
- `vtkVisibleCellSelector = obj.SafeDownCast (vtkObject o)`
- `obj.SetRenderer (vtkRenderer )` - Call to let this know where to select within.
- `obj.SetArea (int x0, int y0, int x1, int y1)` - Call to set the selection area region. This crops the selected area to the renderers pixel limits.
- `obj.SetProcessorId (int pid)` - Call to let this know what processor number to render as in the processor select pass. Internally this adds 1 to pid because 0 is reserved for miss.
- `int = obj.GetProcessorId ()` - Call to let this know what processor number to render as in the processor select pass. Internally this adds 1 to pid because 0 is reserved for miss.
- `obj.SetRenderPasses (int DoProcessor, int DoActor, int DoCellIdHi, int DoCellIdMid, int DoCellIdLo,` - Call to let this know what selection render passes to do. If you have only one processor or one actor, you can leave DoProcessor and DoActor as false (the default). If you have less than $2\hat{4}8$ cells in any actor, you do not need the CellIdHi pass, or similarly if you have less than $2\hat{2}4$ cells, you do not need DoCellIdMid. The DoPointId will enable another render pass for determining visible vertices.
- `obj.Select ()` - Execute the selection algorithm.
- `obj.GetSelectedIds (vtkIdTypeArray ToCopyInto)` - After Select(), this will return the list of selected Ids. The ProcessorId and Actor Id are returned in the first two components. The CellId is returned in the last two components (only 64 bits total).
- `obj.GetSelectedIds (vtkSelection ToCopyInto)` - After Select(), this will return the list of selected Ids.

- `obj.GetSelectedVertices (vtkIdTypeArray VertexPointers, vtkIdTypeArray VertexIds)` - After Select(), (assuming DoVertexId is on), the will return arrays that describe which cell vertices are visible. The VertexPointers array contains one index into the VertexIds array for every visible cell. Any index may be -1 in which case no vertices were visible for that cell. The VertexIds array contains a set of integers for each cell that has visible vertices. The first entry in the set is the number of visible vertices. The rest are visible vertex ranks. A set such at 2,0,4, means that a particular polygon's first and fifth vertices were visible.
- `vtkProp = obj.GetActorFromId (vtkIdType id)` - After a select, this will return a pointer to the actor corresponding to a particular id. This will return NULL if id is out of range.
- `obj.PrintSelectedIds (vtkIdTypeArray IdsToPrint)` - For debugging - prints out the list of selected ids.

39.198 vtkVolume

39.198.1 Usage

vtkVolume is used to represent a volumetric entity in a rendering scene. It inherits functions related to the volume's position, orientation and origin from vtkProp3D. The volume maintains a reference to the volumetric data (i.e., the volume mapper). The volume also contains a reference to a volume property which contains all common volume rendering parameters.

To create an instance of class vtkVolume, simply invoke its constructor as follows

```
obj = vtkVolume
```

39.198.2 Methods

The class vtkVolume has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolume class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolume = obj.NewInstance ()`
- `vtkVolume = obj.SafeDownCast (vtkObject o)`
- `obj.SetMapper (vtkAbstractVolumeMapper mapper)` - Set/Get the volume mapper.
- `vtkAbstractVolumeMapper = obj.GetMapper ()` - Set/Get the volume mapper.
- `obj.SetProperty (vtkVolumeProperty property)` - Set/Get the volume property.
- `vtkVolumeProperty = obj.GetProperty ()` - Set/Get the volume property.
- `obj.GetVolumes (vtkPropCollection vc)` - For some exporters and other other operations we must be able to collect all the actors or volumes. This method is used in that process.
- `obj.Update ()` - Update the volume rendering pipeline by updating the volume mapper
- `double = obj.GetBounds ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `obj.GetBounds (double bounds[6])` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.

- `double = obj.GetMinXBound ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `double = obj.GetMaxXBound ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `double = obj.GetMinYBound ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `double = obj.GetMaxYBound ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `double = obj.GetMinZBound ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `double = obj.GetMaxZBound ()` - Get the bounds - either all six at once (xmin, xmax, ymin, ymax, zmin, zmax) or one at a time.
- `long = obj.GetMTime ()` - Return the MTime also considering the property etc.
- `long = obj.GetRedrawMTime ()` - Return the mtime of anything that would cause the rendered image to appear differently. Usually this involves checking the mtime of the prop plus anything else it depends on such as properties, mappers, etc.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this vtkVolume. Overloads the virtual vtkProp method.

39.199 vtkVolumeCollection

39.199.1 Usage

vtkVolumeCollection represents and provides methods to manipulate a list of volumes (i.e., vtkVolume and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkVolumeCollection, simply invoke its constructor as follows

```
obj = vtkVolumeCollection
```

39.199.2 Methods

The class vtkVolumeCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeCollection = obj.NewInstance ()`
- `vtkVolumeCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkVolume a)` - Get the next Volume in the list. Return NULL when at the end of the list.
- `vtkVolume = obj.GetNextVolume ()` - Get the next Volume in the list. Return NULL when at the end of the list.
- `vtkVolume = obj.GetNextItem ()` - Access routine provided for compatibility with previous versions of VTK. Please use the GetNextVolume() variant where possible.

39.200 vtkVolumeProperty

39.200.1 Usage

vtkVolumeProperty is used to represent common properties associated with volume rendering. This includes properties for determining the type of interpolation to use when sampling a volume, the color of a volume, the scalar opacity of a volume, the gradient opacity of a volume, and the shading parameters of a volume.

When the scalar opacity or the gradient opacity of a volume is not set, then the function is defined to be a constant value of 1.0. When a scalar and gradient opacity are both set simultaneously, then the opacity is defined to be the product of the scalar opacity and gradient opacity transfer functions.

Most properties can be set per "component" for volume mappers that support multiple independent components. If you are using 2 component data as LV or 4 component data as RGBV (as specified in the mapper) only the first scalar opacity and gradient opacity transfer functions will be used (and all color functions will be ignored). Omitting the index parameter on the Set/Get methods will access index = 0.

To create an instance of class vtkVolumeProperty, simply invoke its constructor as follows

```
obj = vtkVolumeProperty
```

39.200.2 Methods

The class vtkVolumeProperty has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeProperty class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeProperty = obj.NewInstance ()`
- `vtkVolumeProperty = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkVolumeProperty p)`
- `long = obj.GetMTime ()` - Get the modified time for this object (or the properties registered with this object).
- `obj.SetIndependentComponents (int )` - Does the data have independent components, or do some define color only? If IndependentComponents is On (the default) then each component will be independently passed through a lookup table to determine RGBA, shaded. Some volume Mappers can handle 1 to 4 component unsigned char or unsigned short data (see each mapper header file to determine functionality). If IndependentComponents is Off, then you must have either 2 or 4 component data. For 2 component data, the first is passed through the first color transfer function and the second component is passed through the first opacity transfer function. Normals will be generated off of the second component. For 4 component data, the first three will directly represent RGB (no lookup table). The fourth component will be passed through the first scalar opacity transfer function for opacity. Normals will be generated from the fourth component.
- `int = obj.GetIndependentComponentsMinValue ()` - Does the data have independent components, or do some define color only? If IndependentComponents is On (the default) then each component will be independently passed through a lookup table to determine RGBA, shaded. Some volume Mappers can handle 1 to 4 component unsigned char or unsigned short data (see each mapper header file to determine functionality). If IndependentComponents is Off, then you must have either 2 or 4 component data. For 2 component data, the first is passed through the first color transfer function and the second component is passed through the first opacity transfer function. Normals will be generated off of the second component. For 4 component data, the first three will directly represent RGB (no lookup table). The fourth component will be passed through the first scalar opacity transfer function for opacity. Normals will be generated from the fourth component.

- `int = obj.GetIndependentComponentsMaxValue ()` - Does the data have independent components, or do some define color only? If IndependentComponents is On (the default) then each component will be independently passed through a lookup table to determine RGBA, shaded. Some volume Mappers can handle 1 to 4 component unsigned char or unsigned short data (see each mapper header file to determine functionality). If IndependentComponents is Off, then you must have either 2 or 4 component data. For 2 component data, the first is passed through the first color transfer function and the second component is passed through the first opacity transfer function. Normals will be generated off of the second component. For 4 component data, the first three will directly represent RGB (no lookup table). The fourth component will be passed through the first scalar opacity transfer function for opacity. Normals will be generated from the fourth component.

- `int = obj.GetIndependentComponents ()` - Does the data have independent components, or do some define color only? If IndependentComponents is On (the default) then each component will be independently passed through a lookup table to determine RGBA, shaded. Some volume Mappers can handle 1 to 4 component unsigned char or unsigned short data (see each mapper header file to determine functionality). If IndependentComponents is Off, then you must have either 2 or 4 component data. For 2 component data, the first is passed through the first color transfer function and the second component is passed through the first opacity transfer function. Normals will be generated off of the second component. For 4 component data, the first three will directly represent RGB (no lookup table). The fourth component will be passed through the first scalar opacity transfer function for opacity. Normals will be generated from the fourth component.

- `obj.IndependentComponentsOn ()` - Does the data have independent components, or do some define color only? If IndependentComponents is On (the default) then each component will be independently passed through a lookup table to determine RGBA, shaded. Some volume Mappers can handle 1 to 4 component unsigned char or unsigned short data (see each mapper header file to determine functionality). If IndependentComponents is Off, then you must have either 2 or 4 component data. For 2 component data, the first is passed through the first color transfer function and the second component is passed through the first opacity transfer function. Normals will be generated off of the second component. For 4 component data, the first three will directly represent RGB (no lookup table). The fourth component will be passed through the first scalar opacity transfer function for opacity. Normals will be generated from the fourth component.

- `obj.IndependentComponentsOff ()` - Does the data have independent components, or do some define color only? If IndependentComponents is On (the default) then each component will be independently passed through a lookup table to determine RGBA, shaded. Some volume Mappers can handle 1 to 4 component unsigned char or unsigned short data (see each mapper header file to determine functionality). If IndependentComponents is Off, then you must have either 2 or 4 component data. For 2 component data, the first is passed through the first color transfer function and the second component is passed through the first opacity transfer function. Normals will be generated off of the second component. For 4 component data, the first three will directly represent RGB (no lookup table). The fourth component will be passed through the first scalar opacity transfer function for opacity. Normals will be generated from the fourth component.

- `obj.SetInterpolationType (int )` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.

- `int = obj.GetInterpolationTypeMinValue ()` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.

- `int = obj.GetInterpolationTypeMaxValue ()` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.

- `int = obj.GetInterpolationType ()` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.

- `obj.SetInterpolationTypeToNearest ()` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.

- `obj.SetInterpolationTypeToLinear ()` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.
- `string = obj.GetInterpolationTypeAsString (void )` - Set the interpolation type for sampling a volume. Initial value is VTK_NEAREST_INTERPOLATION.
- `obj.SetComponentWeight (int index, double value)` - Set/Get the scalar component weights
- `double = obj.GetComponentWeight (int index)` - Set/Get the scalar component weights
- `obj.SetColor (int index, vtkPiecewiseFunction function)` - Set the color of a volume to a gray level transfer function for the component indicated by index. This will set the color channels for this component to 1.
- `obj.SetColor (vtkPiecewiseFunction f)` - Set the color of a volume to a gray level transfer function for the component indicated by index. This will set the color channels for this component to 1.
- `obj.SetColor (int index, vtkColorTransferFunction function)` - Set the color of a volume to an RGB transfer function for the component indicated by index. This will set the color channels for this component to 3. This will also recompute the color channels
- `obj.SetColor (vtkColorTransferFunction f)` - Set the color of a volume to an RGB transfer function for the component indicated by index. This will set the color channels for this component to 3. This will also recompute the color channels
- `int = obj.GetColorChannels (int index)` - Get the number of color channels in the transfer function for the given component.
- `int = obj.GetColorChannels ()` - Get the number of color channels in the transfer function for the given component.
- `vtkPiecewiseFunction = obj.GetGrayTransferFunction (int index)` - Get the gray transfer function. If no transfer function has been set for this component, a default one is created and returned.
- `vtkPiecewiseFunction = obj.GetGrayTransferFunction ()` - Get the gray transfer function. If no transfer function has been set for this component, a default one is created and returned.
- `vtkColorTransferFunction = obj.GetRGBTransferFunction (int index)` - Get the RGB transfer function for the given component. If no transfer function has been set for this component, a default one is created and returned.
- `vtkColorTransferFunction = obj.GetRGBTransferFunction ()` - Get the RGB transfer function for the given component. If no transfer function has been set for this component, a default one is created and returned.
- `obj.SetScalarOpacity (int index, vtkPiecewiseFunction function)` - Set the opacity of a volume to an opacity transfer function based on scalar value for the component indicated by index.
- `obj.SetScalarOpacity (vtkPiecewiseFunction f)` - Set the opacity of a volume to an opacity transfer function based on scalar value for the component indicated by index.
- `vtkPiecewiseFunction = obj.GetScalarOpacity (int index)` - Get the scalar opacity transfer function for the given component. If no transfer function has been set for this component, a default one is created and returned.
- `vtkPiecewiseFunction = obj.GetScalarOpacity ()` - Get the scalar opacity transfer function for the given component. If no transfer function has been set for this component, a default one is created and returned.

- `obj.SetScalarOpacityUnitDistance (int index, double distance)` - Set/Get the unit distance on which the scalar opacity transfer function is defined. By default this is 1.0, meaning that over a distance of 1.0 units, a given opacity (from the transfer function) is accumulated. This is adjusted for the actual sampling distance during rendering.

- `obj.SetScalarOpacityUnitDistance (double distance)` - Set/Get the unit distance on which the scalar opacity transfer function is defined. By default this is 1.0, meaning that over a distance of 1.0 units, a given opacity (from the transfer function) is accumulated. This is adjusted for the actual sampling distance during rendering.

- `double = obj.GetScalarOpacityUnitDistance (int index)` - Set/Get the unit distance on which the scalar opacity transfer function is defined. By default this is 1.0, meaning that over a distance of 1.0 units, a given opacity (from the transfer function) is accumulated. This is adjusted for the actual sampling distance during rendering.

- `double = obj.GetScalarOpacityUnitDistance ()` - Set the opacity of a volume to an opacity transfer function based on gradient magnitude for the given component.

- `obj.SetGradientOpacity (int index, vtkPiecewiseFunction function)` - Set the opacity of a volume to an opacity transfer function based on gradient magnitude for the given component.

- `obj.SetGradientOpacity (vtkPiecewiseFunction function)` - Get the gradient magnitude opacity transfer function for the given component. If no transfer function has been set for this component, a default one is created and returned. This default function is always returned if DisableGradientOpacity is On for that component.

- `vtkPiecewiseFunction = obj.GetGradientOpacity (int index)` - Get the gradient magnitude opacity transfer function for the given component. If no transfer function has been set for this component, a default one is created and returned. This default function is always returned if DisableGradientOpacity is On for that component.

- `vtkPiecewiseFunction = obj.GetGradientOpacity ()` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `obj.SetDisableGradientOpacity (int index, int value)` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `obj.SetDisableGradientOpacity (int value)` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `obj.DisableGradientOpacityOn (int index)` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `obj.DisableGradientOpacityOn ()` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `obj.DisableGradientOpacityOff (int index)` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function

for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `obj.DisableGradientOpacityOff ()` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `int = obj.GetDisableGradientOpacity (int index)` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `int = obj.GetDisableGradientOpacity ()` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `vtkPiecewiseFunction = obj.GetStoredGradientOpacity (int index)` - Enable/Disable the gradient opacity function for the given component. If set to true, any call to GetGradientOpacity() will return a default function for this component. Note that the gradient opacity function is still stored, it is not set or reset and can be retrieved using GetStoredGradientOpacity().

- `vtkPiecewiseFunction = obj.GetStoredGradientOpacity ()` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `obj.SetShade (int index, int value)` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `obj.SetShade (int value)` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `int = obj.GetShade (int index)` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `int = obj.GetShade ()` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `obj.ShadeOn (int index)` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `obj.ShadeOn ()` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `obj.ShadeOff (int index)` - Set/Get the shading of a volume. If shading is turned off, then the mapper for the volume will not perform shading calculations. If shading is turned on, the mapper may perform shading calculations - in some cases shading does not apply (for example, in a maximum intensity projection) and therefore shading will not be performed even if this flag is on. For a compositing type of mapper, turning shading off is generally the same as setting ambient=1, diffuse=0, specular=0. Shading can be independently turned on/off per component.

- `obj.ShadeOff ()` - Set/Get the ambient lighting coefficient.

- `obj.SetAmbient (int index, double value)` - Set/Get the ambient lighting coefficient.

- `obj.SetAmbient (double value)` - Set/Get the ambient lighting coefficient.

- `double = obj.GetAmbient (int index)` - Set/Get the ambient lighting coefficient.

- `double = obj.GetAmbient ()` - Set/Get the diffuse lighting coefficient.

- `obj.SetDiffuse (int index, double value)` - Set/Get the diffuse lighting coefficient.

- `obj.SetDiffuse (double value)` - Set/Get the diffuse lighting coefficient.

- `double = obj.GetDiffuse (int index)` - Set/Get the diffuse lighting coefficient.

- `double = obj.GetDiffuse ()` - Set/Get the specular lighting coefficient.

- `obj.SetSpecular (int index, double value)` - Set/Get the specular lighting coefficient.

- `obj.SetSpecular (double value)` - Set/Get the specular lighting coefficient.

- `double = obj.GetSpecular (int index)` - Set/Get the specular lighting coefficient.

- `double = obj.GetSpecular ()` - Set/Get the specular power.

- `obj.SetSpecularPower (int index, double value)` - Set/Get the specular power.

- `obj.SetSpecularPower (double value)` - Set/Get the specular power.

- `double = obj.GetSpecularPower (int index)` - Set/Get the specular power.

- `double = obj.GetSpecularPower ()`

39.201 vtkVolumetricPass

39.201.1 Usage

vtkVolumetricPass renders the volumetric geometry of all the props that have the keys contained in vtkRenderState.

This pass expects an initialized depth buffer and color buffer. Initialized buffers means they have been cleared with farest z-value and background color/gradient/transparent color.

To create an instance of class vtkVolumetricPass, simply invoke its constructor as follows

```
obj = vtkVolumetricPass
```

39.201.2 Methods

The class vtkVolumetricPass has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumetricPass class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumetricPass = obj.NewInstance ()`
- `vtkVolumetricPass = obj.SafeDownCast (vtkObject o)`

39.202 vtkVRMLExporter

39.202.1 Usage

vtkVRMLExporter is a concrete subclass of vtkExporter that writes VRML 2.0 files. This is based on the VRML 2.0 draft #3 but it should be pretty stable since we aren't using any of the newer features.

To create an instance of class vtkVRMLExporter, simply invoke its constructor as follows

```
obj = vtkVRMLExporter
```

39.202.2 Methods

The class vtkVRMLExporter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVRMLExporter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVRMLExporter = obj.NewInstance ()`
- `vtkVRMLExporter = obj.SafeDownCast (vtkObject o)`
- `obj.SetFileName (string )` - Specify the name of the VRML file to write.
- `string = obj.GetFileName ()` - Specify the name of the VRML file to write.
- `obj.SetSpeed (double )` - Specify the Speed of navigation. Default is 4.
- `double = obj.GetSpeed ()` - Specify the Speed of navigation. Default is 4.

39.203 vtkWindowToImageFilter

39.203.1 Usage

vtkWindowToImageFilter provides methods needed to read the data in a vtkWindow and use it as input to the imaging pipeline. This is useful for saving an image to a file for example. The window can be read as either RGB or RGBA pixels; in addition, the depth buffer can also be read. RGB and RGBA pixels are of type unsigned char, while Z-Buffer data is returned as floats. Use this filter to convert RenderWindows or ImageWindows to an image format.

To create an instance of class vtkWindowToImageFilter, simply invoke its constructor as follows

```
obj = vtkWindowToImageFilter
```

39.203.2 Methods

The class vtkWindowToImageFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWindowToImageFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWindowToImageFilter = obj.NewInstance ()`
- `vtkWindowToImageFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkWindow input)` - Indicates what renderer to get the pixel data from. Initial value is 0.
- `vtkWindow = obj.GetInput ()` - Returns which renderer is being used as the source for the pixel data. Initial value is 0.
- `obj.SetMagnification (int )` - The magnification of the current render window. Initial value is 1.
- `int = obj.GetMagnificationMinValue ()` - The magnification of the current render window. Initial value is 1.
- `int = obj.GetMagnificationMaxValue ()` - The magnification of the current render window. Initial value is 1.
- `int = obj.GetMagnification ()` - The magnification of the current render window. Initial value is 1.
- `obj.ReadFrontBufferOn ()` - Set/Get the flag that determines which buffer to read from. The default is to read from the front buffer.
- `obj.ReadFrontBufferOff ()` - Set/Get the flag that determines which buffer to read from. The default is to read from the front buffer.
- `int = obj.GetReadFrontBuffer ()` - Set/Get the flag that determines which buffer to read from. The default is to read from the front buffer.
- `obj.SetReadFrontBuffer (int )` - Set/Get the flag that determines which buffer to read from. The default is to read from the front buffer.
- `obj.ShouldRerenderOn ()` - Set/get whether to re-render the input window. Initial value is true. (This option makes no difference if Magnification ¿ 1.)

- `obj.ShouldRerenderOff ()` - Set/get whether to re-render the input window. Initial value is true. (This option makes no difference if Magnification ¿ 1.)
- `obj.SetShouldRerender (int )` - Set/get whether to re-render the input window. Initial value is true. (This option makes no difference if Magnification ¿ 1.)
- `int = obj.GetShouldRerender ()` - Set/get whether to re-render the input window. Initial value is true. (This option makes no difference if Magnification ¿ 1.)
- `obj.SetViewport (double , double , double , double )` - Set/get the extents to be used to generate the image. Initial value is 0,0,1,1 (This option does not work if Magnification ¿ 1.)
- `obj.SetViewport (double a[4])` - Set/get the extents to be used to generate the image. Initial value is 0,0,1,1 (This option does not work if Magnification ¿ 1.)
- `double = obj. GetViewport ()` - Set/get the extents to be used to generate the image. Initial value is 0,0,1,1 (This option does not work if Magnification ¿ 1.)
- `obj.SetInputBufferType (int )` - Set/get the window buffer from which data will be read. Choices include VTK_RGB (read the color image from the window), VTK_RGBA (same, but include the alpha channel), and VTK_ZBUFFER (depth buffer, returned as a float array). Initial value is VTK_RGB.
- `int = obj.GetInputBufferType ()` - Set/get the window buffer from which data will be read. Choices include VTK_RGB (read the color image from the window), VTK_RGBA (same, but include the alpha channel), and VTK_ZBUFFER (depth buffer, returned as a float array). Initial value is VTK_RGB.
- `obj.SetInputBufferTypeToRGB ()` - Set/get the window buffer from which data will be read. Choices include VTK_RGB (read the color image from the window), VTK_RGBA (same, but include the alpha channel), and VTK_ZBUFFER (depth buffer, returned as a float array). Initial value is VTK_RGB.
- `obj.SetInputBufferTypeToRGBA ()` - Set/get the window buffer from which data will be read. Choices include VTK_RGB (read the color image from the window), VTK_RGBA (same, but include the alpha channel), and VTK_ZBUFFER (depth buffer, returned as a float array). Initial value is VTK_RGB.
- `obj.SetInputBufferTypeToZBuffer ()` - Set/get the window buffer from which data will be read. Choices include VTK_RGB (read the color image from the window), VTK_RGBA (same, but include the alpha channel), and VTK_ZBUFFER (depth buffer, returned as a float array). Initial value is VTK_RGB.
- `vtkImageData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.

39.204 vtkWorldPointPicker

39.204.1 Usage

vtkWorldPointPicker is used to find the x,y,z world coordinate of a screen x,y,z. This picker cannot pick actors and/or mappers, it simply determines an x-y-z coordinate in world space. (It will always return a x-y-z, even if the selection point is not over a prop/actor.)

To create an instance of class vtkWorldPointPicker, simply invoke its constructor as follows

```
obj = vtkWorldPointPicker
```

39.204.2 Methods

The class vtkWorldPointPicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWorldPointPicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWorldPointPicker = obj.NewInstance ()`
- `vtkWorldPointPicker = obj.SafeDownCast (vtkObject o)`
- `int = obj.Pick (double selectionX, double selectionY, double selectionZ, vtkRenderer renderer)` - Perform the pick. (This method overload's the superclass.)
- `int = obj.Pick (double selectionPt[3], vtkRenderer renderer)` - Perform the pick. (This method overload's the superclass.)

39.205 vtkXGPUInfoList

39.205.1 Usage

vtkXGPUInfoList implements Probe() method of vtkGPUInfoList through some X server extensions API. NV-CONTROL for Nvidia. ATIFGLEXTENSION for ATI is not supported yet. There is no support for other vendors.

To create an instance of class vtkXGPUInfoList, simply invoke its constructor as follows

```
obj = vtkXGPUInfoList
```

39.205.2 Methods

The class vtkXGPUInfoList has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXGPUInfoList class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXGPUInfoList = obj.NewInstance ()`
- `vtkXGPUInfoList = obj.SafeDownCast (vtkObject o)`
- `obj.Probe ()` - Build the list of vtkInfoGPU if not done yet.

39.206 vtkXOpenGLRenderWindow

39.206.1 Usage

vtkXOpenGLRenderWindow is a concrete implementation of the abstract class vtkRenderWindow. vtkOpenGLRenderer interfaces to the OpenGL graphics library. Application programmers should normally use vtkRenderWindow instead of the OpenGL specific version.

To create an instance of class vtkXOpenGLRenderWindow, simply invoke its constructor as follows

```
obj = vtkXOpenGLRenderWindow
```

39.206.2 Methods

The class vtkXOpenGLRenderWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXOpenGLRenderWindow class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXOpenGLRenderWindow = obj.NewInstance ()`
- `vtkXOpenGLRenderWindow = obj.SafeDownCast (vtkObject o)`
- `obj.Start (void )` - Begin the rendering process.
- `obj.Frame (void )` - End the rendering process and display the image.
- `obj.WindowInitialize (void )` - Initialize the window for rendering.
- `obj.Initialize (void )` - Initialize the rendering window. This will setup all system-specific resources. This method and Finalize() must be symmetric and it should be possible to call them multiple times, even changing WindowId in-between. This is what WindowRemap does.
- `obj.Finalize (void )` - "Deinitialize" the rendering window. This will shutdown all system-specific resources. After having called this, it should be possible to destroy a window that was used for a SetWindowId() call without any ill effects.
- `obj.SetFullScreen (int )` - Change the window to fill the entire screen.
- `obj.WindowRemap (void )` - Resize the window.
- `obj.PrefFullScreen (void )` - Set the preferred window size to full screen.
- `obj.SetSize (int , int )` - Specify the size of the rendering window in pixels.
- `obj.SetSize (int a[2])` - Specify the size of the rendering window in pixels.
- `int = obj.GetDesiredDepth ()` - Get the X properties of an ideal rendering window.
- `obj.SetStereoCapableWindow (int capable)` - Prescribe that the window be created in a stereo-capable mode. This method must be called before the window is realized. This method overrides the superclass method since this class can actually check whether the window has been realized yet.
- `obj.MakeCurrent ()` - Make this window the current OpenGL context.
- `bool = obj.IsCurrent ()` - Tells if this window is the current OpenGL context for the calling thread.
- `obj.SetForceMakeCurrent ()` - If called, allow MakeCurrent() to skip cache-check when called. MakeCurrent() reverts to original behavior of cache-checking on the next render.
- `string = obj.ReportCapabilities ()` - Get report of capabilities for the render window
- `int = obj.SupportsOpenGL ()` - Does this render window support OpenGL? 0-false, 1-true
- `int = obj.IsDirect ()` - Is this render window using hardware acceleration? 0-false, 1-true
- `obj.SetWindowName (string )`
- `obj.SetPosition (int , int )` - Move the window to a new position on the display.
- `obj.SetPosition (int a[2])` - Move the window to a new position on the display.

- `obj.HideCursor ()` - Hide or Show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead.
- `obj.ShowCursor ()` - Hide or Show the mouse cursor, it is nice to be able to hide the default cursor if you want VTK to display a 3D cursor instead.
- `obj.SetCurrentCursor (int )` - Change the shape of the cursor
- `int = obj.GetEventPending ()` - Check to see if a mouse button has been pressed. All other events are ignored by this method. This is a useful check to abort a long render.
- `obj.SetWindowInfo (string info)` - Set this RenderWindow's X window id to a pre-existing window.
- `obj.SetNextWindowInfo (string info)` - Set the window info that will be used after WindowRemap()
- `obj.SetParentInfo (string info)` - Sets the X window id of the window that WILL BE created.
- `obj.Render ()` - This computes the size of the render window before calling the supper classes render
- `obj.SetOffScreenRendering (int i)` - Render without displaying the window.

39.207 vtkXRenderWindowInteractor

39.207.1 Usage

vtkXRenderWindowInteractor is a convenience object that provides event bindings to common graphics functions. For example, camera and actor functions such as zoom-in/zoom-out, azimuth, roll, and pan. IT is one of the window system specific subclasses of vtkRenderWindowInteractor. Please see vtkRenderWindowInteractor documentation for event bindings.

To create an instance of class vtkXRenderWindowInteractor, simply invoke its constructor as follows

```
obj = vtkXRenderWindowInteractor
```

39.207.2 Methods

The class vtkXRenderWindowInteractor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXRenderWindowInteractor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXRenderWindowInteractor = obj.NewInstance ()`
- `vtkXRenderWindowInteractor = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Initializes the event handlers without an XtAppContext. This is good for when you don't have a user interface, but you still want to have mouse interaction.
- `obj.TerminateApp ()` - Break the event loop on 'q','e' keypress. Want more ???
- `int = obj.GetBreakLoopFlag ()` - The BreakLoopFlag is checked in the Start() method. Setting it to anything other than zero will cause the interactor loop to terminate and return to the calling function.
- `obj.SetBreakLoopFlag (int )` - The BreakLoopFlag is checked in the Start() method. Setting it to anything other than zero will cause the interactor loop to terminate and return to the calling function.

- `obj.BreakLoopFlagOff ()` - The BreakLoopFlag is checked in the Start() method. Setting it to anything other than zero will cause the interactor loop to terminate and return to the calling function.
- `obj.BreakLoopFlagOn ()` - The BreakLoopFlag is checked in the Start() method. Setting it to anything other than zero will cause the interactor loop to terminate and return to the calling function.
- `obj.Enable ()` - Enable/Disable interactions. By default interactors are enabled when initialized. Initialize() must be called prior to enabling/disabling interaction. These methods are used when a window/widget is being shared by multiple renderers and interactors. This allows a "modal" display where one interactor is active when its data is to be displayed and all other interactors associated with the widget are disabled when their data is not displayed.
- `obj.Disable ()` - Enable/Disable interactions. By default interactors are enabled when initialized. Initialize() must be called prior to enabling/disabling interaction. These methods are used when a window/widget is being shared by multiple renderers and interactors. This allows a "modal" display where one interactor is active when its data is to be displayed and all other interactors associated with the widget are disabled when their data is not displayed.
- `obj.Start ()` - This will start up the X event loop and never return. If you call this method it will loop processing X events until the application is exited.
- `obj.UpdateSize (int , int )` - Update the Size data member and set the associated RenderWindow's size.
- `obj.GetMousePosition (int x, int y)` - Re-defines virtual function to get mouse position by querying X-server.

Chapter 40

Visualization Toolkit View Classes

40.1 vtkConvertSelectionDomain

40.1.1 Usage

vtkConvertSelectionDomain converts a selection from one domain to another using known domain mappings. The domain mappings are described by a vtkMultiBlockDataSet containing one or more vtkTables.

The first input port is for the input selection (or collection of annotations in a vtkAnnotationLayers object), while the second port is for the multi-block of mappings, and the third port is for the data that is being selected on.

If the second or third port is not set, this filter will pass the selection/annotation to the output unchanged.

The second output is the selection associated with the "current annotation" normally representing the current interactive selection.

To create an instance of class vtkConvertSelectionDomain, simply invoke its constructor as follows

```
obj = vtkConvertSelectionDomain
```

40.1.2 Methods

The class vtkConvertSelectionDomain has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConvertSelectionDomain class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConvertSelectionDomain = obj.NewInstance ()`
- `vtkConvertSelectionDomain = obj.SafeDownCast (vtkObject o)`

40.2 vtkDataRepresentation

40.2.1 Usage

vtkDataRepresentation the superclass for representations of data objects. This class itself may be instantiated and used as a representation that simply holds a connection to a pipeline.

If there are multiple representations present in a view, you should use a subclass of vtkDataRepresentation. The representation is responsible for taking the input pipeline connection and converting it to an object usable by a view. In the most common case, the representation will contain the pipeline necessary to convert a data object into an actor or set of actors.

The representation has a concept of a selection. If the user performs a selection operation on the view, the view forwards this on to its representations. The representation is responsible for displaying that selection in an appropriate way.

Representation selections may also be linked. The representation shares the selection by converting it into a view-independent format, then setting the selection on its vtkAnnotationLink. Other representations sharing the same selection link instance will get the same selection from the selection link when the view is updated. The application is responsible for linking representations as appropriate by setting the same vtkAnnotationLink on each linked representation.

To create an instance of class vtkDataRepresentation, simply invoke its constructor as follows

```
obj = vtkDataRepresentation
```

40.2.2 Methods

The class vtkDataRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataRepresentation = obj.NewInstance ()`
- `vtkDataRepresentation = obj.SafeDownCast (vtkObject o)`
- `vtkAlgorithmOutput = obj.GetInputConnection (int port, int index)` - The annotation link for this representation. To link annotations, set the same vtkAnnotationLink object in multiple representations.
- `vtkAnnotationLink = obj.GetAnnotationLink ()` - The annotation link for this representation. To link annotations, set the same vtkAnnotationLink object in multiple representations.
- `obj.SetAnnotationLink (vtkAnnotationLink link)` - The annotation link for this representation. To link annotations, set the same vtkAnnotationLink object in multiple representations.
- `obj.ApplyViewTheme (vtkViewTheme )` - The view calls this method when a selection occurs. The representation takes this selection and converts it into a selection on its data by calling ConvertSelection, then calls UpdateSelection with the converted selection. Subclasses should not overrride this method, but should instead override ConvertSelection. The optional third argument specifies whether the selection should be added to the previous selection on this representation.
- `obj.Select (vtkView view, vtkSelection selection)` - The view calls this method when a selection occurs. The representation takes this selection and converts it into a selection on its data by calling ConvertSelection, then calls UpdateSelection with the converted selection. Subclasses should not overrride this method, but should instead override ConvertSelection. The optional third argument specifies whether the selection should be added to the previous selection on this representation.
- `obj.Select (vtkView view, vtkSelection selection, bool extend)` - The view calls this method when a selection occurs. The representation takes this selection and converts it into a selection on its data by calling ConvertSelection, then calls UpdateSelection with the converted selection. Subclasses should not overrride this method, but should instead override ConvertSelection. The optional third argument specifies whether the selection should be added to the previous selection on this representation.
- `obj.SetSelectable (bool )` - Whether this representation is able to handle a selection. Default is true.

- `bool = obj.GetSelectable ()` - Whether this representation is able to handle a selection. Default is true.
- `obj.SelectableOn ()` - Whether this representation is able to handle a selection. Default is true.
- `obj.SelectableOff ()` - Whether this representation is able to handle a selection. Default is true.
- `obj.UpdateSelection (vtkSelection selection)` - Updates the selection in the selection link and fires a selection change event. Subclasses should not overrride this method, but should instead override ConvertSelection. The optional second argument specifies whether the selection should be added to the previous selection on this representation.
- `obj.UpdateSelection (vtkSelection selection, bool extend)` - Updates the selection in the selection link and fires a selection change event. Subclasses should not overrride this method, but should instead override ConvertSelection. The optional second argument specifies whether the selection should be added to the previous selection on this representation.
- `vtkAlgorithmOutput = obj.GetInternalAnnotationOutputPort ()` - The output port that contains the annotations whose selections are localized for a particular input data object. This should be used when connecting the internal pipelines.
- `vtkAlgorithmOutput = obj.GetInternalAnnotationOutputPort (int port)` - The output port that contains the annotations whose selections are localized for a particular input data object. This should be used when connecting the internal pipelines.
- `vtkAlgorithmOutput = obj.GetInternalAnnotationOutputPort (int port, int conn)` - The output port that contains the annotations whose selections are localized for a particular input data object. This should be used when connecting the internal pipelines.
- `vtkAlgorithmOutput = obj.GetInternalSelectionOutputPort ()` - The output port that contains the selection associated with the current annotation (normally the interactive selection). This should be used when connecting the internal pipelines.
- `vtkAlgorithmOutput = obj.GetInternalSelectionOutputPort (int port)` - The output port that contains the selection associated with the current annotation (normally the interactive selection). This should be used when connecting the internal pipelines.
- `vtkAlgorithmOutput = obj.GetInternalSelectionOutputPort (int port, int conn)` - The output port that contains the selection associated with the current annotation (normally the interactive selection). This should be used when connecting the internal pipelines.
- `vtkAlgorithmOutput = obj.GetInternalOutputPort ()` - Retrieves an output port for the input data object at the specified port and connection index. This may be connected to the representation's internal pipeline.
- `vtkAlgorithmOutput = obj.GetInternalOutputPort (int port)` - Retrieves an output port for the input data object at the specified port and connection index. This may be connected to the representation's internal pipeline.
- `vtkAlgorithmOutput = obj.GetInternalOutputPort (int port, int conn)` - Retrieves an output port for the input data object at the specified port and connection index. This may be connected to the representation's internal pipeline.
- `obj.SetSelectionType (int )` - Set the selection type produced by this view. This should be one of the content type constants defined in vtkSelectionNode.h. Common values are vtkSelectionNode::INDICES vtkSelectionNode::PEDIGREEIDS vtkSelectionNode::VALUES
- `int = obj.GetSelectionType ()` - Set the selection type produced by this view. This should be one of the content type constants defined in vtkSelectionNode.h. Common values are vtkSelectionNode::INDICES vtkSelectionNode::PEDIGREEIDS vtkSelectionNode::VALUES

- `obj.SetSelectionArrayNames (vtkStringArray names)` - If a VALUES selection, the arrays used to produce a selection.
- `vtkStringArray = obj.GetSelectionArrayNames ()` - If a VALUES selection, the arrays used to produce a selection.
- `obj.SetSelectionArrayName (string name)` - If a VALUES selection, the array used to produce a selection.
- `string = obj.GetSelectionArrayName ()` - If a VALUES selection, the array used to produce a selection.

40.3 vtkEmptyRepresentation

40.3.1 Usage

To create an instance of class vtkEmptyRepresentation, simply invoke its constructor as follows

```
obj = vtkEmptyRepresentation
```

40.3.2 Methods

The class vtkEmptyRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEmptyRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEmptyRepresentation = obj.NewInstance ()`
- `vtkEmptyRepresentation = obj.SafeDownCast (vtkObject o)`
- `vtkAlgorithmOutput = obj.GetInternalAnnotationOutputPort ()` - Since this representation has no inputs, override superclass implementation with one that ignores "port" and "conn" and still allows it to have an annotation output.
- `vtkAlgorithmOutput = obj.GetInternalAnnotationOutputPort (int port)` - Since this representation has no inputs, override superclass implementation with one that ignores "port" and "conn" and still allows it to have an annotation output.
- `vtkAlgorithmOutput = obj.GetInternalAnnotationOutputPort (int port, int conn)` - Since this representation has no inputs, override superclass implementation with one that ignores "port" and "conn" and still allows it to have an annotation output.

40.4 vtkGraphLayoutView

40.4.1 Usage

vtkGraphLayoutView performs graph layout and displays a vtkGraph. You may color and label the vertices and edges using fields in the graph. If coordinates are already assigned to the graph vertices in your graph, set the layout strategy to PassThrough in this view. The default layout is Fast2D which is fast but not that good, for better layout set the layout to Simple2D or ForceDirected. There are also tree and circle layout strategies. :)

.SEE ALSO vtkFast2DLayoutStrategy vtkSimple2DLayoutStrategy vtkForceDirectedLayoutStrategy

.SECTION Thanks Thanks a bunch to the holographic unfolding pattern.

To create an instance of class vtkGraphLayoutView, simply invoke its constructor as follows

```
obj = vtkGraphLayoutView
```

40.4.2 Methods

The class vtkGraphLayoutView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphLayoutView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphLayoutView = obj.NewInstance ()`
- `vtkGraphLayoutView = obj.SafeDownCast (vtkObject o)`
- `obj.SetVertexLabelArrayName (string name)` - The array to use for vertex labeling. Default is "label".
- `string = obj.GetVertexLabelArrayName ()` - The array to use for vertex labeling. Default is "label".
- `obj.SetEdgeLabelArrayName (string name)` - The array to use for edge labeling. Default is "label".
- `string = obj.GetEdgeLabelArrayName ()` - The array to use for edge labeling. Default is "label".
- `obj.SetVertexLabelVisibility (bool vis)` - Whether to show vertex labels. Default is off.
- `bool = obj.GetVertexLabelVisibility ()` - Whether to show vertex labels. Default is off.
- `obj.VertexLabelVisibilityOn ()` - Whether to show vertex labels. Default is off.
- `obj.VertexLabelVisibilityOff ()` - Whether to show vertex labels. Default is off.
- `obj.SetHideVertexLabelsOnInteraction (bool vis)` - Whether to hide vertex labels during mouse interactions. Default is off.
- `bool = obj.GetHideVertexLabelsOnInteraction ()` - Whether to hide vertex labels during mouse interactions. Default is off.
- `obj.HideVertexLabelsOnInteractionOn ()` - Whether to hide vertex labels during mouse interactions. Default is off.
- `obj.HideVertexLabelsOnInteractionOff ()` - Whether to hide vertex labels during mouse interactions. Default is off.
- `obj.SetEdgeVisibility (bool vis)` - Whether to show the edges at all. Default is on
- `bool = obj.GetEdgeVisibility ()` - Whether to show the edges at all. Default is on
- `obj.EdgeVisibilityOn ()` - Whether to show the edges at all. Default is on
- `obj.EdgeVisibilityOff ()` - Whether to show the edges at all. Default is on
- `obj.SetEdgeLabelVisibility (bool vis)` - Whether to show edge labels. Default is off.
- `bool = obj.GetEdgeLabelVisibility ()` - Whether to show edge labels. Default is off.
- `obj.EdgeLabelVisibilityOn ()` - Whether to show edge labels. Default is off.
- `obj.EdgeLabelVisibilityOff ()` - Whether to show edge labels. Default is off.

- `obj.SetHideEdgeLabelsOnInteraction (bool vis)` - Whether to hide edge labels during mouse interactions. Default is off.
- `bool = obj.GetHideEdgeLabelsOnInteraction ()` - Whether to hide edge labels during mouse interactions. Default is off.
- `obj.HideEdgeLabelsOnInteractionOn ()` - Whether to hide edge labels during mouse interactions. Default is off.
- `obj.HideEdgeLabelsOnInteractionOff ()` - Whether to hide edge labels during mouse interactions. Default is off.
- `obj.SetVertexColorArrayName (string name)` - The array to use for coloring vertices. Default is "color".
- `string = obj.GetVertexColorArrayName ()` - The array to use for coloring vertices. Default is "color".
- `obj.SetColorVertices (bool vis)` - Whether to color vertices. Default is off.
- `bool = obj.GetColorVertices ()` - Whether to color vertices. Default is off.
- `obj.ColorVerticesOn ()` - Whether to color vertices. Default is off.
- `obj.ColorVerticesOff ()` - Whether to color vertices. Default is off.
- `obj.SetEdgeColorArrayName (string name)` - The array to use for coloring edges. Default is "color".
- `string = obj.GetEdgeColorArrayName ()` - The array to use for coloring edges. Default is "color".
- `obj.SetColorEdges (bool vis)` - Whether to color edges. Default is off.
- `bool = obj.GetColorEdges ()` - Whether to color edges. Default is off.
- `obj.ColorEdgesOn ()` - Whether to color edges. Default is off.
- `obj.ColorEdgesOff ()` - Whether to color edges. Default is off.
- `obj.SetEnabledEdgesArrayName (string name)` - The array to use for coloring edges.
- `string = obj.GetEnabledEdgesArrayName ()` - The array to use for coloring edges.
- `obj.SetEnableEdgesByArray (bool vis)` - Whether to color edges. Default is off.
- `int = obj.GetEnableEdgesByArray ()` - Whether to color edges. Default is off.
- `obj.SetEnabledVerticesArrayName (string name)` - The array to use for coloring vertices.
- `string = obj.GetEnabledVerticesArrayName ()` - The array to use for coloring vertices.
- `obj.SetEnableVerticesByArray (bool vis)` - Whether to color vertices. Default is off.
- `int = obj.GetEnableVerticesByArray ()` - Whether to color vertices. Default is off.
- `obj.SetScalingArrayName (string name)` - The array used for scaling (if ScaledGlyphs is ON)
- `string = obj.GetScalingArrayName ()` - The array used for scaling (if ScaledGlyphs is ON)
- `obj.SetScaledGlyphs (bool arg)` - Whether to use scaled glyphs or not. Default is off.
- `bool = obj.GetScaledGlyphs ()` - Whether to use scaled glyphs or not. Default is off.
- `obj.ScaledGlyphsOn ()` - Whether to use scaled glyphs or not. Default is off.

- `obj.ScaledGlyphsOff ()` - Whether to use scaled glyphs or not. Default is off.

- `obj.SetLayoutStrategy (string name)` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToRandom ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToForceDirected ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToSimple2D ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToClustering2D ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToCommunity2D ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToFast2D ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToPassThrough ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToCircular ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToTree ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToCosmicTree ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToCone ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `obj.SetLayoutStrategyToSpanTree ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A

layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `string = obj.GetLayoutStrategyName ()` - The layout strategy to use when performing the graph layout. The possible strings are: - "Random" Randomly places vertices in a box. - "Force Directed" A layout in 3D or 2D simulating forces on edges. - "Simple 2D" A simple 2D force directed layout. - "Clustering 2D" A 2D force directed layout that's just like simple 2D but uses some techniques to cluster better. - "Community 2D" A linear-time 2D layout that's just like Fast 2D but looks for and uses a community array to 'accentuate' clusters. - "Fast 2D" A linear-time 2D layout. - "Pass Through" Use locations assigned to the input. - "Circular" Places vertices uniformly on a circle. - "Cone" Cone tree layout. - "Span Tree" Span Tree Layout. Default is "Simple 2D".

- `vtkGraphLayoutStrategy = obj.GetLayoutStrategy ()` - The layout strategy to use when performing the graph layout. This signature allows an application to create a layout object directly and simply set the pointer through this method.

- `obj.SetLayoutStrategy (vtkGraphLayoutStrategy s)` - The layout strategy to use when performing the graph layout. This signature allows an application to create a layout object directly and simply set the pointer through this method.

- `obj.SetEdgeLayoutStrategy (string name)` - The layout strategy to use when performing the edge layout. The possible strings are: "Arc Parallel" - Arc parallel edges and self loops. "Pass Through" - Use edge routes assigned to the input. Default is "Arc Parallel".

- `obj.SetEdgeLayoutStrategyToArcParallel ()` - The layout strategy to use when performing the edge layout. The possible strings are: "Arc Parallel" - Arc parallel edges and self loops. "Pass Through" - Use edge routes assigned to the input. Default is "Arc Parallel".

- `obj.SetEdgeLayoutStrategyToPassThrough ()` - The layout strategy to use when performing the edge layout. The possible strings are: "Arc Parallel" - Arc parallel edges and self loops. "Pass Through" - Use edge routes assigned to the input. Default is "Arc Parallel".

- `string = obj.GetEdgeLayoutStrategyName ()` - The layout strategy to use when performing the edge layout. The possible strings are: "Arc Parallel" - Arc parallel edges and self loops. "Pass Through" - Use edge routes assigned to the input. Default is "Arc Parallel".

- `vtkEdgeLayoutStrategy = obj.GetEdgeLayoutStrategy ()` - The layout strategy to use when performing the edge layout. This signature allows an application to create a layout object directly and simply set the pointer through this method.

- `obj.SetEdgeLayoutStrategy (vtkEdgeLayoutStrategy s)` - The layout strategy to use when performing the edge layout. This signature allows an application to create a layout object directly and simply set the pointer through this method.

- `obj.AddIconType (string type, int index)` - Associate the icon at index "index" in the vtkTexture to all vertices containing "type" as a value in the vertex attribute array specified by IconArrayName.

- `obj.ClearIconTypes ()` - Clear all icon mappings.

- `obj.SetIconAlignment (int alignment)` - Specify where the icons should be placed in relation to the vertex. See vtkIconGlyphFilter.h for possible values.

- `obj.SetIconVisibility (bool b)` - Whether icons are visible (default off).

- `bool = obj.GetIconVisibility ()` - Whether icons are visible (default off).
- `obj.IconVisibilityOn ()` - Whether icons are visible (default off).
- `obj.IconVisibilityOff ()` - Whether icons are visible (default off).
- `obj.SetIconArrayName (string name)` - The array used for assigning icons
- `string = obj.GetIconArrayName ()` - The array used for assigning icons
- `obj.SetGlyphType (int type)` - The type of glyph to use for the vertices
- `int = obj.GetGlyphType ()` - The type of glyph to use for the vertices
- `obj.SetVertexLabelFontSize (int size)` - The size of the font used for vertex labeling
- `int = obj.GetVertexLabelFontSize ()` - The size of the font used for vertex labeling
- `obj.SetEdgeLabelFontSize (int size)` - The size of the font used for edge labeling
- `int = obj.GetEdgeLabelFontSize ()` - The size of the font used for edge labeling
- `obj.SetEdgeScalarBarVisibility (bool vis)` - Whether the scalar bar for edges is visible. Default is off.
- `bool = obj.GetEdgeScalarBarVisibility ()` - Whether the scalar bar for edges is visible. Default is off.
- `obj.SetVertexScalarBarVisibility (bool vis)` - Whether the scalar bar for vertices is visible. Default is off.
- `bool = obj.GetVertexScalarBarVisibility ()` - Whether the scalar bar for vertices is visible. Default is off.
- `obj.ZoomToSelection ()` - Reset the camera based on the bounds of the selected region.
- `int = obj.IsLayoutComplete ()` - Is the graph layout complete? This method is useful for when the strategy is iterative and the application wants to show the iterative progress of the graph layout See Also: UpdateLayout();
- `obj.UpdateLayout ()` - This method is useful for when the strategy is iterative and the application wants to show the iterative progress of the graph layout. The application would have something like while(!IsLayoutComplete()) UpdateLayout(); See Also: IsLayoutComplete();

40.5 vtkHierarchicalGraphPipeline

40.5.1 Usage

vtkHierarchicalGraphPipeline renders bundled edges that are meant to be viewed as an overlay on a tree. This class is not for general use, but is used in the internals of vtkRenderedHierarchyRepresentation and vtkRenderedTreeAreaRepresentation.

To create an instance of class vtkHierarchicalGraphPipeline, simply invoke its constructor as follows

```
obj = vtkHierarchicalGraphPipeline
```

40.5.2 Methods

The class vtkHierarchicalGraphPipeline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalGraphPipeline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalGraphPipeline = obj.NewInstance ()`
- `vtkHierarchicalGraphPipeline = obj.SafeDownCast (vtkObject o)`
- `vtkActor = obj.GetActor ()` - The actor associated with the hierarchical graph.
- `vtkActor2D = obj.GetLabelActor ()` - The actor associated with the hierarchical graph.
- `obj.SetBundlingStrength (double strength)` - The bundling strength for the bundled edges.
- `double = obj.GetBundlingStrength ()` - The bundling strength for the bundled edges.
- `obj.SetLabelArrayName (string name)` - The edge label array name.
- `string = obj.GetLabelArrayName ()` - The edge label array name.
- `obj.SetLabelVisibility (bool vis)` - The edge label visibility.
- `bool = obj.GetLabelVisibility ()` - The edge label visibility.
- `obj.LabelVisibilityOn ()` - The edge label visibility.
- `obj.LabelVisibilityOff ()` - The edge label visibility.
- `obj.SetLabelTextProperty (vtkTextProperty prop)` - The edge label text property.
- `vtkTextProperty = obj.GetLabelTextProperty ()` - The edge label text property.
- `obj.SetColorArrayName (string name)` - The edge color array.
- `string = obj.GetColorArrayName ()` - The edge color array.
- `obj.SetColorEdgesByArray (bool vis)` - Whether to color the edges by an array.
- `bool = obj.GetColorEdgesByArray ()` - Whether to color the edges by an array.
- `obj.ColorEdgesByArrayOn ()` - Whether to color the edges by an array.
- `obj.ColorEdgesByArrayOff ()` - Whether to color the edges by an array.
- `obj.SetVisibility (bool vis)` - The visibility of this graph.
- `bool = obj.GetVisibility ()` - The visibility of this graph.
- `obj.VisibilityOn ()` - The visibility of this graph.
- `obj.VisibilityOff ()` - The visibility of this graph.
- `vtkSelection = obj.ConvertSelection (vtkDataRepresentation rep, vtkSelection sel)` - Returns a new selection relevant to this graph based on an input selection and the view that this graph is contained in.

- `obj.PrepareInputConnections (vtkAlgorithmOutput graphConn, vtkAlgorithmOutput treeConn, vtkAlgorith` - Sets the input connections for this graph. graphConn is the input graph connection. treeConn is the input tree connection. annConn is the annotation link connection.
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Applies the view theme to this graph.
- `obj.SetHoverArrayName (string )` - The array to use while hovering over an edge.
- `string = obj.GetHoverArrayName ()` - The array to use while hovering over an edge.
- `obj.SetSplineType (int type)` - The spline mode to use in vtkSplineGraphEdges. vtkSplineGraphEdges::CUSTOM uses a vtkCardinalSpline. vtkSplineGraphEdges::BSPLINE uses a b-spline. The default is CUSTOM.
- `int = obj.GetSplineType ()` - The spline mode to use in vtkSplineGraphEdges. vtkSplineGraphEdges::CUSTOM uses a vtkCardinalSpline. vtkSplineGraphEdges::BSPLINE uses a b-spline. The default is CUSTOM.
- `obj.RegisterProgress (vtkRenderView view)` - Register progress with a view.

40.6 vtkHierarchicalGraphView

40.6.1 Usage

Takes a graph and a hierarchy (currently a tree) and lays out the graph vertices based on their categorization within the hierarchy.

.SEE ALSO vtkGraphLayoutView

.SECTION Thanks Thanks to the turtle with jets for feet, without you this class wouldn't have been possible.

To create an instance of class vtkHierarchicalGraphView, simply invoke its constructor as follows

```
obj = vtkHierarchicalGraphView
```

40.6.2 Methods

The class vtkHierarchicalGraphView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalGraphView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalGraphView = obj.NewInstance ()`
- `vtkHierarchicalGraphView = obj.SafeDownCast (vtkObject o)`
- `vtkDataRepresentation = obj.SetHierarchyFromInputConnection (vtkAlgorithmOutput conn)` - Set the tree and graph representations to the appropriate input ports.
- `vtkDataRepresentation = obj.SetHierarchyFromInput (vtkDataObject input)` - Set the tree and graph representations to the appropriate input ports.
- `vtkDataRepresentation = obj.SetGraphFromInputConnection (vtkAlgorithmOutput conn)` - Set the tree and graph representations to the appropriate input ports.
- `vtkDataRepresentation = obj.SetGraphFromInput (vtkDataObject input)` - Set the tree and graph representations to the appropriate input ports.
- `obj.SetGraphEdgeLabelArrayName (string name)` - The array to use for edge labeling. Default is "label".

- `string = obj.GetGraphEdgeLabelArrayName ()` - The array to use for edge labeling. Default is "label".
- `obj.SetGraphEdgeLabelVisibility (bool vis)` - Whether to show edge labels. Default is off.
- `bool = obj.GetGraphEdgeLabelVisibility ()` - Whether to show edge labels. Default is off.
- `obj.GraphEdgeLabelVisibilityOn ()` - Whether to show edge labels. Default is off.
- `obj.GraphEdgeLabelVisibilityOff ()` - Whether to show edge labels. Default is off.
- `obj.SetGraphEdgeColorArrayName (string name)` - The array to use for coloring edges. Default is "color".
- `string = obj.GetGraphEdgeColorArrayName ()` - The array to use for coloring edges. Default is "color".
- `obj.SetGraphEdgeColorToSplineFraction ()` - Set the color to be the spline fraction
- `obj.SetColorGraphEdgesByArray (bool vis)` - Whether to color edges. Default is off.
- `bool = obj.GetColorGraphEdgesByArray ()` - Whether to color edges. Default is off.
- `obj.ColorGraphEdgesByArrayOn ()` - Whether to color edges. Default is off.
- `obj.ColorGraphEdgesByArrayOff ()` - Whether to color edges. Default is off.
- `obj.SetBundlingStrength (double strength)` - Set the bundling strength.
- `double = obj.GetBundlingStrength ()` - Set the bundling strength.
- `obj.SetGraphVisibility (bool b)` - Whether the graph edges are visible (default off).
- `bool = obj.GetGraphVisibility ()` - Whether the graph edges are visible (default off).
- `obj.GraphVisibilityOn ()` - Whether the graph edges are visible (default off).
- `obj.GraphVisibilityOff ()` - Whether the graph edges are visible (default off).
- `obj.SetGraphEdgeLabelFontSize (int size)` - The size of the font used for edge labeling
- `int = obj.GetGraphEdgeLabelFontSize ()` - The size of the font used for edge labeling

40.7 vtkIcicleView

40.7.1 Usage

vtkIcicleView shows a vtkTree in horizontal layers where each vertex in the tree is represented by a bar. Child sectors are below (or above) parent sectors, and may be colored and sized by various parameters.

To create an instance of class vtkIcicleView, simply invoke its constructor as follows

```
obj = vtkIcicleView
```

40.7.2 Methods

The class vtkIcicleView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIcicleView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIcicleView = obj.NewInstance ()`
- `vtkIcicleView = obj.SafeDownCast (vtkObject o)`
- `obj.SetTopToBottom (bool value)` - Sets whether the stacks go from top to bottom or bottom to top.
- `bool = obj.GetTopToBottom ()` - Sets whether the stacks go from top to bottom or bottom to top.
- `obj.TopToBottomOn ()` - Sets whether the stacks go from top to bottom or bottom to top.
- `obj.TopToBottomOff ()` - Sets whether the stacks go from top to bottom or bottom to top.
- `obj.SetRootWidth (double width)` - Set the width of the root node
- `double = obj.GetRootWidth ()` - Set the width of the root node
- `obj.SetLayerThickness (double thickness)` - Set the thickness of each layer
- `double = obj.GetLayerThickness ()` - Set the thickness of each layer
- `obj.SetUseGradientColoring (bool value)` - Turn on/off gradient coloring.
- `bool = obj.GetUseGradientColoring ()` - Turn on/off gradient coloring.
- `obj.UseGradientColoringOn ()` - Turn on/off gradient coloring.
- `obj.UseGradientColoringOff ()` - Turn on/off gradient coloring.

40.8 vtkInteractorStyleAreaSelectHover

40.8.1 Usage

The vtkInteractorStyleAreaSelectHover specifically works with pipelines that create a hierarchical tree. Such pipelines will have a vtkAreaLayout filter which must be passed to this interactor style for it to function correctly. This interactor style allows only 2D panning and zooming, rubber band selection and provides a balloon containing the name of the vertex hovered over.

To create an instance of class vtkInteractorStyleAreaSelectHover, simply invoke its constructor as follows

```
obj = vtkInteractorStyleAreaSelectHover
```

40.8.2 Methods

The class vtkInteractorStyleAreaSelectHover has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleAreaSelectHover class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkInteractorStyleAreaSelectHover = obj.NewInstance ()`
- `vtkInteractorStyleAreaSelectHover = obj.SafeDownCast (vtkObject o)`
- `obj.SetLayout (vtkAreaLayout layout)` - Must be set to the vtkAreaLayout used to compute the bounds of each vertex.
- `vtkAreaLayout = obj.GetLayout ()` - Must be set to the vtkAreaLayout used to compute the bounds of each vertex.
- `obj.SetLabelField (string )` - The name of the field to use when displaying text in the hover balloon.
- `string = obj.GetLabelField ()` - The name of the field to use when displaying text in the hover balloon.
- `obj.SetUseRectangularCoordinates (bool )` - Determine whether or not to use rectangular coordinates instead of polar coordinates.
- `bool = obj.GetUseRectangularCoordinates ()` - Determine whether or not to use rectangular coordinates instead of polar coordinates.
- `obj.UseRectangularCoordinatesOn ()` - Determine whether or not to use rectangular coordinates instead of polar coordinates.
- `obj.UseRectangularCoordinatesOff ()` - Determine whether or not to use rectangular coordinates instead of polar coordinates.
- `obj.OnMouseMove ()` - Overridden from vtkInteractorStyleImage to provide the desired interaction behavior.
- `obj.SetInteractor (vtkRenderWindowInteractor rwi)` - Set the interactor that this interactor style works with.
- `obj.SetHighLightColor (double r, double g, double b)` - Set the color used to highlight the hovered vertex.
- `obj.SetHighLightWidth (double lw)` - The width of the line around the hovered vertex.
- `double = obj.GetHighLightWidth ()` - The width of the line around the hovered vertex.
- `vtkIdType = obj.GetIdAtPos (int x, int y)` - Obtain the tree vertex id at the position specified.

40.9 vtkInteractorStyleTreeMapHover

40.9.1 Usage

The vtkInteractorStyleTreeMapHover specifically works with pipelines that create a tree map. Such pipelines will have a vtkTreeMapLayout filter and a vtkTreeMapToPolyData filter, both of which must be passed to this interactor style for it to function correctly. This interactor style allows only 2D panning and zooming, and additionally provides a balloon containing the name of the vertex hovered over, and allows the user to highlight a vertex by clicking on it.

To create an instance of class vtkInteractorStyleTreeMapHover, simply invoke its constructor as follows

```
obj = vtkInteractorStyleTreeMapHover
```

40.9.2 Methods

The class vtkInteractorStyleTreeMapHover has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInteractorStyleTreeMapHover class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInteractorStyleTreeMapHover = obj.NewInstance ()`
- `vtkInteractorStyleTreeMapHover = obj.SafeDownCast (vtkObject o)`
- `obj.SetLayout (vtkTreeMapLayout layout)` - Must be set to the vtkTreeMapLayout used to compute the bounds of each vertex for the tree map.
- `vtkTreeMapLayout = obj.GetLayout ()` - Must be set to the vtkTreeMapLayout used to compute the bounds of each vertex for the tree map.
- `obj.SetTreeMapToPolyData (vtkTreeMapToPolyData filter)` - Must be set to the vtkTreeMapToPolyData used to convert the tree map into polydata.
- `vtkTreeMapToPolyData = obj.GetTreeMapToPolyData ()` - Must be set to the vtkTreeMapToPolyData used to convert the tree map into polydata.
- `obj.SetLabelField (string )` - The name of the field to use when displaying text in the hover balloon.
- `string = obj.GetLabelField ()` - The name of the field to use when displaying text in the hover balloon.
- `obj.OnMouseMove ()` - Overridden from vtkInteractorStyleImage to provide the desired interaction behavior.
- `obj.OnLeftButtonUp ()` - Overridden from vtkInteractorStyleImage to provide the desired interaction behavior.
- `obj.HighLightItem (vtkIdType id)` - Highlights a specific vertex.
- `obj.HighLightCurrentSelectedItem ()` - Highlights a specific vertex.
- `obj.SetInteractor (vtkRenderWindowInteractor rwi)`
- `obj.SetHighLightColor (double r, double g, double b)` - Set the color used to highlight the hovered vertex.
- `obj.SetSelectionLightColor (double r, double g, double b)` - Set the color used to highlight the selected vertex.
- `obj.SetHighLightWidth (double lw)` - The width of the line around the hovered vertex.
- `double = obj.GetHighLightWidth ()` - The width of the line around the hovered vertex.
- `obj.SetSelectionWidth (double lw)` - The width of the line around the selected vertex.
- `double = obj.GetSelectionWidth ()` - The width of the line around the selected vertex.

40.10 vtkParallelCoordinatesHistogramRepresentation

40.10.1 Usage

A parallel coordinates plot represents each variable in a multivariate data set as a separate axis. Individual samples of that data set are represented as a polyline that pass through each variable axis at positions that correspond to data values. This class can generate parallel coordinates plots identical to its superclass (vtkParallelCoordinatesRepresentation) and has the same interaction styles.

In addition to the standard parallel coordinates plot, this class also can draw a histogram summary of the parallel coordinates plot. Rather than draw every row in an input data set, first it computes a 2D histogram for all neighboring variable axes, then it draws bar (thickness corresponds to bin size) for each bin the histogram with opacity weighted by the number of rows contained in the bin. The result is essentially a density map.

Because this emphasizes dense regions over sparse outliers, this class also uses a vtkComputeHistogram2DOutliers instance to identify outlier table rows and draws those as standard parallel coordinates lines.

To create an instance of class vtkParallelCoordinatesHistogramRepresentation, simply invoke its constructor as follows

```
obj = vtkParallelCoordinatesHistogramRepresentation
```

40.10.2 Methods

The class vtkParallelCoordinatesHistogramRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelCoordinatesHistogramRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelCoordinatesHistogramRepresentation = obj.NewInstance ()`
- `vtkParallelCoordinatesHistogramRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply the theme to this view.
- `obj.SetUseHistograms (int )` - Whether to use the histogram rendering mode or the superclass's line rendering mode
- `int = obj.GetUseHistograms ()` - Whether to use the histogram rendering mode or the superclass's line rendering mode
- `obj.UseHistogramsOn ()` - Whether to use the histogram rendering mode or the superclass's line rendering mode
- `obj.UseHistogramsOff ()` - Whether to use the histogram rendering mode or the superclass's line rendering mode
- `obj.SetShowOutliers (int )` - Whether to compute and show outlier lines
- `int = obj.GetShowOutliers ()` - Whether to compute and show outlier lines
- `obj.ShowOutliersOn ()` - Whether to compute and show outlier lines
- `obj.ShowOutliersOff ()` - Whether to compute and show outlier lines
- `obj.SetHistogramLookupTableRange (double , double )` - Control over the range of the lookup table used to draw the histogram quads.

- `obj.SetHistogramLookupTableRange (double a[2])` - Control over the range of the lookup table used to draw the histogram quads.
- `double = obj. GetHistogramLookupTableRange ()` - Control over the range of the lookup table used to draw the histogram quads.
- `obj.SetPreferredNumberOfOutliers (int )` - Target maximum number of outliers to be drawn, although not guaranteed.
- `int = obj.GetPreferredNumberOfOutliers ()` - Target maximum number of outliers to be drawn, although not guaranteed.
- `int = obj.SwapAxisPositions (int position1, int position2)` - Calls superclass swap, and assures that only histograms affected by the swap get recomputed.
- `int = obj.SetRangeAtPosition (int position, double range[2])` - Calls the superclass method, and assures that only the two histograms affect by this call get recomputed.

40.11 vtkParallelCoordinatesRepresentation

40.11.1 Usage

A parallel coordinates plot represents each variable in a multivariate data set as a separate axis. Individual samples of that data set are represented as a polyline that pass through each variable axis at positions that correspond to data values. vtkParallelCoordinatesRepresentation generates this plot when added to a vtkParallelCoordinatesView, which handles interaction and highlighting. Sample polylines can alternatively be represented as s-curves by enabling the UseCurves flag.

There are three selection modes: lasso, angle, and function. Lasso selection picks sample lines that pass through a polyline. Angle selection picks sample lines that have similar slope to a line segment. Function selection picks sample lines that are near a linear function defined on two variables. This function specified by passing two (x,y) variable value pairs.

All primitives are plotted in normalized view coordinates [0,1].

To create an instance of class vtkParallelCoordinatesRepresentation, simply invoke its constructor as follows

```
obj = vtkParallelCoordinatesRepresentation
```

40.11.2 Methods

The class vtkParallelCoordinatesRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelCoordinatesRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelCoordinatesRepresentation = obj.NewInstance ()`
- `vtkParallelCoordinatesRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply the theme to this view. CellColor is used for line coloring and titles. EdgeLabelColor is used for axis color. CellOpacity is used for line opacity.
- `string = obj.GetHoverText (vtkView view, int x, int y)` - Returns the hover text at an x,y location.

- `int = obj.SetPositionAndSize (double position, double size)` - Change the position of the plot
- `int = obj.GetPositionAndSize (double position, double size)` - Change the position of the plot
- `obj.SetAxisTitles (vtkStringArray )` - Set/Get the axis titles
- `obj.SetAxisTitles (vtkAlgorithmOutput )` - Set/Get the axis titles
- `obj.SetPlotTitle (string )` - Set the title for the entire plot
- `int = obj.GetNumberOfAxes ()` - Get the number of axes in the plot
- `int = obj.GetNumberOfSamples ()`
- `obj.SetNumberOfAxisLabels (int num)` - Set/Get the number of labels to display on each axis
- `int = obj.GetNumberOfAxisLabels ()` - Set/Get the number of labels to display on each axis
- `int = obj.SwapAxisPositions (int position1, int position2)` - Move an axis to a particular screen position. Using these methods requires an Update() before they will work properly.
- `int = obj.SetXCoordinateOfPosition (int position, double xcoord)` - Move an axis to a particular screen position. Using these methods requires an Update() before they will work properly.
- `double = obj.GetXCoordinateOfPosition (int axis)` - Move an axis to a particular screen position. Using these methods requires an Update() before they will work properly.
- `obj.GetXCoordinatesOfPositions (double coords)` - Move an axis to a particular screen position. Using these methods requires an Update() before they will work properly.
- `int = obj.GetPositionNearXCoordinate (double xcoord)` - Move an axis to a particular screen position. Using these methods requires an Update() before they will work properly.
- `obj.SetUseCurves (int )` - Whether or not to display using curves
- `int = obj.GetUseCurves ()` - Whether or not to display using curves
- `obj.UseCurvesOn ()` - Whether or not to display using curves
- `obj.UseCurvesOff ()` - Whether or not to display using curves
- `obj.SetCurveResolution (int )` - Resolution of the curves displayed, enabled by setting UseCurves
- `int = obj.GetCurveResolution ()` - Resolution of the curves displayed, enabled by setting UseCurves
- `double = obj.GetLineOpacity ()` - Access plot properties
- `double = obj.GetFontSize ()` - Access plot properties
- `double = obj. GetLineColor ()` - Access plot properties
- `double = obj. GetAxisColor ()` - Access plot properties
- `double = obj. GetAxisLabelColor ()` - Access plot properties
- `obj.SetLineOpacity (double )` - Access plot properties
- `obj.SetFontSize (double )` - Access plot properties
- `obj.SetLineColor (double , double , double )` - Access plot properties

- `obj.SetLineColor (double  a[3])` - Access plot properties
- `obj.SetAxisColor (double , double , double )` - Access plot properties
- `obj.SetAxisColor (double  a[3])` - Access plot properties
- `obj.SetAxisLabelColor (double , double , double )` - Access plot properties
- `obj.SetAxisLabelColor (double  a[3])` - Access plot properties
- `obj.SetAngleBrushThreshold (double )` - Maximum angle difference (in degrees) of selection using angle/function brushes
- `double = obj.GetAngleBrushThreshold ()` - Maximum angle difference (in degrees) of selection using angle/function brushes
- `obj.SetFunctionBrushThreshold (double )` - Maximum angle difference (in degrees) of selection using angle/function brushes
- `double = obj.GetFunctionBrushThreshold ()` - Maximum angle difference (in degrees) of selection using angle/function brushes
- `int = obj.GetRangeAtPosition (int position, double range[2])` - Set/get the value range of the axis at a particular screen position
- `int = obj.SetRangeAtPosition (int position, double range[2])` - Set/get the value range of the axis at a particular screen position
- `obj.ResetAxes ()` - Reset the axes to their default positions and orders
- `obj.LassoSelect (int brushClass, int brushOperator, vtkPoints brushPoints)` - Do a selection of the lines. See the main description for how to use these functions. RangeSelect is currently stubbed out.
- `obj.AngleSelect (int brushClass, int brushOperator, double p1, double p2)` - Do a selection of the lines. See the main description for how to use these functions. RangeSelect is currently stubbed out.
- `obj.FunctionSelect (int brushClass, int brushOperator, double p1, double p2, double q1, double q2)` - Do a selection of the lines. See the main description for how to use these functions. RangeSelect is currently stubbed out.
- `obj.RangeSelect (int brushClass, int brushOperator, double p1, double p2)` - Do a selection of the lines. See the main description for how to use these functions. RangeSelect is currently stubbed out.

40.12 vtkParallelCoordinatesView

40.12.1 Usage

This class manages interaction with the vtkParallelCoordinatesRepresentation. There are two inspection modes: axis manipulation and line selection. In axis manipulation mode, PC axes can be dragged and reordered with the LMB, axis ranges can be increased/decreased by dragging up/down with the LMB, and RMB controls zoom and pan.

In line selection mode, there are three subclasses of selections: lasso, angle, and function selection. Lasso selection lets the user brush a line and select all PC lines that pass nearby. Angle selection lets the user draw a representative line between axes and select all lines that have similar orientation. Function selection lets the user draw two representative lines between a pair of axes and select all lines that match the linear interpolation of those lines.

There are several self-explanatory operators for combining selections: ADD, SUBTRACT REPLACE, and INTERSECT.

To create an instance of class vtkParallelCoordinatesView, simply invoke its constructor as follows

```
obj = vtkParallelCoordinatesView
```

40.12.2 Methods

The class vtkParallelCoordinatesView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelCoordinatesView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelCoordinatesView = obj.NewInstance ()`
- `vtkParallelCoordinatesView = obj.SafeDownCast (vtkObject o)`
- `obj.SetBrushMode (int )`
- `obj.SetBrushModeToLasso ()`
- `obj.SetBrushModeToAngle ()`
- `obj.SetBrushModeToFunction ()`
- `obj.SetBrushModeToAxisThreshold ()`
- `int = obj.GetBrushMode ()`
- `obj.SetBrushOperator (int )`
- `obj.SetBrushOperatorToAdd ()`
- `obj.SetBrushOperatorToSubtract ()`
- `obj.SetBrushOperatorToIntersect ()`
- `obj.SetBrushOperatorToReplace ()`
- `int = obj.GetBrushOperator ()`
- `obj.SetInspectMode (int )`
- `obj.SetInspectModeToManipulateAxes ()`
- `obj.SetInpsectModeToSelectData ()`
- `int = obj.GetInspectMode ()`
- `obj.SetMaximumNumberOfBrushPoints (int )`
- `int = obj.GetMaximumNumberOfBrushPoints ()`
- `obj.SetCurrentBrushClass (int )`
- `int = obj.GetCurrentBrushClass ()`
- `obj.ApplyViewTheme (vtkViewTheme theme)`

40.13 vtkRenderedGraphRepresentation

40.13.1 Usage

To create an instance of class vtkRenderedGraphRepresentation, simply invoke its constructor as follows

```
obj = vtkRenderedGraphRepresentation
```

40.13.2 Methods

The class vtkRenderedGraphRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderedGraphRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderedGraphRepresentation = obj.NewInstance ()`
- `vtkRenderedGraphRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.SetVertexLabelArrayName (string name)`
- `string = obj.GetVertexLabelArrayName ()`
- `obj.SetVertexLabelPriorityArrayName (string name)`
- `string = obj.GetVertexLabelPriorityArrayName ()`
- `obj.SetVertexLabelVisibility (bool b)`
- `bool = obj.GetVertexLabelVisibility ()`
- `obj.VertexLabelVisibilityOn ()`
- `obj.VertexLabelVisibilityOff ()`
- `obj.SetVertexLabelTextProperty (vtkTextProperty p)`
- `vtkTextProperty = obj.GetVertexLabelTextProperty ()`
- `obj.SetVertexHoverArrayName (string )`
- `string = obj.GetVertexHoverArrayName ()`
- `obj.SetHideVertexLabelsOnInteraction (bool )` - Whether to hide the display of vertex labels during mouse interaction. Default is off.
- `bool = obj.GetHideVertexLabelsOnInteraction ()` - Whether to hide the display of vertex labels during mouse interaction. Default is off.
- `obj.HideVertexLabelsOnInteractionOn ()` - Whether to hide the display of vertex labels during mouse interaction. Default is off.
- `obj.HideVertexLabelsOnInteractionOff ()` - Whether to hide the display of vertex labels during mouse interaction. Default is off.
- `obj.SetEdgeLabelArrayName (string name)`
- `string = obj.GetEdgeLabelArrayName ()`

- obj.SetEdgeLabelPriorityArrayName (string name)
- string = obj.GetEdgeLabelPriorityArrayName ()
- obj.SetEdgeLabelVisibility (bool b)
- bool = obj.GetEdgeLabelVisibility ()
- obj.EdgeLabelVisibilityOn ()
- obj.EdgeLabelVisibilityOff ()
- obj.SetEdgeLabelTextProperty (vtkTextProperty p)
- vtkTextProperty = obj.GetEdgeLabelTextProperty ()
- obj.SetEdgeHoverArrayName (string)
- string = obj.GetEdgeHoverArrayName ()
- obj.SetHideEdgeLabelsOnInteraction (bool) - Whether to hide the display of edge labels during mouse interaction. Default is off.
- bool = obj.GetHideEdgeLabelsOnInteraction () - Whether to hide the display of edge labels during mouse interaction. Default is off.
- obj.HideEdgeLabelsOnInteractionOn () - Whether to hide the display of edge labels during mouse interaction. Default is off.
- obj.HideEdgeLabelsOnInteractionOff () - Whether to hide the display of edge labels during mouse interaction. Default is off.
- obj.SetVertexIconArrayName (string name)
- string = obj.GetVertexIconArrayName ()
- obj.SetVertexIconPriorityArrayName (string name)
- string = obj.GetVertexIconPriorityArrayName ()
- obj.SetVertexIconVisibility (bool b)
- bool = obj.GetVertexIconVisibility ()
- obj.VertexIconVisibilityOn ()
- obj.VertexIconVisibilityOff ()
- obj.AddVertexIconType (string name, int type)
- obj.ClearVertexIconTypes ()
- obj.SetUseVertexIconTypeMap (bool b)
- bool = obj.GetUseVertexIconTypeMap ()
- obj.UseVertexIconTypeMapOn ()
- obj.UseVertexIconTypeMapOff ()
- obj.SetVertexIconAlignment (int align)
- int = obj.GetVertexIconAlignment ()
- obj.SetVertexSelectedIcon (int icon)

- `int = obj.GetVertexSelectedIcon ()`
- `obj.SetVertexIconSelectionMode (int mode)` - Set the mode to one of ¡ul¿ ¡li¿vtkApplyIcons::SELECTED_ICON - use VertexSelectedIcon ¡li¿vtkApplyIcons::SELECTED_OFFSET - use VertexSelectedIcon as offset ¡li¿vtkApplyIcons::ANNOTATION_ICON - use current annotation icon ¡li¿vtkApplyIcons::IGNORE_SELECTION - ignore selected elements ¡/ul¿ The default is IGNORE_SELECTION.
- `int = obj.GetVertexIconSelectionMode ()` - Set the mode to one of ¡ul¿ ¡li¿vtkApplyIcons::SELECTED_ICON - use VertexSelectedIcon ¡li¿vtkApplyIcons::SELECTED_OFFSET - use VertexSelectedIcon as offset ¡li¿vtkApplyIcons::ANNOTATION_ICON - use current annotation icon ¡li¿vtkApplyIcons::IGNORE_SELECTION - ignore selected elements ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetVertexIconSelectionModeToSelectedIcon ()` - Set the mode to one of ¡ul¿ ¡li¿vtkApplyIcons::SELECTED_IC - use VertexSelectedIcon ¡li¿vtkApplyIcons::SELECTED_OFFSET - use VertexSelectedIcon as offset ¡li¿vtkApplyIcons::ANNOTATION_ICON - use current annotation icon ¡li¿vtkApplyIcons::IGNORE_SELECTION - ignore selected elements ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetVertexIconSelectionModeToSelectedOffset ()` - Set the mode to one of ¡ul¿ ¡li¿vtkApplyIcons::SELECTED - use VertexSelectedIcon ¡li¿vtkApplyIcons::SELECTED_OFFSET - use VertexSelectedIcon as offset ¡li¿vtkApplyIcons::ANNOTATION_ICON - use current annotation icon ¡li¿vtkApplyIcons::IGNORE_SELECTION - ignore selected elements ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetVertexIconSelectionModeToAnnotationIcon ()` - Set the mode to one of ¡ul¿ ¡li¿vtkApplyIcons::SELECTED - use VertexSelectedIcon ¡li¿vtkApplyIcons::SELECTED_OFFSET - use VertexSelectedIcon as offset ¡li¿vtkApplyIcons::ANNOTATION_ICON - use current annotation icon ¡li¿vtkApplyIcons::IGNORE_SELECTION - ignore selected elements ¡/ul¿ The default is IGNORE_SELECTION.
- `obj.SetVertexIconSelectionModeToIgnoreSelection ()`
- `obj.SetEdgeIconArrayName (string name)`
- `string = obj.GetEdgeIconArrayName ()`
- `obj.SetEdgeIconPriorityArrayName (string name)`
- `string = obj.GetEdgeIconPriorityArrayName ()`
- `obj.SetEdgeIconVisibility (bool b)`
- `bool = obj.GetEdgeIconVisibility ()`
- `obj.EdgeIconVisibilityOn ()`
- `obj.EdgeIconVisibilityOff ()`
- `obj.AddEdgeIconType (string name, int type)`
- `obj.ClearEdgeIconTypes ()`
- `obj.SetUseEdgeIconTypeMap (bool b)`
- `bool = obj.GetUseEdgeIconTypeMap ()`
- `obj.UseEdgeIconTypeMapOn ()`
- `obj.UseEdgeIconTypeMapOff ()`
- `obj.SetEdgeIconAlignment (int align)`
- `int = obj.GetEdgeIconAlignment ()`
- `obj.SetColorVerticesByArray (bool b)`

- `bool = obj.GetColorVerticesByArray ()`
- `obj.ColorVerticesByArrayOn ()`
- `obj.ColorVerticesByArrayOff ()`
- `obj.SetVertexColorArrayName (string name)`
- `string = obj.GetVertexColorArrayName ()`
- `obj.SetColorEdgesByArray (bool b)`
- `bool = obj.GetColorEdgesByArray ()`
- `obj.ColorEdgesByArrayOn ()`
- `obj.ColorEdgesByArrayOff ()`
- `obj.SetEdgeColorArrayName (string name)`
- `string = obj.GetEdgeColorArrayName ()`
- `obj.SetEnableVerticesByArray (bool b)`
- `bool = obj.GetEnableVerticesByArray ()`
- `obj.EnableVerticesByArrayOn ()`
- `obj.EnableVerticesByArrayOff ()`
- `obj.SetEnabledVerticesArrayName (string name)`
- `string = obj.GetEnabledVerticesArrayName ()`
- `obj.SetEnableEdgesByArray (bool b)`
- `bool = obj.GetEnableEdgesByArray ()`
- `obj.EnableEdgesByArrayOn ()`
- `obj.EnableEdgesByArrayOff ()`
- `obj.SetEnabledEdgesArrayName (string name)`
- `string = obj.GetEnabledEdgesArrayName ()`
- `obj.SetEdgeVisibility (bool b)`
- `bool = obj.GetEdgeVisibility ()`
- `obj.EdgeVisibilityOn ()`
- `obj.EdgeVisibilityOff ()`
- `obj.SetLayoutStrategy (vtkGraphLayoutStrategy strategy)` - Set/get the graph layout strategy.
- `vtkGraphLayoutStrategy = obj.GetLayoutStrategy ()` - Set/get the graph layout strategy.
- `obj.SetLayoutStrategy (string name)` - Get/set the layout strategy by name.
- `string = obj.GetLayoutStrategyName ()` - Get/set the layout strategy by name.
- `obj.SetLayoutStrategyToRandom ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToForceDirected ()` - Set predefined layout strategies.

- `obj.SetLayoutStrategyToSimple2D ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToClustering2D ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToCommunity2D ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToFast2D ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToPassThrough ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToCircular ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToTree ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToCosmicTree ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToCone ()` - Set predefined layout strategies.
- `obj.SetLayoutStrategyToSpanTree ()` - Set the layout strategy to use coordinates from arrays. The x array must be specified. The y and z arrays are optional.
- `obj.SetLayoutStrategyToAssignCoordinates (string xarr, string yarr, string zarr)` - Set the layout strategy to use coordinates from arrays. The x array must be specified. The y and z arrays are optional.
- `obj.SetLayoutStrategyToTree (bool radial, double angle, double leafSpacing, double logSpacing)` - Set the layout strategy to a tree layout. Radial indicates whether to do a radial or standard top-down tree layout. The angle parameter is the angular distance spanned by the tree. Leaf spacing is a value from 0 to 1 indicating how much of the radial layout should be allocated to leaf nodes (as opposed to between tree branches). The log spacing value is a non-negative value where ¿ 1 will create expanding levels, ¡ 1 will create contracting levels, and = 1 makes all levels the same size. See vtkTreeLayoutStrategy for more information.
- `obj.SetLayoutStrategyToCosmicTree (string nodeSizeArrayName, bool sizeLeafNodesOnlytrue, int layout` - Set the layout strategy to a cosmic tree layout. nodeSizeArrayName is the array used to size the circles (default is NULL, which makes leaf nodes the same size). sizeLeafNodesOnly only uses the leaf node sizes, and computes the parent size as the sum of the child sizes (default true). layoutDepth stops layout at a certain depth (default is 0, which does the entire tree). layoutRoot is the vertex that will be considered the root node of the layout (default is -1, which will use the tree's root). See vtkCosmicTreeLayoutStrategy for more information.
- `obj.SetEdgeLayoutStrategy (vtkEdgeLayoutStrategy strategy)` - Set/get the graph layout strategy.
- `vtkEdgeLayoutStrategy = obj.GetEdgeLayoutStrategy ()` - Set/get the graph layout strategy.
- `obj.SetEdgeLayoutStrategyToArcParallel ()` - Set/get the graph layout strategy.
- `obj.SetEdgeLayoutStrategyToPassThrough ()` - Set the edge layout strategy to a geospatial arced strategy appropriate for vtkGeoView.
- `obj.SetEdgeLayoutStrategyToGeo (double explodeFactor)` - Set the edge layout strategy to a geospatial arced strategy appropriate for vtkGeoView.
- `obj.SetEdgeLayoutStrategy (string name)` - Set the edge layout strategy by name.
- `string = obj.GetEdgeLayoutStrategyName ()` - Set the edge layout strategy by name.
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply a theme to this representation.
- `obj.SetGlyphType (int type)` - Set the graph vertex glyph type.

- `int = obj.GetGlyphType ()` - Set the graph vertex glyph type.
- `obj.SetScaling (bool b)` - Set whether to scale vertex glyphs.
- `bool = obj.GetScaling ()` - Set whether to scale vertex glyphs.
- `obj.ScalingOn ()` - Set whether to scale vertex glyphs.
- `obj.ScalingOff ()` - Set whether to scale vertex glyphs.
- `obj.SetScalingArrayName (string name)` - Set the glyph scaling array name.
- `string = obj.GetScalingArrayName ()` - Set the glyph scaling array name.
- `obj.SetVertexScalarBarVisibility (bool b)` - Vertex/edge scalar bar visibility.
- `bool = obj.GetVertexScalarBarVisibility ()` - Vertex/edge scalar bar visibility.
- `obj.SetEdgeScalarBarVisibility (bool b)` - Vertex/edge scalar bar visibility.
- `bool = obj.GetEdgeScalarBarVisibility ()` - Vertex/edge scalar bar visibility.
- `bool = obj.IsLayoutComplete ()` - Whether the current graph layout is complete.
- `obj.UpdateLayout ()` - Performs another iteration on the graph layout.
- `obj.ComputeSelectedGraphBounds (double bounds[6])` - Compute the bounding box of the selected subgraph.

40.14 vtkRenderedHierarchyRepresentation

40.14.1 Usage

To create an instance of class vtkRenderedHierarchyRepresentation, simply invoke its constructor as follows

```
obj = vtkRenderedHierarchyRepresentation
```

40.14.2 Methods

The class vtkRenderedHierarchyRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderedHierarchyRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderedHierarchyRepresentation = obj.NewInstance ()`
- `vtkRenderedHierarchyRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraphEdgeLabelArrayName (string name)` -
- `obj.SetGraphEdgeLabelArrayName (string name, int idx)` -
- `string = obj.GetGraphEdgeLabelArrayName ()` -
- `string = obj.GetGraphEdgeLabelArrayName (int idx)` -
- `obj.SetGraphEdgeLabelVisibility (bool vis)`

- obj.SetGraphEdgeLabelVisibility (bool vis, int idx)
- bool = obj.GetGraphEdgeLabelVisibility ()
- bool = obj.GetGraphEdgeLabelVisibility (int idx)
- obj.GraphEdgeLabelVisibilityOn ()
- obj.GraphEdgeLabelVisibilityOff ()
- obj.SetGraphEdgeColorArrayName (string name)
- obj.SetGraphEdgeColorArrayName (string name, int idx)
- string = obj.GetGraphEdgeColorArrayName ()
- string = obj.GetGraphEdgeColorArrayName (int idx)
- obj.SetColorGraphEdgesByArray (bool vis)
- obj.SetColorGraphEdgesByArray (bool vis, int idx)
- bool = obj.GetColorGraphEdgesByArray ()
- bool = obj.GetColorGraphEdgesByArray (int idx)
- obj.ColorGraphEdgesByArrayOn ()
- obj.ColorGraphEdgesByArrayOff ()
- obj.SetGraphEdgeColorToSplineFraction ()
- obj.SetGraphEdgeColorToSplineFraction (int idx)
- obj.SetGraphVisibility (bool vis)
- obj.SetGraphVisibility (bool vis, int idx)
- bool = obj.GetGraphVisibility ()
- bool = obj.GetGraphVisibility (int idx)
- obj.GraphVisibilityOn ()
- obj.GraphVisibilityOff ()
- obj.SetBundlingStrength (double strength)
- obj.SetBundlingStrength (double strength, int idx)
- double = obj.GetBundlingStrength ()
- double = obj.GetBundlingStrength (int idx)
- obj.SetGraphEdgeLabelFontSize (int size)
- obj.SetGraphEdgeLabelFontSize (int size, int idx)
- int = obj.GetGraphEdgeLabelFontSize ()
- int = obj.GetGraphEdgeLabelFontSize (int idx)

40.15 vtkRenderedRepresentation

40.15.1 Usage

To create an instance of class vtkRenderedRepresentation, simply invoke its constructor as follows

```
obj = vtkRenderedRepresentation
```

40.15.2 Methods

The class vtkRenderedRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderedRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderedRepresentation = obj.NewInstance ()`
- `vtkRenderedRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.SetLabelRenderMode (int )` - Set the label render mode. vtkRenderView::QT - Use Qt-based labeler with fitted labeling and unicode support. Requires VTK_USE_QT to be on. vtkRenderView::FREETYPE - Use standard freetype text rendering.
- `int = obj.GetLabelRenderMode ()` - Set the label render mode. vtkRenderView::QT - Use Qt-based labeler with fitted labeling and unicode support. Requires VTK_USE_QT to be on. vtkRenderView::FREETYPE - Use standard freetype text rendering.

40.16 vtkRenderedSurfaceRepresentation

40.16.1 Usage

vtkRenderedSurfaceRepresentation is used to show a geometric dataset in a view. The representation uses a vtkGeometryFilter to convert the dataset to polygonal data (e.g. volumetric data is converted to its external surface). The representation may then be added to vtkRenderView.

To create an instance of class vtkRenderedSurfaceRepresentation, simply invoke its constructor as follows

```
obj = vtkRenderedSurfaceRepresentation
```

40.16.2 Methods

The class vtkRenderedSurfaceRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderedSurfaceRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderedSurfaceRepresentation = obj.NewInstance ()`
- `vtkRenderedSurfaceRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.SetCellColorArrayName (string arrayName)`
- `string = obj.GetCellColorArrayName ()` - Apply a theme to this representation.
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply a theme to this representation.

40.17 vtkRenderedTreeAreaRepresentation

40.17.1 Usage

To create an instance of class vtkRenderedTreeAreaRepresentation, simply invoke its constructor as follows

```
obj = vtkRenderedTreeAreaRepresentation
```

40.17.2 Methods

The class vtkRenderedTreeAreaRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderedTreeAreaRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderedTreeAreaRepresentation = obj.NewInstance ()`
- `vtkRenderedTreeAreaRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.SetLabelRenderMode (int mode)` - Set the label render mode. QT - Use vtkQtTreeRingLabeler with fitted labeling and unicode support. Requires VTK_USE_QT to be on. FREETYPE - Use standard freetype text rendering.
- `obj.SetAreaLabelArrayName (string name)` - The array to use for area labeling. Default is "label".
- `string = obj.GetAreaLabelArrayName ()` - The array to use for area labeling. Default is "label".
- `obj.SetAreaSizeArrayName (string name)` - The array to use for area sizes. Default is "size".
- `string = obj.GetAreaSizeArrayName ()` - The array to use for area sizes. Default is "size".
- `obj.SetAreaLabelPriorityArrayName (string name)` - The array to use for area labeling priority. Default is "GraphVertexDegree".
- `string = obj.GetAreaLabelPriorityArrayName ()` - The array to use for area labeling priority. Default is "GraphVertexDegree".
- `obj.SetGraphEdgeLabelArrayName (string name)` - The array to use for edge labeling. Default is "label".
- `obj.SetGraphEdgeLabelArrayName (string name, int idx)` - The array to use for edge labeling. Default is "label".
- `string = obj.GetGraphEdgeLabelArrayName ()` - The array to use for edge labeling. Default is "label".
- `string = obj.GetGraphEdgeLabelArrayName (int idx)` - The array to use for edge labeling. Default is "label".
- `obj.SetGraphEdgeLabelTextProperty (vtkTextProperty tp)` - The text property for the graph edge labels.
- `obj.SetGraphEdgeLabelTextProperty (vtkTextProperty tp, int idx)` - The text property for the graph edge labels.
- `vtkTextProperty = obj.GetGraphEdgeLabelTextProperty ()` - The text property for the graph edge labels.

- `vtkTextProperty = obj.GetGraphEdgeLabelTextProperty (int idx)` - The text property for the graph edge labels.
- `obj.SetAreaHoverArrayName (string )` - The name of the array whose value appears when the mouse hovers over a rectangle in the treemap.
- `string = obj.GetAreaHoverArrayName ()` - The name of the array whose value appears when the mouse hovers over a rectangle in the treemap.
- `obj.SetAreaLabelVisibility (bool vis)` - Whether to show area labels. Default is off.
- `bool = obj.GetAreaLabelVisibility ()` - Whether to show area labels. Default is off.
- `obj.AreaLabelVisibilityOn ()` - Whether to show area labels. Default is off.
- `obj.AreaLabelVisibilityOff ()` - Whether to show area labels. Default is off.
- `obj.SetAreaLabelTextProperty (vtkTextProperty tp)` - The text property for the area labels.
- `vtkTextProperty = obj.GetAreaLabelTextProperty ()` - The text property for the area labels.
- `obj.SetGraphEdgeLabelVisibility (bool vis)` - Whether to show edge labels. Default is off.
- `obj.SetGraphEdgeLabelVisibility (bool vis, int idx)` - Whether to show edge labels. Default is off.
- `bool = obj.GetGraphEdgeLabelVisibility ()` - Whether to show edge labels. Default is off.
- `bool = obj.GetGraphEdgeLabelVisibility (int idx)` - Whether to show edge labels. Default is off.
- `obj.GraphEdgeLabelVisibilityOn ()` - Whether to show edge labels. Default is off.
- `obj.GraphEdgeLabelVisibilityOff ()` - Whether to show edge labels. Default is off.
- `obj.SetAreaColorArrayName (string name)` - The array to use for coloring vertices. Default is "color".
- `string = obj.GetAreaColorArrayName ()` - The array to use for coloring vertices. Default is "color".
- `obj.SetColorAreasByArray (bool vis)` - Whether to color vertices. Default is off.
- `bool = obj.GetColorAreasByArray ()` - Whether to color vertices. Default is off.
- `obj.ColorAreasByArrayOn ()` - Whether to color vertices. Default is off.
- `obj.ColorAreasByArrayOff ()` - Whether to color vertices. Default is off.
- `obj.SetGraphEdgeColorArrayName (string name)` - The array to use for coloring edges. Default is "color".
- `obj.SetGraphEdgeColorArrayName (string name, int idx)` - The array to use for coloring edges. Default is "color".
- `string = obj.GetGraphEdgeColorArrayName ()` - The array to use for coloring edges. Default is "color".
- `string = obj.GetGraphEdgeColorArrayName (int idx)` - The array to use for coloring edges. Default is "color".
- `obj.SetGraphEdgeColorToSplineFraction ()` - Set the color to be the spline fraction
- `obj.SetGraphEdgeColorToSplineFraction (int idx)` - Set the color to be the spline fraction

- `obj.SetColorGraphEdgesByArray (bool vis)` - Whether to color edges. Default is off.
- `obj.SetColorGraphEdgesByArray (bool vis, int idx)` - Whether to color edges. Default is off.
- `bool = obj.GetColorGraphEdgesByArray ()` - Whether to color edges. Default is off.
- `bool = obj.GetColorGraphEdgesByArray (int idx)` - Whether to color edges. Default is off.
- `obj.ColorGraphEdgesByArrayOn ()` - Whether to color edges. Default is off.
- `obj.ColorGraphEdgesByArrayOff ()` - Whether to color edges. Default is off.
- `obj.SetGraphHoverArrayName (string name)` - The name of the array whose value appears when the mouse hovers over a graph edge.
- `obj.SetGraphHoverArrayName (string name, int idx)` - The name of the array whose value appears when the mouse hovers over a graph edge.
- `string = obj.GetGraphHoverArrayName ()` - The name of the array whose value appears when the mouse hovers over a graph edge.
- `string = obj.GetGraphHoverArrayName (int idx)` - The name of the array whose value appears when the mouse hovers over a graph edge.
- `obj.SetShrinkPercentage (double value)` - Set the region shrink percentage between 0.0 and 1.0.
- `double = obj.GetShrinkPercentage ()` - Set the region shrink percentage between 0.0 and 1.0.
- `obj.SetGraphBundlingStrength (double strength)` - Set the bundling strength.
- `obj.SetGraphBundlingStrength (double strength, int idx)` - Set the bundling strength.
- `double = obj.GetGraphBundlingStrength ()` - Set the bundling strength.
- `double = obj.GetGraphBundlingStrength (int idx)` - Set the bundling strength.
- `obj.SetGraphSplineType (int type, int idx)` - Sets the spline type for the graph edges. vtkSplineGraphEdges::CUSTOM uses a vtkCardinalSpline. vtkSplineGraphEdges::BSPLINE uses a b-spline. The default is CUSTOM.
- `int = obj.GetGraphSplineType (int idx)` - Sets the spline type for the graph edges. vtkSplineGraphEdges::CUSTOM uses a vtkCardinalSpline. vtkSplineGraphEdges::BSPLINE uses a b-spline. The default is CUSTOM.
- `obj.SetAreaLayoutStrategy (vtkAreaLayoutStrategy strategy)` - The layout strategy for producing spatial regions for the tree.
- `vtkAreaLayoutStrategy = obj.GetAreaLayoutStrategy ()` - The layout strategy for producing spatial regions for the tree.
- `obj.SetAreaToPolyData (vtkPolyDataAlgorithm areaToPoly)` - The filter for converting areas to polydata. This may e.g. be vtkTreeMapToPolyData or vtkTreeRingToPolyData. The filter must take a vtkTree as input and produce vtkPolyData.
- `vtkPolyDataAlgorithm = obj.GetAreaToPolyData ()` - The filter for converting areas to polydata. This may e.g. be vtkTreeMapToPolyData or vtkTreeRingToPolyData. The filter must take a vtkTree as input and produce vtkPolyData.
- `obj.SetUseRectangularCoordinates (bool )` - Whether the area represents radial or rectangular coordinates.

- `bool = obj.GetUseRectangularCoordinates ()` - Whether the area represents radial or rectangular coordinates.
- `obj.UseRectangularCoordinatesOn ()` - Whether the area represents radial or rectangular coordinates.
- `obj.UseRectangularCoordinatesOff ()` - Whether the area represents radial or rectangular coordinates.
- `obj.SetAreaLabelMapper (vtkLabeledDataMapper mapper)` - The mapper for rendering labels on areas. This may e.g. be vtkDynamic2DLabelMapper or vtkTreeMapLabelMapper.
- `vtkLabeledDataMapper = obj.GetAreaLabelMapper ()` - The mapper for rendering labels on areas. This may e.g. be vtkDynamic2DLabelMapper or vtkTreeMapLabelMapper.
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Apply the theme to this view.
- `obj.SetEdgeScalarBarVisibility (bool b)` - Visibility of scalar bar actor for edges.
- `bool = obj.GetEdgeScalarBarVisibility ()` - Visibility of scalar bar actor for edges.

40.18 vtkRenderView

40.18.1 Usage

vtkRenderView is a view which contains a vtkRenderer. You may add vtkActors directly to the renderer, or add certain vtkDataRepresentation subclasses to the renderer. The render view supports drag selection with the mouse to select cells.

This class is also the parent class for any more specialized view which uses a renderer.

To create an instance of class vtkRenderView, simply invoke its constructor as follows

```
obj = vtkRenderView
```

40.18.2 Methods

The class vtkRenderView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRenderView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRenderView = obj.NewInstance ()`
- `vtkRenderView = obj.SafeDownCast (vtkObject o)`
- `vtkRenderer = obj.GetRenderer ()` - Gets the renderer for this view.
- `vtkRenderWindow = obj.GetRenderWindow ()` - Get a handle to the render window.
- `vtkRenderWindowInteractor = obj.GetInteractor ()` - The render window interactor.
- `obj.SetInteractor (vtkRenderWindowInteractor interactor)` - The render window interactor.
- `obj.SetInteractorStyle (vtkInteractorObserver style)` - The interactor style associated with the render view.
- `vtkInteractorObserver = obj.GetInteractorStyle ()` - The interactor style associated with the render view.

- `obj.SetInteractionMode (int mode)` - Set the interaction mode for the view. Choices are: vtkRenderView::INTERACTION_MODE_2D - 2D interactor vtkRenderView::INTERACTION_MODE_3D - 3D interactor
- `int = obj.GetInteractionMode ()` - Set the interaction mode for the view. Choices are: vtkRenderView::INTERACTION_MODE_2D - 2D interactor vtkRenderView::INTERACTION_MODE_3D - 3D interactor
- `obj.SetInteractionModeTo2D ()` - Set the interaction mode for the view. Choices are: vtkRenderView::INTERACTION_MODE_2D - 2D interactor vtkRenderView::INTERACTION_MODE_3D - 3D interactor
- `obj.SetInteractionModeTo3D ()` - Applies a view theme to this view.
- `obj.ApplyViewTheme (vtkViewTheme theme)` - Applies a view theme to this view.
- `obj.SetTransform (vtkAbstractTransform transform)` - Set the view's transform. All vtkRenderedRepresentations added to this view should use this transform.
- `vtkAbstractTransform = obj.GetTransform ()` - Set the view's transform. All vtkRenderedRepresentations added to this view should use this transform.
- `obj.SetDisplayHoverText (bool b)` - Whether the view should display hover text.
- `bool = obj.GetDisplayHoverText ()` - Whether the view should display hover text.
- `obj.DisplayHoverTextOn ()` - Whether the view should display hover text.
- `obj.DisplayHoverTextOff ()` - Whether the view should display hover text.
- `obj.SetSelectionMode (int )` - Sets the selection mode for the render view. SURFACE selection uses vtkHardwareSelector to perform a selection of visible cells. FRUSTUM selection just creates a view frustum selection, which will select everything in the frustum.
- `int = obj.GetSelectionModeMinValue ()` - Sets the selection mode for the render view. SURFACE selection uses vtkHardwareSelector to perform a selection of visible cells. FRUSTUM selection just creates a view frustum selection, which will select everything in the frustum.
- `int = obj.GetSelectionModeMaxValue ()` - Sets the selection mode for the render view. SURFACE selection uses vtkHardwareSelector to perform a selection of visible cells. FRUSTUM selection just creates a view frustum selection, which will select everything in the frustum.
- `int = obj.GetSelectionMode ()` - Sets the selection mode for the render view. SURFACE selection uses vtkHardwareSelector to perform a selection of visible cells. FRUSTUM selection just creates a view frustum selection, which will select everything in the frustum.
- `obj.SetSelectionModeToSurface ()` - Sets the selection mode for the render view. SURFACE selection uses vtkHardwareSelector to perform a selection of visible cells. FRUSTUM selection just creates a view frustum selection, which will select everything in the frustum.
- `obj.SetSelectionModeToFrustum ()` - Updates the representations, then calls Render() on the render window associated with this view.
- `obj.Render ()` - Updates the representations, then calls Render() on the render window associated with this view.
- `obj.ResetCamera ()` - Updates the representations, then calls ResetCamera() on the renderer associated with this view.
- `obj.ResetCameraClippingRange ()` - Updates the representations, then calls ResetCameraClippingRange() on the renderer associated with this view.

- `obj.AddLabels (vtkAlgorithmOutput conn)` - Add labels from an input connection with an associated text property. The output must be a vtkLabelHierarchy (normally the output of vtkPointSetToLabelHierarchy).
- `obj.RemoveLabels (vtkAlgorithmOutput conn)` - Remove labels from an input connection.
- `obj.SetIconTexture (vtkTexture texture)` - Set the icon sheet to use for rendering icons.
- `vtkTexture = obj.GetIconTexture ()` - Set the icon sheet to use for rendering icons.
- `obj.SetIconSize (int , int )` - Set the size of each icon in the icon texture.
- `obj.SetIconSize (int  a[2])` - Set the size of each icon in the icon texture.
- `int = obj. GetIconSize ()` - Set the size of each icon in the icon texture.
- `obj.SetLabelPlacementMode (int mode)` - Label placement mode. NO_OVERLAP uses vtkLabelPlacementMapper, which has a faster startup time and works with 2D or 3D labels. ALL displays all labels (Warning: This may cause incredibly slow render times on datasets with more than a few hundred labels).
- `int = obj.GetLabelPlacementMode ()` - Label placement mode. NO_OVERLAP uses vtkLabelPlacementMapper, which has a faster startup time and works with 2D or 3D labels. ALL displays all labels (Warning: This may cause incredibly slow render times on datasets with more than a few hundred labels).
- `obj.SetLabelPlacementModeToNoOverlap ()` - Label placement mode. NO_OVERLAP uses vtkLabelPlacementMapper, which has a faster startup time and works with 2D or 3D labels. ALL displays all labels (Warning: This may cause incredibly slow render times on datasets with more than a few hundred labels).
- `obj.SetLabelPlacementModeToAll ()` - Label render mode. FREETYPE uses the freetype label rendering. QT uses more advanced Qt-based label rendering.
- `obj.SetLabelRenderMode (int mode)` - Label render mode. FREETYPE uses the freetype label rendering. QT uses more advanced Qt-based label rendering.
- `int = obj.GetLabelRenderMode ()` - Label render mode. FREETYPE uses the freetype label rendering. QT uses more advanced Qt-based label rendering.
- `obj.SetLabelRenderModeToFreetype ()` - Label render mode. FREETYPE uses the freetype label rendering. QT uses more advanced Qt-based label rendering.
- `obj.SetLabelRenderModeToQt ()`

40.19 vtkTreeAreaView

40.19.1 Usage

Takes a graph and a hierarchy (currently a tree) and lays out the graph vertices based on their categorization within the hierarchy.

.SEE ALSO vtkGraphLayoutView

.SECTION Thanks Thanks to Jason Shepherd for implementing this class

To create an instance of class vtkTreeAreaView, simply invoke its constructor as follows

```
obj = vtkTreeAreaView
```

40.19.2 Methods

The class vtkTreeAreaView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeAreaView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeAreaView = obj.NewInstance ()`
- `vtkTreeAreaView = obj.SafeDownCast (vtkObject o)`
- `vtkDataRepresentation = obj.SetTreeFromInputConnection (vtkAlgorithmOutput conn)` - Set the tree and graph representations to the appropriate input ports.
- `vtkDataRepresentation = obj.SetTreeFromInput (vtkTree input)` - Set the tree and graph representations to the appropriate input ports.
- `vtkDataRepresentation = obj.SetGraphFromInputConnection (vtkAlgorithmOutput conn)` - Set the tree and graph representations to the appropriate input ports.
- `vtkDataRepresentation = obj.SetGraphFromInput (vtkGraph input)` - Set the tree and graph representations to the appropriate input ports.
- `obj.SetAreaLabelArrayName (string name)` - The array to use for area labeling. Default is "label".
- `string = obj.GetAreaLabelArrayName ()` - The array to use for area labeling. Default is "label".
- `obj.SetAreaSizeArrayName (string name)` - The array to use for area sizes. Default is "size".
- `string = obj.GetAreaSizeArrayName ()` - The array to use for area sizes. Default is "size".
- `obj.SetLabelPriorityArrayName (string name)` - The array to use for area labeling priority. Default is "GraphVertexDegree".
- `string = obj.GetLabelPriorityArrayName ()` - The array to use for area labeling priority. Default is "GraphVertexDegree".
- `obj.SetEdgeLabelArrayName (string name)` - The array to use for edge labeling. Default is "label".
- `string = obj.GetEdgeLabelArrayName ()` - The array to use for edge labeling. Default is "label".
- `obj.SetAreaHoverArrayName (string name)` - The name of the array whose value appears when the mouse hovers over a rectangle in the treemap. This must be a string array.
- `string = obj.GetAreaHoverArrayName ()` - The name of the array whose value appears when the mouse hovers over a rectangle in the treemap. This must be a string array.
- `obj.SetAreaLabelVisibility (bool vis)` - Whether to show area labels. Default is off.
- `bool = obj.GetAreaLabelVisibility ()` - Whether to show area labels. Default is off.
- `obj.AreaLabelVisibilityOn ()` - Whether to show area labels. Default is off.
- `obj.AreaLabelVisibilityOff ()` - Whether to show area labels. Default is off.
- `obj.SetEdgeLabelVisibility (bool vis)` - Whether to show edge labels. Default is off.
- `bool = obj.GetEdgeLabelVisibility ()` - Whether to show edge labels. Default is off.

- `obj.EdgeLabelVisibilityOn ()` - Whether to show edge labels. Default is off.
- `obj.EdgeLabelVisibilityOff ()` - Whether to show edge labels. Default is off.
- `obj.SetAreaColorArrayName (string name)` - The array to use for coloring vertices. Default is "color".
- `string = obj.GetAreaColorArrayName ()` - The array to use for coloring vertices. Default is "color".
- `obj.SetColorAreas (bool vis)` - Whether to color vertices. Default is off.
- `bool = obj.GetColorAreas ()` - Whether to color vertices. Default is off.
- `obj.ColorAreasOn ()` - Whether to color vertices. Default is off.
- `obj.ColorAreasOff ()` - Whether to color vertices. Default is off.
- `obj.SetEdgeColorArrayName (string name)` - The array to use for coloring edges. Default is "color".
- `string = obj.GetEdgeColorArrayName ()` - The array to use for coloring edges. Default is "color".
- `obj.SetEdgeColorToSplineFraction ()` - Set the color to be the spline fraction
- `obj.SetShrinkPercentage (double value)` - Set the region shrink percentage between 0.0 and 1.0.
- `double = obj.GetShrinkPercentage ()` - Set the region shrink percentage between 0.0 and 1.0.
- `obj.SetColorEdges (bool vis)` - Whether to color edges. Default is off.
- `bool = obj.GetColorEdges ()` - Whether to color edges. Default is off.
- `obj.ColorEdgesOn ()` - Whether to color edges. Default is off.
- `obj.ColorEdgesOff ()` - Whether to color edges. Default is off.
- `obj.SetBundlingStrength (double strength)` - Set the bundling strength.
- `double = obj.GetBundlingStrength ()` - Set the bundling strength.
- `obj.SetAreaLabelFontSize (int size)` - The size of the font used for area labeling
- `int = obj.GetAreaLabelFontSize ()` - The size of the font used for area labeling
- `obj.SetEdgeLabelFontSize (int size)` - The size of the font used for edge labeling
- `int = obj.GetEdgeLabelFontSize ()` - The size of the font used for edge labeling
- `obj.SetLayoutStrategy (vtkAreaLayoutStrategy strategy)` - The layout strategy for producing spatial regions for the tree.
- `vtkAreaLayoutStrategy = obj.GetLayoutStrategy ()` - The layout strategy for producing spatial regions for the tree.
- `obj.SetUseRectangularCoordinates (bool rect)` - Whether the area represents radial or rectangular coordinates.
- `bool = obj.GetUseRectangularCoordinates ()` - Whether the area represents radial or rectangular coordinates.
- `obj.UseRectangularCoordinatesOn ()` - Whether the area represents radial or rectangular coordinates.
- `obj.UseRectangularCoordinatesOff ()` - Whether the area represents radial or rectangular coordinates.
- `obj.SetEdgeScalarBarVisibility (bool b)` - Visibility of scalar bar actor for edges.
- `bool = obj.GetEdgeScalarBarVisibility ()` - Visibility of scalar bar actor for edges.

40.20 vtkTreeMapView

40.20.1 Usage

vtkTreeMapView shows a vtkTree in a tree map, where each vertex in the tree is represented by a box. Child boxes are contained within the parent box, and may be colored and sized by various parameters.

To create an instance of class vtkTreeMapView, simply invoke its constructor as follows

```
obj = vtkTreeMapView
```

40.20.2 Methods

The class vtkTreeMapView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeMapView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeMapView = obj.NewInstance ()`
- `vtkTreeMapView = obj.SafeDownCast (vtkObject o)`
- `obj.SetLayoutStrategy (vtkAreaLayoutStrategy s)` - Sets the treemap layout strategy
- `obj.SetLayoutStrategy (string name)` - Sets the treemap layout strategy
- `obj.SetLayoutStrategyToBox ()` - Sets the treemap layout strategy
- `obj.SetLayoutStrategyToSliceAndDice ()` - Sets the treemap layout strategy
- `obj.SetLayoutStrategyToSquarify ()` - Sets the treemap layout strategy
- `obj.SetFontSizeRange (int maxSize, int minSize, int delta)` - The sizes of the fonts used for labeling.
- `obj.GetFontSizeRange (int range[3])` - The sizes of the fonts used for labeling.

40.21 vtkTreeRingView

40.21.1 Usage

Accepts a graph and a hierarchy - currently a tree - and provides a hierarchy-aware display. Currently, this means displaying the hierarchy using a tree ring layout, then rendering the graph vertices as leaves of the tree with curved graph edges between leaves.

.SEE ALSO vtkGraphLayoutView

.SECTION Thanks Thanks to Jason Shepherd for implementing this class

To create an instance of class vtkTreeRingView, simply invoke its constructor as follows

```
obj = vtkTreeRingView
```

40.21.2 Methods

The class vtkTreeRingView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeRingView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeRingView = obj.NewInstance ()`
- `vtkTreeRingView = obj.SafeDownCast (vtkObject o)`
- `obj.SetRootAngles (double start, double end)` - Set the root angles for laying out the hierarchy.
- `obj.SetRootAtCenter (bool value)` - Sets whether the root is at the center or around the outside.
- `bool = obj.GetRootAtCenter ()` - Sets whether the root is at the center or around the outside.
- `obj.RootAtCenterOn ()` - Sets whether the root is at the center or around the outside.
- `obj.RootAtCenterOff ()` - Sets whether the root is at the center or around the outside.
- `obj.SetLayerThickness (double thickness)` - Set the thickness of each layer.
- `double = obj.GetLayerThickness ()` - Set the thickness of each layer.
- `obj.SetInteriorRadius (double thickness)` - Set the interior radius of the tree (i.e. the size of the "hole" in the center).
- `double = obj.GetInteriorRadius ()` - Set the interior radius of the tree (i.e. the size of the "hole" in the center).
- `obj.SetInteriorLogSpacingValue (double thickness)` - Set the log spacing factor for the invisible interior tree used for routing edges of the overlaid graph.
- `double = obj.GetInteriorLogSpacingValue ()` - Set the log spacing factor for the invisible interior tree used for routing edges of the overlaid graph.

40.22 vtkView

40.22.1 Usage

vtkView is the superclass for views. A view is generally an area of an application's canvas devoted to displaying one or more VTK data objects. Associated representations (subclasses of vtkDataRepresentation) are responsible for converting the data into a displayable format. These representations are then added to the view.

For views which display only one data object at a time you may set a data object or pipeline connection directly on the view itself (e.g. vtkGraphLayoutView, vtkLandscapeView, vtkTreeMapView). The view will internally create a vtkDataRepresentation for the data.

A view has the concept of linked selection. If the same data is displayed in multiple views, their selections may be linked by setting the same vtkAnnotationLink on their representations (see vtkDataRepresentation).

To create an instance of class vtkView, simply invoke its constructor as follows

```
obj = vtkView
```

40.22.2 Methods

The class vtkView has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkView class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkView = obj.NewInstance ()`
- `vtkView = obj.SafeDownCast (vtkObject o)`
- `obj.AddRepresentation (vtkDataRepresentation rep)` - Adds the representation to the view.
- `obj.SetRepresentation (vtkDataRepresentation rep)` - Set the representation to the view.
- `vtkDataRepresentation = obj.AddRepresentationFromInputConnection (vtkAlgorithmOutput conn)` - Convenience method which creates a simple representation with the connection and adds it to the view. Returns the representation internally created. NOTE: The returned representation pointer is not reference-counted, so you MUST call Register() on the representation if you want to keep a reference to it.
- `vtkDataRepresentation = obj.SetRepresentationFromInputConnection (vtkAlgorithmOutput conn)` - Convenience method which sets the representation with the connection and adds it to the view. Returns the representation internally created. NOTE: The returned representation pointer is not reference-counted, so you MUST call Register() on the representation if you want to keep a reference to it.
- `vtkDataRepresentation = obj.AddRepresentationFromInput (vtkDataObject input)` - Convenience method which creates a simple representation with the specified input and adds it to the view. NOTE: The returned representation pointer is not reference-counted, so you MUST call Register() on the representation if you want to keep a reference to it.
- `vtkDataRepresentation = obj.SetRepresentationFromInput (vtkDataObject input)` - Convenience method which sets the representation to the specified input and adds it to the view. NOTE: The returned representation pointer is not reference-counted, so you MUST call Register() on the representation if you want to keep a reference to it.
- `obj.RemoveRepresentation (vtkDataRepresentation rep)` - Removes the representation from the view.
- `obj.RemoveRepresentation (vtkAlgorithmOutput rep)` - Removes any representation with this connection from the view.
- `obj.RemoveAllRepresentations ()` - Removes all representations from the view.
- `int = obj.GetNumberOfRepresentations ()` - Returns the number of representations from first port(0) in this view.
- `vtkDataRepresentation = obj.GetRepresentation (int index)` - The representation at a specified index.
- `bool = obj.IsRepresentationPresent (vtkDataRepresentation rep)` - Check to see if a representation is present in the view.
- `obj.Update ()` - Update the view.

- `obj.ApplyViewTheme (vtkViewTheme )` - Meant for use by subclasses and vtkRepresentation subclasses. Call this method to register vtkObjects (generally vtkAlgorithm subclasses) which fire vtkCommand::ProgressEvent with the view. The view listens to vtkCommand::ProgressEvent and fires ViewProgressEvent with ViewProgressEventCallData containing the message and the progress amount. If message is not provided, then the class name for the algorithm is used.
- `obj.RegisterProgress (vtkObject algorithm, string messageNULL)` - Meant for use by subclasses and vtkRepresentation subclasses. Call this method to register vtkObjects (generally vtkAlgorithm subclasses) which fire vtkCommand::ProgressEvent with the view. The view listens to vtkCommand::ProgressEvent and fires ViewProgressEvent with ViewProgressEventCallData containing the message and the progress amount. If message is not provided, then the class name for the algorithm is used.
- `obj.UnRegisterProgress (vtkObject algorithm)` - Unregister objects previously registered with RegisterProgress.

40.23 vtkViewUpdater

40.23.1 Usage

vtkViewUpdater registers with annotation change events for a set of annotation links, and updates all views when an annotation link fires an annotation changed event. This is often needed when multiple views share a selection with vtkAnnotationLink.

To create an instance of class vtkViewUpdater, simply invoke its constructor as follows

```
obj = vtkViewUpdater
```

40.23.2 Methods

The class vtkViewUpdater has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkViewUpdater class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkViewUpdater = obj.NewInstance ()`
- `vtkViewUpdater = obj.SafeDownCast (vtkObject o)`
- `obj.AddView (vtkView view)`
- `obj.AddAnnotationLink (vtkAnnotationLink link)`

Chapter 41

Visualization Toolkit Volume Rendering Classes

41.1 vtkDirectionEncoder

41.1.1 Usage

Given a direction, encode it into an integer value. This value should be less than 65536, which is the maximum number of encoded directions supported by this superclass. A direction encoded is used to encode normals in a volume for use during volume rendering, and the amount of space that is allocated per normal is 2 bytes. This is an abstract superclass - see the subclasses for specific implementation details.

To create an instance of class vtkDirectionEncoder, simply invoke its constructor as follows

```
obj = vtkDirectionEncoder
```

41.1.2 Methods

The class vtkDirectionEncoder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDirectionEncoder class.

- `string = obj.GetClassName ()` - Get the name of this class
- `int = obj.IsA (string name)` - Get the name of this class
- `vtkDirectionEncoder = obj.NewInstance ()` - Get the name of this class
- `vtkDirectionEncoder = obj.SafeDownCast (vtkObject o)` - Get the name of this class
- `int = obj.GetEncodedDirection (float n[3])` - Given a normal vector n, return the encoded direction
- `float = obj.GetDecodedGradient (int value)` - / Given an encoded value, return a pointer to the normal vector
- `int = obj.GetNumberOfEncodedDirections (void )` - Return the number of encoded directions

41.2 vtkEncodedGradientEstimator

41.2.1 Usage

vtkEncodedGradientEstimator is an abstract superclass for gradient estimation. It takes a scalar input of vtkImageData, computes a gradient value for every point, and encodes this value into a three byte value (2 for direction, 1 for magnitude) using the vtkDirectionEncoder. The direction encoder is defaulted to a vtkRecursiveSphereDirectionEncoder, but can be overridden with the SetDirectionEncoder method. The scale and the bias values for the gradient magnitude are used to convert it into a one byte value according to v = m*scale + bias where m is the magnitude and v is the resulting one byte value.

To create an instance of class vtkEncodedGradientEstimator, simply invoke its constructor as follows

```
obj = vtkEncodedGradientEstimator
```

41.2.2 Methods

The class vtkEncodedGradientEstimator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEncodedGradientEstimator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEncodedGradientEstimator = obj.NewInstance ()`
- `vtkEncodedGradientEstimator = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData )` - Set/Get the scalar input for which the normals will be calculated
- `vtkImageData = obj.GetInput ()` - Set/Get the scalar input for which the normals will be calculated
- `obj.SetGradientMagnitudeScale (float )` - Set/Get the scale and bias for the gradient magnitude
- `float = obj.GetGradientMagnitudeScale ()` - Set/Get the scale and bias for the gradient magnitude
- `obj.SetGradientMagnitudeBias (float )` - Set/Get the scale and bias for the gradient magnitude
- `float = obj.GetGradientMagnitudeBias ()` - Set/Get the scale and bias for the gradient magnitude
- `obj.SetBoundsClip (int )` - Turn on / off the bounding of the normal computation by the this-¿Bounds bounding box
- `int = obj.GetBoundsClipMinValue ()` - Turn on / off the bounding of the normal computation by the this-¿Bounds bounding box
- `int = obj.GetBoundsClipMaxValue ()` - Turn on / off the bounding of the normal computation by the this-¿Bounds bounding box
- `int = obj.GetBoundsClip ()` - Turn on / off the bounding of the normal computation by the this-¿Bounds bounding box
- `obj.BoundsClipOn ()` - Turn on / off the bounding of the normal computation by the this-¿Bounds bounding box
- `obj.BoundsClipOff ()` - Turn on / off the bounding of the normal computation by the this-¿Bounds bounding box

- `obj.SetBounds (int , int , int , int , int , int )` - Set / Get the bounds of the computation (used if this-¿ComputationBounds is 1.) The bounds are specified xmin, xmax, ymin, ymax, zmin, zmax.
- `obj.SetBounds (int a[6])` - Set / Get the bounds of the computation (used if this-¿ComputationBounds is 1.) The bounds are specified xmin, xmax, ymin, ymax, zmin, zmax.
- `int = obj. GetBounds ()` - Set / Get the bounds of the computation (used if this-¿ComputationBounds is 1.) The bounds are specified xmin, xmax, ymin, ymax, zmin, zmax.
- `obj.Update (void )` - Recompute the encoded normals and gradient magnitudes.
- `int = obj.GetEncodedNormalIndex (int xyz\_index)` - Get the encoded normal at an x,y,z location in the volume
- `int = obj.GetEncodedNormalIndex (int x\_index, int y\_index, int z\_index)` - Get the encoded normal at an x,y,z location in the volume
- `obj.SetNumberOfThreads (int )` - Get/Set the number of threads to create when encoding normals This defaults to the number of available processors on the machine
- `int = obj.GetNumberOfThreadsMinValue ()` - Get/Set the number of threads to create when encoding normals This defaults to the number of available processors on the machine
- `int = obj.GetNumberOfThreadsMaxValue ()` - Get/Set the number of threads to create when encoding normals This defaults to the number of available processors on the machine
- `int = obj.GetNumberOfThreads ()` - Get/Set the number of threads to create when encoding normals This defaults to the number of available processors on the machine
- `obj.SetDirectionEncoder (vtkDirectionEncoder direnc)` - Set / Get the direction encoder used to encode normal directions to fit within two bytes
- `vtkDirectionEncoder = obj.GetDirectionEncoder ()` - Set / Get the direction encoder used to encode normal directions to fit within two bytes
- `obj.SetComputeGradientMagnitudes (int )` - If you don't want to compute gradient magnitudes (but you do want normals for shading) this can be used. Be careful - if if you a non-constant gradient magnitude transfer function and you turn this on, it may crash
- `int = obj.GetComputeGradientMagnitudes ()` - If you don't want to compute gradient magnitudes (but you do want normals for shading) this can be used. Be careful - if if you a non-constant gradient magnitude transfer function and you turn this on, it may crash
- `obj.ComputeGradientMagnitudesOn ()` - If you don't want to compute gradient magnitudes (but you do want normals for shading) this can be used. Be careful - if if you a non-constant gradient magnitude transfer function and you turn this on, it may crash
- `obj.ComputeGradientMagnitudesOff ()` - If you don't want to compute gradient magnitudes (but you do want normals for shading) this can be used. Be careful - if if you a non-constant gradient magnitude transfer function and you turn this on, it may crash
- `obj.SetCylinderClip (int )` - If the data in each slice is only contained within a circle circumscribed within the slice, and the slice is square, then don't compute anything outside the circle. This circle through the slices forms a cylinder.
- `int = obj.GetCylinderClip ()` - If the data in each slice is only contained within a circle circumscribed within the slice, and the slice is square, then don't compute anything outside the circle. This circle through the slices forms a cylinder.

- `obj.CylinderClipOn ()` - If the data in each slice is only contained within a circle circumscribed within the slice, and the slice is square, then don't compute anything outside the circle. This circle through the slices forms a cylinder.
- `obj.CylinderClipOff ()` - If the data in each slice is only contained within a circle circumscribed within the slice, and the slice is square, then don't compute anything outside the circle. This circle through the slices forms a cylinder.
- `float = obj.GetLastUpdateTimeInSeconds ()` - Get the time required for the last update in seconds or cpu seconds
- `float = obj.GetLastUpdateTimeInCPUSeconds ()` - Get the time required for the last update in seconds or cpu seconds
- `int = obj.GetUseCylinderClip ()`
- `obj.SetZeroNormalThreshold (float v)` - Set / Get the ZeroNormalThreshold - this defines the minimum magnitude of a gradient that is considered sufficient to define a direction. Gradients with magnitudes at or less than this value are given a "zero normal" index. These are handled specially in the shader, and you can set the intensity of light for these zero normals in the gradient shader.
- `float = obj.GetZeroNormalThreshold ()` - Set / Get the ZeroNormalThreshold - this defines the minimum magnitude of a gradient that is considered sufficient to define a direction. Gradients with magnitudes at or less than this value are given a "zero normal" index. These are handled specially in the shader, and you can set the intensity of light for these zero normals in the gradient shader.
- `obj.SetZeroPad (int )` - Assume that the data value outside the volume is zero when computing normals.
- `int = obj.GetZeroPadMinValue ()` - Assume that the data value outside the volume is zero when computing normals.
- `int = obj.GetZeroPadMaxValue ()` - Assume that the data value outside the volume is zero when computing normals.
- `int = obj.GetZeroPad ()` - Assume that the data value outside the volume is zero when computing normals.
- `obj.ZeroPadOn ()` - Assume that the data value outside the volume is zero when computing normals.
- `obj.ZeroPadOff ()` - Assume that the data value outside the volume is zero when computing normals.

41.3 vtkEncodedGradientShader

41.3.1 Usage

vtkEncodedGradientShader computes shading tables for encoded normals that indicates the amount of diffuse and specular illumination that is received from all light sources at a surface location with that normal. For diffuse illumination this is accurate, but for specular illumination it is approximate for perspective projections since the center view direction is always used as the view direction. Since the shading table is dependent on the volume (for the transformation that must be applied to the normals to put them into world coordinates) there is a shading table per volume. This is necessary because multiple volumes can share a volume mapper.

To create an instance of class vtkEncodedGradientShader, simply invoke its constructor as follows

```
obj = vtkEncodedGradientShader
```

41.3.2 Methods

The class vtkEncodedGradientShader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEncodedGradientShader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEncodedGradientShader = obj.NewInstance ()`
- `vtkEncodedGradientShader = obj.SafeDownCast (vtkObject o)`
- `obj.SetZeroNormalDiffuseIntensity (float )` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `float = obj.GetZeroNormalDiffuseIntensityMinValue ()` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `float = obj.GetZeroNormalDiffuseIntensityMaxValue ()` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `float = obj.GetZeroNormalDiffuseIntensity ()` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `obj.SetZeroNormalSpecularIntensity (float )` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `float = obj.GetZeroNormalSpecularIntensityMinValue ()` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `float = obj.GetZeroNormalSpecularIntensityMaxValue ()` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `float = obj.GetZeroNormalSpecularIntensity ()` - Set / Get the intensity diffuse / specular light used for the zero normals.
- `obj.UpdateShadingTable (vtkRenderer ren, vtkVolume vol, vtkEncodedGradientEstimator gradest)` - Cause the shading table to be updated
- `obj.SetActiveComponent (int )` - Set the active component for shading. This component's ambient / diffuse / specular / specular power values will be used to create the shading table. The default is 1.0
- `int = obj.GetActiveComponentMinValue ()` - Set the active component for shading. This component's ambient / diffuse / specular / specular power values will be used to create the shading table. The default is 1.0
- `int = obj.GetActiveComponentMaxValue ()` - Set the active component for shading. This component's ambient / diffuse / specular / specular power values will be used to create the shading table. The default is 1.0
- `int = obj.GetActiveComponent ()` - Set the active component for shading. This component's ambient / diffuse / specular / specular power values will be used to create the shading table. The default is 1.0

41.4 vtkFiniteDifferenceGradientEstimator

41.4.1 Usage

vtkFiniteDifferenceGradientEstimator is a concrete subclass of vtkEncodedGradientEstimator that uses a central differences technique to estimate the gradient. The gradient at some sample location (x,y,z) would be estimated by:

nx = (f(x-dx,y,z) - f(x+dx,y,z)) / 2*dx; ny = (f(x,y-dy,z) - f(x,y+dy,z)) / 2*dy; nz = (f(x,y,z-dz) - f(x,y,z+dz)) / 2*dz;

This value is normalized to determine a unit direction vector and a magnitude. The normal is computed in voxel space, and dx = dy = dz = SampleSpacingInVoxels. A scaling factor is applied to convert this normal from voxel space to world coordinates.

To create an instance of class vtkFiniteDifferenceGradientEstimator, simply invoke its constructor as follows

```
obj = vtkFiniteDifferenceGradientEstimator
```

41.4.2 Methods

The class vtkFiniteDifferenceGradientEstimator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFiniteDifferenceGradientEstimator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFiniteDifferenceGradientEstimator = obj.NewInstance ()`
- `vtkFiniteDifferenceGradientEstimator = obj.SafeDownCast (vtkObject o)`
- `obj.SetSampleSpacingInVoxels (int )` - Set/Get the spacing between samples for the finite differences method used to compute the normal. This spacing is in voxel units.
- `int = obj.GetSampleSpacingInVoxels ()` - Set/Get the spacing between samples for the finite differences method used to compute the normal. This spacing is in voxel units.

41.5 vtkFixedPointRayCastImage

41.5.1 Usage

This is a helper class for storing the ray cast image including the underlying data and the size of the image. This class is not intended to be used directly - just as an internal class in the vtkFixedPointVolumeRayCastMapper so that multiple mappers can share the same image. This class also stored the ZBuffer (if necessary due to intermixed geometry). Perhaps this class could be generalized in the future to be used for other ray cast methods other than the fixed point method.

To create an instance of class vtkFixedPointRayCastImage, simply invoke its constructor as follows

```
obj = vtkFixedPointRayCastImage
```

41.5.2 Methods

The class vtkFixedPointRayCastImage has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointRayCastImage class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointRayCastImage = obj.NewInstance ()`
- `vtkFixedPointRayCastImage = obj.SafeDownCast (vtkObject o)`
- `obj.SetImageViewportSize (int , int )` - Set / Get the ImageViewportSize. This is the size of the whole viewport in pixels.
- `obj.SetImageViewportSize (int a[2])` - Set / Get the ImageViewportSize. This is the size of the whole viewport in pixels.
- `int = obj. GetImageViewportSize ()` - Set / Get the ImageViewportSize. This is the size of the whole viewport in pixels.
- `obj.SetImageMemorySize (int , int )` - Set / Get the ImageMemorySize. This is the size in pixels of the Image ivar. This will be a power of two in order to ensure that the texture can be rendered by graphics hardware that requires power of two textures.
- `obj.SetImageMemorySize (int a[2])` - Set / Get the ImageMemorySize. This is the size in pixels of the Image ivar. This will be a power of two in order to ensure that the texture can be rendered by graphics hardware that requires power of two textures.
- `int = obj. GetImageMemorySize ()` - Set / Get the ImageMemorySize. This is the size in pixels of the Image ivar. This will be a power of two in order to ensure that the texture can be rendered by graphics hardware that requires power of two textures.
- `obj.SetImageInUseSize (int , int )` - Set / Get the size of the image we are actually using. As long as the memory size is big enough, but not too big, we won't bother deleting and re-allocated, we'll just continue to use the memory size we have. This size will always be equal to or less than the ImageMemorySize.
- `obj.SetImageInUseSize (int a[2])` - Set / Get the size of the image we are actually using. As long as the memory size is big enough, but not too big, we won't bother deleting and re-allocated, we'll just continue to use the memory size we have. This size will always be equal to or less than the ImageMemorySize.
- `int = obj. GetImageInUseSize ()` - Set / Get the size of the image we are actually using. As long as the memory size is big enough, but not too big, we won't bother deleting and re-allocated, we'll just continue to use the memory size we have. This size will always be equal to or less than the ImageMemorySize.
- `obj.SetImageOrigin (int , int )` - Set / Get the origin of the image. This is the starting pixel within the whole viewport that our Image starts on. That is, we could be generating just a subregion of the whole viewport due to the fact that our volume occupies only a portion of the viewport. The Image pixels will start from this location.
- `obj.SetImageOrigin (int a[2])` - Set / Get the origin of the image. This is the starting pixel within the whole viewport that our Image starts on. That is, we could be generating just a subregion of the whole viewport due to the fact that our volume occupies only a portion of the viewport. The Image pixels will start from this location.
- `int = obj. GetImageOrigin ()` - Set / Get the origin of the image. This is the starting pixel within the whole viewport that our Image starts on. That is, we could be generating just a subregion of the whole viewport due to the fact that our volume occupies only a portion of the viewport. The Image pixels will start from this location.

- `obj.SetImageSampleDistance (float )` - Set / Get the ImageSampleDistance that will be used for rendering. This is a copy of the value stored in the mapper. It is stored here for sharing between all mappers that are participating in the creation of this image.

- `float = obj.GetImageSampleDistance ()` - Set / Get the ImageSampleDistance that will be used for rendering. This is a copy of the value stored in the mapper. It is stored here for sharing between all mappers that are participating in the creation of this image.

- `obj.AllocateImage ()` - Call this method once the ImageMemorySize has been set the allocate the image. If an image already exists, it will be deleted first.

- `obj.ClearImage ()` - Clear the image to (0,0,0,0) for each pixel.

- `obj.SetZBufferSize (int , int )` - Set / Get the size of the ZBuffer in pixels. The zbuffer will be captured for the region of the screen covered by the ImageInUseSize image. However, due to subsampling, the size of the ImageInUseSize image may be smaller than this ZBuffer image which will be captured at screen resolution.

- `obj.SetZBufferSize (int  a[2])` - Set / Get the size of the ZBuffer in pixels. The zbuffer will be captured for the region of the screen covered by the ImageInUseSize image. However, due to subsampling, the size of the ImageInUseSize image may be smaller than this ZBuffer image which will be captured at screen resolution.

- `int = obj. GetZBufferSize ()` - Set / Get the size of the ZBuffer in pixels. The zbuffer will be captured for the region of the screen covered by the ImageInUseSize image. However, due to subsampling, the size of the ImageInUseSize image may be smaller than this ZBuffer image which will be captured at screen resolution.

- `obj.SetZBufferOrigin (int , int )` - Set / Get the origin of the ZBuffer. This is the distance from the lower left corner of the viewport where the ZBuffer started (multiply the ImageOrigin by the ImageSampleDistance) This is the pixel location on the full resolution viewport where the ZBuffer capture will start. These values are used to convert the (x,y) pixel location within the ImageInUseSize image into a ZBuffer location.

- `obj.SetZBufferOrigin (int  a[2])` - Set / Get the origin of the ZBuffer. This is the distance from the lower left corner of the viewport where the ZBuffer started (multiply the ImageOrigin by the ImageSampleDistance) This is the pixel location on the full resolution viewport where the ZBuffer capture will start. These values are used to convert the (x,y) pixel location within the ImageInUseSize image into a ZBuffer location.

- `int = obj. GetZBufferOrigin ()` - Set / Get the origin of the ZBuffer. This is the distance from the lower left corner of the viewport where the ZBuffer started (multiply the ImageOrigin by the ImageSampleDistance) This is the pixel location on the full resolution viewport where the ZBuffer capture will start. These values are used to convert the (x,y) pixel location within the ImageInUseSize image into a ZBuffer location.

- `obj.SetUseZBuffer (int )` - The UseZBuffer flag indicates whether the ZBuffer is in use. The ZBuffer is captured and used when IntermixIntersectingGeometry is on in the mapper, and when there are props that have been rendered before the current volume.

- `int = obj.GetUseZBufferMinValue ()` - The UseZBuffer flag indicates whether the ZBuffer is in use. The ZBuffer is captured and used when IntermixIntersectingGeometry is on in the mapper, and when there are props that have been rendered before the current volume.

- `int = obj.GetUseZBufferMaxValue ()` - The UseZBuffer flag indicates whether the ZBuffer is in use. The ZBuffer is captured and used when IntermixIntersectingGeometry is on in the mapper, and when there are props that have been rendered before the current volume.

- `int = obj.GetUseZBuffer ()` - The UseZBuffer flag indicates whether the ZBuffer is in use. The ZBuffer is captured and used when IntermixIntersectingGeometry is on in the mapper, and when there are props that have been rendered before the current volume.
- `obj.UseZBufferOn ()` - The UseZBuffer flag indicates whether the ZBuffer is in use. The ZBuffer is captured and used when IntermixIntersectingGeometry is on in the mapper, and when there are props that have been rendered before the current volume.
- `obj.UseZBufferOff ()` - The UseZBuffer flag indicates whether the ZBuffer is in use. The ZBuffer is captured and used when IntermixIntersectingGeometry is on in the mapper, and when there are props that have been rendered before the current volume.
- `float = obj.GetZBufferValue (int x, int y)` - Get the ZBuffer value corresponding to location (x,y) where (x,y) are indexing into the ImageInUse image. This must be converted to the zbuffer image coordinates. Nearest neighbor value is returned. If UseZBuffer is off, then 1.0 is always returned.
- `obj.AllocateZBuffer ()`

41.6 vtkFixedPointVolumeRayCastCompositeGOHelper

41.6.1 Usage

This is one of the helper classes for the vtkFixedPointVolumeRayCastMapper. It will generate composite images using an alpha blending operation. This class should not be used directly, it is a helper class for the mapper and has no user-level API.

To create an instance of class vtkFixedPointVolumeRayCastCompositeGOHelper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastCompositeGOHelper
```

41.6.2 Methods

The class vtkFixedPointVolumeRayCastCompositeGOHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastCompositeGOHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastCompositeGOHelper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastCompositeGOHelper = obj.SafeDownCast (vtkObject o)`
- `obj.GenerateImage (int threadID, int threadCount, vtkVolume vol, vtkFixedPointVolumeRayCastMapper m`

41.7 vtkFixedPointVolumeRayCastCompositeGOShadeHelper

41.7.1 Usage

This is one of the helper classes for the vtkFixedPointVolumeRayCastMapper. It will generate composite images using an alpha blending operation. This class should not be used directly, it is a helper class for the mapper and has no user-level API.

To create an instance of class vtkFixedPointVolumeRayCastCompositeGOShadeHelper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastCompositeGOShadeHelper
```

41.7.2 Methods

The class vtkFixedPointVolumeRayCastCompositeGOShadeHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastCompositeGOShadeHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastCompositeGOShadeHelper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastCompositeGOShadeHelper = obj.SafeDownCast (vtkObject o)`
- `obj.GenerateImage (int threadID, int threadCount, vtkVolume vol, vtkFixedPointVolumeRayCastMapper m`

41.8 vtkFixedPointVolumeRayCastCompositeHelper

41.8.1 Usage

This is one of the helper classes for the vtkFixedPointVolumeRayCastMapper. It will generate composite images using an alpha blending operation. This class should not be used directly, it is a helper class for the mapper and has no user-level API.

To create an instance of class vtkFixedPointVolumeRayCastCompositeHelper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastCompositeHelper
```

41.8.2 Methods

The class vtkFixedPointVolumeRayCastCompositeHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastCompositeHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastCompositeHelper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastCompositeHelper = obj.SafeDownCast (vtkObject o)`
- `obj.GenerateImage (int threadID, int threadCount, vtkVolume vol, vtkFixedPointVolumeRayCastMapper m`

41.9 vtkFixedPointVolumeRayCastCompositeShadeHelper

41.9.1 Usage

This is one of the helper classes for the vtkFixedPointVolumeRayCastMapper. It will generate composite images using an alpha blending operation. This class should not be used directly, it is a helper class for the mapper and has no user-level API.

To create an instance of class vtkFixedPointVolumeRayCastCompositeShadeHelper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastCompositeShadeHelper
```

41.9.2 Methods

The class vtkFixedPointVolumeRayCastCompositeShadeHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastCompositeShadeHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastCompositeShadeHelper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastCompositeShadeHelper = obj.SafeDownCast (vtkObject o)`
- `obj.GenerateImage (int threadID, int threadCount, vtkVolume vol, vtkFixedPointVolumeRayCastMapper m`

41.10 vtkFixedPointVolumeRayCastHelper

41.10.1 Usage

This is the abstract superclass of all helper classes for the vtkFixedPointVolumeRayCastMapper. This class should not be used directly.

To create an instance of class vtkFixedPointVolumeRayCastHelper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastHelper
```

41.10.2 Methods

The class vtkFixedPointVolumeRayCastHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastHelper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastHelper = obj.SafeDownCast (vtkObject o)`
- `obj.GenerateImage (int , int , vtkVolume , vtkFixedPointVolumeRayCastMapper )`

41.11 vtkFixedPointVolumeRayCastMapper

41.11.1 Usage

This is a software ray caster for rendering volumes in vtkImageData. It works with all input data types and up to four components. It performs composite or MIP rendering, and can be intermixed with geometric data. Space leaping is used to speed up the rendering process. In addition, calculation are performed in 15 bit fixed point precision. This mapper is threaded, and will interleave scan lines across processors.

This mapper is a good replacement for vtkVolumeRayCastMapper EXCEPT: - it does not do isosurface ray casting - it does only interpolate before classify compositing - it does only maximum scalar value MIP

The vtkVolumeRayCastMapper CANNOT be used in these instances when a vtkFixedPointVolumeRay-CastMapper can be used: - if the data is not unsigned char or unsigned short - if the data has more than one component

This mapper handles all data type from unsigned char through double. However, some of the internal calcultions are performed in float and therefore even the full float range may cause problems for this mapper (both in scalar data values and in spacing between samples).

Space leaping is performed by creating a sub-sampled volume. 4x4x4 cells in the original volume are represented by a min, max, and combined gradient and flag value. The min max volume has three unsigned shorts per 4x4x4 group of cells from the original volume - one reprenting the minumum scalar index (the scalar value adjusted to fit in the 15 bit range), the maximum scalar index, and a third unsigned short which is both the maximum gradient opacity in the neighborhood (an unsigned char) and the flag that is filled in for the current lookup tables to indicate whether this region can be skipped.

To create an instance of class vtkFixedPointVolumeRayCastMapper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastMapper
```

41.11.2 Methods

The class vtkFixedPointVolumeRayCastMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastMapper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetSampleDistance (float )` - Set/Get the distance between samples used for rendering when AutoAdjustSampleDistances is off, or when this mapper has more than 1 second allocated to it for rendering.
- `float = obj.GetSampleDistance ()` - Set/Get the distance between samples used for rendering when AutoAdjustSampleDistances is off, or when this mapper has more than 1 second allocated to it for rendering.
- `obj.SetInteractiveSampleDistance (float )` - Set/Get the distance between samples when interactive rendering is happening. In this case, interactive is defined as this volume mapper having less than 1 second allocated for rendering. When AutoAdjustSampleDistance is On, and the allocated render time is less than 1 second, then this InteractiveSampleDistance will be used instead of the SampleDistance above.
- `float = obj.GetInteractiveSampleDistance ()` - Set/Get the distance between samples when interactive rendering is happening. In this case, interactive is defined as this volume mapper having less than 1 second allocated for rendering. When AutoAdjustSampleDistance is On, and the allocated render time is less than 1 second, then this InteractiveSampleDistance will be used instead of the SampleDistance above.
- `obj.SetImageSampleDistance (float )` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.
- `float = obj.GetImageSampleDistanceMinValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.

- `float = obj.GetImageSampleDistanceMaxValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.

- `float = obj.GetImageSampleDistance ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.

- `obj.SetMinimumImageSampleDistance (float )` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.

- `float = obj.GetMinimumImageSampleDistanceMinValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.

- `float = obj.GetMinimumImageSampleDistanceMaxValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.

- `float = obj.GetMinimumImageSampleDistance ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.

- `obj.SetMaximumImageSampleDistance (float )` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.

- `float = obj.GetMaximumImageSampleDistanceMinValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.

- `float = obj.GetMaximumImageSampleDistanceMaxValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.

- `float = obj.GetMaximumImageSampleDistance ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.

- `obj.SetAutoAdjustSampleDistances (int )` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance and the SampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use). If this is an interactive render (more than 1 frame per second) the SampleDistance will be increased, otherwise it will not be altered (a binary decision, as opposed to the ImageSampleDistance which will vary continuously).

- `int = obj.GetAutoAdjustSampleDistancesMinValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance and the SampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use). If this is an interactive render (more than 1 frame per second) the SampleDistance will be increased, otherwise it will not be altered (a binary decision, as opposed to the ImageSampleDistance which will vary continuously).

- `int = obj.GetAutoAdjustSampleDistancesMaxValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance and the SampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use). If this is an interactive render (more than 1 frame per second) the SampleDistance will be increased, otherwise it will not be altered (a binary decision, as opposed to the ImageSampleDistance which will vary continuously).

- `int = obj.GetAutoAdjustSampleDistances ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance and the SampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use). If this is an interactive render (more than 1 frame per second) the SampleDistance will be increased, otherwise it will not be altered (a binary decision, as opposed to the ImageSampleDistance which will vary continuously).

- `obj.AutoAdjustSampleDistancesOn ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance and the SampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use). If this is an interactive render (more than 1 frame per second) the SampleDistance will be increased, otherwise it will not be altered (a binary decision, as opposed to the ImageSampleDistance which will vary continuously).

- `obj.AutoAdjustSampleDistancesOff ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance and the SampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use). If this is an interactive render (more than 1 frame per second) the SampleDistance will be increased, otherwise it will not be altered (a binary decision, as opposed to the ImageSampleDistance which will vary continuously).

- `obj.SetLockSampleDistanceToInputSpacing (int )` - Automatically compute the sample distance from the data spacing. When the number of voxels is 8, the sample distance will be roughly 1/200 the average voxel size. The distance will grow proportionally to numVoxels$\hat{}$(1/3) until it reaches 1/2 average voxel size when number of voxels is 1E6. Note that ScalarOpacityUnitDistance is still taken into account and if different than 1, will effect the sample distance.

- `int = obj.GetLockSampleDistanceToInputSpacingMinValue ()` - Automatically compute the sample distance from the data spacing. When the number of voxels is 8, the sample distance will be roughly 1/200 the average voxel size. The distance will grow proportionally to numVoxels$\hat{}$(1/3) until it reaches 1/2 average voxel size when number of voxels is 1E6. Note that ScalarOpacityUnitDistance is still taken into account and if different than 1, will effect the sample distance.

- `int = obj.GetLockSampleDistanceToInputSpacingMaxValue ()` - Automatically compute the sample distance from the data spacing. When the number of voxels is 8, the sample distance will be roughly 1/200 the average voxel size. The distance will grow proportionally to numVoxels$\hat{}$(1/3) until it reaches 1/2 average voxel size when number of voxels is 1E6. Note that ScalarOpacityUnitDistance is still taken into account and if different than 1, will effect the sample distance.

- `int = obj.GetLockSampleDistanceToInputSpacing ()` - Automatically compute the sample distance from the data spacing. When the number of voxels is 8, the sample distance will be roughly 1/200 the average voxel size. The distance will grow proportionally to numVoxels$\hat{}$(1/3) until it reaches 1/2 average voxel size when number of voxels is 1E6. Note that ScalarOpacityUnitDistance is still taken into account and if different than 1, will effect the sample distance.

- `obj.LockSampleDistanceToInputSpacingOn ()` - Automatically compute the sample distance from the data spacing. When the number of voxels is 8, the sample distance will be roughly 1/200 the average voxel size. The distance will grow proportionally to numVoxels$\hat{}$(1/3) until it reaches 1/2 average voxel size when number of voxels is 1E6. Note that ScalarOpacityUnitDistance is still taken into account and if different than 1, will effect the sample distance.

- `obj.LockSampleDistanceToInputSpacingOff ()` - Automatically compute the sample distance from the data spacing. When the number of voxels is 8, the sample distance will be roughly 1/200 the average voxel size. The distance will grow proportionally to numVoxels$\hat{}$(1/3) until it reaches 1/2 average voxel size when number of voxels is 1E6. Note that ScalarOpacityUnitDistance is still taken into account and if different than 1, will effect the sample distance.

- `obj.SetNumberOfThreads (int num)` - Set/Get the number of threads to use. This by default is equal to the number of available processors detected.

- `int = obj.GetNumberOfThreads ()` - Set/Get the number of threads to use. This by default is equal to the number of available processors detected.

- `obj.SetIntermixIntersectingGeometry (int )` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

- `int = obj.GetIntermixIntersectingGeometryMinValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometryMaxValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometry ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.IntermixIntersectingGeometryOn ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.IntermixIntersectingGeometryOff ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `float = obj.ComputeRequiredImageSampleDistance (float desiredTime, vtkRenderer ren)` - What is the image sample distance required to achieve the desired time? A version of this method is provided that does not require the volume argument since if you are using an LODProp3D you may not know this information. If you use this version you must be certain that the ray cast mapper is only used for one volume (and not shared among multiple volumes)
- `float = obj.ComputeRequiredImageSampleDistance (float desiredTime, vtkRenderer ren, vtkVolume vol)` - What is the image sample distance required to achieve the desired time? A version of this method is provided that does not require the volume argument since if you are using an LODProp3D you may not know this information. If you use this version you must be certain that the ray cast mapper is only used for one volume (and not shared among multiple volumes)
- `vtkRenderWindow = obj.GetRenderWindow ()`
- `vtkFixedPointVolumeRayCastMIPHelper = obj.GetMIPHelper ()`
- `vtkFixedPointVolumeRayCastCompositeHelper = obj.GetCompositeHelper ()`
- `vtkFixedPointVolumeRayCastCompositeGOHelper = obj.GetCompositeGOHelper ()`
- `vtkFixedPointVolumeRayCastCompositeGOShadeHelper = obj.GetCompositeGOShadeHelper ()`
- `vtkFixedPointVolumeRayCastCompositeShadeHelper = obj.GetCompositeShadeHelper ()`
- `float = obj. GetTableShift ()`
- `float = obj. GetTableScale ()`
- `int = obj.GetShadingRequired ()`
- `int = obj.GetGradientOpacityRequired ()`
- `vtkDataArray = obj.GetCurrentScalars ()`
- `vtkDataArray = obj.GetPreviousScalars ()`
- `vtkVolume = obj.GetVolume ()`
- `obj.ComputeRayInfo (int x, int y, int pos[3], int dir[3], int numSteps)`
- `obj.InitializeRayInfo (vtkVolume vol)`
- `int = obj.ShouldUseNearestNeighborInterpolation (vtkVolume vol)`
- `obj.SetRayCastImage (vtkFixedPointRayCastImage )` - Set / Get the underlying image object. One will be automatically created - only need to set it when using from an AMR mapper which renders multiple times into the same image.

- `vtkFixedPointRayCastImage = obj.GetRayCastImage ()` - Set / Get the underlying image object. One will be automatically created - only need to set it when using from an AMR mapper which renders multiple times into the same image.

- `int = obj.PerImageInitialization (vtkRenderer , vtkVolume , int , double , double , int )`

- `obj.PerVolumeInitialization (vtkRenderer , vtkVolume )`

- `obj.PerSubVolumeInitialization (vtkRenderer , vtkVolume , int )`

- `obj.RenderSubVolume ()`

- `obj.DisplayRenderedImage (vtkRenderer , vtkVolume )`

- `obj.AbortRender ()`

- `obj.CreateCanonicalView (vtkVolume volume, vtkImageData image, int blend\_mode, double viewDirectio`

- `float = obj.GetEstimatedRenderTime (vtkRenderer ren, vtkVolume vol)` - Get an estimate of the rendering time for a given volume / renderer. Only valid if this mapper has been used to render that volume for that renderer previously. Estimate is good when the viewing parameters have not changed much since that last render.

- `float = obj.GetEstimatedRenderTime (vtkRenderer ren)` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.

- `obj.SetFinalColorWindow (float )` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.

- `float = obj.GetFinalColorWindow ()` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.

- `obj.SetFinalColorLevel (float )` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.

- `float = obj.GetFinalColorLevel ()` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.

- `int = obj.GetFlipMIPComparison ()`

41.12 vtkFixedPointVolumeRayCastMIPHelper

41.12.1 Usage

This is one of the helper classes for the vtkFixedPointVolumeRayCastMapper. It will generate maximum intensity images. This class should not be used directly, it is a helper class for the mapper and has no user-level API.

To create an instance of class vtkFixedPointVolumeRayCastMIPHelper, simply invoke its constructor as follows

```
obj = vtkFixedPointVolumeRayCastMIPHelper
```

41.12.2 Methods

The class vtkFixedPointVolumeRayCastMIPHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFixedPointVolumeRayCastMIPHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFixedPointVolumeRayCastMIPHelper = obj.NewInstance ()`
- `vtkFixedPointVolumeRayCastMIPHelper = obj.SafeDownCast (vtkObject o)`
- `obj.GenerateImage (int threadID, int threadCount, vtkVolume vol, vtkFixedPointVolumeRayCastMapper m`

41.13 vtkGPUVolumeRayCastMapper

41.13.1 Usage

vtkGPUVolumeRayCastMapper is a volume mapper that performs ray casting on the GPU using fragment programs.

To create an instance of class vtkGPUVolumeRayCastMapper, simply invoke its constructor as follows

```
obj = vtkGPUVolumeRayCastMapper
```

41.13.2 Methods

The class vtkGPUVolumeRayCastMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGPUVolumeRayCastMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGPUVolumeRayCastMapper = obj.NewInstance ()`
- `vtkGPUVolumeRayCastMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetAutoAdjustSampleDistances (int )` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `int = obj.GetAutoAdjustSampleDistancesMinValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistancesMaxValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistances ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.AutoAdjustSampleDistancesOn ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.AutoAdjustSampleDistancesOff ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.SetSampleDistance (float )` - Set/Get the distance between samples used for rendering when AutoAdjustSampleDistances is off, or when this mapper has more than 1 second allocated to it for rendering. Initial value is 1.0.
- `float = obj.GetSampleDistance ()` - Set/Get the distance between samples used for rendering when AutoAdjustSampleDistances is off, or when this mapper has more than 1 second allocated to it for rendering. Initial value is 1.0.
- `obj.SetImageSampleDistance (float )` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.
- `float = obj.GetImageSampleDistanceMinValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.
- `float = obj.GetImageSampleDistanceMaxValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.
- `float = obj.GetImageSampleDistance ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels. This value will be adjusted to meet a desired frame rate when AutoAdjustSampleDistances is on.
- `obj.SetMinimumImageSampleDistance (float )` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.
- `float = obj.GetMinimumImageSampleDistanceMinValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.
- `float = obj.GetMinimumImageSampleDistanceMaxValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.
- `float = obj.GetMinimumImageSampleDistance ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted.

- `obj.SetMaximumImageSampleDistance (float )` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.
- `float = obj.GetMaximumImageSampleDistanceMinValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.
- `float = obj.GetMaximumImageSampleDistanceMaxValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.
- `float = obj.GetMaximumImageSampleDistance ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted.
- `obj.SetFinalColorWindow (float )` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.
- `float = obj.GetFinalColorWindow ()` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.
- `obj.SetFinalColorLevel (float )` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.
- `float = obj.GetFinalColorLevel ()` - Set/Get the window / level applied to the final color. This allows brightness / contrast adjustments on the final image. window is the width of the window. level is the center of the window. Initial window value is 1.0 Initial level value is 0.5 window cannot be null but can be negative, this way values will be reversed. —window— can be larger than 1.0 level can be any real value.
- `obj.SetMaxMemoryInBytes (vtkIdType )` - Maximum size of the 3D texture in GPU memory. Will default to the size computed from the graphics card. Can be adjusted by the user.
- `vtkIdType = obj.GetMaxMemoryInBytes ()` - Maximum size of the 3D texture in GPU memory. Will default to the size computed from the graphics card. Can be adjusted by the user.
- `obj.SetMaxMemoryFraction (float )` - Maximum fraction of the MaxMemoryInBytes that should be used to hold the texture. Valid values are 0.1 to 1.0.
- `float = obj.GetMaxMemoryFractionMinValue ()` - Maximum fraction of the MaxMemoryInBytes that should be used to hold the texture. Valid values are 0.1 to 1.0.
- `float = obj.GetMaxMemoryFractionMaxValue ()` - Maximum fraction of the MaxMemoryInBytes that should be used to hold the texture. Valid values are 0.1 to 1.0.
- `float = obj.GetMaxMemoryFraction ()` - Maximum fraction of the MaxMemoryInBytes that should be used to hold the texture. Valid values are 0.1 to 1.0.
- `obj.SetReportProgress (bool )` - Tells if the mapper will report intermediate progress. Initial value is true. As the progress works with a GL blocking call (glFinish()), this can be useful for huge dataset but can slow down rendering of small dataset. It should be set to true for big dataset or complex shading and streaming but to false for small datasets.

- `bool = obj.GetReportProgress ()` - Tells if the mapper will report intermediate progress. Initial value is true. As the progress works with a GL blocking call (glFinish()), this can be useful for huge dataset but can slow down rendering of small dataset. It should be set to true for big dataset or complex shading and streaming but to false for small datasets.
- `int = obj.IsRenderSupported (vtkRenderWindow , vtkVolumeProperty )`
- `obj.CreateCanonicalView (vtkRenderer ren, vtkVolume volume, vtkImageData image, int blend\_mode, do`
- `obj.SetMaskInput (vtkImageData mask)`
- `vtkImageData = obj.GetMaskInput ()`
- `obj.SetMaskBlendFactor (float )` - Tells how much mask color transfer function is used compared to the standard color transfer function when the mask is true. 0.0 means only standard color transfer function. 1.0 means only mask color tranfer function. Initial value is 1.0.
- `float = obj.GetMaskBlendFactorMinValue ()` - Tells how much mask color transfer function is used compared to the standard color transfer function when the mask is true. 0.0 means only standard color transfer function. 1.0 means only mask color tranfer function. Initial value is 1.0.
- `float = obj.GetMaskBlendFactorMaxValue ()` - Tells how much mask color transfer function is used compared to the standard color transfer function when the mask is true. 0.0 means only standard color transfer function. 1.0 means only mask color tranfer function. Initial value is 1.0.
- `float = obj.GetMaskBlendFactor ()` - Tells how much mask color transfer function is used compared to the standard color transfer function when the mask is true. 0.0 means only standard color transfer function. 1.0 means only mask color tranfer function. Initial value is 1.0.

41.14 vtkHAVSVolumeMapper

41.14.1 Usage

vtkHAVSVolumeMapper is a class that renders polygonal data (represented as an unstructured grid) using the Hardware-Assisted Visibility Sorting (HAVS) algorithm. First the unique triangles are sorted in object space, then they are sorted in image space using a fixed size A-buffer implemented on the GPU called the k-buffer. The HAVS algorithm excels at rendering large datasets quickly. The trade-off is that the algorithm may produce some rendering artifacts due to an insufficient k size (currently 2 or 6 is supported) or read/write race conditions.

A built in level-of-detail (LOD) approach samples the geometry using one of two heuristics (field or area). If LOD is enabled, the amount of geometry that is sampled and rendered changes dynamically to stay within the target frame rate. The field sampling method generally works best for datasets with cell sizes that don't vary much in size. On the contrary, the area sampling approach gives better approximations when the volume has a lot of variation in cell size.

The HAVS algorithm uses several advanced features on graphics hardware. The k-buffer sorting network is implemented using framebuffer objects (FBOs) with multiple render targets (MRTs). Therefore, only cards that support these features can run the algorithm (at least an ATI 9500 or an NVidia NV40 (6600)).

.SECTION Notes

Several issues had to be addressed to get the HAVS algorithm working within the vtk framework. These additions forced the code to forsake speed for the sake of compliance and robustness.

The HAVS algorithm operates on the triangles that compose the mesh. Therefore, before rendering, the cells are decomposed into unique triangles and stored on the GPU for efficient rendering. The use of GPU data structures is only recommended if the entire geometry can fit in graphics memory. Otherwise this feature should be disabled.

Another new feature is the handling of mixed data types (eg., polygonal data with volume data). This is handled by reading the z-buffer from the current window and copying it into the framebuffer object for off-screen rendering. The depth test is then enabled so that the volume only appears over the opaque geometry.

Finally, the results of the off-screen rendering are blended into the framebuffer as a transparent, view-aligned texture.

Instead of using a preintegrated 3D lookup table for storing the ray integral, this implementation uses partial pre-integration. This improves the performance of dynamic transfer function updates by avoiding a costly preprocess of the table.

A final change to the original algorithm is the handling of non-convexities in the mesh. Due to read/write hazards that may create undesired artifacts with non-convexities when using a inside/outside toggle in the fragment program, another approach was employed. To handle non-convexities, the fragment shader determines if a ray-gap is larger than the max cell size and kill the fragment if so. This approximation performs rather well in practice but may miss small non-convexities.

For more information on the HAVS algorithm see:

"Hardware-Assisted Visibility Sorting for Unstructured Volume Rendering" by S. P. Callahan, M. Ikits, J. L. D. Comba, and C. T. Silva, IEEE Transactions of Visualization and Computer Graphics; May/June 2005.

For more information on the Level-of-Detail algorithm, see:

"Interactive Rendering of Large Unstructured Grids Using Dynamic Level-of-Detail" by S. P. Callahan, J. L. D. Comba, P. Shirley, and C. T. Silva, Proceedings of IEEE Visualization '05, Oct. 2005.

.SECTION Acknowledgments

This code was developed by Steven P. Callahan under the supervision of Prof. Claudio T. Silva. The code also contains contributions from Milan Ikits, Linh Ha, Huy T. Vo, Carlos E. Scheidegger, and Joao L. D. Comba.

The work was supported by grants, contracts, and gifts from the National Science Foundation, the Department of Energy, the Army Research Office, and IBM.

The port of HAVS to VTK and ParaView has been primarily supported by Sandia National Labs.

To create an instance of class vtkHAVSVolumeMapper, simply invoke its constructor as follows

```
obj = vtkHAVSVolumeMapper
```

41.14.2 Methods

The class vtkHAVSVolumeMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHAVSVolumeMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHAVSVolumeMapper = obj.NewInstance ()`
- `vtkHAVSVolumeMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetPartiallyRemoveNonConvexities (bool )` - regions by removing ray segments larger than the max cell size.
- `bool = obj.GetPartiallyRemoveNonConvexities ()` - regions by removing ray segments larger than the max cell size.
- `obj.SetLevelOfDetailTargetTime (float )` - Set/get the desired level of detail target time measured in frames/sec.
- `float = obj.GetLevelOfDetailTargetTime ()` - Set/get the desired level of detail target time measured in frames/sec.
- `obj.SetLevelOfDetail (bool )` - Turn on/off level-of-detail volume rendering
- `bool = obj.GetLevelOfDetail ()` - Turn on/off level-of-detail volume rendering

- `obj.SetLevelOfDetailMethod (int )` - Set/get the current level-of-detail method
- `int = obj.GetLevelOfDetailMethod ()` - Set/get the current level-of-detail method
- `obj.SetLevelOfDetailMethodField ()` - Set/get the current level-of-detail method
- `obj.SetLevelOfDetailMethodArea ()` - Set the kbuffer size
- `obj.SetKBufferSize (int )` - Set the kbuffer size
- `int = obj.GetKBufferSize ()` - Set the kbuffer size
- `obj.SetKBufferSizeTo2 ()` - Set the kbuffer size
- `obj.SetKBufferSizeTo6 ()` - Check hardware support for the HAVS algorithm. Necessary features include off-screen rendering, 32-bit fp textures, multiple render targets, and framebuffer objects. Subclasses must override this method to indicate if supported by Hardware.
- `bool = obj.SupportedByHardware ()` - Set/get whether or not the data structures should be stored on the GPU for better peformance.
- `obj.SetGPUDataStructures (bool )` - Set/get whether or not the data structures should be stored on the GPU for better peformance.
- `bool = obj.GetGPUDataStructures ()` - Set/get whether or not the data structures should be stored on the GPU for better peformance.

41.15 vtkOpenGLGPUVolumeRayCastMapper

41.15.1 Usage

This is the concrete implementation of a ray cast image display helper - a helper class responsible for drawing the image to the screen.

To create an instance of class vtkOpenGLGPUVolumeRayCastMapper, simply invoke its constructor as follows

```
obj = vtkOpenGLGPUVolumeRayCastMapper
```

41.15.2 Methods

The class vtkOpenGLGPUVolumeRayCastMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLGPUVolumeRayCastMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLGPUVolumeRayCastMapper = obj.NewInstance ()`
- `vtkOpenGLGPUVolumeRayCastMapper = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsRenderSupported (vtkRenderWindow window, vtkVolumeProperty property)` - Based on hardware and properties, we may or may not be able to render using 3D texture mapping. This indicates if 3D texture mapping is supported by the hardware, and if the other extensions necessary to support the specific properties are available.

41.16 vtkOpenGLHAVSVolumeMapper

41.16.1 Usage

vtkHAVSVolumeMapper is a class that renders polygonal data (represented as an unstructured grid) using the Hardware-Assisted Visibility Sorting (HAVS) algorithm. First the unique triangles are sorted in object space, then they are sorted in image space using a fixed size A-buffer implemented on the GPU called the k-buffer. The HAVS algorithm excels at rendering large datasets quickly. The trade-off is that the algorithm may produce some rendering artifacts due to an insufficient k size (currently 2 or 6 is supported) or read/write race conditions.

A built in level-of-detail (LOD) approach samples the geometry using one of two heuristics (field or area). If LOD is enabled, the amount of geometry that is sampled and rendered changes dynamically to stay within the target frame rate. The field sampling method generally works best for datasets with cell sizes that don't vary much in size. On the contrary, the area sampling approach gives better approximations when the volume has a lot of variation in cell size.

The HAVS algorithm uses several advanced features on graphics hardware. The k-buffer sorting network is implemented using framebuffer objects (FBOs) with multiple render targets (MRTs). Therefore, only cards that support these features can run the algorithm (at least an ATI 9500 or an NVidia NV40 (6600)).

.SECTION Notes

Several issues had to be addressed to get the HAVS algorithm working within the vtk framework. These additions forced the code to forsake speed for the sake of compliance and robustness.

The HAVS algorithm operates on the triangles that compose the mesh. Therefore, before rendering, the cells are decomposed into unique triangles and stored on the GPU for efficient rendering. The use of GPU data structures is only recommended if the entire geometry can fit in graphics memory. Otherwise this feature should be disabled.

Another new feature is the handling of mixed data types (eg., polygonal data with volume data). This is handled by reading the z-buffer from the current window and copying it into the framebuffer object for off-screen rendering. The depth test is then enabled so that the volume only appears over the opaque geometry. Finally, the results of the off-screen rendering are blended into the framebuffer as a transparent, view-aligned texture.

Instead of using a preintegrated 3D lookup table for storing the ray integral, this implementation uses partial pre-integration. This improves the performance of dynamic transfer function updates by avoiding a costly preprocess of the table.

A final change to the original algorithm is the handling of non-convexities in the mesh. Due to read/write hazards that may create undesired artifacts with non-convexities when using a inside/outside toggle in the fragment program, another approach was employed. To handle non-convexities, the fragment shader determines if a ray-gap is larger than the max cell size and kill the fragment if so. This approximation performs rather well in practice but may miss small non-convexities.

For more information on the HAVS algorithm see:

"Hardware-Assisted Visibility Sorting for Unstructured Volume Rendering" by S. P. Callahan, M. Ikits, J. L. D. Comba, and C. T. Silva, IEEE Transactions of Visualization and Computer Graphics; May/June 2005.

For more information on the Level-of-Detail algorithm, see:

"Interactive Rendering of Large Unstructured Grids Using Dynamic Level-of-Detail" by S. P. Callahan, J. L. D. Comba, P. Shirley, and C. T. Silva, Proceedings of IEEE Visualization '05, Oct. 2005.

.SECTION Acknowledgments

This code was developed by Steven P. Callahan under the supervision of Prof. Claudio T. Silva. The code also contains contributions from Milan Ikits, Linh Ha, Huy T. Vo, Carlos E. Scheidegger, and Joao L. D. Comba.

The work was supported by grants, contracts, and gifts from the National Science Foundation, the Department of Energy, the Army Research Office, and IBM.

The port of HAVS to VTK and ParaView has been primarily supported by Sandia National Labs.

To create an instance of class vtkOpenGLHAVSVolumeMapper, simply invoke its constructor as follows

```
obj = vtkOpenGLHAVSVolumeMapper
```

41.16.2 Methods

The class vtkOpenGLHAVSVolumeMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLHAVSVolumeMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLHAVSVolumeMapper = obj.NewInstance ()`
- `vtkOpenGLHAVSVolumeMapper = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer ren, vtkVolume vol)` - Render the volume
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `obj.SetGPUDataStructures (bool )` - Set/get whether or not the data structures should be stored on the GPU for better peformance.
- `bool = obj.SupportedByHardware ()` - Check hardware support for the HAVS algorithm. Necessary features include off-screen rendering, 32-bit fp textures, multiple render targets, and framebuffer objects. Subclasses must override this method to indicate if supported by Hardware.

41.17 vtkOpenGLRayCastImageDisplayHelper

41.17.1 Usage

This is the concrete implementation of a ray cast image display helper - a helper class responsible for drawing the image to the screen.

To create an instance of class vtkOpenGLRayCastImageDisplayHelper, simply invoke its constructor as follows

```
obj = vtkOpenGLRayCastImageDisplayHelper
```

41.17.2 Methods

The class vtkOpenGLRayCastImageDisplayHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLRayCastImageDisplayHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLRayCastImageDisplayHelper = obj.NewInstance ()`
- `vtkOpenGLRayCastImageDisplayHelper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderTexture (vtkVolume vol, vtkRenderer ren, int imageMemorySize[2], int imageViewportSize[2]`
- `obj.RenderTexture (vtkVolume vol, vtkRenderer ren, int imageMemorySize[2], int imageViewportSize[2]`
- `obj.RenderTexture (vtkVolume vol, vtkRenderer ren, vtkFixedPointRayCastImage image, float requested`

41.18 vtkOpenGLVolumeTextureMapper2D

41.18.1 Usage

vtkOpenGLVolumeTextureMapper2D renders a volume using 2D texture mapping.

To create an instance of class vtkOpenGLVolumeTextureMapper2D, simply invoke its constructor as follows

```
obj = vtkOpenGLVolumeTextureMapper2D
```

41.18.2 Methods

The class vtkOpenGLVolumeTextureMapper2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLVolumeTextureMapper2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLVolumeTextureMapper2D = obj.NewInstance ()`
- `vtkOpenGLVolumeTextureMapper2D = obj.SafeDownCast (vtkObject o)`

41.19 vtkOpenGLVolumeTextureMapper3D

41.19.1 Usage

vtkOpenGLVolumeTextureMapper3D renders a volume using 3D texture mapping. See vtkVolumeTextureMapper3D for full description.

To create an instance of class vtkOpenGLVolumeTextureMapper3D, simply invoke its constructor as follows

```
obj = vtkOpenGLVolumeTextureMapper3D
```

41.19.2 Methods

The class vtkOpenGLVolumeTextureMapper3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOpenGLVolumeTextureMapper3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOpenGLVolumeTextureMapper3D = obj.NewInstance ()`
- `vtkOpenGLVolumeTextureMapper3D = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsRenderSupported (vtkVolumeProperty )` - Is hardware rendering supported? No if the input data is more than one independent component, or if the hardware does not support the required extensions
- `int = obj.GetInitialized ()`
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this texture. The parameter window could be used to determine which graphic resources to release.

41.20 vtkProjectedTetrahedraMapper

41.20.1 Usage

vtkProjectedTetrahedraMapper is an implementation of the classic Projected Tetrahedra algorithm presented by Shirley and Tuchman in "A Polygonal Approximation to Direct Scalar Volume Rendering" in Computer Graphics, December 1990.

.SECTION Bugs This mapper relies highly on the implementation of the OpenGL pipeline. A typical hardware driver has lots of options and some settings can cause this mapper to produce artifacts.

To create an instance of class vtkProjectedTetrahedraMapper, simply invoke its constructor as follows

```
obj = vtkProjectedTetrahedraMapper
```

41.20.2 Methods

The class vtkProjectedTetrahedraMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProjectedTetrahedraMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProjectedTetrahedraMapper = obj.NewInstance ()`
- `vtkProjectedTetrahedraMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetVisibilitySort (vtkVisibilitySort sort)`
- `vtkVisibilitySort = obj.GetVisibilitySort ()`

41.21 vtkRayCastImageDisplayHelper

41.21.1 Usage

This is a helper class for drawing images created from ray casting on the screen. This is the abstract device-independent superclass.

To create an instance of class vtkRayCastImageDisplayHelper, simply invoke its constructor as follows

```
obj = vtkRayCastImageDisplayHelper
```

41.21.2 Methods

The class vtkRayCastImageDisplayHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRayCastImageDisplayHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRayCastImageDisplayHelper = obj.NewInstance ()`
- `vtkRayCastImageDisplayHelper = obj.SafeDownCast (vtkObject o)`
- `obj.RenderTexture (vtkVolume vol, vtkRenderer ren, int imageMemorySize[2], int imageViewportSize[2]`
- `obj.RenderTexture (vtkVolume vol, vtkRenderer ren, int imageMemorySize[2], int imageViewportSize[2]`

- obj.RenderTexture (vtkVolume vol, vtkRenderer ren, vtkFixedPointRayCastImage image, float requested
- obj.SetPreMultipliedColors (int)
- int = obj.GetPreMultipliedColorsMinValue ()
- int = obj.GetPreMultipliedColorsMaxValue ()
- int = obj.GetPreMultipliedColors ()
- obj.PreMultipliedColorsOn ()
- obj.PreMultipliedColorsOff ()
- obj.SetPixelScale (float) - Set / Get the pixel scale to be applied to the image before display. Can be set to scale the incoming pixel values - for example the fixed point mapper uses the unsigned short API but with 15 bit values so needs a scale of 2.0.
- float = obj.GetPixelScale () - Set / Get the pixel scale to be applied to the image before display. Can be set to scale the incoming pixel values - for example the fixed point mapper uses the unsigned short API but with 15 bit values so needs a scale of 2.0.

41.22 vtkRecursiveSphereDirectionEncoder

41.22.1 Usage

vtkRecursiveSphereDirectionEncoder is a direction encoder which uses the vertices of a recursive subdivision of an octahedron (with the vertices pushed out onto the surface of an enclosing sphere) to encode directions into a two byte value.

To create an instance of class vtkRecursiveSphereDirectionEncoder, simply invoke its constructor as follows

```
obj = vtkRecursiveSphereDirectionEncoder
```

41.22.2 Methods

The class vtkRecursiveSphereDirectionEncoder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, obj is an instance of the vtkRecursiveSphereDirectionEncoder class.

- string = obj.GetClassName ()
- int = obj.IsA (string name)
- vtkRecursiveSphereDirectionEncoder = obj.NewInstance ()
- vtkRecursiveSphereDirectionEncoder = obj.SafeDownCast (vtkObject o)
- int = obj.GetEncodedDirection (float n[3]) - Given a normal vector n, return the encoded direction
- float = obj.GetDecodedGradient (int value) - / Given an encoded value, return a pointer to the normal vector
- int = obj.GetNumberOfEncodedDirections (void) - Return the number of encoded directions

- `obj.SetRecursionDepth (int )` - Set / Get the recursion depth for the subdivision. This indicates how many time one triangle on the initial 8-sided sphere model is replaced by four triangles formed by connecting triangle edge midpoints. A recursion level of 0 yields 8 triangles with 6 unique vertices. The normals are the vectors from the sphere center through the vertices. The number of directions will be 11 since the four normals with 0 z values will be duplicated in the table - once with +0 values and the other time with -0 values, and an addition index will be used to represent the (0,0,0) normal. If we instead choose a recursion level of 6 (the maximum that can fit within 2 bytes) the number of directions is 16643, with 16386 unique directions and a zero normal.

- `int = obj.GetRecursionDepthMinValue ()` - Set / Get the recursion depth for the subdivision. This indicates how many time one triangle on the initial 8-sided sphere model is replaced by four triangles formed by connecting triangle edge midpoints. A recursion level of 0 yields 8 triangles with 6 unique vertices. The normals are the vectors from the sphere center through the vertices. The number of directions will be 11 since the four normals with 0 z values will be duplicated in the table - once with +0 values and the other time with -0 values, and an addition index will be used to represent the (0,0,0) normal. If we instead choose a recursion level of 6 (the maximum that can fit within 2 bytes) the number of directions is 16643, with 16386 unique directions and a zero normal.

- `int = obj.GetRecursionDepthMaxValue ()` - Set / Get the recursion depth for the subdivision. This indicates how many time one triangle on the initial 8-sided sphere model is replaced by four triangles formed by connecting triangle edge midpoints. A recursion level of 0 yields 8 triangles with 6 unique vertices. The normals are the vectors from the sphere center through the vertices. The number of directions will be 11 since the four normals with 0 z values will be duplicated in the table - once with +0 values and the other time with -0 values, and an addition index will be used to represent the (0,0,0) normal. If we instead choose a recursion level of 6 (the maximum that can fit within 2 bytes) the number of directions is 16643, with 16386 unique directions and a zero normal.

- `int = obj.GetRecursionDepth ()` - Set / Get the recursion depth for the subdivision. This indicates how many time one triangle on the initial 8-sided sphere model is replaced by four triangles formed by connecting triangle edge midpoints. A recursion level of 0 yields 8 triangles with 6 unique vertices. The normals are the vectors from the sphere center through the vertices. The number of directions will be 11 since the four normals with 0 z values will be duplicated in the table - once with +0 values and the other time with -0 values, and an addition index will be used to represent the (0,0,0) normal. If we instead choose a recursion level of 6 (the maximum that can fit within 2 bytes) the number of directions is 16643, with 16386 unique directions and a zero normal.

41.23 vtkSphericalDirectionEncoder

41.23.1 Usage

vtkSphericalDirectionEncoder is a direction encoder which uses spherical coordinates for mapping (nx, ny, nz) into an azimuth, elevation pair.

To create an instance of class vtkSphericalDirectionEncoder, simply invoke its constructor as follows

```
obj = vtkSphericalDirectionEncoder
```

41.23.2 Methods

The class vtkSphericalDirectionEncoder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphericalDirectionEncoder class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkSphericalDirectionEncoder = obj.NewInstance ()`
- `vtkSphericalDirectionEncoder = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetEncodedDirection (float n[3])` - Given a normal vector n, return the encoded direction
- `float = obj.GetDecodedGradient (int value)` - / Given an encoded value, return a pointer to the normal vector
- `int = obj.GetNumberOfEncodedDirections (void )` - Get the decoded gradient table. There are this-¿GetNumberOfEncodedDirections() entries in the table, each containing a normal (direction) vector. This is a flat structure - 3 times the number of directions floats in an array.

41.24 vtkUnstructuredGridBunykRayCastFunction

41.24.1 Usage

vtkUnstructuredGridBunykRayCastFunction is a concrete implementation of a ray cast function for unstructured grid data. This class was based on the paper "Simple, Fast, Robust Ray Casting of Irregular Grids" by Paul Bunyk, Arie Kaufmna, and Claudio Silva. This method is quite memory intensive (with extra explicit copies of the data) and therefore should not be used for very large data. This method assumes that the input data is composed entirely of tetras - use vtkDataSetTriangleFilter before setting the input on the mapper.

The basic idea of this method is as follows:

1) Enumerate the triangles. At each triangle have space for some information that will be used during rendering. This includes which tetra the triangles belong to, the plane equation and the Barycentric coefficients.

2) Keep a reference to all four triangles for each tetra.

3) At the beginning of each render, do the precomputation. This includes creating an array of transformed points (in view coordinates) and computing the view dependent info per triangle (plane equations and barycentric coords in view space)

4) Find all front facing boundary triangles (a triangle is on the boundary if it belongs to only one tetra). For each triangle, find all pixels in the image that intersect the triangle, and add this to the sorted (by depth) intersection list at each pixel.

5) For each ray cast, traverse the intersection list. At each intersection, accumulate opacity and color contribution per tetra along the ray until you reach an exiting triangle (on the boundary).

To create an instance of class vtkUnstructuredGridBunykRayCastFunction, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridBunykRayCastFunction
```

41.24.2 Methods

The class vtkUnstructuredGridBunykRayCastFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridBunykRayCastFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridBunykRayCastFunction = obj.NewInstance ()`
- `vtkUnstructuredGridBunykRayCastFunction = obj.SafeDownCast (vtkObject o)`

41.25 vtkUnstructuredGridHomogeneousRayIntegrator

41.25.1 Usage

vtkUnstructuredGridHomogeneousRayIntegrator performs homogeneous ray integration. This is a good method to use when volume rendering scalars that are defined on cells.

To create an instance of class vtkUnstructuredGridHomogeneousRayIntegrator, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridHomogeneousRayIntegrator
```

41.25.2 Methods

The class vtkUnstructuredGridHomogeneousRayIntegrator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridHomogeneousRayIntegrator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridHomogeneousRayIntegrator = obj.NewInstance ()`
- `vtkUnstructuredGridHomogeneousRayIntegrator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkVolume volume, vtkDataArray scalars)`
- `obj.Integrate (vtkDoubleArray intersectionLengths, vtkDataArray nearIntersections, vtkDataArray far`
- `obj.SetTransferFunctionTableSize (int )` - For quick lookup, the transfer function is sampled into a table. This parameter sets how big of a table to use. By default, 1024 entries are used.
- `int = obj.GetTransferFunctionTableSize ()` - For quick lookup, the transfer function is sampled into a table. This parameter sets how big of a table to use. By default, 1024 entries are used.

41.26 vtkUnstructuredGridLinearRayIntegrator

41.26.1 Usage

vtkUnstructuredGridLinearRayIntegrator performs piecewise linear ray integration. Considering that transfer functions in VTK are piecewise linear, this class should give the "correct" integration under most circumstances. However, the computations performed are fairly hefty and should, for the most part, only be used as a benchmark for other, faster methods.

To create an instance of class vtkUnstructuredGridLinearRayIntegrator, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridLinearRayIntegrator
```

41.26.2 Methods

The class vtkUnstructuredGridLinearRayIntegrator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridLinearRayIntegrator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkUnstructuredGridLinearRayIntegrator = obj.NewInstance ()`
- `vtkUnstructuredGridLinearRayIntegrator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkVolume volume, vtkDataArray scalars)`
- `obj.Integrate (vtkDoubleArray intersectionLengths, vtkDataArray nearIntersections, vtkDataArray far`

41.27 vtkUnstructuredGridPartialPreIntegration

41.27.1 Usage

vtkUnstructuredGridPartialPreIntegration performs piecewise linear ray integration. This will give the same results as vtkUnstructuredGridLinearRayIntegration (with potentially a error due to table lookup quantization), but should be notably faster. The algorithm used is given by Moreland and Angel, "A Fast High Accuracy Volume Renderer for Unstructured Data."

This class is thread safe only after the first instance is created.

To create an instance of class vtkUnstructuredGridPartialPreIntegration, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridPartialPreIntegration
```

41.27.2 Methods

The class vtkUnstructuredGridPartialPreIntegration has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridPartialPreIntegration class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridPartialPreIntegration = obj.NewInstance ()`
- `vtkUnstructuredGridPartialPreIntegration = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkVolume volume, vtkDataArray scalars)`
- `obj.Integrate (vtkDoubleArray intersectionLengths, vtkDataArray nearIntersections, vtkDataArray far`

41.28 vtkUnstructuredGridPreIntegration

41.28.1 Usage

vtkUnstructuredGridPreIntegration performs ray integration by looking into a precomputed table. The result should be equivalent to that computed by vtkUnstructuredGridLinearRayIntegrator and vtkUnstructuredGridPartialPreIntegration, but faster than either one. The pre-integration algorithm was first introduced by Roettger, Kraus, and Ertl in "Hardware-Accelerated Volume And Isosurface Rendering Based On Cell-Projection."

Due to table size limitations, a table can only be indexed by independent scalars. Thus, dependent scalars are not supported.

To create an instance of class vtkUnstructuredGridPreIntegration, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridPreIntegration
```

41.28.2 Methods

The class vtkUnstructuredGridPreIntegration has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridPreIntegration class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridPreIntegration = obj.NewInstance ()`
- `vtkUnstructuredGridPreIntegration = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkVolume volume, vtkDataArray scalars)`
- `obj.Integrate (vtkDoubleArray intersectionLengths, vtkDataArray nearIntersections, vtkDataArray far`
- `vtkUnstructuredGridVolumeRayIntegrator = obj.GetIntegrator ()` - The class used to fill the pre integration table. By default, a vtkUnstructuredGridPartialPreIntegration is built.
- `obj.SetIntegrator (vtkUnstructuredGridVolumeRayIntegrator )` - The class used to fill the pre integration table. By default, a vtkUnstructuredGridPartialPreIntegration is built.
- `obj.SetIntegrationTableScalarResolution (int )` - Set/Get the size of the integration table built.
- `int = obj.GetIntegrationTableScalarResolution ()` - Set/Get the size of the integration table built.
- `obj.SetIntegrationTableLengthResolution (int )` - Set/Get the size of the integration table built.
- `int = obj.GetIntegrationTableLengthResolution ()` - Set/Get the size of the integration table built.
- `double = obj.GetIntegrationTableScalarShift (int component)` - Get how an integration table is indexed.
- `double = obj.GetIntegrationTableScalarScale (int component)` - Get how an integration table is indexed.
- `double = obj.GetIntegrationTableLengthScale ()` - Get how an integration table is indexed.
- `int = obj.GetIncrementalPreIntegration ()` - Get/set whether to use incremental pre-integration (by default it's on). Incremental pre-integration is much faster but can introduce error due to numerical imprecision. Under most circumstances, the error is not noticable.
- `obj.SetIncrementalPreIntegration (int )` - Get/set whether to use incremental pre-integration (by default it's on). Incremental pre-integration is much faster but can introduce error due to numerical imprecision. Under most circumstances, the error is not noticable.
- `obj.IncrementalPreIntegrationOn ()` - Get/set whether to use incremental pre-integration (by default it's on). Incremental pre-integration is much faster but can introduce error due to numerical imprecision. Under most circumstances, the error is not noticable.
- `obj.IncrementalPreIntegrationOff ()` - Get/set whether to use incremental pre-integration (by default it's on). Incremental pre-integration is much faster but can introduce error due to numerical imprecision. Under most circumstances, the error is not noticable.

41.29 vtkUnstructuredGridVolumeMapper

41.29.1 Usage

vtkUnstructuredGridVolumeMapper is the abstract definition of a volume mapper for unstructured data (vtkUnstructuredGrid). Several basic types of volume mappers are supported as subclasses

To create an instance of class vtkUnstructuredGridVolumeMapper, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridVolumeMapper
```

41.29.2 Methods

The class vtkUnstructuredGridVolumeMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridVolumeMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridVolumeMapper = obj.NewInstance ()`
- `vtkUnstructuredGridVolumeMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkUnstructuredGrid )` - Set/Get the input data
- `obj.SetInput (vtkDataSet )` - Set/Get the input data
- `vtkUnstructuredGrid = obj.GetInput ()` - Set/Get the input data
- `obj.SetBlendMode (int )`
- `obj.SetBlendModeToComposite ()`
- `obj.SetBlendModeToMaximumIntensity ()`
- `int = obj.GetBlendMode ()`

41.30 vtkUnstructuredGridVolumeRayCastFunction

41.30.1 Usage

vtkUnstructuredGridVolumeRayCastFunction is a superclass for ray casting functions that can be used within a vtkUnstructuredGridVolumeRayCastMapper.

To create an instance of class vtkUnstructuredGridVolumeRayCastFunction, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridVolumeRayCastFunction
```

41.30.2 Methods

The class vtkUnstructuredGridVolumeRayCastFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridVolumeRayCastFunction class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkUnstructuredGridVolumeRayCastFunction = obj.NewInstance ()`
- `vtkUnstructuredGridVolumeRayCastFunction = obj.SafeDownCast (vtkObject o)`

41.31 vtkUnstructuredGridVolumeRayCastIterator

41.31.1 Usage

vtkUnstructuredGridVolumeRayCastIterator is a superclass for iterating over the intersections of a viewing ray with a group of unstructured cells. These iterators are created with a vtkUnstructuredGridVolumeRayCastFunction.

To create an instance of class vtkUnstructuredGridVolumeRayCastIterator, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridVolumeRayCastIterator
```

41.31.2 Methods

The class vtkUnstructuredGridVolumeRayCastIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridVolumeRayCastIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridVolumeRayCastIterator = obj.NewInstance ()`
- `vtkUnstructuredGridVolumeRayCastIterator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (int x, int y)` - Initializes the iteration to the start of the ray at the given screen coordinates.
- `vtkIdType = obj.GetNextIntersections (vtkIdList intersectedCells, vtkDoubleArray intersectionLengt` - Get the intersections of the next several cells. The cell ids are stored in ţntersectedCells and the length of each ray segment within the cell is stored in ţntersectionLengths. The point scalars şcalars are interpolated and stored in ņearIntersections and ţarIntersections. ţntersectedCells, ţntersectionLengths, or şcalars may be ŅULL to supress passing the associated information. The number of intersections actually encountered is returned. 0 is returned if and only if no more intersections are to be found.
- `obj.SetBounds (double , double )` - Set/get the bounds of the cast ray (in viewing coordinates). By default the range is [0,1].
- `obj.SetBounds (double  a[2])` - Set/get the bounds of the cast ray (in viewing coordinates). By default the range is [0,1].
- `double = obj. GetBounds ()` - Set/get the bounds of the cast ray (in viewing coordinates). By default the range is [0,1].
- `obj.SetMaxNumberOfIntersections (vtkIdType )`
- `vtkIdType = obj.GetMaxNumberOfIntersections ()`

41.32 vtkUnstructuredGridVolumeRayCastMapper

41.32.1 Usage

This is a software ray caster for rendering volumes in vtkUnstructuredGrid.

To create an instance of class vtkUnstructuredGridVolumeRayCastMapper, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridVolumeRayCastMapper
```

41.32.2 Methods

The class vtkUnstructuredGridVolumeRayCastMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridVolumeRayCastMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridVolumeRayCastMapper = obj.NewInstance ()`
- `vtkUnstructuredGridVolumeRayCastMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetImageSampleDistance (float )` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `float = obj.GetImageSampleDistanceMinValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `float = obj.GetImageSampleDistanceMaxValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `float = obj.GetImageSampleDistance ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `obj.SetMinimumImageSampleDistance (float )` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMinimumImageSampleDistanceMinValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMinimumImageSampleDistanceMaxValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMinimumImageSampleDistance ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `obj.SetMaximumImageSampleDistance (float )` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMaximumImageSampleDistanceMinValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMaximumImageSampleDistanceMaxValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted

- `float = obj.GetMaximumImageSampleDistance ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `obj.SetAutoAdjustSampleDistances (int )` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistancesMinValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistancesMaxValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistances ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.AutoAdjustSampleDistancesOn ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.AutoAdjustSampleDistancesOff ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.SetNumberOfThreads (int )` - Set/Get the number of threads to use. This by default is equal to the number of available processors detected.
- `int = obj.GetNumberOfThreads ()` - Set/Get the number of threads to use. This by default is equal to the number of available processors detected.
- `obj.SetIntermixIntersectingGeometry (int )` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometryMinValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometryMaxValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometry ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.IntermixIntersectingGeometryOn ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.IntermixIntersectingGeometryOff ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.SetRayCastFunction (vtkUnstructuredGridVolumeRayCastFunction f)` - Set/Get the helper class for casting rays.
- `vtkUnstructuredGridVolumeRayCastFunction = obj.GetRayCastFunction ()` - Set/Get the helper class for casting rays.
- `obj.SetRayIntegrator (vtkUnstructuredGridVolumeRayIntegrator ri)` - Set/Get the helper class for integrating rays. If set to NULL, a default integrator will be assigned.

- `vtkUnstructuredGridVolumeRayIntegrator = obj.GetRayIntegrator ()` - Set/Get the helper class for integrating rays. If set to NULL, a default integrator will be assigned.

- `obj.CastRays (int threadID, int threadCount)`

41.33 vtkUnstructuredGridVolumeRayIntegrator

41.33.1 Usage

vtkUnstructuredGridVolumeRayIntegrator is a superclass for ray integration functions that can be used within a vtkUnstructuredGridVolumeRayCastMapper.

To create an instance of class vtkUnstructuredGridVolumeRayIntegrator, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridVolumeRayIntegrator
```

41.33.2 Methods

The class vtkUnstructuredGridVolumeRayIntegrator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridVolumeRayIntegrator class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkUnstructuredGridVolumeRayIntegrator = obj.NewInstance ()`

- `vtkUnstructuredGridVolumeRayIntegrator = obj.SafeDownCast (vtkObject o)`

- `obj.Initialize (vtkVolume volume, vtkDataArray scalars)` - Set up the integrator with the given properties and scalars.

- `obj.Integrate (vtkDoubleArray intersectionLengths, vtkDataArray nearIntersections, vtkDataArray far` - Given a set of intersections (defined by the three arrays), compute the peicewise integration of the array in front to back order. /c intersectionLengths holds the lengths of each peicewise segment. /c nearIntersections and /c farIntersections hold the scalar values at the front and back of each segment. /c color should contain the RGBA value of the volume in front of the segments passed in, and the result will be placed back into /c color.

41.34 vtkUnstructuredGridVolumeZSweepMapper

41.34.1 Usage

This is a volume mapper for unstructured grid implemented with the ZSweep algorithm. This is a software projective method.

To create an instance of class vtkUnstructuredGridVolumeZSweepMapper, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridVolumeZSweepMapper
```

41.34.2 Methods

The class vtkUnstructuredGridVolumeZSweepMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridVolumeZSweepMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridVolumeZSweepMapper = obj.NewInstance ()`
- `vtkUnstructuredGridVolumeZSweepMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetImageSampleDistance (float )` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `float = obj.GetImageSampleDistanceMinValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `float = obj.GetImageSampleDistanceMaxValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `float = obj.GetImageSampleDistance ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `obj.SetMinimumImageSampleDistance (float )` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMinimumImageSampleDistanceMinValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMinimumImageSampleDistanceMaxValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMinimumImageSampleDistance ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `obj.SetMaximumImageSampleDistance (float )` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMaximumImageSampleDistanceMinValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMaximumImageSampleDistanceMaxValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `float = obj.GetMaximumImageSampleDistance ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `obj.SetAutoAdjustSampleDistances (int )` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistancesMinValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `int = obj.GetAutoAdjustSampleDistancesMaxValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `int = obj.GetAutoAdjustSampleDistances ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.AutoAdjustSampleDistancesOn ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.AutoAdjustSampleDistancesOff ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).
- `obj.SetIntermixIntersectingGeometry (int )` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometryMinValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometryMaxValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetIntermixIntersectingGeometry ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.IntermixIntersectingGeometryOn ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `obj.IntermixIntersectingGeometryOff ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.
- `int = obj.GetMaxPixelListSize ()` - Maximum size allowed for a pixel list. Default is 32. During the rendering, if a list of pixel is full, incremental compositing is performed. Even if it is a user setting, it is an advanced parameter. You have to understand how the algorithm works to change this value.
- `obj.SetMaxPixelListSize (int size)` - Change the maximum size allowed for a pixel list. It is an advanced parameter.
- `obj.SetRayIntegrator (vtkUnstructuredGridVolumeRayIntegrator ri)` - Set/Get the helper class for integrating rays. If set to NULL, a default integrator will be assigned.
- `vtkUnstructuredGridVolumeRayIntegrator = obj.GetRayIntegrator ()` - Set/Get the helper class for integrating rays. If set to NULL, a default integrator will be assigned.

41.35 vtkVolumeMapper

41.35.1 Usage

vtkVolumeMapper is the abstract definition of a volume mapper for regular rectilinear data (vtkImageData). Several basic types of volume mappers are supported.

To create an instance of class vtkVolumeMapper, simply invoke its constructor as follows

```
obj = vtkVolumeMapper
```

41.35.2 Methods

The class vtkVolumeMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeMapper = obj.NewInstance ()`
- `vtkVolumeMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData )` - Set/Get the input data
- `obj.SetInput (vtkDataSet )` - Set/Get the input data
- `vtkImageData = obj.GetInput ()` - Set/Get the input data
- `obj.SetBlendMode (int )` - Set/Get the blend mode. Currently this is only supported by the vtkFixedPointVolumeRayCastMapper - other mappers have different ways to set this (supplying a function to a vtkVolumeRayCastMapper) or don't have any options (vtkVolumeTextureMapper2D supports only compositing)
- `obj.SetBlendModeToComposite ()` - Set/Get the blend mode. Currently this is only supported by the vtkFixedPointVolumeRayCastMapper - other mappers have different ways to set this (supplying a function to a vtkVolumeRayCastMapper) or don't have any options (vtkVolumeTextureMapper2D supports only compositing)
- `obj.SetBlendModeToMaximumIntensity ()` - Set/Get the blend mode. Currently this is only supported by the vtkFixedPointVolumeRayCastMapper - other mappers have different ways to set this (supplying a function to a vtkVolumeRayCastMapper) or don't have any options (vtkVolumeTextureMapper2D supports only compositing)
- `obj.SetBlendModeToMinimumIntensity ()` - Set/Get the blend mode. Currently this is only supported by the vtkFixedPointVolumeRayCastMapper - other mappers have different ways to set this (supplying a function to a vtkVolumeRayCastMapper) or don't have any options (vtkVolumeTextureMapper2D supports only compositing)
- `int = obj.GetBlendMode ()` - Set/Get the blend mode. Currently this is only supported by the vtkFixedPointVolumeRayCastMapper - other mappers have different ways to set this (supplying a function to a vtkVolumeRayCastMapper) or don't have any options (vtkVolumeTextureMapper2D supports only compositing)
- `obj.SetCropping (int )` - Turn On/Off orthogonal cropping. (Clipping planes are perpendicular to the coordinate axes.)
- `int = obj.GetCroppingMinValue ()` - Turn On/Off orthogonal cropping. (Clipping planes are perpendicular to the coordinate axes.)
- `int = obj.GetCroppingMaxValue ()` - Turn On/Off orthogonal cropping. (Clipping planes are perpendicular to the coordinate axes.)
- `int = obj.GetCropping ()` - Turn On/Off orthogonal cropping. (Clipping planes are perpendicular to the coordinate axes.)
- `obj.CroppingOn ()` - Turn On/Off orthogonal cropping. (Clipping planes are perpendicular to the coordinate axes.)

- `obj.CroppingOff ()` - Turn On/Off orthogonal cropping. (Clipping planes are perpendicular to the coordinate axes.)
- `obj.SetCroppingRegionPlanes (double , double , double , double , double , double )` - Set/Get the Cropping Region Planes (xmin, xmax, ymin, ymax, zmin, zmax) These planes are defined in volume coordinates - spacing and origin are considered.
- `obj.SetCroppingRegionPlanes (double a[6])` - Set/Get the Cropping Region Planes (xmin, xmax, ymin, ymax, zmin, zmax) These planes are defined in volume coordinates - spacing and origin are considered.
- `double = obj. GetCroppingRegionPlanes ()` - Set/Get the Cropping Region Planes (xmin, xmax, ymin, ymax, zmin, zmax) These planes are defined in volume coordinates - spacing and origin are considered.
- `double = obj. GetVoxelCroppingRegionPlanes ()` - Get the cropping region planes in voxels. Only valid during the rendering process
- `obj.SetCroppingRegionFlags (int )` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `int = obj.GetCroppingRegionFlagsMinValue ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `int = obj.GetCroppingRegionFlagsMaxValue ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `int = obj.GetCroppingRegionFlags ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `obj.SetCroppingRegionFlagsToSubVolume ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.

- `obj.SetCroppingRegionFlagsToFence ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `obj.SetCroppingRegionFlagsToInvertedFence ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `obj.SetCroppingRegionFlagsToCross ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.
- `obj.SetCroppingRegionFlagsToInvertedCross ()` - Set the flags for the cropping regions. The clipping planes divide the volume into 27 regions - there is one bit for each region. The regions start from the one containing voxel (0,0,0), moving along the x axis fastest, the y axis next, and the z axis slowest. These are represented from the lowest bit to bit number 27 in the integer containing the flags. There are several convenience functions to set some common configurations - subvolume (the default), fence (between any of the clip plane pairs), inverted fence, cross (between any two of the clip plane pairs) and inverted cross.

41.36 vtkVolumeOutlineSource

41.36.1 Usage

vtkVolumeOutlineSource generates a wireframe outline that corresponds to the cropping region of a vtkVolumeMapper. It requires a vtkVolumeMapper as input. The GenerateFaces option turns on the solid faces of the outline, and the GenerateScalars option generates color scalars. When GenerateScalars is on, it is possible to set an "ActivePlaneId" value in the range [0..6] to highlight one of the six cropping planes. .SECTION Thanks Thanks to David Gobbi for contributing this class to VTK.

To create an instance of class vtkVolumeOutlineSource, simply invoke its constructor as follows

```
obj = vtkVolumeOutlineSource
```

41.36.2 Methods

The class vtkVolumeOutlineSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeOutlineSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeOutlineSource = obj.NewInstance ()`

- `vtkVolumeOutlineSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetVolumeMapper (vtkVolumeMapper mapper)` - Set the mapper that has the cropping region that the outline will be generated for. The mapper must have an input, because the bounds of the data must be computed in order to generate the outline.
- `vtkVolumeMapper = obj.GetVolumeMapper ()` - Set the mapper that has the cropping region that the outline will be generated for. The mapper must have an input, because the bounds of the data must be computed in order to generate the outline.
- `obj.SetGenerateScalars (int )` - Set whether to generate color scalars for the output. By default, the output has no scalars and the color must be set in the property of the actor.
- `obj.GenerateScalarsOn ()` - Set whether to generate color scalars for the output. By default, the output has no scalars and the color must be set in the property of the actor.
- `obj.GenerateScalarsOff ()` - Set whether to generate color scalars for the output. By default, the output has no scalars and the color must be set in the property of the actor.
- `int = obj.GetGenerateScalars ()` - Set whether to generate color scalars for the output. By default, the output has no scalars and the color must be set in the property of the actor.
- `obj.SetGenerateFaces (int )` - Set whether to generate polygonal faces for the output. By default, only lines are generated. The faces will form a closed, watertight surface.
- `obj.GenerateFacesOn ()` - Set whether to generate polygonal faces for the output. By default, only lines are generated. The faces will form a closed, watertight surface.
- `obj.GenerateFacesOff ()` - Set whether to generate polygonal faces for the output. By default, only lines are generated. The faces will form a closed, watertight surface.
- `int = obj.GetGenerateFaces ()` - Set whether to generate polygonal faces for the output. By default, only lines are generated. The faces will form a closed, watertight surface.
- `obj.SetColor (double , double , double )` - Set the color of the outline. This has no effect unless GenerateScalars is On. The default color is red.
- `obj.SetColor (double  a[3])` - Set the color of the outline. This has no effect unless GenerateScalars is On. The default color is red.
- `double = obj. GetColor ()` - Set the color of the outline. This has no effect unless GenerateScalars is On. The default color is red.
- `obj.SetActivePlaneId (int )` - Set the active plane, e.g. to display which plane is currently being modified by an interaction. Set this to -1 if there is no active plane. The default value is -1.
- `int = obj.GetActivePlaneId ()` - Set the active plane, e.g. to display which plane is currently being modified by an interaction. Set this to -1 if there is no active plane. The default value is -1.
- `obj.SetActivePlaneColor (double , double , double )` - Set the color of the active cropping plane. This has no effect unless GenerateScalars is On and ActivePlaneId is non-negative. The default color is yellow.
- `obj.SetActivePlaneColor (double  a[3])` - Set the color of the active cropping plane. This has no effect unless GenerateScalars is On and ActivePlaneId is non-negative. The default color is yellow.
- `double = obj. GetActivePlaneColor ()` - Set the color of the active cropping plane. This has no effect unless GenerateScalars is On and ActivePlaneId is non-negative. The default color is yellow.

41.37 vtkVolumePicker

41.37.1 Usage

vtkVolumePicker is a subclass of vtkCellPicker. It has one advantage over vtkCellPicker for volumes: it will be able to correctly perform picking when CroppingPlanes are present. This isn't possible for vtkCellPicker since it doesn't link to the VolumeRendering classes and hence cannot access information about the CroppingPlanes.

To create an instance of class vtkVolumePicker, simply invoke its constructor as follows

```
obj = vtkVolumePicker
```

41.37.2 Methods

The class vtkVolumePicker has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumePicker class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumePicker = obj.NewInstance ()`
- `vtkVolumePicker = obj.SafeDownCast (vtkObject o)`
- `obj.SetPickCroppingPlanes (int )` - Set whether to pick the cropping planes of props that have them. If this is set, then the pick will be done on the cropping planes rather than on the data. The GetCroppingPlaneId() method will return the index of the cropping plane of the volume that was picked. This setting is only relevant to the picking of volumes.
- `obj.PickCroppingPlanesOn ()` - Set whether to pick the cropping planes of props that have them. If this is set, then the pick will be done on the cropping planes rather than on the data. The GetCroppingPlaneId() method will return the index of the cropping plane of the volume that was picked. This setting is only relevant to the picking of volumes.
- `obj.PickCroppingPlanesOff ()` - Set whether to pick the cropping planes of props that have them. If this is set, then the pick will be done on the cropping planes rather than on the data. The GetCroppingPlaneId() method will return the index of the cropping plane of the volume that was picked. This setting is only relevant to the picking of volumes.
- `int = obj.GetPickCroppingPlanes ()` - Set whether to pick the cropping planes of props that have them. If this is set, then the pick will be done on the cropping planes rather than on the data. The GetCroppingPlaneId() method will return the index of the cropping plane of the volume that was picked. This setting is only relevant to the picking of volumes.
- `int = obj.GetCroppingPlaneId ()` - Get the index of the cropping plane that the pick ray passed through on its way to the prop. This will be set regardless of whether PickCroppingPlanes is on. The crop planes are ordered as follows: xmin, xmax, ymin, ymax, zmin, zmax. If the volume is not cropped, the value will bet set to -1.

41.38 vtkVolumeProMapper

41.38.1 Usage

vtkVolumeProMapper is the superclass for VolumePRO volume rendering mappers. Any functionality that is general across all VolumePRO implementations is placed here in this class. Subclasses of this class are for

the specific board implementations. Subclasses of that are for underlying graphics languages. Users should not create subclasses directly - a vtkVolumeProMapper will automatically create the object of the right type.

If you do not have the VolumePRO libraries when building this object, then the New method will create a default renderer that will not render. You can check the NumberOfBoards ivar to see if it is a real rendering class. To build with the VolumePRO board see vtkVolumeProVP1000Mapper.h for instructions.

For more information on the VolumePRO hardware, please see:

http://www.terarecon.com/products/volumepro_prod.html

If you encounter any problems with this class, please inform Kitware, Inc. at kitware@kitware.com.

To create an instance of class vtkVolumeProMapper, simply invoke its constructor as follows

```
obj = vtkVolumeProMapper
```

41.38.2 Methods

The class vtkVolumeProMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeProMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeProMapper = obj.NewInstance ()`
- `vtkVolumeProMapper = obj.SafeDownCast (vtkObject o)`
- `obj.Render (vtkRenderer , vtkVolume )` - Set the blend mode
- `obj.SetBlendMode (int )` - Set the blend mode
- `int = obj.GetBlendModeMinValue ()` - Set the blend mode
- `int = obj.GetBlendModeMaxValue ()` - Set the blend mode
- `int = obj.GetBlendMode ()` - Set the blend mode
- `obj.SetBlendModeToComposite ()` - Set the blend mode
- `obj.SetBlendModeToMaximumIntensity ()` - Set the blend mode
- `obj.SetBlendModeToMinimumIntensity ()` - Set the blend mode
- `string = obj.GetBlendModeAsString (void )` - Set the blend mode
- `obj.SetSubVolume (int , int , int , int , int , int )` - Set the subvolume
- `obj.SetSubVolume (int  a[6])` - Set the subvolume
- `int = obj. GetSubVolume ()` - Set the subvolume
- `obj.SetCursor (int )` - Turn the cursor on / off
- `int = obj.GetCursorMinValue ()` - Turn the cursor on / off
- `int = obj.GetCursorMaxValue ()` - Turn the cursor on / off
- `int = obj.GetCursor ()` - Turn the cursor on / off
- `obj.CursorOn ()` - Turn the cursor on / off
- `obj.CursorOff ()` - Turn the cursor on / off

- `obj.SetCursorType (int )` - Set the type of the cursor
- `int = obj.GetCursorTypeMinValue ()` - Set the type of the cursor
- `int = obj.GetCursorTypeMaxValue ()` - Set the type of the cursor
- `int = obj.GetCursorType ()` - Set the type of the cursor
- `obj.SetCursorTypeToCrossHair ()` - Set the type of the cursor
- `obj.SetCursorTypeToPlane ()` - Set the type of the cursor
- `string = obj.GetCursorTypeAsString (void )` - Set the type of the cursor
- `obj.SetCursorPosition (double , double , double )` - Set/Get the cursor position
- `obj.SetCursorPosition (double  a[3])` - Set/Get the cursor position
- `double = obj. GetCursorPosition ()` - Set/Get the cursor position
- `obj.SetCursorXAxisColor (double , double , double )` - Set/Get the cursor color
- `obj.SetCursorXAxisColor (double  a[3])` - Set/Get the cursor color
- `double = obj. GetCursorXAxisColor ()` - Set/Get the cursor color
- `obj.SetCursorYAxisColor (double , double , double )` - Set/Get the cursor color
- `obj.SetCursorYAxisColor (double  a[3])` - Set/Get the cursor color
- `double = obj. GetCursorYAxisColor ()` - Set/Get the cursor color
- `obj.SetCursorZAxisColor (double , double , double )` - Set/Get the cursor color
- `obj.SetCursorZAxisColor (double  a[3])` - Set/Get the cursor color
- `double = obj. GetCursorZAxisColor ()` - Set/Get the cursor color
- `obj.SetSuperSampling (int )` - Turn supersampling on/off
- `int = obj.GetSuperSamplingMinValue ()` - Turn supersampling on/off
- `int = obj.GetSuperSamplingMaxValue ()` - Turn supersampling on/off
- `int = obj.GetSuperSampling ()` - Turn supersampling on/off
- `obj.SuperSamplingOn ()` - Turn supersampling on/off
- `obj.SuperSamplingOff ()` - Turn supersampling on/off
- `obj.SetSuperSamplingFactor (double x, double y, double z)` - Set the supersampling factors
- `obj.SetSuperSamplingFactor (double f[3])` - Set the supersampling factors
- `double = obj. GetSuperSamplingFactor ()` - Set the supersampling factors
- `obj.SetCutPlane (int )` - Turn on / off the cut plane
- `int = obj.GetCutPlaneMinValue ()` - Turn on / off the cut plane
- `int = obj.GetCutPlaneMaxValue ()` - Turn on / off the cut plane
- `int = obj.GetCutPlane ()` - Turn on / off the cut plane
- `obj.CutPlaneOn ()` - Turn on / off the cut plane

- `obj.CutPlaneOff ()` - Turn on / off the cut plane
- `obj.SetCutPlaneEquation (double , double , double , double )` - Set/Get the cut plane equation
- `obj.SetCutPlaneEquation (double a[4])` - Set/Get the cut plane equation
- `double = obj. GetCutPlaneEquation ()` - Set/Get the cut plane equation
- `obj.SetCutPlaneThickness (double )` - Set / Get the cut plane thickness
- `double = obj.GetCutPlaneThicknessMinValue ()` - Set / Get the cut plane thickness
- `double = obj.GetCutPlaneThicknessMaxValue ()` - Set / Get the cut plane thickness
- `double = obj.GetCutPlaneThickness ()` - Set / Get the cut plane thickness
- `obj.SetCutPlaneFallOffDistance (int )` - Set / Get the cut plane falloff value for intensities
- `int = obj.GetCutPlaneFallOffDistanceMinValue ()` - Set / Get the cut plane falloff value for intensities
- `int = obj.GetCutPlaneFallOffDistanceMaxValue ()` - Set / Get the cut plane falloff value for intensities
- `int = obj.GetCutPlaneFallOffDistance ()` - Set / Get the cut plane falloff value for intensities
- `obj.SetGradientOpacityModulation (int )` - Set/Get the gradient magnitude opacity modulation
- `int = obj.GetGradientOpacityModulationMinValue ()` - Set/Get the gradient magnitude opacity modulation
- `int = obj.GetGradientOpacityModulationMaxValue ()` - Set/Get the gradient magnitude opacity modulation
- `int = obj.GetGradientOpacityModulation ()` - Set/Get the gradient magnitude opacity modulation
- `obj.GradientOpacityModulationOn ()` - Set/Get the gradient magnitude opacity modulation
- `obj.GradientOpacityModulationOff ()` - Set/Get the gradient magnitude opacity modulation
- `obj.SetGradientDiffuseModulation (int )` - Set/Get the gradient magnitude diffuse modulation
- `int = obj.GetGradientDiffuseModulationMinValue ()` - Set/Get the gradient magnitude diffuse modulation
- `int = obj.GetGradientDiffuseModulationMaxValue ()` - Set/Get the gradient magnitude diffuse modulation
- `int = obj.GetGradientDiffuseModulation ()` - Set/Get the gradient magnitude diffuse modulation
- `obj.GradientDiffuseModulationOn ()` - Set/Get the gradient magnitude diffuse modulation
- `obj.GradientDiffuseModulationOff ()` - Set/Get the gradient magnitude diffuse modulation
- `obj.SetGradientSpecularModulation (int )` - Set/Get the gradient magnitude specular modulation
- `int = obj.GetGradientSpecularModulationMinValue ()` - Set/Get the gradient magnitude specular modulation
- `int = obj.GetGradientSpecularModulationMaxValue ()` - Set/Get the gradient magnitude specular modulation

- `int = obj.GetGradientSpecularModulation ()` - Set/Get the gradient magnitude specular modulation
- `obj.GradientSpecularModulationOn ()` - Set/Get the gradient magnitude specular modulation
- `obj.GradientSpecularModulationOff ()` - Set/Get the gradient magnitude specular modulation
- `int = obj.GetNoHardware ()` - Conveniece methods for debugging
- `int = obj.GetWrongVLIVersion ()` - Conveniece methods for debugging
- `int = obj.GetNumberOfBoards ()` - Access methods for some board info
- `int = obj.GetMajorBoardVersion ()` - Access methods for some board info
- `int = obj.GetMinorBoardVersion ()` - Access methods for some board info
- `int = obj.GetAvailableBoardMemory ()` - Access methods for some board info
- `obj.GetLockSizesForBoardMemory (int , int , int , int )` - Access methods for some board info
- `obj.SetIntermixIntersectingGeometry (int )` - Specify whether any geometry intersects the volume.
- `int = obj.GetIntermixIntersectingGeometryMinValue ()` - Specify whether any geometry intersects the volume.
- `int = obj.GetIntermixIntersectingGeometryMaxValue ()` - Specify whether any geometry intersects the volume.
- `int = obj.GetIntermixIntersectingGeometry ()` - Specify whether any geometry intersects the volume.
- `obj.IntermixIntersectingGeometryOn ()` - Specify whether any geometry intersects the volume.
- `obj.IntermixIntersectingGeometryOff ()` - Specify whether any geometry intersects the volume.
- `obj.SetAutoAdjustMipmapLevels (int )` - If set to 1, this mapper will select a mipmap level to use based on the AllocatedRenderTime of the volume and the amount of time used by the previous render.
- `int = obj.GetAutoAdjustMipmapLevelsMinValue ()` - If set to 1, this mapper will select a mipmap level to use based on the AllocatedRenderTime of the volume and the amount of time used by the previous render.
- `int = obj.GetAutoAdjustMipmapLevelsMaxValue ()` - If set to 1, this mapper will select a mipmap level to use based on the AllocatedRenderTime of the volume and the amount of time used by the previous render.
- `int = obj.GetAutoAdjustMipmapLevels ()` - If set to 1, this mapper will select a mipmap level to use based on the AllocatedRenderTime of the volume and the amount of time used by the previous render.
- `obj.AutoAdjustMipmapLevelsOn ()` - If set to 1, this mapper will select a mipmap level to use based on the AllocatedRenderTime of the volume and the amount of time used by the previous render.
- `obj.AutoAdjustMipmapLevelsOff ()` - If set to 1, this mapper will select a mipmap level to use based on the AllocatedRenderTime of the volume and the amount of time used by the previous render.
- `obj.SetMinimumMipmapLevel (int )` - Specify the minimum mipmap level to use – the highest resolution. Defaults to 0. This is the mipmap level that is used when interaction stops.

- `int = obj.GetMinimumMipmapLevelMinValue ()` - Specify the minimum mipmap level to use – the highest resolution. Defaults to 0. This is the mipmap level that is used when interaction stops.

- `int = obj.GetMinimumMipmapLevelMaxValue ()` - Specify the minimum mipmap level to use – the highest resolution. Defaults to 0. This is the mipmap level that is used when interaction stops.

- `int = obj.GetMinimumMipmapLevel ()` - Specify the minimum mipmap level to use – the highest resolution. Defaults to 0. This is the mipmap level that is used when interaction stops.

- `obj.SetMaximumMipmapLevel (int )` - Specify the maximum mipmap level to use – the lowest resolution. Defaults to 4. It will not help to set the level larger than this unless your volume is very large because for each successive mipmap level, the number of voxels along each axis is cut in half.

- `int = obj.GetMaximumMipmapLevelMinValue ()` - Specify the maximum mipmap level to use – the lowest resolution. Defaults to 4. It will not help to set the level larger than this unless your volume is very large because for each successive mipmap level, the number of voxels along each axis is cut in half.

- `int = obj.GetMaximumMipmapLevelMaxValue ()` - Specify the maximum mipmap level to use – the lowest resolution. Defaults to 4. It will not help to set the level larger than this unless your volume is very large because for each successive mipmap level, the number of voxels along each axis is cut in half.

- `int = obj.GetMaximumMipmapLevel ()` - Specify the maximum mipmap level to use – the lowest resolution. Defaults to 4. It will not help to set the level larger than this unless your volume is very large because for each successive mipmap level, the number of voxels along each axis is cut in half.

- `obj.SetMipmapLevel (int )` - Choose a mipmap level. If AutoAdjustMipmapLevels is off, then this specifies the mipmap level to use during interaction. If AutoAdjustMipmapLevels is on, then this specifies the initial mipmap level to use.

- `int = obj.GetMipmapLevelMinValue ()` - Choose a mipmap level. If AutoAdjustMipmapLevels is off, then this specifies the mipmap level to use during interaction. If AutoAdjustMipmapLevels is on, then this specifies the initial mipmap level to use.

- `int = obj.GetMipmapLevelMaxValue ()` - Choose a mipmap level. If AutoAdjustMipmapLevels is off, then this specifies the mipmap level to use during interaction. If AutoAdjustMipmapLevels is on, then this specifies the initial mipmap level to use.

- `int = obj.GetMipmapLevel ()` - Choose a mipmap level. If AutoAdjustMipmapLevels is off, then this specifies the mipmap level to use during interaction. If AutoAdjustMipmapLevels is on, then this specifies the initial mipmap level to use.

41.39 vtkVolumeRayCastCompositeFunction

41.39.1 Usage

vtkVolumeRayCastCompositeFunction is a ray function that can be used within a vtkVolumeRayCastMapper. This function performs compositing along the ray according to the properties stored in the vtkVolumeProperty for the volume.

To create an instance of class vtkVolumeRayCastCompositeFunction, simply invoke its constructor as follows

```
obj = vtkVolumeRayCastCompositeFunction
```

41.39.2 Methods

The class vtkVolumeRayCastCompositeFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeRayCastCompositeFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeRayCastCompositeFunction = obj.NewInstance ()`
- `vtkVolumeRayCastCompositeFunction = obj.SafeDownCast (vtkObject o)`
- `obj.SetCompositeMethod (int )` - Set the CompositeMethod to either Classify First or Interpolate First
- `int = obj.GetCompositeMethodMinValue ()` - Set the CompositeMethod to either Classify First or Interpolate First
- `int = obj.GetCompositeMethodMaxValue ()` - Set the CompositeMethod to either Classify First or Interpolate First
- `int = obj.GetCompositeMethod ()` - Set the CompositeMethod to either Classify First or Interpolate First
- `obj.SetCompositeMethodToInterpolateFirst ()` - Set the CompositeMethod to either Classify First or Interpolate First
- `obj.SetCompositeMethodToClassifyFirst ()` - Set the CompositeMethod to either Classify First or Interpolate First
- `string = obj.GetCompositeMethodAsString (void )` - Set the CompositeMethod to either Classify First or Interpolate First

41.40 vtkVolumeRayCastFunction

41.40.1 Usage

vtkVolumeRayCastFunction is a superclass for ray casting functions that can be used within a vtkVolumeRayCastMapper. This includes for example, vtkVolumeRayCastCompositeFunction, vtkVolumeRayCastMIPFunction, and vtkVolumeRayCastIsosurfaceFunction.

To create an instance of class vtkVolumeRayCastFunction, simply invoke its constructor as follows

```
obj = vtkVolumeRayCastFunction
```

41.40.2 Methods

The class vtkVolumeRayCastFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeRayCastFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeRayCastFunction = obj.NewInstance ()`

- `vtkVolumeRayCastFunction = obj.SafeDownCast (vtkObject o)`
- `float = obj.GetZeroOpacityThreshold (vtkVolume vol)` - Get the value below which all scalar values are considered to have 0 opacity.

41.41 vtkVolumeRayCastIsosurfaceFunction

41.41.1 Usage

vtkVolumeRayCastIsosurfaceFunction is a volume ray cast function that intersects a ray with an analytic isosurface in a scalar field. The color and shading parameters are defined in the vtkVolumeProperty of the vtkVolume, as well as the interpolation type to use when locating the surface (either a nearest neighbor approach or a tri-linear interpolation approach)

To create an instance of class vtkVolumeRayCastIsosurfaceFunction, simply invoke its constructor as follows

```
obj = vtkVolumeRayCastIsosurfaceFunction
```

41.41.2 Methods

The class vtkVolumeRayCastIsosurfaceFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeRayCastIsosurfaceFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeRayCastIsosurfaceFunction = obj.NewInstance ()`
- `vtkVolumeRayCastIsosurfaceFunction = obj.SafeDownCast (vtkObject o)`
- `float = obj.GetZeroOpacityThreshold (vtkVolume vol)` - Get the scalar value below which all scalar values have 0 opacity
- `obj.SetIsoValue (double )` - Set/Get the value of IsoValue.
- `double = obj.GetIsoValue ()` - Set/Get the value of IsoValue.

41.42 vtkVolumeRayCastMapper

41.42.1 Usage

This is a software ray caster for rendering volumes in vtkImageData.

To create an instance of class vtkVolumeRayCastMapper, simply invoke its constructor as follows

```
obj = vtkVolumeRayCastMapper
```

41.42.2 Methods

The class vtkVolumeRayCastMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeRayCastMapper class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkVolumeRayCastMapper = obj.NewInstance ()`
- `vtkVolumeRayCastMapper = obj.SafeDownCast (vtkObject o)`
- `obj.SetSampleDistance (double )` - Set/Get the distance between samples. This variable is only used for sampling ray casting methods. Methods that compute a ray value by stepping cell-by-cell are not affected by this value.
- `double = obj.GetSampleDistance ()` - Set/Get the distance between samples. This variable is only used for sampling ray casting methods. Methods that compute a ray value by stepping cell-by-cell are not affected by this value.
- `obj.SetVolumeRayCastFunction (vtkVolumeRayCastFunction )` - Get / Set the volume ray cast function. This is used to process values found along the ray to compute a final pixel value.
- `vtkVolumeRayCastFunction = obj.GetVolumeRayCastFunction ()` - Get / Set the volume ray cast function. This is used to process values found along the ray to compute a final pixel value.
- `obj.SetGradientEstimator (vtkEncodedGradientEstimator gradest)` - Set / Get the gradient estimator used to estimate normals
- `vtkEncodedGradientEstimator = obj.GetGradientEstimator ()` - Set / Get the gradient estimator used to estimate normals
- `vtkEncodedGradientShader = obj.GetGradientShader ()` - Get the gradient shader.
- `obj.SetImageSampleDistance (double )` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `double = obj.GetImageSampleDistanceMinValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `double = obj.GetImageSampleDistanceMaxValue ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `double = obj.GetImageSampleDistance ()` - Sampling distance in the XY image dimensions. Default value of 1 meaning 1 ray cast per pixel. If set to 0.5, 4 rays will be cast per pixel. If set to 2.0, 1 ray will be cast for every 4 (2 by 2) pixels.
- `obj.SetMinimumImageSampleDistance (double )` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `double = obj.GetMinimumImageSampleDistanceMinValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `double = obj.GetMinimumImageSampleDistanceMaxValue ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `double = obj.GetMinimumImageSampleDistance ()` - This is the minimum image sample distance allow when the image sample distance is being automatically adjusted
- `obj.SetMaximumImageSampleDistance (double )` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted
- `double = obj.GetMaximumImageSampleDistanceMinValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted

- `double = obj.GetMaximumImageSampleDistanceMaxValue ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted

- `double = obj.GetMaximumImageSampleDistance ()` - This is the maximum image sample distance allow when the image sample distance is being automatically adjusted

- `obj.SetAutoAdjustSampleDistances (int )` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `int = obj.GetAutoAdjustSampleDistancesMinValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `int = obj.GetAutoAdjustSampleDistancesMaxValue ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `int = obj.GetAutoAdjustSampleDistances ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `obj.AutoAdjustSampleDistancesOn ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `obj.AutoAdjustSampleDistancesOff ()` - If AutoAdjustSampleDistances is on, the the ImageSampleDistance will be varied to achieve the allocated render time of this prop (controlled by the desired update rate and any culling in use).

- `obj.SetNumberOfThreads (int num)` - Set/Get the number of threads to use. This by default is equal to the number of available processors detected.

- `int = obj.GetNumberOfThreads ()` - Set/Get the number of threads to use. This by default is equal to the number of available processors detected.

- `obj.SetIntermixIntersectingGeometry (int )` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

- `int = obj.GetIntermixIntersectingGeometryMinValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

- `int = obj.GetIntermixIntersectingGeometryMaxValue ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

- `int = obj.GetIntermixIntersectingGeometry ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

- `obj.IntermixIntersectingGeometryOn ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

- `obj.IntermixIntersectingGeometryOff ()` - If IntermixIntersectingGeometry is turned on, the zbuffer will be captured and used to limit the traversal of the rays.

41.43 vtkVolumeRayCastMIPFunction

41.43.1 Usage

vtkVolumeRayCastMIPFunction is a volume ray cast function that computes the maximum value encountered along the ray. This is either the maximum scalar value, or the maximum opacity, as defined by the MaximizeMethod. The color and opacity returned by this function is based on the color, scalar opacity, and gradient opacity transfer functions defined in the vtkVolumeProperty of the vtkVolume.

To create an instance of class vtkVolumeRayCastMIPFunction, simply invoke its constructor as follows

```
obj = vtkVolumeRayCastMIPFunction
```

41.43.2 Methods

The class vtkVolumeRayCastMIPFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeRayCastMIPFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeRayCastMIPFunction = obj.NewInstance ()`
- `vtkVolumeRayCastMIPFunction = obj.SafeDownCast (vtkObject o)`
- `float = obj.GetZeroOpacityThreshold (vtkVolume vol)` - Get the scalar value below which all scalar values have zero opacity.
- `obj.SetMaximizeMethod (int )` - Set the MaximizeMethod to either ScalarValue or Opacity.
- `int = obj.GetMaximizeMethodMinValue ()` - Set the MaximizeMethod to either ScalarValue or Opacity.
- `int = obj.GetMaximizeMethodMaxValue ()` - Set the MaximizeMethod to either ScalarValue or Opacity.
- `int = obj.GetMaximizeMethod ()` - Set the MaximizeMethod to either ScalarValue or Opacity.
- `obj.SetMaximizeMethodToScalarValue ()` - Set the MaximizeMethod to either ScalarValue or Opacity.
- `obj.SetMaximizeMethodToOpacity ()` - Set the MaximizeMethod to either ScalarValue or Opacity.
- `string = obj.GetMaximizeMethodAsString (void )` - Set the MaximizeMethod to either ScalarValue or Opacity.

41.44 vtkVolumeRenderingFactory

41.44.1 Usage

To create an instance of class vtkVolumeRenderingFactory, simply invoke its constructor as follows

```
obj = vtkVolumeRenderingFactory
```

41.44.2 Methods

The class vtkVolumeRenderingFactory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeRenderingFactory class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeRenderingFactory = obj.NewInstance ()`
- `vtkVolumeRenderingFactory = obj.SafeDownCast (vtkObject o)`

41.45 vtkVolumeTextureMapper

41.45.1 Usage

vtkVolumeTextureMapper is the abstract definition of a volume mapper that uses a texture mapping approach.

To create an instance of class vtkVolumeTextureMapper, simply invoke its constructor as follows

```
obj = vtkVolumeTextureMapper
```

41.45.2 Methods

The class vtkVolumeTextureMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeTextureMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeTextureMapper = obj.NewInstance ()`
- `vtkVolumeTextureMapper = obj.SafeDownCast (vtkObject o)`
- `obj.Update ()` - Update the volume rendering pipeline by updating the scalar input
- `obj.SetGradientEstimator (vtkEncodedGradientEstimator gradest)` - Set / Get the gradient estimator used to estimate normals
- `vtkEncodedGradientEstimator = obj.GetGradientEstimator ()` - Set / Get the gradient estimator used to estimate normals
- `vtkEncodedGradientShader = obj.GetGradientShader ()` - Get the gradient shader.

41.46 vtkVolumeTextureMapper2D

41.46.1 Usage

vtkVolumeTextureMapper2D renders a volume using 2D texture mapping.

To create an instance of class vtkVolumeTextureMapper2D, simply invoke its constructor as follows

```
obj = vtkVolumeTextureMapper2D
```

41.46.2 Methods

The class vtkVolumeTextureMapper2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeTextureMapper2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeTextureMapper2D = obj.NewInstance ()`
- `vtkVolumeTextureMapper2D = obj.SafeDownCast (vtkObject o)`
- `obj.SetTargetTextureSize (int , int )` - Target size in pixels of each size of the texture for downloading. Default is 512x512 - so a 512x512 texture will be tiled with as many slices of the volume as possible, then all the quads will be rendered. This can be set to optimize for a particular architecture. This must be set with numbers that are a power of two.
- `obj.SetTargetTextureSize (int a[2])` - Target size in pixels of each size of the texture for downloading. Default is 512x512 - so a 512x512 texture will be tiled with as many slices of the volume as possible, then all the quads will be rendered. This can be set to optimize for a particular architecture. This must be set with numbers that are a power of two.
- `int = obj. GetTargetTextureSize ()` - Target size in pixels of each size of the texture for downloading. Default is 512x512 - so a 512x512 texture will be tiled with as many slices of the volume as possible, then all the quads will be rendered. This can be set to optimize for a particular architecture. This must be set with numbers that are a power of two.
- `obj.SetMaximumNumberOfPlanes (int )` - This is the maximum number of planes that will be created for texture mapping the volume. If the volume has more voxels than this along the viewing direction, then planes of the volume will be skipped to ensure that this maximum is not violated. A skip factor is used, and is incremented until the maximum condition is satisfied.
- `int = obj.GetMaximumNumberOfPlanes ()` - This is the maximum number of planes that will be created for texture mapping the volume. If the volume has more voxels than this along the viewing direction, then planes of the volume will be skipped to ensure that this maximum is not violated. A skip factor is used, and is incremented until the maximum condition is satisfied.
- `obj.SetMaximumStorageSize (int )` - This is the maximum size of saved textures in bytes. If this size is large enough to hold the RGBA textures for all three directions (XxYxZx3x4 is the approximate value - it is actually a bit larger due to wasted space in the textures) then the textures will be saved.
- `int = obj.GetMaximumStorageSize ()` - This is the maximum size of saved textures in bytes. If this size is large enough to hold the RGBA textures for all three directions (XxYxZx3x4 is the approximate value - it is actually a bit larger due to wasted space in the textures) then the textures will be saved.

41.47 vtkVolumeTextureMapper3D

41.47.1 Usage

vtkVolumeTextureMapper3D renders a volume using 3D texture mapping. This class is actually an abstract superclass - with all the actual work done by vtkOpenGLVolumeTextureMapper3D.

This mappers currently supports:

- any data type as input - one component, or two or four non-independent components - composite blending - intermixed opaque geometry - multiple volumes can be rendered if they can be sorted into back-to-front order (use the vtkFrustumCoverageCuller)

This mapper does not support: - more than one independent component - maximum intensity projection

Internally, this mapper will potentially change the resolution of the input data. The data will be resampled to be a power of two in each direction, and also no greater than 128*256*256 voxels (any aspect) for one or two component data, or 128*128*256 voxels (any aspect) for four component data. The limits are currently hardcoded after a check using the GL_PROXY_TEXTURE3D because some graphics drivers were always responding "yes" to the proxy call despite not being able to allocate that much texture memory.

Currently, calculations are computed using 8 bits per RGBA channel. In the future this should be expanded to handle newer boards that can support 15 bit float compositing.

This mapper supports two main families of graphics hardware: nvidia and ATI. There are two different implementations of 3D texture mapping used - one based on nvidia's GL_NV_texture_shader2 and GL_NV_register_combiners2 extension, and one based on ATI's GL_ATI_fragment_shader (supported also by some nvidia boards) To use this class in an application that will run on various hardware configurations, you should have a back-up volume rendering method. You should create a vtkVolumeTextureMapper3D, assign its input, make sure you have a current OpenGL context (you've rendered at least once), then call IsRenderSupported with a vtkVolumeProperty as an argument. This method will return 0 if the input has more than one independent component, or if the graphics hardware does not support the set of required extensions for using at least one of the two implemented methods (nvidia or ati)

.SECTION Thanks Thanks to Alexandre Gouaillard at the Megason Lab, Department of Systems Biology, Harvard Medical School https://wiki.med.harvard.edu/SysBio/Megason/ for the idea and initial patch to speed-up rendering with compressed textures.

To create an instance of class vtkVolumeTextureMapper3D, simply invoke its constructor as follows

```
obj = vtkVolumeTextureMapper3D
```

41.47.2 Methods

The class vtkVolumeTextureMapper3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVolumeTextureMapper3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVolumeTextureMapper3D = obj.NewInstance ()`
- `vtkVolumeTextureMapper3D = obj.SafeDownCast (vtkObject o)`
- `obj.SetSampleDistance (float )` - The distance at which to space sampling planes. This may not be honored for interactive renders. An interactive render is defined as one that has less than 1 second of allocated render time.
- `float = obj.GetSampleDistance ()` - The distance at which to space sampling planes. This may not be honored for interactive renders. An interactive render is defined as one that has less than 1 second of allocated render time.
- `int = obj. GetVolumeDimensions ()` - These are the dimensions of the 3D texture
- `float = obj. GetVolumeSpacing ()` - This is the spacing of the 3D texture
- `int = obj.IsRenderSupported (vtkVolumeProperty )` - Based on hardware and properties, we may or may not be able to render using 3D texture mapping. This indicates if 3D texture mapping is supported by the hardware, and if the other extensions necessary to support the specific properties are available.
- `int = obj.GetNumberOfPolygons ()` - Allow access to the number of polygons used for the rendering.

- `float = obj.GetActualSampleDistance ()` - Allow access to the actual sample distance used to render the image.
- `obj.SetPreferredRenderMethod (int )` - Set the preferred render method. If it is supported, this one will be used. Don't allow ATI_METHOD - it is not actually supported.
- `int = obj.GetPreferredRenderMethodMinValue ()` - Set the preferred render method. If it is supported, this one will be used. Don't allow ATI_METHOD - it is not actually supported.
- `int = obj.GetPreferredRenderMethodMaxValue ()` - Set the preferred render method. If it is supported, this one will be used. Don't allow ATI_METHOD - it is not actually supported.
- `obj.SetPreferredMethodToFragmentProgram ()` - Set the preferred render method. If it is supported, this one will be used. Don't allow ATI_METHOD - it is not actually supported.
- `obj.SetPreferredMethodToNVidia ()` - Set the preferred render method. If it is supported, this one will be used. Don't allow ATI_METHOD - it is not actually supported.
- `int = obj.GetPreferredRenderMethod ()` - Set the preferred render method. If it is supported, this one will be used. Don't allow ATI_METHOD - it is not actually supported.
- `obj.SetUseCompressedTexture (bool )` - Set/Get if the mapper use compressed textures (if supported by the hardware). Initial value is false. There are two reasons to use compressed textures: 1. rendering can be 4 times faster. 2. It saves some VRAM. There is one reason to not use compressed textures: quality may be lower than with uncompressed textures.
- `bool = obj.GetUseCompressedTexture ()` - Set/Get if the mapper use compressed textures (if supported by the hardware). Initial value is false. There are two reasons to use compressed textures: 1. rendering can be 4 times faster. 2. It saves some VRAM. There is one reason to not use compressed textures: quality may be lower than with uncompressed textures.

Chapter 42

Visualization Toolkit Widget Classes

42.1 vtk3DWidget

42.1.1 Usage

vtk3DWidget is an abstract superclass for 3D interactor observers. These 3D widgets represent themselves in the scene, and have special callbacks associated with them that allows interactive manipulation of the widget. Inparticular, the difference between a vtk3DWidget and its abstract superclass vtkInteractorObserver is that vtk3DWidgets are "placed" in 3D space. vtkInteractorObservers have no notion of where they are placed, and may not exist in 3D space at all. 3D widgets also provide auxiliary functions like producing a transformation, creating polydata (for seeding streamlines, probes, etc.) or creating implicit functions. See the concrete subclasses for particulars.

Typically the widget is used by specifying a vtkProp3D or VTK dataset as input, and then invoking the "On" method to activate it. (You can also specify a bounding box to help position the widget.) Prior to invoking the On() method, the user may also wish to use the PlaceWidget() to initially position it. The 'i' (for "interactor") keypresses also can be used to turn the widgets on and off (methods exist to change the key value and enable keypress activiation).

To support interactive manipulation of objects, this class (and subclasses) invoke the events StartInteractionEvent, InteractionEvent, and EndInteractionEvent. These events are invoked when the vtk3DWidget enters a state where rapid response is desired: mouse motion, etc. The events can be used, for example, to set the desired update frame rate (StartInteractionEvent), operate on the vtkProp3D or other object (InteractionEvent), and set the desired frame rate back to normal values (EndInteractionEvent).

Note that the Priority attribute inherited from vtkInteractorObserver has a new default value which is now 0.5 so that all 3D widgets have a higher priority than the usual interactor styles.

To create an instance of class vtk3DWidget, simply invoke its constructor as follows

```
obj = vtk3DWidget
```

42.1.2 Methods

The class vtk3DWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtk3DWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtk3DWidget = obj.NewInstance ()`
- `vtk3DWidget = obj.SafeDownCast (vtkObject o)`

- `obj.PlaceWidget (double bounds[6])` - This method is used to initially place the widget. The placement of the widget depends on whether a Prop3D or input dataset is provided. If one of these two is provided, they will be used to obtain a bounding box, around which the widget is placed. Otherwise, you can manually specify a bounds with the PlaceWidget(bounds) method. Note: PlaceWidget(bounds) is required by all subclasses; the other methods are provided as convenience methods.

- `obj.PlaceWidget ()` - This method is used to initially place the widget. The placement of the widget depends on whether a Prop3D or input dataset is provided. If one of these two is provided, they will be used to obtain a bounding box, around which the widget is placed. Otherwise, you can manually specify a bounds with the PlaceWidget(bounds) method. Note: PlaceWidget(bounds) is required by all subclasses; the other methods are provided as convenience methods.

- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - This method is used to initially place the widget. The placement of the widget depends on whether a Prop3D or input dataset is provided. If one of these two is provided, they will be used to obtain a bounding box, around which the widget is placed. Otherwise, you can manually specify a bounds with the PlaceWidget(bounds) method. Note: PlaceWidget(bounds) is required by all subclasses; the other methods are provided as convenience methods.

- `obj.SetProp3D (vtkProp3D )` - Specify a vtkProp3D around which to place the widget. This is not required, but if supplied, it is used to initially position the widget.

- `vtkProp3D = obj.GetProp3D ()` - Specify a vtkProp3D around which to place the widget. This is not required, but if supplied, it is used to initially position the widget.

- `obj.SetInput (vtkDataSet )` - Specify the input dataset. This is not required, but if supplied, and no vtkProp3D is specified, it is used to initially position the widget.

- `vtkDataSet = obj.GetInput ()` - Specify the input dataset. This is not required, but if supplied, and no vtkProp3D is specified, it is used to initially position the widget.

- `obj.SetPlaceFactor (double )` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `double = obj.GetPlaceFactorMinValue ()` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `double = obj.GetPlaceFactorMaxValue ()` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `double = obj.GetPlaceFactor ()` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `obj.SetHandleSize (double )` - Set/Get the factor that controls the size of the handles that appear as part of the widget. These handles (like spheres, etc.) are used to manipulate the widget, and are sized as a fraction of the screen diagonal.

- `double = obj.GetHandleSizeMinValue ()` - Set/Get the factor that controls the size of the handles that appear as part of the widget. These handles (like spheres, etc.) are used to manipulate the widget, and are sized as a fraction of the screen diagonal.

- `double = obj.GetHandleSizeMaxValue ()` - Set/Get the factor that controls the size of the handles that appear as part of the widget. These handles (like spheres, etc.) are used to manipulate the widget, and are sized as a fraction of the screen diagonal.
- `double = obj.GetHandleSize ()` - Set/Get the factor that controls the size of the handles that appear as part of the widget. These handles (like spheres, etc.) are used to manipulate the widget, and are sized as a fraction of the screen diagonal.

42.2 vtkAbstractPolygonalHandleRepresentation3D

42.2.1 Usage

This class serves as the geometrical representation of a vtkHandleWidget. The handle can be represented by an arbitrary polygonal data (vtkPolyData), set via SetHandle(vtkPolyData *). The actual position of the handle will be initially assumed to be (0,0,0). You can specify an offset from this position if desired. This class differs from vtkPolygonalHandleRepresentation3D in that the handle will always remain front facing, ie it maintains a fixed orientation with respect to the camera. This is done by using vtkFollowers internally to render the actors.

To create an instance of class vtkAbstractPolygonalHandleRepresentation3D, simply invoke its constructor as follows

```
obj = vtkAbstractPolygonalHandleRepresentation3D
```

42.2.2 Methods

The class vtkAbstractPolygonalHandleRepresentation3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractPolygonalHandleRepresentation3D class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkAbstractPolygonalHandleRepresentation3D = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkAbstractPolygonalHandleRepresentation3D = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetWorldPosition (double p[3])` - Set the position of the point in world and display coordinates.
- `obj.SetDisplayPosition (double p[3])` - Set the position of the point in world and display coordinates.
- `obj.SetHandle (vtkPolyData )` - Set/get the handle polydata.
- `vtkPolyData = obj.GetHandle ()` - Set/get the handle polydata.
- `obj.SetProperty (vtkProperty )` - Set/Get the handle properties when unselected and selected.
- `obj.SetSelectedProperty (vtkProperty )` - Set/Get the handle properties when unselected and selected.
- `vtkProperty = obj.GetProperty ()` - Set/Get the handle properties when unselected and selected.
- `vtkProperty = obj.GetSelectedProperty ()` - Set/Get the handle properties when unselected and selected.

- `vtkAbstractTransform = obj.GetTransform ()` - Get the transform used to transform the generic handle polydata before placing it in the render window
- `obj.BuildRepresentation ()` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.WidgetInteraction (double eventPos[2])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.DeepCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.GetActors (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.
- `obj.SetLabelVisibility (int )` - A label may be associated with the seed. The string can be set via SetLabelText. The visibility of the label can be turned on / off.
- `int = obj.GetLabelVisibility ()` - A label may be associated with the seed. The string can be set via SetLabelText. The visibility of the label can be turned on / off.
- `obj.LabelVisibilityOn ()` - A label may be associated with the seed. The string can be set via SetLabelText. The visibility of the label can be turned on / off.
- `obj.LabelVisibilityOff ()` - A label may be associated with the seed. The string can be set via SetLabelText. The visibility of the label can be turned on / off.
- `obj.SetLabelText (string label)` - A label may be associated with the seed. The string can be set via SetLabelText. The visibility of the label can be turned on / off.
- `string = obj.GetLabelText ()` - A label may be associated with the seed. The string can be set via SetLabelText. The visibility of the label can be turned on / off.
- `obj.SetLabelTextScale (double scale[3])` - Scale text (font size along each dimension).
- `vtkFollower = obj.GetLabelTextActor ()` - Get the label text actor
- `obj.SetUniformScale (double scale)` - The handle may be scaled uniformly in all three dimensions using this API. The handle can also be scaled interactively using the right mouse button.
- `obj.SetHandleVisibility (int )` - Toogle the visibility of the handle on and off
- `int = obj.GetHandleVisibility ()` - Toogle the visibility of the handle on and off
- `obj.HandleVisibilityOn ()` - Toogle the visibility of the handle on and off
- `obj.HandleVisibilityOff ()` - Toogle the visibility of the handle on and off

42.3 vtkAbstractWidget

42.3.1 Usage

The vtkAbstractWidget defines an API and implements methods common to all widgets using the interaction/representation design. In this design, the term interaction means that part of the widget that performs event handling, while the representation corresponds to a vtkProp (or the subclass vtkWidgetRepresentation) used to represent the widget. vtkAbstractWidget also implements some methods common to all subclasses.

Note that vtkAbstractWidget provides access to the vtkWidgetEventTranslator. This class is responsible for translating VTK events (defined in vtkCommand.h) into widget events (defined in vtkWidgetEvent.h). This class can be manipulated so that different VTK events can be mapped into widget events, thereby allowing the modification of event bindings. Each subclass of vtkAbstractWidget defines the events to which it responds.

To create an instance of class vtkAbstractWidget, simply invoke its constructor as follows

```
obj = vtkAbstractWidget
```

42.3.2 Methods

The class vtkAbstractWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractWidget class.

- `string = obj.GetClassName ()` - Standard macros implementing standard VTK methods.
- `int = obj.IsA (string name)` - Standard macros implementing standard VTK methods.
- `vtkAbstractWidget = obj.NewInstance ()` - Standard macros implementing standard VTK methods.
- `vtkAbstractWidget = obj.SafeDownCast (vtkObject o)` - Standard macros implementing standard VTK methods.
- `obj.SetEnabled (int )` - Methods for activating this widget. Note that the widget representation must be specified or the widget will not appear. ProcessEvents (On by default) must be On for Enabled widget to respond to interaction. If ProcessEvents is Off, enabling/disabling a widget merely affects the visibility of the representation.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Set this to Off to disable interaction. On by default. Subclasses must overide SetProcessEvents() to make sure that they pass on the flag to all component widgets.
- `int = obj.GetProcessEventsMinValue ()` - Methods to change the whether the widget responds to interaction. Set this to Off to disable interaction. On by default. Subclasses must overide SetProcessEvents() to make sure that they pass on the flag to all component widgets.
- `int = obj.GetProcessEventsMaxValue ()` - Methods to change the whether the widget responds to interaction. Set this to Off to disable interaction. On by default. Subclasses must overide SetProcessEvents() to make sure that they pass on the flag to all component widgets.
- `int = obj.GetProcessEvents ()` - Methods to change the whether the widget responds to interaction. Set this to Off to disable interaction. On by default. Subclasses must overide SetProcessEvents() to make sure that they pass on the flag to all component widgets.
- `obj.ProcessEventsOn ()` - Methods to change the whether the widget responds to interaction. Set this to Off to disable interaction. On by default. Subclasses must overide SetProcessEvents() to make sure that they pass on the flag to all component widgets.

- `obj.ProcessEventsOff ()` - Methods to change the whether the widget responds to interaction. Set this to Off to disable interaction. On by default. Subclasses must overide SetProcessEvents() to make sure that they pass on the flag to all component widgets.
- `vtkWidgetEventTranslator = obj.GetEventTranslator ()` - Create the default widget representation if one is not set. The representation defines the geometry of the widget (i.e., how it appears) as well as providing special methods for manipulting the state and appearance of the widget.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set. The representation defines the geometry of the widget (i.e., how it appears) as well as providing special methods for manipulting the state and appearance of the widget.
- `obj.Render ()` - This method is called by subclasses when a render method is to be invoked on the vtkRenderWindowInteractor. This method should be called (instead of vtkRenderWindow::Render() because it has built into it optimizations for minimizing renders and/or speeding renders.
- `obj.SetParent (vtkAbstractWidget parent)` - Specifying a parent to this widget is used when creating composite widgets. It is an internal method not meant to be used by the public. When a widget has a parent, it defers the rendering to the parent. It may also defer managing the cursor (see ManagesCursor ivar).
- `vtkAbstractWidget = obj.GetParent ()` - Specifying a parent to this widget is used when creating composite widgets. It is an internal method not meant to be used by the public. When a widget has a parent, it defers the rendering to the parent. It may also defer managing the cursor (see ManagesCursor ivar).
- `vtkWidgetRepresentation = obj.GetRepresentation ()` - Turn on or off the management of the cursor. Cursor management is typically disabled for subclasses when composite widgets are created. For example, vtkHandleWidgets are often used to create composite widgets, and the parent widget takes over the cursor management.
- `obj.SetManagesCursor (int )` - Turn on or off the management of the cursor. Cursor management is typically disabled for subclasses when composite widgets are created. For example, vtkHandleWidgets are often used to create composite widgets, and the parent widget takes over the cursor management.
- `int = obj.GetManagesCursor ()` - Turn on or off the management of the cursor. Cursor management is typically disabled for subclasses when composite widgets are created. For example, vtkHandleWidgets are often used to create composite widgets, and the parent widget takes over the cursor management.
- `obj.ManagesCursorOn ()` - Turn on or off the management of the cursor. Cursor management is typically disabled for subclasses when composite widgets are created. For example, vtkHandleWidgets are often used to create composite widgets, and the parent widget takes over the cursor management.
- `obj.ManagesCursorOff ()` - Turn on or off the management of the cursor. Cursor management is typically disabled for subclasses when composite widgets are created. For example, vtkHandleWidgets are often used to create composite widgets, and the parent widget takes over the cursor management.
- `obj.SetPriority (float )` - Override the superclass method. This will automatically change the priority of the widget. Unlike the superclass documentation, no methods such as SetInteractor to null and reset it etc. are necessary

42.4 vtkAffineRepresentation

42.4.1 Usage

This class defines an API for affine transformation widget representations. These representations interact with vtkAffineWidget. The basic functionality of the affine representation is to maintain a transformation matrix.

This class may be subclassed so that alternative representations can be created. The class defines an API and a default implementation that the vtkAffineWidget interacts with to render itself in the scene.

To create an instance of class vtkAffineRepresentation, simply invoke its constructor as follows

```
obj = vtkAffineRepresentation
```

42.4.2 Methods

The class vtkAffineRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAffineRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkAffineRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkAffineRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.GetTransform (vtkTransform t)` - Retrieve a linear transform characterizing the affine transformation generated by this widget. This method copies its internal transform into the transform provided. The transform is relative to the initial placement of the representation (i.e., when PlaceWidget() is invoked).
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class properly act like a vtkWidgetRepresentation.

42.5 vtkAffineRepresentation2D

42.5.1 Usage

This class is used to represent a vtkAffineWidget. This representation consists of three parts: a box, a circle, and a cross. The box is used for scaling and shearing, the circle for rotation, and the cross for translation. These parts are drawn in the overlay plane and maintain a constant size (width and height) specified in terms of normalized viewport coordinates.

The representation maintains an internal transformation matrix (see superclass' GetTransform() method). The transformations generated by this widget assume that the representation lies in the x-y plane. If this is not the case, the user is responsible for transforming this representation's matrix into the correct coordinate space (by judicious matrix multiplication). Note that the transformation matrix returned by GetTransform() is relative to the last PlaceWidget() invocation. (The PlaceWidget() sets the origin around which rotation and scaling occurs; the origin is the center point of the bounding box provided.)

To create an instance of class vtkAffineRepresentation2D, simply invoke its constructor as follows

```
obj = vtkAffineRepresentation2D
```

42.5.2 Methods

The class vtkAffineRepresentation2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAffineRepresentation2D class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkAffineRepresentation2D = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkAffineRepresentation2D = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetBoxWidth (int )` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `int = obj.GetBoxWidthMinValue ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `int = obj.GetBoxWidthMaxValue ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `int = obj.GetBoxWidth ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `obj.SetCircleWidth (int )` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `int = obj.GetCircleWidthMinValue ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `int = obj.GetCircleWidthMaxValue ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `int = obj.GetCircleWidth ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.
- `obj.SetAxesWidth (int )` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.

- `int = obj.GetAxesWidthMinValue ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.

- `int = obj.GetAxesWidthMaxValue ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.

- `int = obj.GetAxesWidth ()` - Specify the width of the various parts of the representation (in pixels). The three parts are of the representation are the translation axes, the rotation circle, and the scale/shear box. Note that since the widget resizes itself so that the width and height are always the same, only the width needs to be specified.

- `obj.SetOrigin (double o[3])` - Specify the origin of the widget (in world coordinates). The origin is the point where the widget places itself. Note that rotations and scaling occurs around the origin.

- `obj.SetOrigin (double ox, double oy, double oz)` - Specify the origin of the widget (in world coordinates). The origin is the point where the widget places itself. Note that rotations and scaling occurs around the origin.

- `double = obj. GetOrigin ()` - Specify the origin of the widget (in world coordinates). The origin is the point where the widget places itself. Note that rotations and scaling occurs around the origin.

- `obj.GetTransform (vtkTransform t)` - Retrieve a linear transform characterizing the affine transformation generated by this widget. This method copies its internal transform into the transform provided. Note that the PlaceWidget() method initializes the internal matrix to identity. All subsequent widget operations (i.e., scale, translate, rotate, shear) are concatenated with the internal transform.

- `obj.SetProperty (vtkProperty2D )` - Set/Get the properties when unselected and selected.

- `obj.SetSelectedProperty (vtkProperty2D )` - Set/Get the properties when unselected and selected.

- `obj.SetTextProperty (vtkTextProperty )` - Set/Get the properties when unselected and selected.

- `vtkProperty2D = obj.GetProperty ()` - Set/Get the properties when unselected and selected.

- `vtkProperty2D = obj.GetSelectedProperty ()` - Set/Get the properties when unselected and selected.

- `vtkTextProperty = obj.GetTextProperty ()` - Set/Get the properties when unselected and selected.

- `obj.SetDisplayText (int )` - Enable the display of text with numeric values characterizing the transformation. Rotation and shear are expressed in degrees; translation the distance in world coordinates; and scale normalized (sx,sy) values.

- `int = obj.GetDisplayText ()` - Enable the display of text with numeric values characterizing the transformation. Rotation and shear are expressed in degrees; translation the distance in world coordinates; and scale normalized (sx,sy) values.

- `obj.DisplayTextOn ()` - Enable the display of text with numeric values characterizing the transformation. Rotation and shear are expressed in degrees; translation the distance in world coordinates; and scale normalized (sx,sy) values.

- `obj.DisplayTextOff ()` - Enable the display of text with numeric values characterizing the transformation. Rotation and shear are expressed in degrees; translation the distance in world coordinates; and scale normalized (sx,sy) values.

- `obj.PlaceWidget (double bounds[6])` - Subclasses of vtkAffineRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other. Note: PlaceWidget() reinitializes the transformation matrix (i.e., sets it to identity). It also sets the origin for scaling and rotation.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses of vtkAffineRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other. Note: PlaceWidget() reinitializes the transformation matrix (i.e., sets it to identity). It also sets the origin for scaling and rotation.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses of vtkAffineRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other. Note: PlaceWidget() reinitializes the transformation matrix (i.e., sets it to identity). It also sets the origin for scaling and rotation.
- `obj.EndWidgetInteraction (double eventPos[2])` - Subclasses of vtkAffineRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other. Note: PlaceWidget() reinitializes the transformation matrix (i.e., sets it to identity). It also sets the origin for scaling and rotation.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Subclasses of vtkAffineRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other. Note: PlaceWidget() reinitializes the transformation matrix (i.e., sets it to identity). It also sets the origin for scaling and rotation.
- `obj.BuildRepresentation ()` - Subclasses of vtkAffineRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other. Note: PlaceWidget() reinitializes the transformation matrix (i.e., sets it to identity). It also sets the origin for scaling and rotation.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.GetActors2D (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.

42.6 vtkAffineWidget

42.6.1 Usage

The vtkAffineWidget is used to perform affine transformations on objects. (Affine transformations are transformations that keep parallel lines parallel. Affine transformations include translation, scaling, rotation, and shearing.)

To use this widget, set the widget representation. The representation maintains a transformation matrix and other instance variables consistent with the transformations applied by this widget.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - select widget: depending on which part is selected
                       translation, rotation, scaling, or shearing may follow.
LeftButtonReleaseEvent - end selection of widget.
MouseMoveEvent - interactive movement across widget
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkAffineWidget's widget events:

```
vtkWidgetEvent::Select -- focal point is being selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for widget motion
```

In turn, when these widget events are processed, the vtkAffineWidget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkAffineWidget, simply invoke its constructor as follows

```
obj = vtkAffineWidget
```

42.6.2 Methods

The class vtkAffineWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAffineWidget class.

- `string = obj.GetClassName ()` - Standard VTK class macros.
- `int = obj.IsA (string name)` - Standard VTK class macros.
- `vtkAffineWidget = obj.NewInstance ()` - Standard VTK class macros.
- `vtkAffineWidget = obj.SafeDownCast (vtkObject o)` - Standard VTK class macros.
- `obj.SetRepresentation (vtkAffineRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.SetEnabled (int )` - Methods for activiating this widget. This implementation extends the superclasses' in order to resize the widget handles due to a render start event.

42.7 vtkAngleRepresentation

42.7.1 Usage

The vtkAngleRepresentation is a superclass for classes representing the vtkAngleWidget. This representation consists of two rays and three vtkHandleRepresentations to place and manipulate the three points defining the angle representation. (Note: the three points are referred to as Point1, Center, and Point2, at the two end points (Point1 and Point2) and Center (around which the angle is measured).

To create an instance of class vtkAngleRepresentation, simply invoke its constructor as follows

```
obj = vtkAngleRepresentation
```

42.7.2 Methods

The class vtkAngleRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAngleRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkAngleRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkAngleRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `double = obj.GetAngle ()` - This representation and all subclasses must keep an angle (in degrees) consistent with the state of the widget.
- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetCenterWorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetCenterDisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetCenterDisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the three points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetHandleRepresentation (vtkHandleRepresentation handle)` - This method is used to specify the type of handle representation to use for the three internal vtkHandleWidgets within vtkAngleRepresentation. To use this method, create a dummy vtkHandleRepresentation (or subclass), and then invoke this method with this dummy. Then the vtkAngleRepresentation uses this dummy to clone three vtkHandleRepresentations of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkAngle widget.)

- `obj.InstantiateHandleRepresentation ()` - This method is used to specify the type of handle representation to use for the three internal vtkHandleWidgets within vtkAngleRepresentation. To use this method, create a dummy vtkHandleRepresentation (or subclass), and then invoke this method with this dummy. Then the vtkAngleRepresentation uses this dummy to clone three vtkHandleRepresentations of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkAngle widget.)

- `vtkHandleRepresentation = obj.GetPoint1Representation ()` - Set/Get the handle representations used for the vtkAngleRepresentation.

- `vtkHandleRepresentation = obj.GetCenterRepresentation ()` - Set/Get the handle representations used for the vtkAngleRepresentation.

- `vtkHandleRepresentation = obj.GetPoint2Representation ()` - Set/Get the handle representations used for the vtkAngleRepresentation.

- `obj.SetTolerance (int )` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the end points of the representation to be active.

- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the end points of the representation to be active.

- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the end points of the representation to be active.

- `int = obj.GetTolerance ()` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the end points of the representation to be active.

- `obj.SetLabelFormat (string )` - Specify the format to use for labelling the angle. Note that an empty string results in no label, or a format string without a "will not print the angle value.

- `string = obj.GetLabelFormat ()` - Specify the format to use for labelling the angle. Note that an empty string results in no label, or a format string without a "will not print the angle value.

- `obj.SetRay1Visibility (int )` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `int = obj.GetRay1Visibility ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `obj.Ray1VisibilityOn ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `obj.Ray1VisibilityOff ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `obj.SetRay2Visibility (int )` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `int = obj.GetRay2Visibility ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `obj.Ray2VisibilityOn ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `obj.Ray2VisibilityOff ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.

- `obj.SetArcVisibility (int )` - Special methods for turning off the rays and arc that define the cone and arc of the angle.
- `int = obj.GetArcVisibility ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.
- `obj.ArcVisibilityOn ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.
- `obj.ArcVisibilityOff ()` - Special methods for turning off the rays and arc that define the cone and arc of the angle.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.CenterWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.

42.8 vtkAngleRepresentation2D

42.8.1 Usage

The vtkAngleRepresentation2D is a representation for the vtkAngleWidget. This representation consists of two rays and three vtkHandleRepresentations to place and manipulate the three points defining the angle representation. (Note: the three points are referred to as Point1, Center, and Point2, at the two end points (Point1 and Point2) and Center (around which the angle is measured). This particular implementation is a 2D representation, meaning that it draws in the overlay plane.

To create an instance of class vtkAngleRepresentation2D, simply invoke its constructor as follows

```
obj = vtkAngleRepresentation2D
```

42.8.2 Methods

The class vtkAngleRepresentation2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAngleRepresentation2D class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkAngleRepresentation2D = obj.NewInstance ()` - Standard VTK methods.
- `vtkAngleRepresentation2D = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `double = obj.GetAngle ()` - Satisfy the superclasses API.
- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetCenterWorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetCenterDisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetCenterDisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `vtkLeaderActor2D = obj.GetRay1 ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `vtkLeaderActor2D = obj.GetRay2 ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `vtkLeaderActor2D = obj.GetArc ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `obj.BuildRepresentation ()` - Method defined by vtkWidgetRepresentation superclass and needed here.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp superclass.

42.9 vtkAngleRepresentation3D

42.9.1 Usage

The vtkAngleRepresentation3D is a representation for the vtkAngleWidget. This representation consists of two rays and three vtkHandleRepresentations to place and manipulate the three points defining the angle representation. (Note: the three points are referred to as Point1, Center, and Point2, at the two end points (Point1 and Point2) and Center (around which the angle is measured). This particular implementation is a 3D representation, meaning that it draws in the overlay plane.

To create an instance of class vtkAngleRepresentation3D, simply invoke its constructor as follows

```
obj = vtkAngleRepresentation3D
```

42.9.2 Methods

The class vtkAngleRepresentation3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAngleRepresentation3D class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkAngleRepresentation3D = obj.NewInstance ()` - Standard VTK methods.
- `vtkAngleRepresentation3D = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `double = obj.GetAngle ()` - Satisfy the superclasses API. Angle returned is in radians.
- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetCenterWorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetCenterWorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetCenterDisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetCenterDisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `vtkActor = obj.GetRay1 ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `vtkActor = obj.GetRay2 ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `vtkActor = obj.GetArc ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `vtkFollower = obj.GetTextActor ()` - Set/Get the three leaders used to create this representation. By obtaining these leaders the user can set the appropriate properties, etc.
- `obj.SetTextActorScale (double scale[3])` - Scale text.
- `obj.BuildRepresentation ()` - Method defined by vtkWidgetRepresentation superclass and needed here.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Methods required by vtkProp superclass.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Methods required by vtkProp superclass.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods required by vtkProp superclass.

42.10 vtkAngleWidget

42.10.1 Usage

The vtkAngleWidget is used to measure the angle between two rays (defined by three points). The three points (two end points and a center) can be positioned independently, and when they are released, a special PlacePointEvent is invoked so that special operations may be take to reposition the point (snap to grid, etc.) The widget has two different modes of interaction: when initially defined (i.e., placing the three points) and then a manipulate mode (adjusting the position of the three points).

To use this widget, specify an instance of vtkAngleWidget and a representation (a subclass of vtkAngleRepresentation). The widget is implemented using three instances of vtkHandleWidget which are used to position the three points. The representations for these handle widgets are provided by the vtkAngleRepresentation.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - add a point or select a handle
MouseMoveEvent - position the second or third point, or move a handle
LeftButtonReleaseEvent - release the selected handle
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkAngleWidget's widget events:

```
vtkWidgetEvent::AddPoint -- add one point; depending on the state
                            it may the first, second or third point
                            added. Or, if near a handle, select the handle.
vtkWidgetEvent::Move -- position the second or third point, or move the
```

```
                          handle depending on the state.
vtkWidgetEvent::EndSelect -- the handle manipulation process has completed.
```

This widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (beginning to interact)
vtkCommand::EndInteractionEvent (completing interaction)
vtkCommand::InteractionEvent (moving a handle)
vtkCommand::PlacePointEvent (after a point is positioned;
                             call data includes handle id (0,1,2))
```

To create an instance of class vtkAngleWidget, simply invoke its constructor as follows

```
obj = vtkAngleWidget
```

42.10.2 Methods

The class vtkAngleWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAngleWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkAngleWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkAngleWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it is a composite widget and does more than its superclasses' vtkAbstractWidget::SetEnabled() method.
- `obj.SetRepresentation (vtkAngleRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `int = obj.IsAngleValid ()` - A flag indicates whether the angle is valid. The angle value only becomes valid after two of the three points are placed.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Overridden to pass the state to component widgets.

42.11 vtkBalloonRepresentation

42.11.1 Usage

The vtkBalloonRepresentation is used to represent the vtkBalloonWidget. This representation is defined by two items: a text string and an image. At least one of these two items must be defined, but it is allowable to specify both, or just an image or just text. If both the text and image are specified, then methods are available for positioning the text and image with respect to each other.

The balloon representation consists of three parts: text, a rectangular frame behind the text, and an image placed next to the frame and sized to match the frame.

The size of the balloon is ultimately controlled by the text properties (i.e., font size). This representation uses a layout policy as follows.

If there is just text and no image, then the text properties and padding are used to control the size of the balloon.

If there is just an image and no text, then the ImageSize[2] member is used to control the image size. (The image will fit into this rectangle, but will not necessarily fill the whole rectangle, i.e., the image is not stretched).

If there is text and an image, the following approach ia used. First, based on the font size and other related properties (e.g., padding), determine the size of the frame. Second, depending on the layout of the image and text frame, control the size of the neighboring image (since the frame and image share a common edge). However, if this results in an image that is smaller than ImageSize[2], then the image size will be set to ImageSize[2] and the frame will be adjusted accordingly. The text is always placed in the center of the frame if the frame is resized.

To create an instance of class vtkBalloonRepresentation, simply invoke its constructor as follows

```
obj = vtkBalloonRepresentation
```

42.11.2 Methods

The class vtkBalloonRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBalloonRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkBalloonRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkBalloonRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `obj.SetBalloonImage (vtkImageData img)` - Specify/retrieve the image to display in the balloon.
- `vtkImageData = obj.GetBalloonImage ()` - Specify/retrieve the image to display in the balloon.
- `string = obj.GetBalloonText ()` - Specify/retrieve the text to display in the balloon.
- `obj.SetBalloonText (string )` - Specify/retrieve the text to display in the balloon.
- `obj.SetImageSize (int , int )` - Specify the minimum size for the image. Note that this is a bounding rectangle, the image will fit inside of it. However, if the balloon consists of text plus an image, then the image may be bigger than ImageSize[2] to fit into the balloon frame.
- `obj.SetImageSize (int  a[2])` - Specify the minimum size for the image. Note that this is a bounding rectangle, the image will fit inside of it. However, if the balloon consists of text plus an image, then the image may be bigger than ImageSize[2] to fit into the balloon frame.
- `int = obj. GetImageSize ()` - Specify the minimum size for the image. Note that this is a bounding rectangle, the image will fit inside of it. However, if the balloon consists of text plus an image, then the image may be bigger than ImageSize[2] to fit into the balloon frame.
- `obj.SetTextProperty (vtkTextProperty p)` - Set/get the text property (relevant only if text is shown).
- `vtkTextProperty = obj.GetTextProperty ()` - Set/get the text property (relevant only if text is shown).
- `obj.SetFrameProperty (vtkProperty2D p)` - Set/get the frame property (relevant only if text is shown). The frame lies behind the text.

- `vtkProperty2D = obj.GetFrameProperty ()` - Set/get the frame property (relevant only if text is shown). The frame lies behind the text.

- `obj.SetImageProperty (vtkProperty2D p)` - Set/get the image property (relevant only if an image is shown).

- `vtkProperty2D = obj.GetImageProperty ()` - Set/get the image property (relevant only if an image is shown).

- `obj.SetBalloonLayout (int )` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `int = obj.GetBalloonLayout ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToImageLeft ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToImageRight ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToImageBottom ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToImageTop ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToTextLeft ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToTextRight ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToTextTop ()` - Specify the layout of the image and text within the balloon. Note that there are reduncies in these methods, for example SetBalloonLayoutToImageLeft() results in the same effect as SetBalloonLayoutToTextRight(). If only text is specified, or only an image is specified, then it doesn't matter how the layout is specified.

- `obj.SetBalloonLayoutToTextBottom ()` - Set/Get the offset from the mouse pointer from which to place the balloon. The representation will try and honor this offset unless there is a collision with the side of the renderer, in which case the balloon will be repositioned to lie within the rendering window.

- `obj.SetOffset (int , int )` - Set/Get the offset from the mouse pointer from which to place the balloon. The representation will try and honor this offset unless there is a collision with the side of the renderer, in which case the balloon will be repositioned to lie within the rendering window.
- `obj.SetOffset (int a[2])` - Set/Get the offset from the mouse pointer from which to place the balloon. The representation will try and honor this offset unless there is a collision with the side of the renderer, in which case the balloon will be repositioned to lie within the rendering window.
- `int = obj. GetOffset ()` - Set/Get the offset from the mouse pointer from which to place the balloon. The representation will try and honor this offset unless there is a collision with the side of the renderer, in which case the balloon will be repositioned to lie within the rendering window.
- `obj.SetPadding (int )` - Set/Get the padding (in pixels) that is used between the text and the frame.
- `int = obj.GetPaddingMinValue ()` - Set/Get the padding (in pixels) that is used between the text and the frame.
- `int = obj.GetPaddingMaxValue ()` - Set/Get the padding (in pixels) that is used between the text and the frame.
- `int = obj.GetPadding ()` - Set/Get the padding (in pixels) that is used between the text and the frame.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.EndWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp superclass.

42.12 vtkBalloonWidget

42.12.1 Usage

The vtkBalloonWidget is used to popup text and/or an image when the mouse hovers over an instance of vtkProp. The widget keeps track of (vtkProp,vtkBalloon) pairs (where the internal vtkBalloon class is defined by a pair of vtkStdString and vtkImageData), and when the mouse stops moving for a user-specified period of time over the vtkProp, then the vtkBalloon is drawn nearby the vtkProp. Note that an instance of vtkBalloonRepresentation is used to draw the balloon.

To use this widget, specify an instance of vtkBalloonWidget and a representation (e.g., vtkBalloonRepresentation). Then list all instances of vtkProp, a text string, and/or an instance of vtkImageData to be associated with each vtkProp. (Note that you can specify both text and an image, or just one or the other.) You may also wish to specify the hover delay (i.e., set in the superclass vtkHoverWidget).

.SECTION Event Bindings By default, the widget observes the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
MouseMoveEvent - occurs when mouse is moved in render window.
TimerEvent - occurs when the time between events (e.g., mouse move)
             is greater than TimerDuration.
KeyPressEvent - when the ''Enter'' key is pressed after the balloon appears,
                a callback is activited (e.g., WidgetActivateEvent).
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkBalloonWidget's widget events:

```
vtkWidgetEvent::Move -- start the timer
vtkWidgetEvent::TimedOut -- when hovering occurs,
vtkWidgetEvent::SelectAction -- activate any callbacks associated
                                with the balloon.
```

This widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::TimerEvent (when hovering is determined to occur)
vtkCommand::EndInteractionEvent (after a hover has occured and the
                                 mouse begins moving again).
vtkCommand::WidgetActivateEvent (when the balloon is selected with a
                                 keypress).
```

To create an instance of class vtkBalloonWidget, simply invoke its constructor as follows

```
obj = vtkBalloonWidget
```

42.12.2 Methods

The class vtkBalloonWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBalloonWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkBalloonWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkBalloonWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it performs special timer-related operations.
- `obj.SetRepresentation (vtkBalloonRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.AddBalloon (vtkProp prop, string str, vtkImageData img)` - Add and remove text and/or an image to be associated with a vtkProp. You may add one or both of them.
- `obj.AddBalloon (vtkProp prop, string str)` - Add and remove text and/or an image to be associated with a vtkProp. You may add one or both of them.
- `obj.RemoveBalloon (vtkProp prop)` - Add and remove text and/or an image to be associated with a vtkProp. You may add one or both of them.
- `string = obj.GetBalloonString (vtkProp prop)` - Methods to retrieve the information associated with each vtkProp (i.e., the information that makes up each balloon). A NULL will be returned if the vtkProp does not exist, or if a string or image have not been associated with the specified vtkProp.
- `vtkImageData = obj.GetBalloonImage (vtkProp prop)` - Methods to retrieve the information associated with each vtkProp (i.e., the information that makes up each balloon). A NULL will be returned if the vtkProp does not exist, or if a string or image have not been associated with the specified vtkProp.

- `vtkProp = obj.GetCurrentProp ()` - Set/Get the object used to perform pick operations. Since the vtkBalloonWidget operates on vtkProps, the picker must be a subclass of vtkAbstractPropPicker. (Note: if not specified, an instance of vtkPropPicker is used.)

- `obj.SetPicker (vtkAbstractPropPicker )` - Set/Get the object used to perform pick operations. Since the vtkBalloonWidget operates on vtkProps, the picker must be a subclass of vtkAbstractPropPicker. (Note: if not specified, an instance of vtkPropPicker is used.)

- `vtkAbstractPropPicker = obj.GetPicker ()` - Set/Get the object used to perform pick operations. Since the vtkBalloonWidget operates on vtkProps, the picker must be a subclass of vtkAbstractPropPicker. (Note: if not specified, an instance of vtkPropPicker is used.)

42.13 vtkBezierContourLineInterpolator

42.13.1 Usage

The line interpolator interpolates supplied nodes (see InterpolateLine) with bezier line segments. The finess of the curve may be controlled using SetMaximumCurveError and SetMaximumNumberOfLineSegments.

To create an instance of class vtkBezierContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkBezierContourLineInterpolator
```

42.13.2 Methods

The class vtkBezierContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBezierContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.

- `int = obj.IsA (string name)` - Standard methods for instances of this class.

- `vtkBezierContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.

- `vtkBezierContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.

- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)`

- `obj.SetMaximumCurveError (double )` - The difference between a line segment connecting two points and the curve connecting the same points. In the limit of the length of the curve dx -¿ 0, the two values will be the same. The smaller this number, the finer the bezier curve will be interpolated. Default is 0.005

- `double = obj.GetMaximumCurveErrorMinValue ()` - The difference between a line segment connecting two points and the curve connecting the same points. In the limit of the length of the curve dx -¿ 0, the two values will be the same. The smaller this number, the finer the bezier curve will be interpolated. Default is 0.005

- `double = obj.GetMaximumCurveErrorMaxValue ()` - The difference between a line segment connecting two points and the curve connecting the same points. In the limit of the length of the curve dx -¿ 0, the two values will be the same. The smaller this number, the finer the bezier curve will be interpolated. Default is 0.005

- `double = obj.GetMaximumCurveError ()` - The difference between a line segment connecting two points and the curve connecting the same points. In the limit of the length of the curve dx -¿ 0, the two values will be the same. The smaller this number, the finer the bezier curve will be interpolated. Default is 0.005

- `obj.SetMaximumCurveLineSegments (int )` - Maximum number of bezier line segments between two nodes. Larger values create a finer interpolation. Default is 100.

- `int = obj.GetMaximumCurveLineSegmentsMinValue ()` - Maximum number of bezier line segments between two nodes. Larger values create a finer interpolation. Default is 100.

- `int = obj.GetMaximumCurveLineSegmentsMaxValue ()` - Maximum number of bezier line segments between two nodes. Larger values create a finer interpolation. Default is 100.

- `int = obj.GetMaximumCurveLineSegments ()` - Maximum number of bezier line segments between two nodes. Larger values create a finer interpolation. Default is 100.

- `obj.GetSpan (int nodeIndex, vtkIntArray nodeIndices, vtkContourRepresentation rep)` - Span of the interpolator. ie. the number of control points its supposed to interpolate given a node.

  The first argument is the current nodeIndex. ie, you'd be trying to interpolate between nodes "nodeIndex" and "nodeIndex-1", unless you're closing the contour in which case, you're trying to interpolate "nodeIndex" and "Node=0". The node span is returned in a vtkIntArray.

  The node span is returned in a vtkIntArray. The node span returned by this interpolator will be a 2-tuple with a span of 4.

42.14 vtkBiDimensionalRepresentation2D

42.14.1 Usage

The vtkBiDimensionalRepresentation2D is used to represent the bi-dimensional measure in a 2D (overlay) context. This representation consists of two perpendicular lines defined by four vtkHandleRepresentations. The four handles can be independently manipulated consistent with the orthogonal constraint on the lines. (Note: the four points are referred to as Point1, Point2, Point3 and Point4. Point1 and Point2 define the first line; and Point3 and Point4 define the second orthogonal line.)

To create this widget, you click to place the first two points. The third point is mirrored with the fourth point; when you place the third point (which is orthogonal to the lined defined by the first two points), the fourth point is dropped as well. After definition, the four points can be moved (in constrained fashion, preserving orthogonality). Further, the entire widget can be translated by grabbing the center point of the widget; each line can be moved along the other line; and the entire widget can be rotated around its center point.

To create an instance of class vtkBiDimensionalRepresentation2D, simply invoke its constructor as follows

```
obj = vtkBiDimensionalRepresentation2D
```

42.14.2 Methods

The class vtkBiDimensionalRepresentation2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBiDimensionalRepresentation2D class.

- `string = obj.GetClassName ()` - Standard VTK methods.

- `int = obj.IsA (string name)` - Standard VTK methods.

- `vtkBiDimensionalRepresentation2D = obj.NewInstance ()` - Standard VTK methods.

- `vtkBiDimensionalRepresentation2D = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `obj.SetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint3WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint4WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint3WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint4WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint3DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint4DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint3DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint4DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the four points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetLine1Visibility (int )` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `int = obj.GetLine1Visibility ()` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `obj.Line1VisibilityOn ()` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `obj.Line1VisibilityOff ()` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `obj.SetLine2Visibility (int )` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `int = obj.GetLine2Visibility ()` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `obj.Line2VisibilityOn ()` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `obj.Line2VisibilityOff ()` - Special methods for turning off the lines that define the bi-dimensional measure. Generally these methods are used by the vtkBiDimensionalWidget to control the appearance of the widget. Note: turning off Line1 actually turns off Line1 and Line2.
- `obj.SetHandleRepresentation (vtkHandleRepresentation handle)` - This method is used to specify the type of handle representation to use for the four internal vtkHandleRepresentations within vtkBiDimensionalRepresentation2D. To use this method, create a dummy vtkHandleRepresentation (or subclass), and then invoke this method with this dummy. Then the vtkBiDimensionalRepresentation2D uses this dummy to clone four vtkHandleRepresentations of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkBiDimensionalWidget for the purposes of cloning.)
- `obj.InstantiateHandleRepresentation ()` - This method is used to specify the type of handle representation to use for the four internal vtkHandleRepresentations within vtkBiDimensionalRepresentation2D. To use this method, create a dummy vtkHandleRepresentation (or subclass), and then invoke this method with this dummy. Then the vtkBiDimensionalRepresentation2D uses this dummy to clone four vtkHandleRepresentations of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkBiDimensionalWidget for the purposes of cloning.)
- `vtkHandleRepresentation = obj.GetPoint1Representation ()` - Set/Get the handle representations used within the vtkBiDimensionalRepresentation2D. (Note: properties can be set by grabbing these representations and setting the properties appropriately.)

- `vtkHandleRepresentation = obj.GetPoint2Representation ()` - Set/Get the handle representations used within the vtkBiDimensionalRepresentation2D. (Note: properties can be set by grabbing these representations and setting the properties appropriately.)
- `vtkHandleRepresentation = obj.GetPoint3Representation ()` - Set/Get the handle representations used within the vtkBiDimensionalRepresentation2D. (Note: properties can be set by grabbing these representations and setting the properties appropriately.)
- `vtkHandleRepresentation = obj.GetPoint4Representation ()` - Set/Get the handle representations used within the vtkBiDimensionalRepresentation2D. (Note: properties can be set by grabbing these representations and setting the properties appropriately.)
- `vtkProperty2D = obj.GetLineProperty ()` - Retrieve the property used to control the appearance of the two orthogonal lines.
- `vtkProperty2D = obj.GetSelectedLineProperty ()` - Retrieve the property used to control the appearance of the two orthogonal lines.
- `vtkTextProperty = obj.GetTextProperty ()` - Retrieve the property used to control the appearance of the text labels.
- `obj.SetTolerance (int )` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the representation to be active.
- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the representation to be active.
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the representation to be active.
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the representation (in pixels) in which the cursor is considered near enough to the representation to be active.
- `double = obj.GetLength1 ()` - Return the length of the line defined by (Point1,Point2). This is the distance in the world coordinate system.
- `double = obj.GetLength2 ()` - Return the length of the line defined by (Point3,Point4). This is the distance in the world coordinate system.
- `obj.SetLabelFormat (string )` - Specify the format to use for labelling the distance. Note that an empty string results in no label, or a format string without a "will not print the distance value.
- `string = obj.GetLabelFormat ()` - Specify the format to use for labelling the distance. Note that an empty string results in no label, or a format string without a "will not print the distance value.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetDefinition (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.Point2WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.Point3WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetManipulation (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.

- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.Highlight (int highlightOn)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `obj.SetShowLabelAboveWidget (int )` - Toggle whether to display the label above or below the widget. Defaults to 1.
- `int = obj.GetShowLabelAboveWidget ()` - Toggle whether to display the label above or below the widget. Defaults to 1.
- `obj.ShowLabelAboveWidgetOn ()` - Toggle whether to display the label above or below the widget. Defaults to 1.
- `obj.ShowLabelAboveWidgetOff ()` - Toggle whether to display the label above or below the widget. Defaults to 1.
- `obj.SetID (long id)` - Set/get the id to display in the label.
- `long = obj.GetID ()` - Set/get the id to display in the label.
- `string = obj.GetLabelText ()` - Get the text shown in the widget's label.
- `obj.GetLabelPosition (double pos[3])` - Get the position of the widget's label in display coordinates.
- `obj.GetWorldLabelPosition (double pos[3])` - Get the position of the widget's label in display coordinates.

42.15 vtkBiDimensionalWidget

42.15.1 Usage

The vtkBiDimensionalWidget is used to measure the bi-dimensional length of an object. The bi-dimensional measure is defined by two finite, orthogonal lines that intersect within the finite extent of both lines. The lengths of these two lines gives the bi-dimensional measure. Each line is defined by two handle widgets at the end points of each line.

The orthognal constraint on the two lines limits how the four end points can be positioned. The first two points can be placed arbitrarily to define the first line (similar to vtkDistanceWidget). The placement of the third point is limited by the finite extent of the first line. As the third point is placed, the fourth point is placed on the opposite side of the first line. Once the third point is placed, the second line is defined since the fourth point is defined at the same time, but the fourth point can be moved along the second line (i.e., maintaining the orthogonal relationship between the two lines). Onced defined, any of the four points can be moved along their constraint lines. Also, each line can be translated along the other line (in an orthogonal direction), and the whole bi-dimensional widget can be rotated about its center point (see the description of the event bindings). Finally, selecting the point where the two orthogonal axes intersect, the entire widget can be translated in any direction.

Placement of any point results in a special PlacePointEvent invocation so that special operations may be performed to reposition the point. Motion of any point, moving the lines, or rotating the widget cause InteractionEvents to be invoked. Note that the widget has two fundamental modes: a define mode (when initially placing the points) and a manipulate mode (after the points are placed). Line translation and rotation are only possible in manipulate mode.

To use this widget, specify an instance of vtkBiDimensionalWidget and a representation (e.g., vtkBiDimensionalRepresentation2D). The widget is implemented using four instances of vtkHandleWidget which are used to position the end points of the two intersecting lines. The representations for these handle widgets are provided by the vtkBiDimensionalRepresentation2D class.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - define a point or manipulate a handle, line,
                       perform rotation or translate the widget.
MouseMoveEvent - position the points, move a line, rotate or translate the widget
LeftButtonReleaseEvent - release the selected handle and end interaction
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkBiDimensionalWidget's widget events:

```
vtkWidgetEvent::AddPoint -- (In Define mode:) Add one point; depending on the
                            state it may the first, second, third or fourth
                            point added. (In Manipulate mode:) If near a handle,
                            select the handle. Or if near a line, select the line.
vtkWidgetEvent::Move -- (In Define mode:) Position the second, third or fourth
                        point. (In Manipulate mode:) Move the handle, line or widget.
vtkWidgetEvent::EndSelect -- the manipulation process has completed.
```

This widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (beginning to interact)
vtkCommand::EndInteractionEvent (completing interaction)
vtkCommand::InteractionEvent (moving a handle, line or performing rotation)
vtkCommand::PlacePointEvent (after a point is positioned;
                             call data includes handle id (0,1,2,4))
```

To create an instance of class vtkBiDimensionalWidget, simply invoke its constructor as follows

```
obj = vtkBiDimensionalWidget
```

42.15.2 Methods

The class vtkBiDimensionalWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBiDimensionalWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkBiDimensionalWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkBiDimensionalWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it is a composite widget and does more than its superclasses' vtkAbstractWidget::SetEnabled() method.
- `obj.SetRepresentation (vtkBiDimensionalRepresentation2D r)` - Create the default widget representation if one is not set.

- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `int = obj.IsMeasureValid ()` - A flag indicates whether the bi-dimensional measure is valid. The widget becomes valid after two of the four points are placed.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Overridden to pass the state to component widgets.

42.16 vtkBorderRepresentation

42.16.1 Usage

This class is used to represent and render a vtBorderWidget. To use this class, you need to specify the two corners of a rectangular region.

The class is typically subclassed so that specialized representations can be created. The class defines an API and a default implementation that the vtkBorderRepresentation interacts with to render itself in the scene.

To create an instance of class vtkBorderRepresentation, simply invoke its constructor as follows

```
obj = vtkBorderRepresentation
```

42.16.2 Methods

The class vtkBorderRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBorderRepresentation class.

- `string = obj.GetClassName ()` - Define standard methods.
- `int = obj.IsA (string name)` - Define standard methods.
- `vtkBorderRepresentation = obj.NewInstance ()` - Define standard methods.
- `vtkBorderRepresentation = obj.SafeDownCast (vtkObject o)` - Define standard methods.
- `vtkCoordinate = obj.GetPositionCoordinate ()` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,
- `obj.SetPosition (double, double)` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,
- `obj.SetPosition (double a[2])` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,

- `double = obj.GetPosition ()` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,

- `vtkCoordinate = obj.GetPosition2Coordinate ()` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,

- `obj.SetPosition2 (double, double)` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,

- `obj.SetPosition2 (double a[2])` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,

- `double = obj.GetPosition2 ()` - Specify opposite corners of the box defining the boundary of the widget. By default, these coordinates are in the normalized viewport coordinate system, with Position the lower left of the outline, and Position2 relative to Position. Note that using these methods are affected by the ProportionalResize flag. That is, if the aspect ratio of the representation is to be preserved (e.g., ProportionalResize is on), then the rectangle (Position,Position2) is a bounding rectangle. Also,

- `obj.SetShowBorder (int )` - Specify when and if the border should appear. If ShowBorder is "on", then the border will always appear. If ShowBorder is "off" then the border will never appear. If ShowBorder is "active" then the border will appear when the mouse pointer enters the region bounded by the border widget.

- `int = obj.GetShowBorderMinValue ()` - Specify when and if the border should appear. If ShowBorder is "on", then the border will always appear. If ShowBorder is "off" then the border will never appear. If ShowBorder is "active" then the border will appear when the mouse pointer enters the region bounded by the border widget.

- `int = obj.GetShowBorderMaxValue ()` - Specify when and if the border should appear. If ShowBorder is "on", then the border will always appear. If ShowBorder is "off" then the border will never appear. If ShowBorder is "active" then the border will appear when the mouse pointer enters the region bounded by the border widget.

- `int = obj.GetShowBorder ()` - Specify when and if the border should appear. If ShowBorder is "on", then the border will always appear. If ShowBorder is "off" then the border will never appear. If ShowBorder is "active" then the border will appear when the mouse pointer enters the region bounded by the border widget.

- `obj.SetShowBorderToOff ()` - Specify when and if the border should appear. If ShowBorder is "on", then the border will always appear. If ShowBorder is "off" then the border will never appear. If

ShowBorder is "active" then the border will appear when the mouse pointer enters the region bounded by the border widget.

- `obj.SetShowBorderToOn ()` - Specify when and if the border should appear. If ShowBorder is "on", then the border will always appear. If ShowBorder is "off" then the border will never appear. If ShowBorder is "active" then the border will appear when the mouse pointer enters the region bounded by the border widget.
- `obj.SetShowBorderToActive ()` - Specify the properties of the border.
- `vtkProperty2D = obj.GetBorderProperty ()` - Specify the properties of the border.
- `obj.SetProportionalResize (int )` - Indicate whether resizing operations should keep the x-y directions proportional to one another. Also, if ProportionalResize is on, then the rectangle (Position,Position2) is a bounding rectangle, and the representation will be placed in the rectangle in such a way as to preserve the aspect ratio of the representation.
- `int = obj.GetProportionalResize ()` - Indicate whether resizing operations should keep the x-y directions proportional to one another. Also, if ProportionalResize is on, then the rectangle (Position,Position2) is a bounding rectangle, and the representation will be placed in the rectangle in such a way as to preserve the aspect ratio of the representation.
- `obj.ProportionalResizeOn ()` - Indicate whether resizing operations should keep the x-y directions proportional to one another. Also, if ProportionalResize is on, then the rectangle (Position,Position2) is a bounding rectangle, and the representation will be placed in the rectangle in such a way as to preserve the aspect ratio of the representation.
- `obj.ProportionalResizeOff ()` - Indicate whether resizing operations should keep the x-y directions proportional to one another. Also, if ProportionalResize is on, then the rectangle (Position,Position2) is a bounding rectangle, and the representation will be placed in the rectangle in such a way as to preserve the aspect ratio of the representation.
- `obj.SetMinimumSize (int , int )` - Specify a minimum and/or maximum size (in pixels) that this representation can take. These methods require two values: size values in the x and y directions, respectively.
- `obj.SetMinimumSize (int a[2])` - Specify a minimum and/or maximum size (in pixels) that this representation can take. These methods require two values: size values in the x and y directions, respectively.
- `int = obj. GetMinimumSize ()` - Specify a minimum and/or maximum size (in pixels) that this representation can take. These methods require two values: size values in the x and y directions, respectively.
- `obj.SetMaximumSize (int , int )` - Specify a minimum and/or maximum size (in pixels) that this representation can take. These methods require two values: size values in the x and y directions, respectively.
- `obj.SetMaximumSize (int a[2])` - Specify a minimum and/or maximum size (in pixels) that this representation can take. These methods require two values: size values in the x and y directions, respectively.
- `int = obj. GetMaximumSize ()` - Specify a minimum and/or maximum size (in pixels) that this representation can take. These methods require two values: size values in the x and y directions, respectively.
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).

- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `double = obj. GetSelectionPoint ()` - After a selection event within the region interior to the border; the normalized selection coordinates may be obtained.
- `obj.SetMoving (int )` - This is a modifier of the interaction state. When set, widget interaction allows the border (and stuff inside of it) to be translated with mouse motion.
- `int = obj.GetMoving ()` - This is a modifier of the interaction state. When set, widget interaction allows the border (and stuff inside of it) to be translated with mouse motion.
- `obj.MovingOn ()` - This is a modifier of the interaction state. When set, widget interaction allows the border (and stuff inside of it) to be translated with mouse motion.
- `obj.MovingOff ()` - This is a modifier of the interaction state. When set, widget interaction allows the border (and stuff inside of it) to be translated with mouse motion.
- `obj.BuildRepresentation ()` - Subclasses should implement these methods. See the superclasses' documentation for more information.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses should implement these methods. See the superclasses' documentation for more information.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses should implement these methods. See the superclasses' documentation for more information.
- `obj.GetSize (double size[2])` - Subclasses should implement these methods. See the superclasses' documentation for more information.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Subclasses should implement these methods. See the superclasses' documentation for more information.
- `obj.GetActors2D (vtkPropCollection )` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - These methods are necessary to make this representation behave as a vtkProp.

42.17 vtkBorderWidget

42.17.1 Usage

This class is a superclass for 2D widgets that may require a rectangular border. Besides drawing a border, the widget provides methods for resizing and moving the rectangular region (and associated border). The widget provides methods and internal data members so that subclasses can take advantage of this widgets capabilities, requiring only that the subclass defines a "representation", i.e., some combination of props or actors that can be managed in the 2D rectangular region.

The class defines basic positioning functionality, including the ability to size the widget with locked x/y proportions. The area within the border may be made "selectable" as well, meaning that a selection event interior to the widget invokes a virtual SelectRegion() method, which can be used to pick objects or otherwise manipulate data interior to the widget.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
On the boundary of the widget:
  LeftButtonPressEvent - select boundary
  LeftButtonReleaseEvent - deselect boundary
  MouseMoveEvent - move/resize widget depending on which portion of the
                   boundary was selected.
On the interior of the widget:
  LeftButtonPressEvent - invoke SelectButton() callback (if the ivar
                         Selectable is on)
Anywhere on the widget:
  MiddleButtonPressEvent - move the widget
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkBorderWidget's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Translate -- the widget is to be translated
vtkWidgetEvent::Move -- a request for slider motion has been invoked
```

In turn, when these widget events are processed, this widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkBorderWidget, simply invoke its constructor as follows

```
obj = vtkBorderWidget
```

42.17.2 Methods

The class vtkBorderWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBorderWidget class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkBorderWidget = obj.NewInstance ()`
- `vtkBorderWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetSelectable (int )` - Indicate whether the interior region of the widget can be selected or not. If not, then events (such as left mouse down) allow the user to "move" the widget, and no selection is possible. Otherwise the SelectRegion() method is invoked.
- `int = obj.GetSelectable ()` - Indicate whether the interior region of the widget can be selected or not. If not, then events (such as left mouse down) allow the user to "move" the widget, and no selection is possible. Otherwise the SelectRegion() method is invoked.
- `obj.SelectableOn ()` - Indicate whether the interior region of the widget can be selected or not. If not, then events (such as left mouse down) allow the user to "move" the widget, and no selection is possible. Otherwise the SelectRegion() method is invoked.
- `obj.SelectableOff ()` - Indicate whether the interior region of the widget can be selected or not. If not, then events (such as left mouse down) allow the user to "move" the widget, and no selection is possible. Otherwise the SelectRegion() method is invoked.
- `obj.SetResizable (int )` - Indicate whether the boundary of the widget can be resized. If not, the cursor will not change to "resize" type when mouse over the boundary.
- `int = obj.GetResizable ()` - Indicate whether the boundary of the widget can be resized. If not, the cursor will not change to "resize" type when mouse over the boundary.
- `obj.ResizableOn ()` - Indicate whether the boundary of the widget can be resized. If not, the cursor will not change to "resize" type when mouse over the boundary.
- `obj.ResizableOff ()` - Indicate whether the boundary of the widget can be resized. If not, the cursor will not change to "resize" type when mouse over the boundary.
- `obj.SetRepresentation (vtkBorderRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.18 vtkBoundedPlanePointPlacer

42.18.1 Usage

vtkBoundedPlanePointPlacer is a type of point placer that constrains its points to a finite (i.e., bounded) plance.

To create an instance of class vtkBoundedPlanePointPlacer, simply invoke its constructor as follows

```
obj = vtkBoundedPlanePointPlacer
```

42.18.2 Methods

The class vtkBoundedPlanePointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoundedPlanePointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.

- `vtkBoundedPlanePointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkBoundedPlanePointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetProjectionNormal (int )` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `int = obj.GetProjectionNormalMinValue ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `int = obj.GetProjectionNormalMaxValue ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `int = obj.GetProjectionNormal ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `obj.SetProjectionNormalToXAxis ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `obj.SetProjectionNormalToYAxis ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `obj.SetProjectionNormalToZAxis ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `obj.SetProjectionNormalToOblique ()` - If the ProjectionNormal is set to Oblique, then this is the oblique plane used to constrain the handle position.
- `obj.SetObliquePlane (vtkPlane )` - If the ProjectionNormal is set to Oblique, then this is the oblique plane used to constrain the handle position.
- `obj.SetProjectionPosition (double position)` - The position of the bounding plane from the origin along the normal. The origin and normal are defined in the oblique plane when the ProjectionNormal is oblique. For the X, Y, and Z axes projection normals, the normal is the axis direction, and the origin is (0,0,0).
- `double = obj.GetProjectionPosition ()` - The position of the bounding plane from the origin along the normal. The origin and normal are defined in the oblique plane when the ProjectionNormal is oblique. For the X, Y, and Z axes projection normals, the normal is the axis direction, and the origin is (0,0,0).
- `obj.AddBoundingPlane (vtkPlane plane)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `obj.RemoveBoundingPlane (vtkPlane plane)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `obj.RemoveAllBoundingPlanes ()` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.SetBoundingPlanes (vtkPlaneCollection )` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `vtkPlaneCollection = obj.GetBoundingPlanes ()` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.SetBoundingPlanes (vtkPlanes planes)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given a renderer and a display position, compute the world position and world orientation for this point. A plane is defined by a combination of the ProjectionNormal, ProjectionOrigin, and Oblique-Plane ivars. The display position is projected onto this plane to determine a world position, and the orientation is set to the normal of the plane. If the point cannot project onto the plane or if it falls outside the bounds imposed by the BoundingPlanes, then 0 is returned, otherwise 1 is returned to indicate a valid return position and orientation.

- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[3], doubl` - Given a renderer, a display position, and a reference world position, compute the new world position and orientation of this point. This method is typically used by the representation to move the point.

- `int = obj.ValidateWorldPosition (double worldPos[3])` - Give a world position check if it is valid - does it lie on the plane and within the bounds? Returns 1 if it is valid, 0 otherwise.

- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])`

- `int = obj.UpdateWorldPosition (vtkRenderer ren, double worldPos[3], double worldOrient[9])` - If the constraints on this placer are changed, then this method will be called by the representation on each of its points. For this placer, the world position will be converted to a display position, then ComputeWorldPosition will be used to update the point.

42.19 vtkBoxRepresentation

42.19.1 Usage

This class is a concrete representation for the vtkBoxWidget2. It represents a box with seven handles: one on each of the six faces, plus a center handle. Through interaction with the widget, the box representation can be arbitrarily positioned in the 3D space.

To use this representation, you normally use the PlaceWidget() method to position the widget at a specified region in space.

To create an instance of class vtkBoxRepresentation, simply invoke its constructor as follows

```
obj = vtkBoxRepresentation
```

42.19.2 Methods

The class vtkBoxRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoxRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkBoxRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkBoxRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `obj.GetPlanes (vtkPlanes planes)` - Get the planes describing the implicit function defined by the box widget. The user must provide the instance of the class vtkPlanes. Note that vtkPlanes is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data. (The direction of the normals of the planes can be reversed enabling the InsideOut flag.)
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. This data memeber is used in conjunction with the GetPlanes() method. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. This data memeber is used in conjunction with the GetPlanes() method. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. This data memeber is used in conjunction with the GetPlanes() method. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. This data memeber is used in conjunction with the GetPlanes() method. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `obj.GetTransform (vtkTransform t)` - Retrieve a linear transform characterizing the transformation of the box. Note that the transformation is relative to where PlaceWidget() was initially called. This method modifies the transform provided. The transform can be used to control the position of vtkProp3D's, as well as other transformation operations (e.g., vtkTranformPolyData).
- `obj.SetTransform (vtkTransform t)` - Set the position, scale and orientation of the box widget using the transform specified. Note that the transformation is relative to where PlaceWidget() was initially called (i.e., the original bounding box).
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that define the box widget. The polydata consists of 6 quadrilateral faces and 15 points. The first eight points define the eight corner vertices; the next six define the -x,+x, -y,+y, -z,+z face points; and the final point (the 15th out of 15 points) defines the center of the box. These point values are guaranteed to be up-to-date when either the widget's corresponding InteractionEvent or EndInteractionEvent events are invoked. The user provides the vtkPolyData and the points and cells are added to it.
- `vtkProperty = obj.GetHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles, when selected or normal, can be specified.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles, when selected or normal, can be specified.

- `vtkProperty = obj.GetFaceProperty ()` - Get the face properties (the faces of the box). The properties of the face when selected and normal can be set.
- `vtkProperty = obj.GetSelectedFaceProperty ()` - Get the face properties (the faces of the box). The properties of the face when selected and normal can be set.
- `vtkProperty = obj.GetOutlineProperty ()` - Get the outline properties (the outline of the box). The properties of the outline when selected and normal can be set.
- `vtkProperty = obj.GetSelectedOutlineProperty ()` - Get the outline properties (the outline of the box). The properties of the outline when selected and normal can be set.
- `obj.SetOutlineFaceWires (int )` - Control the representation of the outline. This flag enables face wires. By default face wires are off.
- `int = obj.GetOutlineFaceWires ()` - Control the representation of the outline. This flag enables face wires. By default face wires are off.
- `obj.OutlineFaceWiresOn ()` - Control the representation of the outline. This flag enables face wires. By default face wires are off.
- `obj.OutlineFaceWiresOff ()` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `obj.SetOutlineCursorWires (int )` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `int = obj.GetOutlineCursorWires ()` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `obj.OutlineCursorWiresOn ()` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `obj.OutlineCursorWiresOff ()` - Switches handles (the spheres) on or off by manipulating the underlying actor visibility.
- `obj.HandlesOn ()` - Switches handles (the spheres) on or off by manipulating the underlying actor visibility.
- `obj.HandlesOff ()` - Switches handles (the spheres) on or off by manipulating the underlying actor visibility.
- `obj.PlaceWidget (double bounds[6])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `double = obj.GetBounds ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods supporting, and required by, the rendering process.

- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Methods supporting, and required by, the rendering process.

- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Methods supporting, and required by, the rendering process.

- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods supporting, and required by, the rendering process.

- `obj.SetInteractionState (int state)` - The interaction state may be set from a widget (e.g., vtkBoxWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.

42.20 vtkBoxWidget

42.20.1 Usage

This 3D widget defines a region of interest that is represented by an arbitrarily oriented hexahedron with interior face angles of 90 degrees (orthogonal faces). The object creates 7 handles that can be moused on and manipulated. The first six correspond to the six faces, the seventh is in the center of the hexahedron. In addition, a bounding box outline is shown, the "faces" of which can be selected for object rotation or scaling. A nice feature of the object is that the vtkBoxWidget, like any 3D widget, will work with the current interactor style. That is, if vtkBoxWidget does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkBoxWidget will terminate the processing of the event that it handles.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. The interactor will act normally until the "i" key (for "interactor") is pressed, at which point the vtkBoxWidget will appear. (See superclass documentation for information about changing this behavior.) By grabbing the six face handles (use the left mouse button), faces can be moved. By grabbing the center handle (with the left mouse button), the entire hexahedron can be translated. (Translation can also be employed by using the "shift-left-mouse-button" combination inside of the widget.) Scaling is achieved by using the right mouse button "up" the render window (makes the widget bigger) or "down" the render window (makes the widget smaller). To rotate vtkBoxWidget, pick a face (but not a face handle) and move the left mouse. (Note: the mouse button must be held down during manipulation.) Events that occur outside of the widget (i.e., no part of the widget is picked) are propagated to any other registered obsevers (such as the interaction style). Turn off the widget by pressing the "i" key again. (See the superclass documentation on key press activiation.)

The vtkBoxWidget is very flexible. It can be used to select, cut, clip, or perform any other operation that depends on an implicit function (use the GetPlanes() method); or it can be used to transform objects using a linear transformation (use the GetTransform() method). Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (either left or right button).

Some additional features of this class include the ability to control the rendered properties of the widget. You can set the properties of the selected and unselected representations of the parts of the widget. For example, you can set the property for the handles, faces, and outline in their normal and selected states.

To create an instance of class vtkBoxWidget, simply invoke its constructor as follows

```
obj = vtkBoxWidget
```

42.20.2 Methods

The class vtkBoxWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoxWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBoxWidget = obj.NewInstance ()`
- `vtkBoxWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Get the planes describing the implicit function defined by the box widget. The user must provide the instance of the class vtkPlanes. Note that vtkPlanes is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data. (The direction of the normals of the planes can be reversed enabling the InsideOut flag.)
- `obj.GetPlanes (vtkPlanes planes)` - Get the planes describing the implicit function defined by the box widget. The user must provide the instance of the class vtkPlanes. Note that vtkPlanes is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data. (The direction of the normals of the planes can be reversed enabling the InsideOut flag.)
- `obj.SetInsideOut (int )` - Set/Get the InsideOut flag. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `int = obj.GetInsideOut ()` - Set/Get the InsideOut flag. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `obj.InsideOutOn ()` - Set/Get the InsideOut flag. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `obj.InsideOutOff ()` - Set/Get the InsideOut flag. When off, the normals point out of the box. When on, the normals point into the hexahedron. InsideOut is off by default.
- `obj.GetTransform (vtkTransform t)` - Retrieve a linear transform characterizing the transformation of the box. Note that the transformation is relative to where PlaceWidget was initially called. This method modifies the transform provided. The transform can be used to control the position of vtkProp3D's, as well as other transformation operations (e.g., vtkTranformPolyData).
- `obj.SetTransform (vtkTransform t)` - Set the position, scale and orientation of the box widget using the transform specified. Note that the transformation is relative to where PlaceWidget was initially called (i.e., the original bounding box).
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that define the box widget. The polydata consists of 6 quadrilateral faces and 15 points. The first eight points define the eight corner vertices; the next six define the -x,+x, -y,+y, -z,+z face points; and the final point (the 15th out of 15 points) defines the center of the hexahedron. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteractionEvent events are invoked. The user provides the vtkPolyData and the points and cells are added to it.

- `vtkProperty = obj.GetHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be set.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be set.
- `obj.HandlesOn ()` - Switches handles (the spheres) on or off by manipulating the actor visibility.
- `obj.HandlesOff ()` - Switches handles (the spheres) on or off by manipulating the actor visibility.
- `vtkProperty = obj.GetFaceProperty ()` - Get the face properties (the faces of the box). The properties of the face when selected and normal can be set.
- `vtkProperty = obj.GetSelectedFaceProperty ()` - Get the face properties (the faces of the box). The properties of the face when selected and normal can be set.
- `vtkProperty = obj.GetOutlineProperty ()` - Get the outline properties (the outline of the box). The properties of the outline when selected and normal can be set.
- `vtkProperty = obj.GetSelectedOutlineProperty ()` - Get the outline properties (the outline of the box). The properties of the outline when selected and normal can be set.
- `obj.SetOutlineFaceWires (int )` - Control the representation of the outline. This flag enables face wires. By default face wires are off.
- `int = obj.GetOutlineFaceWires ()` - Control the representation of the outline. This flag enables face wires. By default face wires are off.
- `obj.OutlineFaceWiresOn ()` - Control the representation of the outline. This flag enables face wires. By default face wires are off.
- `obj.OutlineFaceWiresOff ()` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `obj.SetOutlineCursorWires (int )` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `int = obj.GetOutlineCursorWires ()` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `obj.OutlineCursorWiresOn ()` - Control the representation of the outline. This flag enables the cursor lines running between the handles. By default cursor wires are on.
- `obj.OutlineCursorWiresOff ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.SetTranslationEnabled (int )` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `int = obj.GetTranslationEnabled ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.TranslationEnabledOn ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.TranslationEnabledOff ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.SetScalingEnabled (int )` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.

- `int = obj.GetScalingEnabled ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.ScalingEnabledOn ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.ScalingEnabledOff ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.SetRotationEnabled (int )` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `int = obj.GetRotationEnabled ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.RotationEnabledOn ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.
- `obj.RotationEnabledOff ()` - Control the behavior of the widget. Translation, rotation, and scaling can all be enabled and disabled.

42.21 vtkBoxWidget2

42.21.1 Usage

This 3D widget interacts with a vtkBoxRepresentation class (i.e., it handles the events that drive its corresponding representation). The representation is assumed to represent a region of interest that is represented by an arbitrarily oriented hexahedron (or box) with interior face angles of 90 degrees (i.e., orthogonal faces). The representation manifests seven handles that can be moused on and manipulated, plus the six faces can also be interacted with. The first six handles are placed on the six faces, the seventh is in the center of the box. In addition, a bounding box outline is shown, the "faces" of which can be selected for object rotation or scaling. A nice feature of vtkBoxWidget2, like any 3D widget, will work with the current interactor style. That is, if vtkBoxWidget2 does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkBoxWidget will terminate the processing of the event that it handles.

To use this widget, you generally pair it with a vtkBoxRepresentation (or a subclass). Variuos options are available in the representation for controlling how the widget appears, and how the widget functions.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
If one of the seven handles are selected:
  LeftButtonPressEvent - select the appropriate handle
  LeftButtonReleaseEvent - release the currently selected handle
  MouseMoveEvent - move the handle
If one of the faces is selected:
  LeftButtonPressEvent - select a box face
  LeftButtonReleaseEvent - release the box face
  MouseMoveEvent - rotate the box
In all the cases, independent of what is picked, the widget responds to the
following VTK events:
  MiddleButtonPressEvent - translate the widget
  MiddleButtonReleaseEvent - release the widget
  RightButtonPressEvent - scale the widget's representation
  RightButtonReleaseEvent - stop scaling the widget
  MouseMoveEvent - scale (if right button) or move (if middle button) the widget
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkBoxWidget2's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Scale -- some part of the widget has been selected
vtkWidgetEvent::EndScale -- the selection process has completed
vtkWidgetEvent::Translate -- some part of the widget has been selected
vtkWidgetEvent::EndTranslate -- the selection process has completed
vtkWidgetEvent::Move -- a request for motion has been invoked
```

In turn, when these widget events are processed, the vtkBoxWidget2 invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkBoxWidget2, simply invoke its constructor as follows

```
obj = vtkBoxWidget2
```

42.21.2 Methods

The class vtkBoxWidget2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoxWidget2 class.

- `string = obj.GetClassName ()` - Standard class methods for type information and printing.
- `int = obj.IsA (string name)` - Standard class methods for type information and printing.
- `vtkBoxWidget2 = obj.NewInstance ()` - Standard class methods for type information and printing.
- `vtkBoxWidget2 = obj.SafeDownCast (vtkObject o)` - Standard class methods for type information and printing.
- `obj.SetRepresentation (vtkBoxRepresentation r)` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.SetTranslationEnabled (int )` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `int = obj.GetTranslationEnabled ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.TranslationEnabledOn ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.TranslationEnabledOff ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.SetScalingEnabled (int )` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `int = obj.GetScalingEnabled ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.

- `obj.ScalingEnabledOn ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.ScalingEnabledOff ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.SetRotationEnabled (int )` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `int = obj.GetRotationEnabled ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.RotationEnabledOn ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.RotationEnabledOff ()` - Control the behavior of the widget (i.e., how it processes events). Translation, rotation, and scaling can all be enabled and disabled.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set. By default, this is an instance of the vtkBoxRepresentation class.

42.22 vtkCameraRepresentation

42.22.1 Usage

This class provides support for interactively saving a series of camera views into an interpolated path (using vtkCameraInterpolator). The class typically works in conjunction with vtkCameraWidget. To use this class simply specify the camera to interpolate and use the methods AddCameraToPath(), AnimatePath(), and InitializePath() to add a new camera view, animate the current views, and initialize the interpolation.

To create an instance of class vtkCameraRepresentation, simply invoke its constructor as follows

```
obj = vtkCameraRepresentation
```

42.22.2 Methods

The class vtkCameraRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCameraRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK class methods.
- `int = obj.IsA (string name)` - Standard VTK class methods.
- `vtkCameraRepresentation = obj.NewInstance ()` - Standard VTK class methods.
- `vtkCameraRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK class methods.
- `obj.SetCamera (vtkCamera camera)` - Specify the camera to interpolate. This must be specified by the user.
- `vtkCamera = obj.GetCamera ()` - Specify the camera to interpolate. This must be specified by the user.
- `obj.SetInterpolator (vtkCameraInterpolator camInt)` - Get the vtkCameraInterpolator used to interpolate and save the sequence of camera views. If not defined, one is created automatically. Note that you can access this object to set the interpolation type (linear, spline) and other instance variables.

- `vtkCameraInterpolator = obj.GetInterpolator ()` - Get the vtkCameraInterpolator used to interpolate and save the sequence of camera views. If not defined, one is created automatically. Note that you can access this object to set the interpolation type (linear, spline) and other instance variables.

- `obj.SetNumberOfFrames (int )` - Set the number of frames to generate when playback is initiated.

- `int = obj.GetNumberOfFramesMinValue ()` - Set the number of frames to generate when playback is initiated.

- `int = obj.GetNumberOfFramesMaxValue ()` - Set the number of frames to generate when playback is initiated.

- `int = obj.GetNumberOfFrames ()` - Set the number of frames to generate when playback is initiated.

- `vtkProperty2D = obj.GetProperty ()` - By obtaining this property you can specify the properties of the representation.

- `obj.AddCameraToPath ()` - These methods are used to create interpolated camera paths. The AddCameraToPath() method adds the view defined by the current camera (via SetCamera()) to the interpolated camera path. AnimatePath() interpolates NumberOfFrames along the current path. InitializePath() resets the interpolated path to its initial, empty configuration.

- `obj.AnimatePath (vtkRenderWindowInteractor rwi)` - These methods are used to create interpolated camera paths. The AddCameraToPath() method adds the view defined by the current camera (via SetCamera()) to the interpolated camera path. AnimatePath() interpolates NumberOfFrames along the current path. InitializePath() resets the interpolated path to its initial, empty configuration.

- `obj.InitializePath ()` - These methods are used to create interpolated camera paths. The AddCameraToPath() method adds the view defined by the current camera (via SetCamera()) to the interpolated camera path. AnimatePath() interpolates NumberOfFrames along the current path. InitializePath() resets the interpolated path to its initial, empty configuration.

- `obj.BuildRepresentation ()` - Satisfy the superclasses' API.

- `obj.GetSize (double size[2])` - These methods are necessary to make this representation behave as a vtkProp.

- `obj.GetActors2D (vtkPropCollection )` - These methods are necessary to make this representation behave as a vtkProp.

- `obj.ReleaseGraphicsResources (vtkWindow )` - These methods are necessary to make this representation behave as a vtkProp.

- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.

- `int = obj.RenderOpaqueGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.

- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.

- `int = obj.HasTranslucentPolygonalGeometry ()` - These methods are necessary to make this representation behave as a vtkProp.

42.23 vtkCameraWidget

42.23.1 Usage

This class provides support for interactively saving a series of camera views into an interpolated path (using vtkCameraInterpolator). To use the class start by specifying a camera to interpolate, and then simply start recording by hitting the "record" button, manipulate the camera (by using an interactor, direct scripting, or any other means), and then save the camera view. Repeat this process to record a series of views. The user can then play back interpolated camera views using the vtkCameraInterpolator.

To create an instance of class vtkCameraWidget, simply invoke its constructor as follows

```
obj = vtkCameraWidget
```

42.23.2 Methods

The class vtkCameraWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCameraWidget class.

- `string = obj.GetClassName ()` - Standar VTK class methods.
- `int = obj.IsA (string name)` - Standar VTK class methods.
- `vtkCameraWidget = obj.NewInstance ()` - Standar VTK class methods.
- `vtkCameraWidget = obj.SafeDownCast (vtkObject o)` - Standar VTK class methods.
- `obj.SetRepresentation (vtkCameraRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.24 vtkCaptionRepresentation

42.24.1 Usage

This class represents vtkCaptionWidget. A caption is defined by some text with a leader (e.g., arrow) that points from the text to a point in the scene. The caption is defined by an instance of vtkCaptionActor2D. It uses the event bindings of its superclass (vtkBorderWidget) to control the placement of the text, and adds the ability to move the attachment point around. In addition, when the caption text is selected, the widget emits a ActivateEvent that observers can watch for. This is useful for opening GUI dialogoues to adjust font characteristics, etc. (Please see the superclass for a description of event bindings.)

Note that this widget extends the behavior of its superclass vtkBorderRepresentation.

To create an instance of class vtkCaptionRepresentation, simply invoke its constructor as follows

```
obj = vtkCaptionRepresentation
```

42.24.2 Methods

The class vtkCaptionRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCaptionRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK class methods.
- `int = obj.IsA (string name)` - Standard VTK class methods.

- `vtkCaptionRepresentation = obj.NewInstance ()` - Standard VTK class methods.
- `vtkCaptionRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK class methods.
- `obj.SetAnchorPosition (double pos[3])` - Specify the position of the anchor (i.e., the point that the caption is anchored to). Note that the position should be specified in world coordinates.
- `obj.GetAnchorPosition (double pos[3])` - Specify the position of the anchor (i.e., the point that the caption is anchored to). Note that the position should be specified in world coordinates.
- `obj.SetCaptionActor2D (vtkCaptionActor2D captionActor)` - Specify the vtkCaptionActor2D to manage. If not specified, then one is automatically created.
- `vtkCaptionActor2D = obj.GetCaptionActor2D ()` - Specify the vtkCaptionActor2D to manage. If not specified, then one is automatically created.
- `obj.SetAnchorRepresentation (vtkPointHandleRepresentation3D )` - Set and get the instances of vtkPointHandleRepresention3D used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `vtkPointHandleRepresentation3D = obj.GetAnchorRepresentation ()` - Set and get the instances of vtkPointHandleRepresention3D used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `obj.BuildRepresentation ()` - Satisfy the superclasses API.
- `obj.GetSize (double size[2])` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.GetActors2D (vtkPropCollection )` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.SetFontFactor (double )` - Set/Get the factor that controls the overall size of the fonts of the caption when the text actor's ScaledText is OFF
- `double = obj.GetFontFactorMinValue ()` - Set/Get the factor that controls the overall size of the fonts of the caption when the text actor's ScaledText is OFF
- `double = obj.GetFontFactorMaxValue ()` - Set/Get the factor that controls the overall size of the fonts of the caption when the text actor's ScaledText is OFF
- `double = obj.GetFontFactor ()` - Set/Get the factor that controls the overall size of the fonts of the caption when the text actor's ScaledText is OFF

42.25 vtkCaptionWidget

42.25.1 Usage

This class provides support for interactively placing a caption on the 2D overlay plane. A caption is defined by some text with a leader (e.g., arrow) that points from the text to a point in the scene. The caption is represented by a vtkCaptionRepresentation. It uses the event bindings of its superclass (vtkBorderWidget) to control the placement of the text, and adds the ability to move the attachment point around. In addition, when the caption text is selected, the widget emits a ActivateEvent that observers can watch for. This is useful for opening GUI dialogoues to adjust font characteristics, etc. (Please see the superclass for a description of event bindings.)

Note that this widget extends the behavior of its superclass vtkBorderWidget. The end point of the leader can be selected and moved around with an internal vtkHandleWidget.

To create an instance of class vtkCaptionWidget, simply invoke its constructor as follows

```
obj = vtkCaptionWidget
```

42.25.2 Methods

The class vtkCaptionWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCaptionWidget class.

- `string = obj.GetClassName ()` - Standard VTK class methods.
- `int = obj.IsA (string name)` - Standard VTK class methods.
- `vtkCaptionWidget = obj.NewInstance ()` - Standard VTK class methods.
- `vtkCaptionWidget = obj.SafeDownCast (vtkObject o)` - Standard VTK class methods.
- `obj.SetEnabled (int enabling)` - Override superclasses' SetEnabled() method because the caption leader has its own dedicated widget.
- `obj.SetRepresentation (vtkCaptionRepresentation r)` - Specify a vtkCaptionActor2D to manage. This is convenient, alternative method to SetRepresentation(). It internally create a vtkCaptionRepresentation and then invokes vtkCaptionRepresentation::SetCaptionActor2D().
- `obj.SetCaptionActor2D (vtkCaptionActor2D capActor)` - Specify a vtkCaptionActor2D to manage. This is convenient, alternative method to SetRepresentation(). It internally create a vtkCaptionRepresentation and then invokes vtkCaptionRepresentation::SetCaptionActor2D().
- `vtkCaptionActor2D = obj.GetCaptionActor2D ()` - Specify a vtkCaptionActor2D to manage. This is convenient, alternative method to SetRepresentation(). It internally create a vtkCaptionRepresentation and then invokes vtkCaptionRepresentation::SetCaptionActor2D().
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.26 vtkCenteredSliderRepresentation

42.26.1 Usage

This class is used to represent and render a vtkCenteredSliderWidget. To use this class, you must at a minimum specify the end points of the slider. Optional instance variable can be used to modify the appearance of the widget.

To create an instance of class vtkCenteredSliderRepresentation, simply invoke its constructor as follows

```
obj = vtkCenteredSliderRepresentation
```

42.26.2 Methods

The class vtkCenteredSliderRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCenteredSliderRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkCenteredSliderRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkCenteredSliderRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `vtkCoordinate = obj.GetPoint1Coordinate ()` - Position the first end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point1Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `vtkCoordinate = obj.GetPoint2Coordinate ()` - Position the second end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point2Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `obj.SetTitleText (string )` - Specify the label text for this widget. If the value is not set, or set to the empty string "", then the label text is not displayed.
- `string = obj.GetTitleText ()` - Specify the label text for this widget. If the value is not set, or set to the empty string "", then the label text is not displayed.
- `vtkProperty2D = obj.GetTubeProperty ()` - Get the properties for the tube and slider
- `vtkProperty2D = obj.GetSliderProperty ()` - Get the properties for the tube and slider
- `vtkProperty2D = obj.GetSelectedProperty ()` - Get the selection property. This property is used to modify the appearance of selected objects (e.g., the slider).
- `vtkTextProperty = obj.GetLabelProperty ()` - Set/Get the properties for the label and title text.
- `obj.PlaceWidget (double bounds[6])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.BuildRepresentation ()` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.

- `obj.WidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.Highlight (int )` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.GetActors (vtkPropCollection )`
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `int = obj.RenderOverlay (vtkViewport )`
- `int = obj.RenderOpaqueGeometry (vtkViewport )`

42.27 vtkCenteredSliderWidget

42.27.1 Usage

The vtkCenteredSliderWidget is used to adjust a scalar value in an application. This class measures deviations form the center point on the slider. Moving the slider modifies the value of the widget, which can be used to set parameters on other objects. Note that the actual appearance of the widget depends on the specific representation for the widget.

To use this widget, set the widget representation. The representation is assumed to consist of a tube, two end caps, and a slider (the details may vary depending on the particulars of the representation). Then in the representation you will typically set minimum and maximum value, as well as the current value. The position of the slider must also be set, as well as various properties.

Note that the value should be obtain from the widget, not from the representation. Also note that Minimum and Maximum values are in terms of value per second. The value you get from this widget's GetValue method is multiplied by time.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
If the slider bead is selected:
  LeftButtonPressEvent - select slider (if on slider)
  LeftButtonReleaseEvent - release slider (if selected)
  MouseMoveEvent - move slider
If the end caps or slider tube are selected:
  LeftButtonPressEvent - move (or animate) to cap or point on tube;
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkCenteredSliderWidget's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for slider motion has been invoked
```

In turn, when these widget events are processed, the vtkCenteredSliderWidget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkCenteredSliderWidget, simply invoke its constructor as follows

```
obj = vtkCenteredSliderWidget
```

42.27.2 Methods

The class vtkCenteredSliderWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCenteredSliderWidget class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkCenteredSliderWidget = obj.NewInstance ()` - Standard macros.
- `vtkCenteredSliderWidget = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetRepresentation (vtkSliderRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `double = obj.GetValue ()` - Get the value fo this widget.

42.28 vtkCheckerboardRepresentation

42.28.1 Usage

The vtkCheckerboardRepresentation is used to implement the representation of the vtkCheckerboardWidget. The user can adjust the number of divisions in each of the i-j directions in a 2D image. A frame appears around the vtkImageActor with sliders along each side of the frame. The user can interactively adjust the sliders to the desired number of checkerboard subdivisions. The representation uses four instances of vtkSliderRepresentation3D to implement itself.

To create an instance of class vtkCheckerboardRepresentation, simply invoke its constructor as follows

```
obj = vtkCheckerboardRepresentation
```

42.28.2 Methods

The class vtkCheckerboardRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCheckerboardRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkCheckerboardRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkCheckerboardRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `obj.SetCheckerboard (vtkImageCheckerboard chkrbrd)` - Specify an instance of vtkImageCheckerboard to manipulate.
- `vtkImageCheckerboard = obj.GetCheckerboard ()` - Specify an instance of vtkImageCheckerboard to manipulate.
- `obj.SetImageActor (vtkImageActor imageActor)` - Specify an instance of vtkImageActor to decorate.
- `vtkImageActor = obj.GetImageActor ()` - Specify an instance of vtkImageActor to decorate.

- `obj.SetCornerOffset (double )` - Specify the offset of the ends of the sliders (on the boundary edges of the image) from the corner of the image. The offset is expressed as a normalized fraction of the border edges.
- `double = obj.GetCornerOffsetMinValue ()` - Specify the offset of the ends of the sliders (on the boundary edges of the image) from the corner of the image. The offset is expressed as a normalized fraction of the border edges.
- `double = obj.GetCornerOffsetMaxValue ()` - Specify the offset of the ends of the sliders (on the boundary edges of the image) from the corner of the image. The offset is expressed as a normalized fraction of the border edges.
- `double = obj.GetCornerOffset ()` - Specify the offset of the ends of the sliders (on the boundary edges of the image) from the corner of the image. The offset is expressed as a normalized fraction of the border edges.
- `obj.SliderValueChanged (int sliderNum)` - This method is invoked by the vtkCheckerboardWidget() when a value of some slider has changed.
- `obj.SetTopRepresentation (vtkSliderRepresentation3D )` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `obj.SetRightRepresentation (vtkSliderRepresentation3D )` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `obj.SetBottomRepresentation (vtkSliderRepresentation3D )` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `obj.SetLeftRepresentation (vtkSliderRepresentation3D )` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `vtkSliderRepresentation3D = obj.GetTopRepresentation ()` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `vtkSliderRepresentation3D = obj.GetRightRepresentation ()` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `vtkSliderRepresentation3D = obj.GetBottomRepresentation ()` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `vtkSliderRepresentation3D = obj.GetLeftRepresentation ()` - Set and get the instances of vtkSliderRepresention used to implement this representation. Normally default representations are created, but you can specify the ones you want to use.
- `obj.BuildRepresentation ()` - Methods required by superclass.
- `obj.GetActors (vtkPropCollection )` - Methods required by superclass.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by superclass.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by superclass.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods required by superclass.

- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods required by superclass.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods required by superclass.

42.29 vtkCheckerboardWidget

42.29.1 Usage

The vtkCheckerboardWidget is used to interactively control an instance of vtkImageCheckerboard (and an associated vtkImageActor used to display the checkerboard). The user can adjust the number of divisions in each of the i-j directions in a 2D image. A frame appears around the vtkImageActor with sliders along each side of the frame. The user can interactively adjust the sliders to the desired number of checkerboard subdivisions.

To use this widget, specify an instance of vtkImageCheckerboard and an instance of vtkImageActor. By default, the widget responds to the following events:

```
If the slider bead is selected:
  LeftButtonPressEvent - select slider (if on slider)
  LeftButtonReleaseEvent - release slider
  MouseMoveEvent - move slider
If the end caps or slider tube of a slider are selected:
  LeftButtonPressEvent - jump (or animate) to cap or point on tube;
```

It is possible to change these event bindings. Please refer to the documentation for vtkSliderWidget for more information. Advanced users may directly access and manipulate the sliders by obtaining the instances of vtkSliderWidget composing the vtkCheckerboard widget.

To create an instance of class vtkCheckerboardWidget, simply invoke its constructor as follows

```
obj = vtkCheckerboardWidget
```

42.29.2 Methods

The class vtkCheckerboardWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCheckerboardWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkCheckerboardWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkCheckerboardWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it is a composite widget and does more than its superclasses' vtkAbstractWidget::SetEnabled() method.
- `obj.SetRepresentation (vtkCheckerboardRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.30 vtkClosedSurfacePointPlacer

42.30.1 Usage

This placer takes a set of boudning planes and constraints the validity within the supplied convex planes. It is used by the ParallelopPipedRepresentation to place constraints on the motion the handles within the parallelopiped.

To create an instance of class vtkClosedSurfacePointPlacer, simply invoke its constructor as follows

```
obj = vtkClosedSurfacePointPlacer
```

42.30.2 Methods

The class vtkClosedSurfacePointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkClosedSurfacePointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkClosedSurfacePointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkClosedSurfacePointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.AddBoundingPlane (vtkPlane plane)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `obj.RemoveBoundingPlane (vtkPlane plane)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `obj.RemoveAllBoundingPlanes ()` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `obj.SetBoundingPlanes (vtkPlaneCollection )` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `vtkPlaneCollection = obj.GetBoundingPlanes ()` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.SetBoundingPlanes (vtkPlanes planes)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given a renderer and a display position, compute the world position and world orientation for this point. A plane is defined by a combination of the ProjectionNormal, ProjectionOrigin, and Oblique-Plane ivars. The display position is projected onto this plane to determine a world position, and the orientation is set to the normal of the plane. If the point cannot project onto the plane or if it falls outside the bounds imposed by the BoundingPlanes, then 0 is returned, otherwise 1 is returned to indicate a valid return position and orientation.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[2], doubl` - Given a renderer, a display position and a reference position, "worldPos" is calculated as : Consider the line "L" that passes through the supplied "displayPos" and is parallel to the direction of projection of the camera. Clip this line segment with the parallelopiped, let's call it "L_segment". The computed world position, "worldPos" will be the point on "L_segment" that is closest to refWorldPos. NOTE: Note that a set of bounding planes must be supplied. The Oblique plane, if supplied is ignored.
- `int = obj.ValidateWorldPosition (double worldPos[3])` - Give a world position check if it is valid - does it lie on the plane and within the bounds? Returns 1 if it is valid, 0 otherwise.
- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])`
- `obj.SetMinimumDistance (double )`
- `double = obj.GetMinimumDistanceMinValue ()`
- `double = obj.GetMinimumDistanceMaxValue ()`
- `double = obj.GetMinimumDistance ()`

42.31 vtkConstrainedPointHandleRepresentation

42.31.1 Usage

This class is used to represent a vtkHandleWidget. It represents a position in 3D world coordinates that is constrained to a specified plane. The default look is to draw a white point when this widget is not selected or active, a thin green circle when it is highlighted, and a thicker cyan circle when it is active (being positioned). Defaults can be adjusted - but take care to define cursor geometry that makes sense for this widget. The geometry will be aligned on the constraining plane, with the plane normal aligned with the X axis of the geometry (similar behavior to vtkGlyph3D).

TODO: still need to work on 1) translation when mouse is outside bounding planes 2) size of the widget

To create an instance of class vtkConstrainedPointHandleRepresentation, simply invoke its constructor as follows

```
obj = vtkConstrainedPointHandleRepresentation
```

42.31.2 Methods

The class vtkConstrainedPointHandleRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConstrainedPointHandleRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.

- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkConstrainedPointHandleRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkConstrainedPointHandleRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetCursorShape (vtkPolyData cursorShape)` - Specify the cursor shape. Keep in mind that the shape will be aligned with the constraining plane by orienting it such that the x axis of the geometry lies along the normal of the plane.
- `vtkPolyData = obj.GetCursorShape ()` - Specify the cursor shape. Keep in mind that the shape will be aligned with the constraining plane by orienting it such that the x axis of the geometry lies along the normal of the plane.
- `obj.SetActiveCursorShape (vtkPolyData activeShape)` - Specify the shape of the cursor (handle) when it is active. This is the geometry that will be used when the mouse is close to the handle or if the user is manipulating the handle.
- `vtkPolyData = obj.GetActiveCursorShape ()` - Specify the shape of the cursor (handle) when it is active. This is the geometry that will be used when the mouse is close to the handle or if the user is manipulating the handle.
- `obj.SetProjectionNormal (int )` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `int = obj.GetProjectionNormalMinValue ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `int = obj.GetProjectionNormalMaxValue ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `int = obj.GetProjectionNormal ()` - Set the projection normal to lie along the x, y, or z axis, or to be oblique. If it is oblique, then the plane is defined in the ObliquePlane ivar.
- `obj.SetProjectionNormalToXAxis ()`
- `obj.SetProjectionNormalToYAxis ()`
- `obj.SetProjectionNormalToZAxis ()`
- `obj.SetProjectionNormalToOblique ()` - If the ProjectionNormal is set to Oblique, then this is the oblique plane used to constrain the handle position
- `obj.SetObliquePlane (vtkPlane )` - If the ProjectionNormal is set to Oblique, then this is the oblique plane used to constrain the handle position
- `vtkPlane = obj.GetObliquePlane ()` - If the ProjectionNormal is set to Oblique, then this is the oblique plane used to constrain the handle position
- `obj.SetProjectionPosition (double position)` - The position of the bounding plane from the origin along the normal. The origin and normal are defined in the oblique plane when the ProjectionNormal is Oblique. For the X, Y, and Z axes projection normals, the normal is the axis direction, and the origin is (0,0,0).
- `double = obj.GetProjectionPosition ()` - The position of the bounding plane from the origin along the normal. The origin and normal are defined in the oblique plane when the ProjectionNormal is Oblique. For the X, Y, and Z axes projection normals, the normal is the axis direction, and the origin is (0,0,0).

- `obj.AddBoundingPlane (vtkPlane plane)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.RemoveBoundingPlane (vtkPlane plane)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.RemoveAllBoundingPlanes ()` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.SetBoundingPlanes (vtkPlaneCollection )` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `vtkPlaneCollection = obj.GetBoundingPlanes ()` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `obj.SetBoundingPlanes (vtkPlanes planes)` - A collection of plane equations used to bound the position of the point. This is in addition to confining the point to a plane - these contraints are meant to, for example, keep a point within the extent of an image. Using a set of plane equations allows for more complex bounds (such as bounding a point to an oblique reliced image that has hexagonal shape) than a simple extent.

- `int = obj.CheckConstraint (vtkRenderer renderer, double pos[2])` - Overridden from the base class. It converts the display co-ordinates to world co-ordinates. It returns 1 if the point lies within the constrained region, otherwise return 0

- `obj.SetPosition (double x, double y, double z)` - Set/Get the position of the point in display coordinates. These are convenience methods that extend the superclasses' GetHandlePosition() method. Note that only the x-y coordinate values are used

- `obj.SetPosition (double xyz[3])` - Set/Get the position of the point in display coordinates. These are convenience methods that extend the superclasses' GetHandlePosition() method. Note that only the x-y coordinate values are used

- `obj.GetPosition (double xyz[3])` - Set/Get the position of the point in display coordinates. These are convenience methods that extend the superclasses' GetHandlePosition() method. Note that only the x-y coordinate values are used

- `vtkProperty = obj.GetProperty ()` - This is the property used when the handle is not active (the mouse is not near the handle)

- `vtkProperty = obj.GetSelectedProperty ()` - This is the property used when the mouse is near the handle (but the user is not yet interacting with it)

- `vtkProperty = obj.GetActiveProperty ()` - This is the property used when the user is interacting with the handle.
- `obj.SetRenderer (vtkRenderer ren)` - Subclasses of vtkConstrainedPointHandleRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.BuildRepresentation ()` - Subclasses of vtkConstrainedPointHandleRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses of vtkConstrainedPointHandleRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses of vtkConstrainedPointHandleRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Subclasses of vtkConstrainedPointHandleRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.SetDisplayPosition (double pos[3])` - Method overridden from Superclass. computes the world co-ordinates using GetIntersectionPosition()
- `obj.GetActors (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.

42.32 vtkContinuousValueWidget

42.32.1 Usage

The vtkContinuousValueWidget is used to adjust a scalar value in an application. Note that the actual appearance of the widget depends on the specific representation for the widget.

To use this widget, set the widget representation. (the details may vary depending on the particulars of the representation).

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
If the slider bead is selected:
  LeftButtonPressEvent - select slider
  LeftButtonReleaseEvent - release slider
  MouseMoveEvent - move slider
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkContinuousValueWidget's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for slider motion has been invoked
```

In turn, when these widget events are processed, the vtkContinuousValueWidget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkContinuousValueWidget, simply invoke its constructor as follows

```
obj = vtkContinuousValueWidget
```

42.32.2 Methods

The class vtkContinuousValueWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContinuousValueWidget class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkContinuousValueWidget = obj.NewInstance ()` - Standard macros.
- `vtkContinuousValueWidget = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetRepresentation (vtkContinuousValueWidgetRepresentation r)` - Get the value for this widget.
- `double = obj.GetValue ()` - Get the value for this widget.
- `obj.SetValue (double v)` - Get the value for this widget.

42.33 vtkContinuousValueWidgetRepresentation

42.33.1 Usage

This class is used mainly as a superclass for continuous value widgets

To create an instance of class vtkContinuousValueWidgetRepresentation, simply invoke its constructor as follows

```
obj = vtkContinuousValueWidgetRepresentation
```

42.33.2 Methods

The class vtkContinuousValueWidgetRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContinuousValueWidgetRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkContinuousValueWidgetRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkContinuousValueWidgetRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `obj.PlaceWidget (double bounds[6])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.BuildRepresentation ()` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.WidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.SetValue (double value)`
- `double = obj.GetValue ()`

42.34 vtkContourLineInterpolator

42.34.1 Usage

vtkContourLineInterpolator is an abstract base class for interpolators that work are used by the contour representation class to interpolate and/or modify nodes in a contour. Subclasses must override the virtual method: ĮnterpolateLine. This is used by the contour representation to give the interpolator a chance to define an interpolation scheme between nodes. See vtkBezierContourLineInterpolator for a concrete implementation. Subclasses may also override, ǪpdateNode. This provides a way for the representation to give the interpolator a chance to modify the nodes, as the user constructs the contours. For instance a sticky contour widget may be implemented that moves nodes to nearby regions of high gradient, to be used in contour guided segmentation.

To create an instance of class vtkContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkContourLineInterpolator
```

42.34.2 Methods

The class vtkContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)` - Subclasses that wish to interpolate a line segment must implement this. For instance vtkBezierContourLineInterpolator adds nodes between idx1 and idx2, that allow the contour to adhere to a bezier curve.
- `int = obj.UpdateNode (vtkRenderer , vtkContourRepresentation , double , int )` - The interpolator is given a chance to update the node. For instance, the vtkImageContourLineInterpolator updates the idx'th node in the contour, so it automatically sticks to edges in the vicinity as the user constructs the contour. Returns 0 if the node (world position) is unchanged.
- `obj.GetSpan (int nodeIndex, vtkIntArray nodeIndices, vtkContourRepresentation rep)` - Span of the interpolator. ie. the number of control points its supposed to interpolate given a node.

  The first argument is the current nodeIndex. ie, you'd be trying to interpolate between nodes "nodeIndex" and "nodeIndex-1", unless you're closing the contour in which case, you're trying to interpolate "nodeIndex" and "Node=0".

  The node span is returned in a vtkIntArray. The default node span is 1 (ie. nodeIndices is a 2 tuple (nodeIndex, nodeIndex-1)). However, it need not always be 1. For instance, cubic spline interpolators, which have a span of 3 control points, it can be larger. See vtkBezierContourLineInterpolator for instance.

42.35 vtkContourRepresentation

42.35.1 Usage

The vtkContourRepresentation is a superclass for various types of representations for the vtkContourWidget.

.SECTION Managing contour points The classes vtkContourRepresentationNode, vtkContourRepresentationInternals, vtkContourRepresentationPoint manage the data structure used to represent nodes and points on a contour. A contour may contain several nodes and several more points. Nodes are usually the result of user clicked points on the contour. Additional points are created between nodes to generate a smooth curve using some Interpolator. See the method ŞetLineInterpolator. ar The data structure stores both the world and display positions for every point. (This may seem like a duplication.) The default behaviour of this class is to use the WorldPosition to do all the math. Typically a point is added at a given display position. Its corresponding world position is computed using the point placer and stored. Any query of the display position of a stored point is done via the Renderer, which computes the display position given a world position.

ar So why maintain the display position ? Consider drawing a contour on a volume widget. You might want the contour to be located at a certain world position in the volume or you might want to be overlayed over the window like an Actor2D. The default behaviour of this class is to provide the former behaviour.

ar To achieve the latter behaviour override the methods that return the display position (to return the set display position instead of computing it from the world positions) and the method ḂuildLines() to interpolate lines using their display positions intead of world positions.

To create an instance of class vtkContourRepresentation, simply invoke its constructor as follows

```
obj = vtkContourRepresentation
```

42.35.2 Methods

The class vtkContourRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContourRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkContourRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkContourRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `int = obj.AddNodeAtWorldPosition (double x, double y, double z)` - Add a node at a specific world position. Returns 0 if the node could not be added, 1 otherwise.
- `int = obj.AddNodeAtWorldPosition (double worldPos[3])` - Add a node at a specific world position. Returns 0 if the node could not be added, 1 otherwise.
- `int = obj.AddNodeAtWorldPosition (double worldPos[3], double worldOrient[9])` - Add a node at a specific world position. Returns 0 if the node could not be added, 1 otherwise.
- `int = obj.AddNodeAtDisplayPosition (double displayPos[2])` - Add a node at a specific display position. This will be converted into a world position according to the current constraints of the point placer. Return 0 if a point could not be added, 1 otherwise.
- `int = obj.AddNodeAtDisplayPosition (int displayPos[2])` - Add a node at a specific display position. This will be converted into a world position according to the current constraints of the point placer. Return 0 if a point could not be added, 1 otherwise.
- `int = obj.AddNodeAtDisplayPosition (int X, int Y)` - Add a node at a specific display position. This will be converted into a world position according to the current constraints of the point placer. Return 0 if a point could not be added, 1 otherwise.
- `int = obj.ActivateNode (double displayPos[2])` - Given a display position, activate a node. The closest node within tolerance will be activated. If a node is activated, 1 will be returned, otherwise 0 will be returned.
- `int = obj.ActivateNode (int displayPos[2])` - Given a display position, activate a node. The closest node within tolerance will be activated. If a node is activated, 1 will be returned, otherwise 0 will be returned.
- `int = obj.ActivateNode (int X, int Y)` - Given a display position, activate a node. The closest node within tolerance will be activated. If a node is activated, 1 will be returned, otherwise 0 will be returned.
- `int = obj.SetActiveNodeToWorldPosition (double pos[3])`
- `int = obj.SetActiveNodeToWorldPosition (double pos[3], double orient[9])`
- `int = obj.SetActiveNodeToDisplayPosition (double pos[2])` - Move the active node based on a specified display position. The display position will be converted into a world position. If the new position is not valid or there is no active node, a 0 will be returned. Otherwise, on success a 1 will be returned.
- `int = obj.SetActiveNodeToDisplayPosition (int pos[2])` - Move the active node based on a specified display position. The display position will be converted into a world position. If the new position is not valid or there is no active node, a 0 will be returned. Otherwise, on success a 1 will be returned.

- `int = obj.SetActiveNodeToDisplayPosition (int X, int Y)` - Move the active node based on a specified display position. The display position will be converted into a world position. If the new position is not valid or there is no active node, a 0 will be returned. Otherwise, on success a 1 will be returned.
- `int = obj.ToggleActiveNodeSelected ()` - Set/Get whether the active or nth node is selected.
- `int = obj.GetActiveNodeSelected ()` - Set/Get whether the active or nth node is selected.
- `int = obj.GetNthNodeSelected (int )` - Set/Get whether the active or nth node is selected.
- `int = obj.SetNthNodeSelected (int )` - Set/Get whether the active or nth node is selected.
- `int = obj.GetActiveNodeWorldPosition (double pos[3])` - Get the world position of the active node. Will return 0 if there is no active node, or 1 otherwise.
- `int = obj.GetActiveNodeWorldOrientation (double orient[9])` - Get the world orientation of the active node. Will return 0 if there is no active node, or 1 otherwise.
- `int = obj.GetActiveNodeDisplayPosition (double pos[2])` - Get the display position of the active node. Will return 0 if there is no active node, or 1 otherwise.
- `int = obj.GetNumberOfNodes ()` - Get the number of nodes.
- `int = obj.GetNthNodeDisplayPosition (int n, double pos[2])` - Get the nth node's display position. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting).
- `int = obj.GetNthNodeWorldPosition (int n, double pos[3])` - Get the nth node's world position. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting).
- `int = obj.GetNthNodeWorldOrientation (int n, double orient[9])` - Get the nth node's world orientation. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting).
- `int = obj.SetNthNodeDisplayPosition (int n, int X, int Y)` - Set the nth node's display position. Display position will be converted into world position according to the constraints of the point placer. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting) or the world position is not valid.
- `int = obj.SetNthNodeDisplayPosition (int n, int pos[2])` - Set the nth node's display position. Display position will be converted into world position according to the constraints of the point placer. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting) or the world position is not valid.
- `int = obj.SetNthNodeDisplayPosition (int n, double pos[2])` - Set the nth node's display position. Display position will be converted into world position according to the constraints of the point placer. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting) or the world position is not valid.
- `int = obj.SetNthNodeWorldPosition (int n, double pos[3])` - Set the nth node's world position. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting) or the world position is not valid according to the point placer.
- `int = obj.SetNthNodeWorldPosition (int n, double pos[3], double orient[9])` - Set the nth node's world position. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting) or the world position is not valid according to the point placer.
- `int = obj.GetNthNodeSlope (int idx, double slope[3])` - Get the nth node's slope. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting).
- `int = obj.GetNumberOfIntermediatePoints (int n)`

- `int = obj.GetIntermediatePointWorldPosition (int n, int idx, double point[3])` - Get the world position of the intermediate point at index idx between nodes n and (n+1) (or n and 0 if n is the last node and the loop is closed). Returns 1 on success or 0 if n or idx are out of range.
- `int = obj.AddIntermediatePointWorldPosition (int n, double point[3])` - Add an intermediate point between node n and n+1 (or n and 0 if n is the last node and the loop is closed). Returns 1 on success or 0 if n is out of range.
- `int = obj.DeleteLastNode ()` - Delete the last node. Returns 1 on success or 0 if there were not any nodes.
- `int = obj.DeleteActiveNode ()` - Delete the active node. Returns 1 on success or 0 if the active node did not indicate a valid node.
- `int = obj.DeleteNthNode (int n)` - Delete the nth node. Return 1 on success or 0 if n is out of range.
- `obj.ClearAllNodes ()` - Delete all nodes.
- `int = obj.AddNodeOnContour (int X, int Y)` - Given a specific X, Y pixel location, add a new node on the contour at this location.
- `obj.SetPixelTolerance (int )` - The tolerance to use when calculations are performed in display coordinates
- `int = obj.GetPixelToleranceMinValue ()` - The tolerance to use when calculations are performed in display coordinates
- `int = obj.GetPixelToleranceMaxValue ()` - The tolerance to use when calculations are performed in display coordinates
- `int = obj.GetPixelTolerance ()` - The tolerance to use when calculations are performed in display coordinates
- `obj.SetWorldTolerance (double )` - The tolerance to use when calculations are performed in world coordinates
- `double = obj.GetWorldToleranceMinValue ()` - The tolerance to use when calculations are performed in world coordinates
- `double = obj.GetWorldToleranceMaxValue ()` - The tolerance to use when calculations are performed in world coordinates
- `double = obj.GetWorldTolerance ()` - The tolerance to use when calculations are performed in world coordinates
- `int = obj.GetCurrentOperation ()` - Set / get the current operation. The widget is either inactive, or it is being translated.
- `obj.SetCurrentOperation (int )` - Set / get the current operation. The widget is either inactive, or it is being translated.
- `int = obj.GetCurrentOperationMinValue ()` - Set / get the current operation. The widget is either inactive, or it is being translated.
- `int = obj.GetCurrentOperationMaxValue ()` - Set / get the current operation. The widget is either inactive, or it is being translated.
- `obj.SetCurrentOperationToInactive ()` - Set / get the current operation. The widget is either inactive, or it is being translated.

- `obj.SetCurrentOperationToTranslate ()` - Set / get the current operation. The widget is either inactive, or it is being translated.
- `obj.SetCurrentOperationToShift ()` - Set / get the current operation. The widget is either inactive, or it is being translated.
- `obj.SetCurrentOperationToScale ()`
- `obj.SetPointPlacer (vtkPointPlacer )`
- `vtkPointPlacer = obj.GetPointPlacer ()`
- `obj.SetLineInterpolator (vtkContourLineInterpolator )` - Set / Get the Line Interpolator. The line interpolator is responsible for generating the line segments connecting nodes.
- `vtkContourLineInterpolator = obj.GetLineInterpolator ()` - Set / Get the Line Interpolator. The line interpolator is responsible for generating the line segments connecting nodes.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modified)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods required by vtkProp superclass.
- `obj.SetClosedLoop (int val)` - Set / Get the ClosedLoop value. This ivar indicates whether the contour forms a closed loop.
- `int = obj.GetClosedLoop ()` - Set / Get the ClosedLoop value. This ivar indicates whether the contour forms a closed loop.
- `obj.ClosedLoopOn ()` - Set / Get the ClosedLoop value. This ivar indicates whether the contour forms a closed loop.
- `obj.ClosedLoopOff ()` - Set / Get the ClosedLoop value. This ivar indicates whether the contour forms a closed loop.
- `obj.SetShowSelectedNodes (int )` - A flag to indicate whether to show the Selected nodes Default is to set it to false.
- `int = obj.GetShowSelectedNodes ()` - A flag to indicate whether to show the Selected nodes Default is to set it to false.
- `obj.ShowSelectedNodesOn ()` - A flag to indicate whether to show the Selected nodes Default is to set it to false.

- `obj.ShowSelectedNodesOff ()` - A flag to indicate whether to show the Selected nodes Default is to set it to false.
- `obj.GetNodePolyData (vtkPolyData poly)` - Get the nodes and not the intermediate points in this contour as a vtkPolyData.

42.36 vtkContourWidget

42.36.1 Usage

The vtkContourWidget is used to select a set of points, and draw lines between these points. The contour may be opened or closed, depending on how the last point is added. The widget handles all processing of widget events (that are triggered by VTK events). The vtkContourRepresentation is responsible for all placement of the points, calculation of the lines, and contour manipulation. This is done through two main helper classes: vtkPointPlacer and vtkContourLineInterpolator. The representation is also responsible for drawing the points and lines.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - triggers a Select event
RightButtonPressEvent - triggers a AddFinalPoint event
MouseMoveEvent - triggers a Move event
LeftButtonReleaseEvent - triggers an EndSelect event
Delete key event - triggers a Delete event
Shift + Delete key event - triggers a Reset event
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkContourWidget's widget events:

```
vtkWidgetEvent::Select
     widget state is:
         Start or
         Define: If we already have at least 2 nodes, test
              whether the current (X,Y) location is near an existing
              node. If so, close the contour and change to Manipulate
              state. Otherwise, attempt to add a node at this (X,Y)
              location.
         Manipulate: If this (X,Y) location activates a node, then
              set the current operation to Translate. Otherwise, if
              this location is near the contour, attempt to add a
              new node on the contour at this (X,Y) location.

vtkWidgetEvent::AddFinalPoint
     widget state is:
         Start: Do nothing.
         Define: If we already have at least 2 nodes, test
              whether the current (X,Y) location is near an existing
              node. If so, close the contour and change to Manipulate
              state. Otherwise, attempt to add a node at this (X,Y)
              location. If we do, then leave the contour open and
              change to Manipulate state.
         Manipulate: Do nothing.

vtkWidgetEvent::Move
```

```
        widget state is:
            Start or
            Define: Do nothing.
            Manipulate: If our operation is Translate, then invoke
                  WidgetInteraction() on the representation. If our
                  operation is Inactive, then just attempt to activate
                  a node at this (X,Y) location.

    vtkWidgetEvent::EndSelect
        widget state is:
            Start or
            Define: Do nothing.
            Manipulate: If our operation is not Inactive, set it to
                  Inactive.

    vtkWidgetEvent::Delete
        widget state is:
            Start: Do nothing.
            Define: Remove the last point on the contour.
            Manipulate: Attempt to activate a node at (X,Y). If
                   we do activate a node, delete it. If we now
                   have less than 3 nodes, go back to Define state.

    vtkWidgetEvent::Reset
        widget state is:
            Start: Do nothing.
            Define: Remove all points and line segments of the contour.
                 Essentially calls Intialize(NULL)
            Manipulate: Do nothing.
```

This widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (beginning to interact)
vtkCommand::EndInteractionEvent (completing interaction)
vtkCommand::InteractionEvent (moving after selecting something)
vtkCommand::PlacePointEvent (after point is positioned;
                             call data includes handle id (0,1))
vtkCommand::WidgetValueChangedEvent (Invoked when the contour is closed
                                     for the first time. )
```

To create an instance of class vtkContourWidget, simply invoke its constructor as follows

```
obj = vtkContourWidget
```

42.36.2 Methods

The class vtkContourWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContourWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.

- `vtkContourWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkContourWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it is a composite widget and does more than its superclasses' vtkAbstractWidget::SetEnabled() method.
- `obj.SetRepresentation (vtkContourRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.CloseLoop ()` - Convenient method to close the contour loop.
- `obj.SetAllowNodePicking (int )` - Set / Get the AllowNodePicking value. This ivar indicates whether the nodes and points between nodes can be picked/un-picked by Ctrl+Click on the node.
- `int = obj.GetAllowNodePicking ()` - Set / Get the AllowNodePicking value. This ivar indicates whether the nodes and points between nodes can be picked/un-picked by Ctrl+Click on the node.
- `obj.AllowNodePickingOn ()` - Set / Get the AllowNodePicking value. This ivar indicates whether the nodes and points between nodes can be picked/un-picked by Ctrl+Click on the node.
- `obj.AllowNodePickingOff ()` - Set / Get the AllowNodePicking value. This ivar indicates whether the nodes and points between nodes can be picked/un-picked by Ctrl+Click on the node.
- `obj.SetFollowCursor (int )` - Follow the cursor ? If this is ON, during definition, the last node of the contour will automatically follow the cursor, without waiting for the the point to be dropped. This may be useful for some interpolators, such as the live-wire interpolator to see the shape of the contour that will be placed as you move the mouse cursor.
- `int = obj.GetFollowCursor ()` - Follow the cursor ? If this is ON, during definition, the last node of the contour will automatically follow the cursor, without waiting for the the point to be dropped. This may be useful for some interpolators, such as the live-wire interpolator to see the shape of the contour that will be placed as you move the mouse cursor.
- `obj.FollowCursorOn ()` - Follow the cursor ? If this is ON, during definition, the last node of the contour will automatically follow the cursor, without waiting for the the point to be dropped. This may be useful for some interpolators, such as the live-wire interpolator to see the shape of the contour that will be placed as you move the mouse cursor.
- `obj.FollowCursorOff ()` - Follow the cursor ? If this is ON, during definition, the last node of the contour will automatically follow the cursor, without waiting for the the point to be dropped. This may be useful for some interpolators, such as the live-wire interpolator to see the shape of the contour that will be placed as you move the mouse cursor.
- `obj.SetContinuousDraw (int )` - Define a contour by continuously drawing with the mouse cursor. Press and hold the left mouse button down to continuously draw. Releasing the left mouse button switches into a snap drawing mode. Terminate the contour by pressing the right mouse button. If you do not want to see the nodes as they are added to the contour, set the opacity to 0 of the representation's property. If you do not want to see the last active node as it is being added, set the opacity to 0 of the representation's active property.
- `int = obj.GetContinuousDraw ()` - Define a contour by continuously drawing with the mouse cursor. Press and hold the left mouse button down to continuously draw. Releasing the left mouse button switches into a snap drawing mode. Terminate the contour by pressing the right mouse button. If you do not want to see the nodes as they are added to the contour, set the opacity to 0 of the representation's property. If you do not want to see the last active node as it is being added, set the opacity to 0 of the representation's active property.

- `obj.ContinuousDrawOn ()` - Define a contour by continuously drawing with the mouse cursor. Press and hold the left mouse button down to continuously draw. Releasing the left mouse button switches into a snap drawing mode. Terminate the contour by pressing the right mouse button. If you do not want to see the nodes as they are added to the contour, set the opacity to 0 of the representation's property. If you do not want to see the last active node as it is being added, set the opacity to 0 of the representation's active property.

- `obj.ContinuousDrawOff ()` - Define a contour by continuously drawing with the mouse cursor. Press and hold the left mouse button down to continuously draw. Releasing the left mouse button switches into a snap drawing mode. Terminate the contour by pressing the right mouse button. If you do not want to see the nodes as they are added to the contour, set the opacity to 0 of the representation's property. If you do not want to see the last active node as it is being added, set the opacity to 0 of the representation's active property.

- `obj.Initialize (vtkPolyData poly, int state)` - Initialize the contour widget from a user supplied set of points. The state of the widget decides if you are still defining the widget, or if you've finished defining (added the last point) are manipulating it. Note that if the polydata supplied is closed, the state will be set to manipulate. State: Define = 0, Manipulate = 1.

- `obj.Initialize ()`

42.37 vtkDijkstraImageContourLineInterpolator

42.37.1 Usage

vtkDijkstraImageContourLineInterpolator interpolates and places contour points on images. The class interpolates nodes by computing a graph lying on the image data. By graph, we mean that the line interpolating the two end points traverses along pixels so as to form a shortest path. A Dijkstra algorithm is used to compute the path.

The class is meant to be used in conjunction with vtkImageActorPointPlacer. One reason for this coupling is a performance issue: both classes need to perform a cell pick, and coupling avoids multiple cell picks (cell picks are slow). Another issue is that the interpolator may need to set the image input to its vtkDijkstraImageGeodesicPath ivar.

To create an instance of class vtkDijkstraImageContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkDijkstraImageContourLineInterpolator
```

42.37.2 Methods

The class vtkDijkstraImageContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDijkstraImageContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.

- `int = obj.IsA (string name)` - Standard methods for instances of this class.

- `vtkDijkstraImageContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.

- `vtkDijkstraImageContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.

- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)` - Subclasses that wish to interpolate a line segment must implement this. For instance vtkBezierContourLineInterpolator adds nodes between idx1 and idx2, that allow the contour to adhere to a bezier curve.

- `obj.SetCostImage (vtkImageData )` - Set the image data for the vtkDijkstraImageGeodesicPath. If not set, the interpolator uses the image data input to the image actor. The image actor is obtained from the expected vtkImageActorPointPlacer.

- `vtkImageData = obj.GetCostImage ()` - Set the image data for the vtkDijkstraImageGeodesicPath. If not set, the interpolator uses the image data input to the image actor. The image actor is obtained from the expected vtkImageActorPointPlacer.

- `vtkDijkstraImageGeodesicPath = obj.GetDijkstraImageGeodesicPath ()` - access to the internal dijkstra path

42.38 vtkDistanceRepresentation

42.38.1 Usage

The vtkDistanceRepresentation is a superclass for various types of representations for the vtkDistanceWidget. Logically subclasses consist of an axis and two handles for placing/manipulating the end points.

To create an instance of class vtkDistanceRepresentation, simply invoke its constructor as follows

```
obj = vtkDistanceRepresentation
```

42.38.2 Methods

The class vtkDistanceRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistanceRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.

- `int = obj.IsA (string name)` - Standard VTK methods.

- `vtkDistanceRepresentation = obj.NewInstance ()` - Standard VTK methods.

- `vtkDistanceRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.

- `double = obj.GetDistance ()` - This representation and all subclasses must keep a distance consistent with the state of the widget.

- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `double = obj.GetPoint1WorldPosition ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `double = obj.GetPoint2WorldPosition ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetHandleRepresentation (vtkHandleRepresentation handle)` - This method is used to specify the type of handle representation to use for the two internal vtkHandleWidgets within vtkDistanceWidget. To use this method, create a dummy vtkHandleWidget (or subclass), and then invoke this method with this dummy. Then the vtkDistanceRepresentation uses this dummy to clone two vtkHandleWidgets of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkDistance widget.)

- `obj.InstantiateHandleRepresentation ()` - This method is used to specify the type of handle representation to use for the two internal vtkHandleWidgets within vtkDistanceWidget. To use this method, create a dummy vtkHandleWidget (or subclass), and then invoke this method with this dummy. Then the vtkDistanceRepresentation uses this dummy to clone two vtkHandleWidgets of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkDistance widget.)

- `vtkHandleRepresentation = obj.GetPoint1Representation ()` - Set/Get the two handle representations used for the vtkDistanceWidget. (Note: properties can be set by grabbing these representations and setting the properties appropriately.)

- `vtkHandleRepresentation = obj.GetPoint2Representation ()` - Set/Get the two handle representations used for the vtkDistanceWidget. (Note: properties can be set by grabbing these representations and setting the properties appropriately.)

- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.

- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.

- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.

- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.

- `obj.SetLabelFormat (string )` - Specify the format to use for labelling the distance. Note that an empty string results in no label, or a format string without a "will not print the distance value.
- `string = obj.GetLabelFormat ()` - Specify the format to use for labelling the distance. Note that an empty string results in no label, or a format string without a "will not print the distance value.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.

42.39 vtkDistanceRepresentation2D

42.39.1 Usage

The vtkDistanceRepresentation2D is a representation for the vtkDistanceWidget. This representation consists of a measuring line (axis) and two vtkHandleWidgets to place the end points of the line. Note that this particular widget draws its representation in the overlay plane.

To create an instance of class vtkDistanceRepresentation2D, simply invoke its constructor as follows

```
obj = vtkDistanceRepresentation2D
```

42.39.2 Methods

The class vtkDistanceRepresentation2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistanceRepresentation2D class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkDistanceRepresentation2D = obj.NewInstance ()` - Standard VTK methods.
- `vtkDistanceRepresentation2D = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `double = obj.GetDistance ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.SetPoint1DisplayPosition (double pos[3])`
- `obj.SetPoint2DisplayPosition (double pos[3])`
- `obj.GetPoint1DisplayPosition (double pos[3])`
- `obj.GetPoint2DisplayPosition (double pos[3])`
- `vtkAxisActor2D = obj.GetAxis ()` - Retrieve the vtkAxisActor2D used to draw the measurement axis. With this properties can be set and so on.
- `obj.BuildRepresentation ()` - Method to satisfy superclasses' API.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods required by vtkProp superclass.

42.40 vtkDistanceWidget

42.40.1 Usage

The vtkDistanceWidget is used to measure the distance between two points. The two end points can be positioned independently, and when they are released, a special PlacePointEvent is invoked so that special operations may be take to reposition the point (snap to grid, etc.) The widget has two different modes of interaction: when initially defined (i.e., placing the two points) and then a manipulate mode (adjusting the position of the two points).

To use this widget, specify an instance of vtkDistanceWidget and a representation (a subclass of vtkDistanceRepresentation). The widget is implemented using two instances of vtkHandleWidget which are used to position the end points of the line. The representations for these two handle widgets are provided by the vtkDistanceRepresentation.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - add a point or select a handle
MouseMoveEvent - position the second point or move a handle
LeftButtonReleaseEvent - release the handle
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkDistanceWidget's widget events:

```
vtkWidgetEvent::AddPoint -- add one point; depending on the state
                            it may the first or second point added. Or,
                            if near a handle, select the handle.
vtkWidgetEvent::Move -- move the second point or handle depending on the state.
vtkWidgetEvent::EndSelect -- the handle manipulation process has completed.
```

This widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (beginning to interact)
vtkCommand::EndInteractionEvent (completing interaction)
vtkCommand::InteractionEvent (moving after selecting something)
vtkCommand::PlacePointEvent (after point is positioned;
                             call data includes handle id (0,1))
```

To create an instance of class vtkDistanceWidget, simply invoke its constructor as follows

```
obj = vtkDistanceWidget
```

42.40.2 Methods

The class vtkDistanceWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistanceWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkDistanceWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkDistanceWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it is a composite widget and does more than its superclasses' vtkAbstractWidget::SetEnabled() method.
- `obj.SetRepresentation (vtkDistanceRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Overridden to pass the state to component widgets.

42.41 vtkEllipsoidTensorProbeRepresentation

42.41.1 Usage

vtkEllipsoidTensorProbeRepresentation is a concrete implementation of vtkTensorProbeRepresentation. It renders tensors as ellipsoids. Locations between two points when probed have the tensors linearly interpolated from the neighboring locations on the polyline.

To create an instance of class vtkEllipsoidTensorProbeRepresentation, simply invoke its constructor as follows

```
obj = vtkEllipsoidTensorProbeRepresentation
```

42.41.2 Methods

The class vtkEllipsoidTensorProbeRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEllipsoidTensorProbeRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.

- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkEllipsoidTensorProbeRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkEllipsoidTensorProbeRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.BuildRepresentation ()`
- `int = obj.RenderOpaqueGeometry (vtkViewport )`
- `int = obj.SelectProbe (int pos[2])` - Can we pick the tensor glyph at the current cursor pos
- `obj.GetActors (vtkPropCollection )` - See vtkProp for details.
- `obj.ReleaseGraphicsResources (vtkWindow )` - See vtkProp for details.

42.42 vtkEvent

42.42.1 Usage

vtkEvent is a class that fully describes a VTK event. It is used by the widgets to help specify the mapping between VTK events and widget events.

To create an instance of class vtkEvent, simply invoke its constructor as follows

```
obj = vtkEvent
```

42.42.2 Methods

The class vtkEvent has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEvent class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkEvent = obj.NewInstance ()` - Standard macros.
- `vtkEvent = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetEventId (long )` - Set the modifier for the event.
- `long = obj.GetEventId ()` - Set the modifier for the event.
- `obj.SetModifier (int )` - Set the modifier for the event.
- `int = obj.GetModifier ()` - Set the modifier for the event.
- `obj.SetKeyCode (char )` - Set the KeyCode for the event.
- `char = obj.GetKeyCode ()` - Set the KeyCode for the event.
- `obj.SetRepeatCount (int )` - Set the repease count for the event.
- `int = obj.GetRepeatCount ()` - Set the repease count for the event.
- `obj.SetKeySym (string )` - Set the complex key symbol (compound key strokes) for the event.
- `string = obj.GetKeySym ()` - Set the complex key symbol (compound key strokes) for the event.

42.43 vtkFocalPlaneContourRepresentation

42.43.1 Usage

The contour will stay on the focal plane irrespective of camera position/orientation changes. The class was written in order to be able to draw contours on a volume widget and have the contours overlayed on the focal plane in order to do contour segmentation. The superclass, vtkContourRepresentation handles contours that are drawn in actual world position co-ordinates, so they would rotate with the camera position/ orientation changes

To create an instance of class vtkFocalPlaneContourRepresentation, simply invoke its constructor as follows

```
obj = vtkFocalPlaneContourRepresentation
```

42.43.2 Methods

The class vtkFocalPlaneContourRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFocalPlaneContourRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkFocalPlaneContourRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkFocalPlaneContourRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `int = obj.GetIntermediatePointWorldPosition (int n, int idx, double point[3])` - Get the world position of the intermediate point at index idx between nodes n and (n+1) (or n and 0 if n is the last node and the loop is closed). Returns 1 on success or 0 if n or idx are out of range.
- `int = obj.GetIntermediatePointDisplayPosition (int n, int idx, double point[3])` - Get the world position of the intermediate point at index idx between nodes n and (n+1) (or n and 0 if n is the last node and the loop is closed). Returns 1 on success or 0 if n or idx are out of range.
- `int = obj.GetNthNodeDisplayPosition (int n, double pos[2])` - Get the nth node's display position. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting).
- `int = obj.GetNthNodeWorldPosition (int n, double pos[3])` - Get the nth node's world position. Will return 1 on success, or 0 if there are not at least (n+1) nodes (0 based counting).
- `obj.UpdateContourWorldPositionsBasedOnDisplayPositions ()` - The class maintains its true contour locations based on display co-ords This method syncs the world co-ords data structure with the display co-ords.
- `int = obj.UpdateContour ()` - The method must be called whenever the contour needs to be updated, usually from RenderOpaqueGeometry()
- `obj.UpdateLines (int index)`

42.44 vtkFocalPlanePointPlacer

42.44.1 Usage

To create an instance of class vtkFocalPlanePointPlacer, simply invoke its constructor as follows

```
obj = vtkFocalPlanePointPlacer
```

42.44.2 Methods

The class vtkFocalPlanePointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFocalPlanePointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkFocalPlanePointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkFocalPlanePointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w`
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[3], doubl` - Given a renderer, a display position, and a reference world position, compute a new world position. The orientation will be the standard coordinate axes, and the computed world position will be created by projecting the display point onto a plane that is parallel to the focal plane and runs through the reference world position. This method is typically used to move existing points.
- `int = obj.ValidateWorldPosition (double worldPos[3])` - Validate a world position. All world positions are valid so these methods always return 1.
- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])` - Validate a world position. All world positions are valid so these methods always return 1.
- `obj.SetOffset (double )` - Optionally specify a signed offset from the focal plane for the points to be placed at. If negative, the constraint plane is offset closer to the camera. If positive, its further away from the camera.
- `double = obj.GetOffset ()` - Optionally specify a signed offset from the focal plane for the points to be placed at. If negative, the constraint plane is offset closer to the camera. If positive, its further away from the camera.
- `obj.SetPointBounds (double , double , double , double , double , double )` - Optionally Restrict the points to a set of bounds. The placer will invalidate points outside these bounds.
- `obj.SetPointBounds (double  a[6])` - Optionally Restrict the points to a set of bounds. The placer will invalidate points outside these bounds.
- `double = obj. GetPointBounds ()` - Optionally Restrict the points to a set of bounds. The placer will invalidate points outside these bounds.

42.45 vtkHandleRepresentation

42.45.1 Usage

This class defines an API for widget handle representations. These representations interact with vtkHandleWidget. Various representations can be used depending on the nature of the handle. The basic functionality of the handle representation is to maintain a position. The position is represented via a vtkCoordinate, meaning that the position can be easily obtained in a variety of coordinate systems.

Optional features for this representation include an active mode (the widget appears only when the mouse pointer is close to it). The active distance is expressed in pixels and represents a circle in display space.

The class may be subclassed so that alternative representations can be created. The class defines an API and a default implementation that the vtkHandleWidget interacts with to render itself in the scene.

To create an instance of class vtkHandleRepresentation, simply invoke its constructor as follows

```
obj = vtkHandleRepresentation
```

42.45.2 Methods

The class vtkHandleRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHandleRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkHandleRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkHandleRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetDisplayPosition (double pos[3])` - Handles usually have their coordinates set in display coordinates (generally by an associated widget) and internally maintain the position in world coordinates. (Using world coordinates insures that handles are rendered in the right position when the camera view changes.) These methods are often subclassed because special constraint operations can be used to control the actual positioning.
- `obj.GetDisplayPosition (double pos[3])` - Handles usually have their coordinates set in display coordinates (generally by an associated widget) and internally maintain the position in world coordinates. (Using world coordinates insures that handles are rendered in the right position when the camera view changes.) These methods are often subclassed because special constraint operations can be used to control the actual positioning.
- `double = obj.GetDisplayPosition ()` - Handles usually have their coordinates set in display coordinates (generally by an associated widget) and internally maintain the position in world coordinates. (Using world coordinates insures that handles are rendered in the right position when the camera view changes.) These methods are often subclassed because special constraint operations can be used to control the actual positioning.
- `obj.SetWorldPosition (double pos[3])` - Handles usually have their coordinates set in display coordinates (generally by an associated widget) and internally maintain the position in world coordinates. (Using world coordinates insures that handles are rendered in the right position when the camera view changes.) These methods are often subclassed because special constraint operations can be used to control the actual positioning.
- `obj.GetWorldPosition (double pos[3])` - Handles usually have their coordinates set in display coordinates (generally by an associated widget) and internally maintain the position in world coordinates. (Using world coordinates insures that handles are rendered in the right position when the camera view changes.) These methods are often subclassed because special constraint operations can be used to control the actual positioning.
- `double = obj.GetWorldPosition ()` - Handles usually have their coordinates set in display coordinates (generally by an associated widget) and internally maintain the position in world coordinates. (Using world coordinates insures that handles are rendered in the right position when the camera view changes.) These methods are often subclassed because special constraint operations can be used to control the actual positioning.
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.

- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the widget to be active.
- `obj.SetActiveRepresentation (int )` - Flag controls whether the widget becomes visible when the mouse pointer moves close to it (i.e., the widget becomes active). By default, ActiveRepresentation is off and the representation is always visible.
- `int = obj.GetActiveRepresentation ()` - Flag controls whether the widget becomes visible when the mouse pointer moves close to it (i.e., the widget becomes active). By default, ActiveRepresentation is off and the representation is always visible.
- `obj.ActiveRepresentationOn ()` - Flag controls whether the widget becomes visible when the mouse pointer moves close to it (i.e., the widget becomes active). By default, ActiveRepresentation is off and the representation is always visible.
- `obj.ActiveRepresentationOff ()` - Flag controls whether the widget becomes visible when the mouse pointer moves close to it (i.e., the widget becomes active). By default, ActiveRepresentation is off and the representation is always visible.
- `obj.SetInteractionState (int )` - The interaction state may be set from a widget (e.g., HandleWidget) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking processwith the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.
- `int = obj.GetInteractionStateMinValue ()` - The interaction state may be set from a widget (e.g., HandleWidget) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking processwith the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.
- `int = obj.GetInteractionStateMaxValue ()` - The interaction state may be set from a widget (e.g., HandleWidget) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking processwith the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.
- `obj.SetConstrained (int )` - Specify whether any motions (such as scale, translate, etc.) are constrained in some way (along an axis, etc.) Widgets can use this to control the resulting motion.
- `int = obj.GetConstrained ()` - Specify whether any motions (such as scale, translate, etc.) are constrained in some way (along an axis, etc.) Widgets can use this to control the resulting motion.
- `obj.ConstrainedOn ()` - Specify whether any motions (such as scale, translate, etc.) are constrained in some way (along an axis, etc.) Widgets can use this to control the resulting motion.
- `obj.ConstrainedOff ()` - Specify whether any motions (such as scale, translate, etc.) are constrained in some way (along an axis, etc.) Widgets can use this to control the resulting motion.
- `int = obj.CheckConstraint (vtkRenderer renderer, double pos[2])` - Method has to be overridden in the subclasses which has constraints on placing the handle (Ex. vtkConstrainedPointHandleRepresentation). It should return 1 if the position is within the constraint, else it should return 0. By default it returns 1.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class properly act like a vtkWidgetRepresentation.

- `obj.DeepCopy (vtkProp prop)` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.SetRenderer (vtkRenderer ren)` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `long = obj.GetMTime ()` - Overload the superclasses' GetMTime() because the internal vtkCoordinates are used to keep the state of the representation.
- `obj.SetPointPlacer (vtkPointPlacer )` - Set/Get the point placer. Point placers can be used to dictate constraints on the placement of handles. As an example, see vtkBoundedPlanePointPlacer (constrains the placement of handles to a set of bounded planes) vtkFocalPlanePointPlacer (constrains placement on the focal plane) etc. The default point placer is vtkPointPlacer (which does not apply any constraints, so the handles are free to move anywhere).
- `vtkPointPlacer = obj.GetPointPlacer ()` - Set/Get the point placer. Point placers can be used to dictate constraints on the placement of handles. As an example, see vtkBoundedPlanePointPlacer (constrains the placement of handles to a set of bounded planes) vtkFocalPlanePointPlacer (constrains placement on the focal plane) etc. The default point placer is vtkPointPlacer (which does not apply any constraints, so the handles are free to move anywhere).

42.46 vtkHandleWidget

42.46.1 Usage

The vtkHandleWidget is used to position a handle. A handle is a widget with a position (in display and world space). Various appearances are available depending on its associated representation. The widget provides methods for translation, including constrained translation along coordinate axes. To use this widget, create and associate a representation with the widget.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - select focal point of widget
LeftButtonReleaseEvent - end selection
MiddleButtonPressEvent - translate widget
MiddleButtonReleaseEvent - end translation
RightButtonPressEvent - scale widget
RightButtonReleaseEvent - end scaling
MouseMoveEvent - interactive movement across widget
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkHandleWidget's widget events:

```
vtkWidgetEvent::Select -- focal point is being selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Translate -- translate the widget
vtkWidgetEvent::EndTranslate -- end widget translation
vtkWidgetEvent::Scale -- scale the widget
vtkWidgetEvent::EndScale -- end scaling the widget
vtkWidgetEvent::Move -- a request for widget motion
```

In turn, when these widget events are processed, the vtkHandleWidget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkHandleWidget, simply invoke its constructor as follows

```
obj = vtkHandleWidget
```

42.46.2 Methods

The class vtkHandleWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHandleWidget class.

- `string = obj.GetClassName ()` - Standard VTK class macros.
- `int = obj.IsA (string name)` - Standard VTK class macros.
- `vtkHandleWidget = obj.NewInstance ()` - Standard VTK class macros.
- `vtkHandleWidget = obj.SafeDownCast (vtkObject o)` - Standard VTK class macros.
- `obj.SetRepresentation (vtkHandleRepresentation r)` - Create the default widget representation if one is not set. By default an instance of vtkPointHandleRepresenation3D is created.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set. By default an instance of vtkPointHandleRepresenation3D is created.
- `obj.SetEnableAxisConstraint (int )` - Enable / disable axis constrained motion of the handles. By default the widget responds to the shift modifier to constrain the handle along the axis closest aligned with the motion vector.
- `int = obj.GetEnableAxisConstraint ()` - Enable / disable axis constrained motion of the handles. By default the widget responds to the shift modifier to constrain the handle along the axis closest aligned with the motion vector.
- `obj.EnableAxisConstraintOn ()` - Enable / disable axis constrained motion of the handles. By default the widget responds to the shift modifier to constrain the handle along the axis closest aligned with the motion vector.
- `obj.EnableAxisConstraintOff ()` - Enable / disable axis constrained motion of the handles. By default the widget responds to the shift modifier to constrain the handle along the axis closest aligned with the motion vector.
- `obj.SetAllowHandleResize (int )` - Allow resizing of handles ? By default the right mouse button scales the handle size.
- `int = obj.GetAllowHandleResize ()` - Allow resizing of handles ? By default the right mouse button scales the handle size.
- `obj.AllowHandleResizeOn ()` - Allow resizing of handles ? By default the right mouse button scales the handle size.
- `obj.AllowHandleResizeOff ()` - Allow resizing of handles ? By default the right mouse button scales the handle size.
- `int = obj.GetWidgetState ()` - Get the widget state.

42.47 vtkHoverWidget

42.47.1 Usage

The vtkHoverWidget is used to invoke an event when hovering in a render window. Hovering occurs when mouse motion (in the render window) does not occur for a specified amount of time (i.e., TimerDuration). This class can be used as is (by observing TimerEvents) or for class derivation for those classes wishing to do more with the hover event.

To use this widget, specify an instance of vtkHoverWidget and specify the time (in milliseconds) defining the hover period. Unlike most widgets, this widget does not require a representation (although subclasses like vtkBalloonWidget do require a representation).

.SECTION Event Bindings By default, the widget observes the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
MouseMoveEvent - manages a timer used to determine whether the mouse
                 is hovering.
TimerEvent - when the time between events (e.g., mouse move), then a
             timer event is invoked.
KeyPressEvent - when the ''Enter'' key is pressed after the balloon appears,
                a callback is activited (e.g., WidgetActivateEvent).
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkHoverWidget's widget events:

```
vtkWidgetEvent::Move -- start (or reset) the timer
vtkWidgetEvent::TimedOut -- when enough time is elapsed between defined
                            VTK events the hover event is invoked.
vtkWidgetEvent::SelectAction -- activate any callbacks associated
                                with the balloon.
```

This widget invokes the following VTK events on itself when the widget determines that it is hovering. Note that observers of this widget can listen for these events and take appropriate action.

```
vtkCommand::TimerEvent (when hovering is determined to occur)
vtkCommand::EndInteractionEvent (after a hover has occured and the
                                 mouse begins moving again).
vtkCommand::WidgetActivateEvent (when the balloon is selected with a
                                 keypress).
```

To create an instance of class vtkHoverWidget, simply invoke its constructor as follows

```
obj = vtkHoverWidget
```

42.47.2 Methods

The class vtkHoverWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHoverWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkHoverWidget = obj.NewInstance ()` - Standard methods for a VTK class.

- `vtkHoverWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetTimerDuration (int )` - Specify the hovering interval (in milliseconds). If after moving the mouse the pointer stays over a vtkProp for this duration, then a vtkTimerEvent::TimerEvent is invoked.
- `int = obj.GetTimerDurationMinValue ()` - Specify the hovering interval (in milliseconds). If after moving the mouse the pointer stays over a vtkProp for this duration, then a vtkTimerEvent::TimerEvent is invoked.
- `int = obj.GetTimerDurationMaxValue ()` - Specify the hovering interval (in milliseconds). If after moving the mouse the pointer stays over a vtkProp for this duration, then a vtkTimerEvent::TimerEvent is invoked.
- `int = obj.GetTimerDuration ()` - Specify the hovering interval (in milliseconds). If after moving the mouse the pointer stays over a vtkProp for this duration, then a vtkTimerEvent::TimerEvent is invoked.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it performs special timer-related operations.
- `obj.CreateDefaultRepresentation ()`

42.48 vtkImageActorPointPlacer

42.48.1 Usage

This PointPlacer is used to constrain the placement of points on the supplied image actor. Additionally, you may set bounds to restrict the placement of the points. The placement of points will then be constrained to lie not only on the ImageActor but also within the bounds specified. If no bounds are specified, they may lie anywhere on the supplied ImageActor.

To create an instance of class vtkImageActorPointPlacer, simply invoke its constructor as follows

```
obj = vtkImageActorPointPlacer
```

42.48.2 Methods

The class vtkImageActorPointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageActorPointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkImageActorPointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkImageActorPointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given and renderer and a display position in pixels, find a world position and orientation. In this class an internal vtkBoundedPlanePointPlacer is used to compute the world position and orientation. The internal placer is set to use the plane of the image actor and the bounds of the image actor as the constraints for placing points.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[2], doubl` - This method is identical to the one above since the reference position is ignored by the bounded plane point placer.

- `int = obj.ValidateWorldPosition (double worldPos[3])` - This method validates a world position by checking to see if the world position is valid according to the constraints of the internal placer (essentially - is this world position on the image?)
- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])` - This method is identical to the one above since the bounded plane point placer ignores orientation
- `int = obj.UpdateWorldPosition (vtkRenderer ren, double worldPos[3], double worldOrient[9])` - Update the world position and orientation according the the current constraints of the placer. Will be called by the representation when it notices that this placer has been modified.
- `int = obj.UpdateInternalState ()` - A method for configuring the internal placer according to the constraints of the image actor. Called by the representation to give the placer a chance to update itself, which may cause the MTime to change, which would then cause the representation to update all of its points
- `obj.SetImageActor (vtkImageActor )` - Set / get the reference vtkImageActor used to place the points. An image actor must be set for this placer to work. An internal bounded plane point placer is created and set to match the bounds of the displayed image.
- `vtkImageActor = obj.GetImageActor ()` - Set / get the reference vtkImageActor used to place the points. An image actor must be set for this placer to work. An internal bounded plane point placer is created and set to match the bounds of the displayed image.
- `obj.SetBounds (double , double , double , double , double , double )` - Optionally, you may set bounds to restrict the placement of the points. The placement of points will then be constrained to lie not only on the ImageActor but also within the bounds specified. If no bounds are specified, they may lie anywhere on the supplied ImageActor.
- `obj.SetBounds (double a[6])` - Optionally, you may set bounds to restrict the placement of the points. The placement of points will then be constrained to lie not only on the ImageActor but also within the bounds specified. If no bounds are specified, they may lie anywhere on the supplied ImageActor.
- `double = obj. GetBounds ()` - Optionally, you may set bounds to restrict the placement of the points. The placement of points will then be constrained to lie not only on the ImageActor but also within the bounds specified. If no bounds are specified, they may lie anywhere on the supplied ImageActor.
- `obj.SetWorldTolerance (double s)` - Set the world tolerance. This propagates it to the internal BoundedPlanePointPlacer.

42.49 vtkImageOrthoPlanes

42.49.1 Usage

vtkImageOrthoPlanes is an event observer class that listens to the events from three vtkImagePlaneWidgets and keeps their orientations and scales synchronized.

To create an instance of class vtkImageOrthoPlanes, simply invoke its constructor as follows

```
obj = vtkImageOrthoPlanes
```

42.49.2 Methods

The class vtkImageOrthoPlanes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageOrthoPlanes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageOrthoPlanes = obj.NewInstance ()`
- `vtkImageOrthoPlanes = obj.SafeDownCast (vtkObject o)`
- `obj.SetPlane (int i, vtkImagePlaneWidget imagePlaneWidget)` - You must set three planes for the widget.
- `vtkImagePlaneWidget = obj.GetPlane (int i)` - You must set three planes for the widget.
- `obj.ResetPlanes ()` - Reset the planes to original scale, rotation, and location.
- `vtkTransform = obj.GetTransform ()` - Get the transform for the planes.
- `obj.HandlePlaneEvent (vtkImagePlaneWidget imagePlaneWidget)` - A public method to be used only by the event callback.

42.50 vtkImagePlaneWidget

42.50.1 Usage

This 3D widget defines a plane that can be interactively placed in an image volume. A nice feature of the object is that the vtkImagePlaneWidget, like any 3D widget, will work with the current interactor style. That is, if vtkImagePlaneWidget does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkImagePlaneWidget will terminate the processing of the event that it handles.

The core functionality of the widget is provided by a vtkImageReslice object which passes its output onto a texture mapping pipeline for fast slicing through volumetric data. See the key methods: GenerateTexturePlane() and UpdatePlane() for implementation details.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. If the "i" key (for "interactor") is pressed, the vtkImagePlaneWidget will appear. (See superclass documentation for information about changing this behavior.)

Selecting the widget with the middle mouse button with and without holding the shift or control keys enables complex reslicing capablilites. To facilitate use, a set of 'margins' (left, right, top, bottom) are shown as a set of plane-axes aligned lines, the properties of which can be changed as a group. Without keyboard modifiers: selecting in the middle of the margins enables translation of the plane along its normal. Selecting one of the corners within the margins enables spinning around the plane's normal at its center. Selecting within a margin allows rotating about the center of the plane around an axis aligned with the margin (i.e., selecting left margin enables rotating around the plane's local y-prime axis). With control key modifier: margin selection enables edge translation (i.e., a constrained form of scaling). Selecting within the margins enables translation of the entire plane. With shift key modifier: uniform plane scaling is enabled. Moving the mouse up enlarges the plane while downward movement shrinks it.

Window-level is achieved by using the right mouse button. Window-level values can be reset by shift + 'r' or control + 'r' while regular reset camera is maintained with 'r' or 'R'. The left mouse button can be used to query the underlying image data with a snap-to cross-hair cursor. Currently, the nearest point in the input image data to the mouse cursor generates the cross-hairs. With oblique slicing, this behaviour may appear unsatisfactory. Text display of window-level and image coordinates/data values are provided by a text actor/mapper pair.

Events that occur outside of the widget (i.e., no part of the widget is picked) are propagated to any other registered obsevers (such as the interaction style). Turn off the widget by pressing the "i" key again (or invoke the Off() method). To support interactive manipulation of objects, this class invokes the events StartInteractionEvent, InteractionEvent, and EndInteractionEvent as well as StartWindowLevelEvent, WindowLevelEvent, EndWindowLevelEvent and ResetWindowLevelEvent.

The vtkImagePlaneWidget has several methods that can be used in conjunction with other VTK objects. The GetPolyData() method can be used to get the polygonal representation of the plane and can be used as input for other VTK objects. Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (either left or right button).

Some additional features of this class include the ability to control the properties of the widget. You can set the properties of: the selected and unselected representations of the plane's outline; the text actor via its vtkTextProperty; the cross-hair cursor. In addition there are methods to constrain the plane so that it is aligned along the x-y-z axes. Finally, one can specify the degree of interpolation (vtkImageReslice): nearest neighbour, linear, and cubic.

To create an instance of class vtkImagePlaneWidget, simply invoke its constructor as follows

```
obj = vtkImagePlaneWidget
```

42.50.2 Methods

The class vtkImagePlaneWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImagePlaneWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImagePlaneWidget = obj.NewInstance ()`
- `vtkImagePlaneWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set the vtkImageData* input for the vtkImageReslice.
- `obj.SetInput (vtkDataSet input)` - Set the vtkImageData* input for the vtkImageReslice.
- `obj.SetOrigin (double x, double y, double z)` - Set/Get the origin of the plane.
- `obj.SetOrigin (double xyz[3])` - Set/Get the origin of the plane.
- `double = obj.GetOrigin ()` - Set/Get the origin of the plane.
- `obj.GetOrigin (double xyz[3])` - Set/Get the origin of the plane.
- `obj.SetPoint1 (double x, double y, double z)` - Set/Get the position of the point defining the first axis of the plane.
- `obj.SetPoint1 (double xyz[3])` - Set/Get the position of the point defining the first axis of the plane.
- `double = obj.GetPoint1 ()` - Set/Get the position of the point defining the first axis of the plane.
- `obj.GetPoint1 (double xyz[3])` - Set/Get the position of the point defining the first axis of the plane.
- `obj.SetPoint2 (double x, double y, double z)` - Set/Get the position of the point defining the second axis of the plane.

- `obj.SetPoint2 (double xyz[3])` - Set/Get the position of the point defining the second axis of the plane.
- `double = obj.GetPoint2 ()` - Set/Get the position of the point defining the second axis of the plane.
- `obj.GetPoint2 (double xyz[3])` - Set/Get the position of the point defining the second axis of the plane.
- `double = obj.GetCenter ()` - Get the center of the plane.
- `obj.GetCenter (double xyz[3])` - Get the center of the plane.
- `double = obj.GetNormal ()` - Get the normal to the plane.
- `obj.GetNormal (double xyz[3])` - Get the normal to the plane.
- `obj.GetVector1 (double v1[3])` - Get the vector from the plane origin to point1.
- `obj.GetVector2 (double v2[3])` - Get the vector from the plane origin to point2.
- `int = obj.GetSliceIndex ()` - Get the slice position in terms of the data extent.
- `obj.SetSliceIndex (int index)` - Set the slice position in terms of the data extent.
- `double = obj.GetSlicePosition ()` - Get the position of the slice along its normal.
- `obj.SetSlicePosition (double position)` - Set the position of the slice along its normal.
- `obj.SetResliceInterpolate (int )` - Set the interpolation to use when texturing the plane.
- `int = obj.GetResliceInterpolate ()` - Set the interpolation to use when texturing the plane.
- `obj.SetResliceInterpolateToNearestNeighbour ()` - Set the interpolation to use when texturing the plane.
- `obj.SetResliceInterpolateToLinear ()` - Set the interpolation to use when texturing the plane.
- `obj.SetResliceInterpolateToCubic ()` - Convenience method to get the vtkImageReslice output.
- `vtkImageData = obj.GetResliceOutput ()` - Convenience method to get the vtkImageReslice output.
- `obj.SetRestrictPlaneToVolume (int )` - Make sure that the plane remains within the volume. Default is On.
- `int = obj.GetRestrictPlaneToVolume ()` - Make sure that the plane remains within the volume. Default is On.
- `obj.RestrictPlaneToVolumeOn ()` - Make sure that the plane remains within the volume. Default is On.
- `obj.RestrictPlaneToVolumeOff ()` - Make sure that the plane remains within the volume. Default is On.
- `obj.SetUserControlledLookupTable (int )` - Let the user control the lookup table. NOTE: apply this method BEFORE applying the SetLookupTable method. Default is Off.
- `int = obj.GetUserControlledLookupTable ()` - Let the user control the lookup table. NOTE: apply this method BEFORE applying the SetLookupTable method. Default is Off.
- `obj.UserControlledLookupTableOn ()` - Let the user control the lookup table. NOTE: apply this method BEFORE applying the SetLookupTable method. Default is Off.

- `obj.UserControlledLookupTableOff ()` - Let the user control the lookup table. NOTE: apply this method BEFORE applying the SetLookupTable method. Default is Off.

- `obj.SetTextureInterpolate (int )` - Specify whether to interpolate the texture or not. When off, the reslice interpolation is nearest neighbour regardless of how the interpolation is set through the API. Set before setting the vtkImageData input. Default is On.

- `int = obj.GetTextureInterpolate ()` - Specify whether to interpolate the texture or not. When off, the reslice interpolation is nearest neighbour regardless of how the interpolation is set through the API. Set before setting the vtkImageData input. Default is On.

- `obj.TextureInterpolateOn ()` - Specify whether to interpolate the texture or not. When off, the reslice interpolation is nearest neighbour regardless of how the interpolation is set through the API. Set before setting the vtkImageData input. Default is On.

- `obj.TextureInterpolateOff ()` - Specify whether to interpolate the texture or not. When off, the reslice interpolation is nearest neighbour regardless of how the interpolation is set through the API. Set before setting the vtkImageData input. Default is On.

- `obj.SetTextureVisibility (int )` - Control the visibility of the actual texture mapped reformatted plane. in some cases you may only want the plane outline for example.

- `int = obj.GetTextureVisibility ()` - Control the visibility of the actual texture mapped reformatted plane. in some cases you may only want the plane outline for example.

- `obj.TextureVisibilityOn ()` - Control the visibility of the actual texture mapped reformatted plane. in some cases you may only want the plane outline for example.

- `obj.TextureVisibilityOff ()` - Control the visibility of the actual texture mapped reformatted plane. in some cases you may only want the plane outline for example.

- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the plane. The polydata consists of (res+1)*(res+1) points, and res*res quadrilateral polygons, where res is the resolution of the plane. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polygons are added to it.

- `vtkPolyDataAlgorithm = obj.GetPolyDataAlgorithm ()` - Satisfies superclass API. This returns a pointer to the underlying vtkPolyData. Make changes to this before calling the initial PlaceWidget() to have the initial placement follow suit. Or, make changes after the widget has been initialised and call UpdatePlacement() to realise.

- `obj.UpdatePlacement (void )` - Satisfies superclass API. This will change the state of the widget to match changes that have been made to the underlying vtkPolyDataSource

- `vtkTexture = obj.GetTexture ()` - Convenience method to get the texture used by this widget. This can be used in external slice viewers.

- `vtkImageMapToColors = obj.GetColorMap ()` - Convenience method to get the vtkImageMapToColors filter used by this widget. The user can properly render other transparent actors in a scene by calling the filter's SetOutputFormatToRGB and PassAlphaToOutputOff.

- `obj.SetColorMap (vtkImageMapToColors )` - Convenience method to get the vtkImageMapToColors filter used by this widget. The user can properly render other transparent actors in a scene by calling the filter's SetOutputFormatToRGB and PassAlphaToOutputOff.

- `obj.SetPlaneProperty (vtkProperty )` - Set/Get the plane's outline properties. The properties of the plane's outline when selected and unselected can be manipulated.

- `vtkProperty = obj.GetPlaneProperty ()` - Set/Get the plane's outline properties. The properties of the plane's outline when selected and unselected can be manipulated.
- `obj.SetSelectedPlaneProperty (vtkProperty )` - Set/Get the plane's outline properties. The properties of the plane's outline when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedPlaneProperty ()` - Set/Get the plane's outline properties. The properties of the plane's outline when selected and unselected can be manipulated.
- `obj.SetPlaneOrientation (int )` - Convenience method sets the plane orientation normal to the x, y, or z axes. Default is XAxes (0).
- `int = obj.GetPlaneOrientation ()` - Convenience method sets the plane orientation normal to the x, y, or z axes. Default is XAxes (0).
- `obj.SetPlaneOrientationToXAxes ()` - Convenience method sets the plane orientation normal to the x, y, or z axes. Default is XAxes (0).
- `obj.SetPlaneOrientationToYAxes ()` - Convenience method sets the plane orientation normal to the x, y, or z axes. Default is XAxes (0).
- `obj.SetPlaneOrientationToZAxes ()` - Set the internal picker to one defined by the user. In this way, a set of three orthogonal planes can share the same picker so that picking is performed correctly. The default internal picker can be re-set/allocated by setting to 0 (NULL).
- `obj.SetPicker (vtkAbstractPropPicker )` - Set the internal picker to one defined by the user. In this way, a set of three orthogonal planes can share the same picker so that picking is performed correctly. The default internal picker can be re-set/allocated by setting to 0 (NULL).
- `obj.SetLookupTable (vtkLookupTable )` - Set/Get the internal lookuptable (lut) to one defined by the user, or, alternatively, to the lut of another vtkImgePlaneWidget. In this way, a set of three orthogonal planes can share the same lut so that window-levelling is performed uniformly among planes. The default internal lut can be re- set/allocated by setting to 0 (NULL).
- `vtkLookupTable = obj.GetLookupTable ()` - Set/Get the internal lookuptable (lut) to one defined by the user, or, alternatively, to the lut of another vtkImgePlaneWidget. In this way, a set of three orthogonal planes can share the same lut so that window-levelling is performed uniformly among planes. The default internal lut can be re- set/allocated by setting to 0 (NULL).
- `obj.SetDisplayText (int )` - Enable/disable text display of window-level, image coordinates and scalar values in a render window.
- `int = obj.GetDisplayText ()` - Enable/disable text display of window-level, image coordinates and scalar values in a render window.
- `obj.DisplayTextOn ()` - Enable/disable text display of window-level, image coordinates and scalar values in a render window.
- `obj.DisplayTextOff ()` - Enable/disable text display of window-level, image coordinates and scalar values in a render window.
- `obj.SetCursorProperty (vtkProperty )` - Set the properties of the cross-hair cursor.
- `vtkProperty = obj.GetCursorProperty ()` - Set the properties of the cross-hair cursor.
- `obj.SetMarginProperty (vtkProperty )` - Set the properties of the margins.
- `vtkProperty = obj.GetMarginProperty ()` - Set the properties of the margins.
- `obj.SetMarginSizeX (double )` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50

- `double = obj.GetMarginSizeXMinValue ()` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `double = obj.GetMarginSizeXMaxValue ()` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `double = obj.GetMarginSizeX ()` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `obj.SetMarginSizeY (double )` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `double = obj.GetMarginSizeYMinValue ()` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `double = obj.GetMarginSizeYMaxValue ()` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `double = obj.GetMarginSizeY ()` - Set the size of the margins based on a percentage of the plane's width and height, limited between 0 and 50
- `obj.SetTextProperty (vtkTextProperty tprop)` - Set/Get the text property for the image data and window-level annotation.
- `vtkTextProperty = obj.GetTextProperty ()` - Set/Get the text property for the image data and window-level annotation.
- `obj.SetTexturePlaneProperty (vtkProperty )` - Set/Get the property for the resliced image.
- `vtkProperty = obj.GetTexturePlaneProperty ()` - Set/Get the property for the resliced image.
- `obj.SetWindowLevel (double window, double level, int copy)` - Set/Get the current window and level values. SetWindowLevel should only be called after SetInput. If a shared lookup table is being used, a callback is required to update the window level values without having to update the lookup table again.
- `obj.GetWindowLevel (double wl[2])` - Set/Get the current window and level values. SetWindowLevel should only be called after SetInput. If a shared lookup table is being used, a callback is required to update the window level values without having to update the lookup table again.
- `double = obj.GetWindow ()` - Set/Get the current window and level values. SetWindowLevel should only be called after SetInput. If a shared lookup table is being used, a callback is required to update the window level values without having to update the lookup table again.
- `double = obj.GetLevel ()` - Get the image coordinate position and voxel value. Currently only supports single component image data.
- `int = obj.GetCursorData (double xyzv[4])` - Get the image coordinate position and voxel value. Currently only supports single component image data.
- `int = obj.GetCursorDataStatus ()` - Get the status of the cursor data. If this returns 1 the CurrentCursorPosition and CurrentImageValue will have current data. If it returns 0, these values are invalid.
- `double = obj. GetCurrentCursorPosition ()` - Get the current cursor position. To be used in conjunction with GetCursorDataStatus.
- `double = obj.GetCurrentImageValue ()` - Get the current image value at the current cursor position. To be used in conjunction with GetCursorDataStatus. The value is VTK_DOUBLE_MAX when the data is invalid.

- `obj.SetUseContinuousCursor (int )` - Choose between voxel centered or continuous cursor probing. With voxel centered probing, the cursor snaps to the nearest voxel and the reported cursor coordinates are extent based. With continuous probing, voxel data is interpolated using vtkDataSetAttributes' InterpolatePoint method and the reported coordinates are 3D spatial continuous.

- `int = obj.GetUseContinuousCursor ()` - Choose between voxel centered or continuous cursor probing. With voxel centered probing, the cursor snaps to the nearest voxel and the reported cursor coordinates are extent based. With continuous probing, voxel data is interpolated using vtkDataSetAttributes' InterpolatePoint method and the reported coordinates are 3D spatial continuous.

- `obj.UseContinuousCursorOn ()` - Choose between voxel centered or continuous cursor probing. With voxel centered probing, the cursor snaps to the nearest voxel and the reported cursor coordinates are extent based. With continuous probing, voxel data is interpolated using vtkDataSetAttributes' InterpolatePoint method and the reported coordinates are 3D spatial continuous.

- `obj.UseContinuousCursorOff ()` - Choose between voxel centered or continuous cursor probing. With voxel centered probing, the cursor snaps to the nearest voxel and the reported cursor coordinates are extent based. With continuous probing, voxel data is interpolated using vtkDataSetAttributes' InterpolatePoint method and the reported coordinates are 3D spatial continuous.

- `obj.SetInteraction (int interact)` - Enable/disable mouse interaction so the widget remains on display.

- `int = obj.GetInteraction ()` - Enable/disable mouse interaction so the widget remains on display.

- `obj.InteractionOn ()` - Enable/disable mouse interaction so the widget remains on display.

- `obj.InteractionOff ()` - Enable/disable mouse interaction so the widget remains on display.

- `obj.SetLeftButtonAction (int )` - Set action associated to buttons.

- `int = obj.GetLeftButtonActionMinValue ()` - Set action associated to buttons.

- `int = obj.GetLeftButtonActionMaxValue ()` - Set action associated to buttons.

- `int = obj.GetLeftButtonAction ()` - Set action associated to buttons.

- `obj.SetMiddleButtonAction (int )` - Set action associated to buttons.

- `int = obj.GetMiddleButtonActionMinValue ()` - Set action associated to buttons.

- `int = obj.GetMiddleButtonActionMaxValue ()` - Set action associated to buttons.

- `int = obj.GetMiddleButtonAction ()` - Set action associated to buttons.

- `obj.SetRightButtonAction (int )` - Set action associated to buttons.

- `int = obj.GetRightButtonActionMinValue ()` - Set action associated to buttons.

- `int = obj.GetRightButtonActionMaxValue ()` - Set action associated to buttons.

- `int = obj.GetRightButtonAction ()` - Set action associated to buttons.

- `obj.SetLeftButtonAutoModifier (int )` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetLeftButtonAutoModifierMinValue ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetLeftButtonAutoModifierMaxValue ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetLeftButtonAutoModifier ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `obj.SetMiddleButtonAutoModifier (int )` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetMiddleButtonAutoModifierMinValue ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetMiddleButtonAutoModifierMaxValue ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetMiddleButtonAutoModifier ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `obj.SetRightButtonAutoModifier (int )` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetRightButtonAutoModifierMinValue ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetRightButtonAutoModifierMaxValue ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION

(see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

- `int = obj.GetRightButtonAutoModifier ()` - Set the auto-modifiers associated to buttons. This allows users to bind some buttons to actions that are usually triggered by a key modifier. For example, if you do not need cursoring, you can bind the left button action to VTK_SLICE_MOTION_ACTION (see above) and the left button auto modifier to VTK_CONTROL_MODIFIER: you end up with the left button controling panning without pressing a key.

42.51 vtkImageTracerWidget

42.51.1 Usage

vtkImageTracerWidget is different from other widgets in three distinct ways: 1) any sub-class of vtkProp can be input rather than just vtkProp3D, so that vtkImageActor can be set as the prop and then traced over, 2) the widget fires pick events at the input prop to decide where to move its handles, 3) the widget has 2D glyphs for handles instead of 3D spheres as is done in other sub-classes of vtk3DWidget. This widget is primarily designed for manually tracing over image data. The button actions and key modifiers are as follows for controlling the widget: 1) left button click over the image, hold and drag draws a free hand line. 2) left button click and release erases the widget line, if it exists, and repositions the first handle. 3) middle button click starts a snap drawn line. The line is terminated by clicking the middle button while depressing the ctrl key. 4) when tracing a continuous or snap drawn line, if the last cursor position is within a specified tolerance to the first handle, the widget line will form a closed loop. 5) right button clicking and holding on any handle that is part of a snap drawn line allows handle dragging: existing line segments are updated accordingly. If the path is open and AutoClose is set to On, the path can be closed by repositioning the first and last points over one another. 6) ctrl key + right button down on any handle will erase it: existing snap drawn line segments are updated accordingly. If the line was formed by continous tracing, the line is deleted leaving one handle. 7) shift key + right button down on any snap drawn line segment will insert a handle at the cursor position. The line segment is split accordingly.

To create an instance of class vtkImageTracerWidget, simply invoke its constructor as follows

```
obj = vtkImageTracerWidget
```

42.51.2 Methods

The class vtkImageTracerWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageTracerWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageTracerWidget = obj.NewInstance ()`
- `vtkImageTracerWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set/Get the handle properties (the 2D glyphs are the handles). The properties of the handles when selected and normal can be manipulated.

- `obj.SetHandleProperty (vtkProperty )` - Set/Get the handle properties (the 2D glyphs are the handles). The properties of the handles when selected and normal can be manipulated.
- `vtkProperty = obj.GetHandleProperty ()` - Set/Get the handle properties (the 2D glyphs are the handles). The properties of the handles when selected and normal can be manipulated.
- `obj.SetSelectedHandleProperty (vtkProperty )` - Set/Get the handle properties (the 2D glyphs are the handles). The properties of the handles when selected and normal can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Set/Get the handle properties (the 2D glyphs are the handles). The properties of the handles when selected and normal can be manipulated.
- `obj.SetLineProperty (vtkProperty )` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetLineProperty ()` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `obj.SetSelectedLineProperty (vtkProperty )` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedLineProperty ()` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `obj.SetViewProp (vtkProp prop)` - Set the prop, usually a vtkImageActor, to trace over.
- `obj.SetProjectToPlane (int )` - Force handles to be on a specific ortho plane. Default is Off.
- `int = obj.GetProjectToPlane ()` - Force handles to be on a specific ortho plane. Default is Off.
- `obj.ProjectToPlaneOn ()` - Force handles to be on a specific ortho plane. Default is Off.
- `obj.ProjectToPlaneOff ()` - Force handles to be on a specific ortho plane. Default is Off.
- `obj.SetProjectionNormal (int )` - Set the projection normal. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively. Since the handles are 2D glyphs, it is necessary to specify a plane on which to generate them, even though ProjectToPlane may be turned off.
- `int = obj.GetProjectionNormalMinValue ()` - Set the projection normal. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively. Since the handles are 2D glyphs, it is necessary to specify a plane on which to generate them, even though ProjectToPlane may be turned off.
- `int = obj.GetProjectionNormalMaxValue ()` - Set the projection normal. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively. Since the handles are 2D glyphs, it is necessary to specify a plane on which to generate them, even though ProjectToPlane may be turned off.
- `int = obj.GetProjectionNormal ()` - Set the projection normal. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively. Since the handles are 2D glyphs, it is necessary to specify a plane on which to generate them, even though ProjectToPlane may be turned off.
- `obj.SetProjectionNormalToXAxes ()` - Set the projection normal. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively. Since the handles are 2D glyphs, it is necessary to specify a plane on which to generate them, even though ProjectToPlane may be turned off.
- `obj.SetProjectionNormalToYAxes ()` - Set the projection normal. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively. Since the handles are 2D glyphs, it is necessary to specify a plane on which to generate them, even though ProjectToPlane may be turned off.
- `obj.SetProjectionNormalToZAxes ()` - Set the position of the widgets' handles in terms of a plane's position. e.g., if ProjectionNormal is 0, all of the x-coordinate values of the handles are set to ProjectionPosition. No attempt is made to ensure that the position is within the bounds of either the underlying image data or the prop on which tracing is performed.

- `obj.SetProjectionPosition (double position)` - Set the position of the widgets' handles in terms of a plane's position. e.g., if ProjectionNormal is 0, all of the x-coordinate values of the handles are set to ProjectionPosition. No attempt is made to ensure that the position is within the bounds of either the underlying image data or the prop on which tracing is performed.
- `double = obj.GetProjectionPosition ()` - Set the position of the widgets' handles in terms of a plane's position. e.g., if ProjectionNormal is 0, all of the x-coordinate values of the handles are set to ProjectionPosition. No attempt is made to ensure that the position is within the bounds of either the underlying image data or the prop on which tracing is performed.
- `obj.SetSnapToImage (int snap)` - Force snapping to image data while tracing. Default is Off.
- `int = obj.GetSnapToImage ()` - Force snapping to image data while tracing. Default is Off.
- `obj.SnapToImageOn ()` - Force snapping to image data while tracing. Default is Off.
- `obj.SnapToImageOff ()` - Force snapping to image data while tracing. Default is Off.
- `obj.SetAutoClose (int )` - In concert with a CaptureRadius value, automatically form a closed path by connecting first to last path points. Default is Off.
- `int = obj.GetAutoClose ()` - In concert with a CaptureRadius value, automatically form a closed path by connecting first to last path points. Default is Off.
- `obj.AutoCloseOn ()` - In concert with a CaptureRadius value, automatically form a closed path by connecting first to last path points. Default is Off.
- `obj.AutoCloseOff ()` - In concert with a CaptureRadius value, automatically form a closed path by connecting first to last path points. Default is Off.
- `obj.SetCaptureRadius (double )` - Set/Get the capture radius for automatic path closing. For image data, capture radius should be half the distance between voxel/pixel centers. Default is 1.0
- `double = obj.GetCaptureRadius ()` - Set/Get the capture radius for automatic path closing. For image data, capture radius should be half the distance between voxel/pixel centers. Default is 1.0
- `obj.GetPath (vtkPolyData pd)` - Grab the points and lines that define the traced path. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and cells representing the line are added to it.
- `vtkGlyphSource2D = obj.GetGlyphSource ()` - Set/Get the type of snapping to image data: center of a pixel/voxel or nearest point defining a pixel/voxel.
- `obj.SetImageSnapType (int )` - Set/Get the type of snapping to image data: center of a pixel/voxel or nearest point defining a pixel/voxel.
- `int = obj.GetImageSnapTypeMinValue ()` - Set/Get the type of snapping to image data: center of a pixel/voxel or nearest point defining a pixel/voxel.
- `int = obj.GetImageSnapTypeMaxValue ()` - Set/Get the type of snapping to image data: center of a pixel/voxel or nearest point defining a pixel/voxel.
- `int = obj.GetImageSnapType ()` - Set/Get the type of snapping to image data: center of a pixel/voxel or nearest point defining a pixel/voxel.
- `obj.SetHandlePosition (int handle, double xyz[3])` - Set/Get the handle position in terms of a zero-based array of handles.
- `obj.SetHandlePosition (int handle, double x, double y, double z)` - Set/Get the handle position in terms of a zero-based array of handles.

- `obj.GetHandlePosition (int handle, double xyz[3])` - Set/Get the handle position in terms of a zero-based array of handles.
- `double = obj.GetHandlePosition (int handle)` - Set/Get the handle position in terms of a zero-based array of handles.
- `int = obj.GetNumberOfHandles ()` - Get the number of handles.
- `obj.SetInteraction (int interact)` - Enable/disable mouse interaction when the widget is visible.
- `int = obj.GetInteraction ()` - Enable/disable mouse interaction when the widget is visible.
- `obj.InteractionOn ()` - Enable/disable mouse interaction when the widget is visible.
- `obj.InteractionOff ()` - Enable/disable mouse interaction when the widget is visible.
- `obj.InitializeHandles (vtkPoints )` - Initialize the widget with a set of points and generate lines between them. If AutoClose is on it will handle the case wherein the first and last points are congruent.
- `int = obj.IsClosed ()` - Is the path closed or open?
- `obj.SetProp (vtkProp prop)` - @deprecated Replaced by vtkImageTracerWidget::SetViewProp() as of VTK 5.0.

42.52 vtkImplicitPlaneRepresentation

42.52.1 Usage

This class is a concrete representation for the vtkImplicitPlaneWidget2. It represents an infinite plane defined by a normal and point in the context of a bounding box. Through interaction with the widget, the plane can be manipulated by adjusting the plane normal or moving the origin point.

To use this representation, you normally define a (plane) origin and (plane) normal. The PlaceWidget() method is also used to intially position the representation.

To create an instance of class vtkImplicitPlaneRepresentation, simply invoke its constructor as follows

```
obj = vtkImplicitPlaneRepresentation
```

42.52.2 Methods

The class vtkImplicitPlaneRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitPlaneRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkImplicitPlaneRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkImplicitPlaneRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `obj.SetOrigin (double x, double y, double z)` - Get the origin of the plane.
- `obj.SetOrigin (double x[3])` - Get the origin of the plane.
- `double = obj.GetOrigin ()` - Get the origin of the plane.
- `obj.GetOrigin (double xyz[3])` - Get the origin of the plane.

- `obj.SetNormal (double x, double y, double z)` - Get the normal to the plane.
- `obj.SetNormal (double x[3])` - Get the normal to the plane.
- `double = obj.GetNormal ()` - Get the normal to the plane.
- `obj.GetNormal (double xyz[3])` - Get the normal to the plane.
- `obj.SetNormalToXAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToXAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToXAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToXAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToYAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToYAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToYAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToYAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToZAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToZAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToZAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToZAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetTubing (int )` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.

- `int = obj.GetTubing ()` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `obj.TubingOn ()` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `obj.TubingOff ()` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `obj.SetDrawPlane (int plane)` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `int = obj.GetDrawPlane ()` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `obj.DrawPlaneOn ()` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `obj.DrawPlaneOff ()` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `obj.SetOutlineTranslation (int )` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `int = obj.GetOutlineTranslation ()` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `obj.OutlineTranslationOn ()` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `obj.OutlineTranslationOff ()` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `obj.SetOutsideBounds (int )` - Turn on/off the ability to move the widget outside of the bounds specified in the initial PlaceWidget() invocation.
- `int = obj.GetOutsideBounds ()` - Turn on/off the ability to move the widget outside of the bounds specified in the initial PlaceWidget() invocation.
- `obj.OutsideBoundsOn ()` - Turn on/off the ability to move the widget outside of the bounds specified in the initial PlaceWidget() invocation.
- `obj.OutsideBoundsOff ()` - Turn on/off the ability to move the widget outside of the bounds specified in the initial PlaceWidget() invocation.
- `obj.SetScaleEnabled (int )` - Turn on/off the ability to scale the widget with the mouse.
- `int = obj.GetScaleEnabled ()` - Turn on/off the ability to scale the widget with the mouse.
- `obj.ScaleEnabledOn ()` - Turn on/off the ability to scale the widget with the mouse.
- `obj.ScaleEnabledOff ()` - Turn on/off the ability to scale the widget with the mouse.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata that defines the plane. The polydata contains a single polygon that is clipped by the bounding box.
- `vtkPolyDataAlgorithm = obj.GetPolyDataAlgorithm ()` - Satisfies superclass API. This returns a pointer to the underlying PolyData (which represents the plane).

- `obj.GetPlane (vtkPlane plane)` - Get the implicit function for the plane. The user must provide the instance of the class vtkPlane. Note that vtkPlane is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data.
- `obj.UpdatePlacement (void )` - Satisfies the superclass API. This will change the state of the widget to match changes that have been made to the underlying PolyDataSource
- `vtkProperty = obj.GetNormalProperty ()` - Get the properties on the normal (line and cone).
- `vtkProperty = obj.GetSelectedNormalProperty ()` - Get the properties on the normal (line and cone).
- `vtkProperty = obj.GetPlaneProperty ()` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedPlaneProperty ()` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.
- `vtkProperty = obj.GetOutlineProperty ()` - Get the property of the outline.
- `vtkProperty = obj.GetSelectedOutlineProperty ()` - Get the property of the outline.
- `vtkProperty = obj.GetEdgesProperty ()` - Get the property of the intersection edges. (This property also applies to the edges when tubed.)
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Methods to interface with the vtkSliderWidget.
- `obj.PlaceWidget (double bounds[6])` - Methods to interface with the vtkSliderWidget.
- `obj.BuildRepresentation ()` - Methods to interface with the vtkSliderWidget.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget.
- `obj.WidgetInteraction (double newEventPos[2])` - Methods to interface with the vtkSliderWidget.
- `obj.EndWidgetInteraction (double newEventPos[2])` - Methods to interface with the vtkSliderWidget.
- `double = obj.GetBounds ()`
- `obj.GetActors (vtkPropCollection pc)`
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `int = obj.RenderOpaqueGeometry (vtkViewport )`
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )`
- `int = obj.HasTranslucentPolygonalGeometry ()`
- `obj.SetInteractionState (int )` - The interaction state may be set from a widget (e.g., vtkImplicitPlaneWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.

- `int = obj.GetInteractionStateMinValue ()` - The interaction state may be set from a widget (e.g., vtkImplicitPlaneWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.

- `int = obj.GetInteractionStateMaxValue ()` - The interaction state may be set from a widget (e.g., vtkImplicitPlaneWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.

- `obj.SetRepresentationState (int )` - Sets the visual appearance of the representation based on the state it is in. This state is usually the same as InteractionState.

- `int = obj.GetRepresentationState ()` - Sets the visual appearance of the representation based on the state it is in. This state is usually the same as InteractionState.

42.53 vtkImplicitPlaneWidget

42.53.1 Usage

This 3D widget defines an infinite plane that can be interactively placed in a scene. The widget is represented by a plane with a normal vector; the plane is contained by a bounding box, and where the plane intersects the bounding box the edges are shown (possibly tubed). The normal can be selected and moved to rotate the plane; the plane itself can be selected and translated in various directions. As the plane is moved, the implicit plane function and polygon (representing the plane cut against the bounding box) is updated.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. If the "i" key (for "interactor") is pressed, the vtkImplicitPlaneWidget will appear. (See superclass documentation for information about changing this behavior.) If you select the normal vector, the plane can be arbitrarily rotated. The plane can be translated along the normal by selecting the plane and moving it. The plane (the plane origin) can also be arbitrary moved by selecting the plane with the middle mouse button. The right mouse button can be used to uniformly scale the bounding box (moving "up" the box scales larger; moving "down" the box scales smaller). Events that occur outside of the widget (i.e., no part of the widget is picked) are propagated to any other registered obsevers (such as the interaction style). Turn off the widget by pressing the "i" key again (or invoke the Off() method).

The vtkImplicitPlaneWidget has several methods that can be used in conjunction with other VTK objects. The GetPolyData() method can be used to get a polygonal representation (the single polygon clipped by the bounding box). Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (either left or right button). (Note: there is also a PlaceWidgetEvent that is invoked when the widget is placed with PlaceWidget().)

Some additional features of this class include the ability to control the properties of the widget. You do this by setting property values on the normal vector (selected and unselected properties); the plane (selected and unselected properties); the outline (selected and unselected properties); and the edges. The edges may also be tubed or not.

To create an instance of class vtkImplicitPlaneWidget, simply invoke its constructor as follows

```
obj = vtkImplicitPlaneWidget
```

42.53.2 Methods

The class vtkImplicitPlaneWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely

intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitPlaneWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitPlaneWidget = obj.NewInstance ()`
- `vtkImplicitPlaneWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Get the origin of the plane.
- `obj.SetOrigin (double x, double y, double z)` - Get the origin of the plane.
- `obj.SetOrigin (double x[3])` - Get the origin of the plane.
- `double = obj.GetOrigin ()` - Get the origin of the plane.
- `obj.GetOrigin (double xyz[3])` - Get the origin of the plane.
- `obj.SetNormal (double x, double y, double z)` - Get the normal to the plane.
- `obj.SetNormal (double x[3])` - Get the normal to the plane.
- `double = obj.GetNormal ()` - Get the normal to the plane.
- `obj.GetNormal (double xyz[3])` - Get the normal to the plane.
- `obj.SetNormalToXAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToXAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToXAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToXAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToYAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToYAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToYAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.

- `obj.NormalToYAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToZAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToZAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToZAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToZAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. If one axis is set on, the other two will be set off. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetTubing (int )` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `int = obj.GetTubing ()` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `obj.TubingOn ()` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `obj.TubingOff ()` - Turn on/off tubing of the wire outline of the plane. The tube thickens the line by wrapping with a vtkTubeFilter.
- `obj.SetDrawPlane (int plane)` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `int = obj.GetDrawPlane ()` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `obj.DrawPlaneOn ()` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `obj.DrawPlaneOff ()` - Enable/disable the drawing of the plane. In some cases the plane interferes with the object that it is operating on (i.e., the plane interferes with the cut surface it produces producing z-buffer artifacts.)
- `obj.SetOutlineTranslation (int )` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `int = obj.GetOutlineTranslation ()` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `obj.OutlineTranslationOn ()` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.
- `obj.OutlineTranslationOff ()` - Turn on/off the ability to translate the bounding box by grabbing it with the left mouse button.

- `obj.SetOutsideBounds (int )` - Turn on/off the ability to move the widget outside of the input's bound
- `int = obj.GetOutsideBounds ()` - Turn on/off the ability to move the widget outside of the input's bound
- `obj.OutsideBoundsOn ()` - Turn on/off the ability to move the widget outside of the input's bound
- `obj.OutsideBoundsOff ()` - Turn on/off the ability to move the widget outside of the input's bound
- `obj.SetScaleEnabled (int )` - Turn on/off the ability to scale with the mouse
- `int = obj.GetScaleEnabled ()` - Turn on/off the ability to scale with the mouse
- `obj.ScaleEnabledOn ()` - Turn on/off the ability to scale with the mouse
- `obj.ScaleEnabledOff ()` - Turn on/off the ability to scale with the mouse
- `obj.SetOriginTranslation (int )` - Turn on/off the ability to translate the origin (sphere) with the left mouse button.
- `int = obj.GetOriginTranslation ()` - Turn on/off the ability to translate the origin (sphere) with the left mouse button.
- `obj.OriginTranslationOn ()` - Turn on/off the ability to translate the origin (sphere) with the left mouse button.
- `obj.OriginTranslationOff ()` - Turn on/off the ability to translate the origin (sphere) with the left mouse button.
- `obj.SetDiagonalRatio (double )` - By default the arrow is 30this ratio in the interval [0-2]
- `double = obj.GetDiagonalRatioMinValue ()` - By default the arrow is 30this ratio in the interval [0-2]
- `double = obj.GetDiagonalRatioMaxValue ()` - By default the arrow is 30this ratio in the interval [0-2]
- `double = obj.GetDiagonalRatio ()` - By default the arrow is 30this ratio in the interval [0-2]
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata that defines the plane. The polydata contains a single polygon that is clipped by the bounding box.
- `vtkPolyDataAlgorithm = obj.GetPolyDataAlgorithm ()` - Satisfies superclass API. This returns a pointer to the underlying PolyData (which represents the plane).
- `obj.GetPlane (vtkPlane plane)` - Get the implicit function for the plane. The user must provide the instance of the class vtkPlane. Note that vtkPlane is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data.
- `obj.UpdatePlacement ()` - Satisfies the superclass API. This will change the state of the widget to match changes that have been made to the underlying PolyDataSource
- `obj.SizeHandles ()` - Control widget appearance
- `vtkProperty = obj.GetNormalProperty ()` - Get the properties on the normal (line and cone).
- `vtkProperty = obj.GetSelectedNormalProperty ()` - Get the properties on the normal (line and cone).
- `vtkProperty = obj.GetPlaneProperty ()` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.

- `vtkProperty = obj.GetSelectedPlaneProperty ()` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.
- `vtkProperty = obj.GetOutlineProperty ()` - Get the property of the outline.
- `vtkProperty = obj.GetSelectedOutlineProperty ()` - Get the property of the outline.
- `vtkProperty = obj.GetEdgesProperty ()` - Get the property of the intersection edges. (This property also applies to the edges when tubed.)

42.54 vtkImplicitPlaneWidget2

42.54.1 Usage

This 3D widget defines an infinite plane that can be interactively placed in a scene. The widget is assumed to consist of four parts: 1) a plane contained in a 2) bounding box, with a 3) plane normal, which is rooted at a 4) point on the plane. (The representation paired with this widget determines the actual geometry of the widget.)

To use this widget, you generally pair it with a vtkImplicitPlaneRepresentation (or a subclass). Variuos options are available for controlling how the representation appears, and how the widget functions.

To create an instance of class vtkImplicitPlaneWidget2, simply invoke its constructor as follows

```
obj = vtkImplicitPlaneWidget2
```

42.54.2 Methods

The class vtkImplicitPlaneWidget2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitPlaneWidget2 class.

- `string = obj.GetClassName ()` - Standard vtkObject methods
- `int = obj.IsA (string name)` - Standard vtkObject methods
- `vtkImplicitPlaneWidget2 = obj.NewInstance ()` - Standard vtkObject methods
- `vtkImplicitPlaneWidget2 = obj.SafeDownCast (vtkObject o)` - Standard vtkObject methods
- `obj.SetRepresentation (vtkImplicitPlaneRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.55 vtkLinearContourLineInterpolator

42.55.1 Usage

The line interpolator interpolates supplied nodes (see InterpolateLine) with line segments. The finess of the curve may be controlled using SetMaximumCurveError and SetMaximumNumberOfLineSegments.

To create an instance of class vtkLinearContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkLinearContourLineInterpolator
```

42.55.2 Methods

The class vtkLinearContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLinearContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkLinearContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkLinearContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)`

42.56 vtkLineRepresentation

42.56.1 Usage

This class is a concrete representation for the vtkLineWidget2. It represents a straight line with three handles: one at the beginning and ending of the line, and one used to translate the line. Through interaction with the widget, the line representation can be arbitrarily placed in the 3D space.

To use this representation, you normally specify the position of the two end points (either in world or display coordinates). The PlaceWidget() method is also used to intially position the representation.

To create an instance of class vtkLineRepresentation, simply invoke its constructor as follows

```
obj = vtkLineRepresentation
```

42.56.2 Methods

The class vtkLineRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLineRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkLineRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkLineRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `obj.GetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `double = obj.GetPoint1WorldPosition ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.
- `obj.GetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `double = obj.GetPoint1DisplayPosition ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint1WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint1DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `double = obj.GetPoint2DisplayPosition ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.GetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `double = obj.GetPoint2WorldPosition ()` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint2WorldPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetPoint2DisplayPosition (double pos[3])` - Methods to Set/Get the coordinates of the two points defining this representation. Note that methods are available for both display and world coordinates.

- `obj.SetHandleRepresentation (vtkPointHandleRepresentation3D handle)` - This method is used to specify the type of handle representation to use for the three internal vtkHandleWidgets within vtkLineWidget2. To use this method, create a dummy vtkHandleWidget (or subclass), and then invoke this method with this dummy. Then the vtkLineRepresentation uses this dummy to clone three vtkHandleWidgets of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkLineWidget2.)

- `obj.InstantiateHandleRepresentation ()` - This method is used to specify the type of handle representation to use for the three internal vtkHandleWidgets within vtkLineWidget2. To use this method, create a dummy vtkHandleWidget (or subclass), and then invoke this method with this dummy. Then the vtkLineRepresentation uses this dummy to clone three vtkHandleWidgets of the same type. Make sure you set the handle representation before the widget is enabled. (The method InstantiateHandleRepresentation() is invoked by the vtkLineWidget2.)

- `vtkPointHandleRepresentation3D = obj.GetPoint1Representation ()` - Get the three handle representations used for the vtkLineWidget2.

- `vtkPointHandleRepresentation3D = obj.GetPoint2Representation ()` - Get the three handle representations used for the vtkLineWidget2.

- `vtkPointHandleRepresentation3D = obj.GetLineHandleRepresentation ()` - Get the three handle representations used for the vtkLineWidget2.

- `vtkProperty = obj.GetEndPointProperty ()` - Get the end-point (sphere) properties. The properties of the end-points when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedEndPointProperty ()` - Get the end-point (sphere) properties. The properties of the end-points when selected and unselected can be manipulated.
- `vtkProperty = obj.GetEndPoint2Property ()` - Get the end-point (sphere) properties. The properties of the end-points when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedEndPoint2Property ()` - Get the end-point (sphere) properties. The properties of the end-points when selected and unselected can be manipulated.
- `vtkProperty = obj.GetLineProperty ()` - Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedLineProperty ()` - Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the line or end point to be active.
- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the line or end point to be active.
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the line or end point to be active.
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the line or end point to be active.
- `obj.SetResolution (int res)` - Set/Get the resolution (number of subdivisions) of the line. A line with resolution greater than one is useful when points along the line are desired; e.g., generating a rake of streamlines.
- `int = obj.GetResolution ()` - Set/Get the resolution (number of subdivisions) of the line. A line with resolution greater than one is useful when points along the line are desired; e.g., generating a rake of streamlines.
- `obj.GetPolyData (vtkPolyData pd)` - Retrieve the polydata (including points) that defines the line. The polydata consists of n+1 points, where n is the resolution of the line. These point values are guaranteed to be up-to-date whenever any one of the three handles are moved. To use this method, the user provides the vtkPolyData as an input argument, and the points and polyline are copied into it.
- `obj.PlaceWidget (double bounds[6])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API.
- `double = obj.GetBounds ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `obj.GetActors (vtkPropCollection pc)` - Methods supporting the rendering process.

- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods supporting the rendering process.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Methods supporting the rendering process.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Methods supporting the rendering process.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods supporting the rendering process.
- `obj.SetInteractionState (int )` - The interaction state may be set from a widget (e.g., vtkLineWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.
- `int = obj.GetInteractionStateMinValue ()` - The interaction state may be set from a widget (e.g., vtkLineWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.
- `int = obj.GetInteractionStateMaxValue ()` - The interaction state may be set from a widget (e.g., vtkLineWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.
- `obj.SetRepresentationState (int )` - Sets the visual appearance of the representation based on the state it is in. This state is usually the same as InteractionState.
- `int = obj.GetRepresentationState ()` - Sets the visual appearance of the representation based on the state it is in. This state is usually the same as InteractionState.
- `long = obj.GetMTime ()` - Overload the superclasses' GetMTime() because internal classes are used to keep the state of the representation.
- `obj.SetRenderer (vtkRenderer ren)` - Overridden to set the rendererer on the internal representations.
- `obj.SetDistanceAnnotationVisibility (int )` - Show the distance between the points
- `int = obj.GetDistanceAnnotationVisibility ()` - Show the distance between the points
- `obj.DistanceAnnotationVisibilityOn ()` - Show the distance between the points
- `obj.DistanceAnnotationVisibilityOff ()` - Show the distance between the points
- `obj.SetDistanceAnnotationFormat (string )` - Specify the format to use for labelling the angle. Note that an empty string results in no label, or a format string without a "will not print the angle value.
- `string = obj.GetDistanceAnnotationFormat ()` - Specify the format to use for labelling the angle. Note that an empty string results in no label, or a format string without a "will not print the angle value.
- `obj.SetDistanceAnnotationScale (double scale[3])` - Scale text (font size along each dimension).
- `double = obj.GetDistance ()` - Get the distance between the points.
- `obj.SetLineColor (double r, double g, double b)` - Convenience method to set the line color. Ideally one should use GetLineProperty()-¿SetColor().

- `vtkProperty = obj.GetDistanceAnnotationProperty ()` - Get the distance annotation property
- `vtkFollower = obj.GetTextActor ()` - Get the text actor

42.57 vtkLineWidget

42.57.1 Usage

This 3D widget defines a line that can be interactively placed in a scene. The line has two handles (at its endpoints), plus the line can be picked to translate it in the scene. A nice feature of the object is that the vtkLineWidget, like any 3D widget, will work with the current interactor style and any other widgets present in the scene. That is, if vtkLineWidget does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkLineWidget will terminate the processing of the event that it handles.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. The interactor will act normally until the "i" key (for "interactor") is pressed, at which point the vtkLineWidget will appear. (See superclass documentation for information about changing this behavior.) By grabbing one of the two end point handles (use the left mouse button), the line can be oriented and stretched (the other end point remains fixed). By grabbing the line itself, or using the middle mouse button, the entire line can be translated. Scaling (about the center of the line) is achieved by using the right mouse button. By moving the mouse "up" the render window the line will be made bigger; by moving "down" the render window the widget will be made smaller. Turn off the widget by pressing the "i" key again (or invoke the Off() method). (Note: picking the line or either one of the two end point handles causes a vtkPointWidget to appear. This widget has the ability to constrain motion to an axis by pressing the "shift" key while moving the mouse.)

The vtkLineWidget has several methods that can be used in conjunction with other VTK objects. The Set/GetResolution() methods control the number of subdivisions of the line; the GetPolyData() method can be used to get the polygonal representation and can be used for things like seeding streamlines. Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (either left or right button).

Some additional features of this class include the ability to control the properties of the widget. You can set the properties of the selected and unselected representations of the line. For example, you can set the property for the handles and line. In addition there are methods to constrain the line so that it is aligned along the x-y-z axes.

To create an instance of class vtkLineWidget, simply invoke its constructor as follows

```
obj = vtkLineWidget
```

42.57.2 Methods

The class vtkLineWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLineWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLineWidget = obj.NewInstance ()`
- `vtkLineWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.

- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set/Get the resolution (number of subdivisions) of the line.
- `obj.SetResolution (int r)` - Set/Get the resolution (number of subdivisions) of the line.
- `int = obj.GetResolution ()` - Set/Get the position of first end point.
- `obj.SetPoint1 (double x, double y, double z)` - Set/Get the position of first end point.
- `obj.SetPoint1 (double x[3])` - Set/Get the position of first end point.
- `double = obj.GetPoint1 ()` - Set/Get the position of first end point.
- `obj.GetPoint1 (double xyz[3])` - Set position of other end point.
- `obj.SetPoint2 (double x, double y, double z)` - Set position of other end point.
- `obj.SetPoint2 (double x[3])` - Set position of other end point.
- `double = obj.GetPoint2 ()` - Set position of other end point.
- `obj.GetPoint2 (double xyz[3])` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `obj.SetAlign (int )` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `int = obj.GetAlignMinValue ()` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `int = obj.GetAlignMaxValue ()` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `int = obj.GetAlign ()` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `obj.SetAlignToXAxis ()` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `obj.SetAlignToYAxis ()` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `obj.SetAlignToZAxis ()` - Force the line widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the line to the axes if it is orginally not aligned.
- `obj.SetAlignToNone ()` - Enable/disable clamping of the point end points to the bounding box of the data. The bounding box is defined from the last PlaceWidget() invocation, and includes the effect of the PlaceFactor which is used to gram/shrink the bounding box.
- `obj.SetClampToBounds (int )` - Enable/disable clamping of the point end points to the bounding box of the data. The bounding box is defined from the last PlaceWidget() invocation, and includes the effect of the PlaceFactor which is used to gram/shrink the bounding box.

- `int = obj.GetClampToBounds ()` - Enable/disable clamping of the point end points to the bounding box of the data. The bounding box is defined from the last PlaceWidget() invocation, and includes the effect of the PlaceFactor which is used to gram/shrink the bounding box.
- `obj.ClampToBoundsOn ()` - Enable/disable clamping of the point end points to the bounding box of the data. The bounding box is defined from the last PlaceWidget() invocation, and includes the effect of the PlaceFactor which is used to gram/shrink the bounding box.
- `obj.ClampToBoundsOff ()` - Enable/disable clamping of the point end points to the bounding box of the data. The bounding box is defined from the last PlaceWidget() invocation, and includes the effect of the PlaceFactor which is used to gram/shrink the bounding box.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the line. The polydata consists of n+1 points, where n is the resolution of the line. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polyline are added to it.
- `vtkProperty = obj.GetHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be manipulated.
- `vtkProperty = obj.GetLineProperty ()` - Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedLineProperty ()` - Get the line properties. The properties of the line when selected and unselected can be manipulated.

42.58 vtkLineWidget2

42.58.1 Usage

This 3D widget defines a straight line that can be interactively placed in a scene. The widget is assumed to consist of two parts: 1) two end points and 2) a straight line connecting the two points. (The representation paired with this widget determines the actual geometry of the widget.) The positioning of the two end points is facilitated by using vtkHandleWidgets to position the points.

To use this widget, you generally pair it with a vtkLineRepresentation (or a subclass). Variuos options are available in the representation for controlling how the widget appears, and how the widget functions.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
 If one of the two end points are selected:
   LeftButtonPressEvent - activate the associated handle widget
   LeftButtonReleaseEvent - release the handle widget associated with the point
   MouseMoveEvent - move the point
 If the line is selected:
   LeftButtonPressEvent - activate a handle widget accociated with the line
   LeftButtonReleaseEvent - release the handle widget associated with the line
   MouseMoveEvent - translate the line
 In all the cases, independent of what is picked, the widget responds to the
 following VTK events:
   MiddleButtonPressEvent - translate the widget
   MiddleButtonReleaseEvent - release the widget
   RightButtonPressEvent - scale the widget's representation
   RightButtonReleaseEvent - stop scaling the widget
   MouseMoveEvent - scale (if right button) or move (if middle button) the widget
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkLineWidget2's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for slider motion has been invoked
```

In turn, when these widget events are processed, the vtkLineWidget2 invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkLineWidget2, simply invoke its constructor as follows

```
obj = vtkLineWidget2
```

42.58.2 Methods

The class vtkLineWidget2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLineWidget2 class.

- `string = obj.GetClassName ()` - Standard vtkObject methods
- `int = obj.IsA (string name)` - Standard vtkObject methods
- `vtkLineWidget2 = obj.NewInstance ()` - Standard vtkObject methods
- `vtkLineWidget2 = obj.SafeDownCast (vtkObject o)` - Standard vtkObject methods
- `obj.SetEnabled (int enabling)` - Override superclasses' SetEnabled() method because the line widget must enable its internal handle widgets.
- `obj.SetRepresentation (vtkLineRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Overridden to pass the state to component widgets.

42.59 vtkLogoRepresentation

42.59.1 Usage

To create an instance of class vtkLogoRepresentation, simply invoke its constructor as follows

```
obj = vtkLogoRepresentation
```

42.59.2 Methods

The class vtkLogoRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLogoRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK class methods.
- `int = obj.IsA (string name)` - Standard VTK class methods.
- `vtkLogoRepresentation = obj.NewInstance ()` - Standard VTK class methods.
- `vtkLogoRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK class methods.
- `obj.SetImage (vtkImageData img)` - Specify/retrieve the image to display in the balloon.
- `vtkImageData = obj.GetImage ()` - Specify/retrieve the image to display in the balloon.
- `obj.SetImageProperty (vtkProperty2D p)` - Set/get the image property (relevant only if an image is shown).
- `vtkProperty2D = obj.GetImageProperty ()` - Set/get the image property (relevant only if an image is shown).
- `obj.BuildRepresentation ()` - Satisfy the superclasses' API.
- `obj.GetActors2D (vtkPropCollection pc)` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.

42.60 vtkLogoWidget

42.60.1 Usage

This class provides support for interactively displaying and manipulating a logo. Logos are defined by an image; this widget simply allows you to interactively place and resize the image logo. To use this widget, simply create a vtkLogoRepresentation (or subclass) and associate it with the vtkLogoWidget.

To create an instance of class vtkLogoWidget, simply invoke its constructor as follows

```
obj = vtkLogoWidget
```

42.60.2 Methods

The class vtkLogoWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLogoWidget class.

- `string = obj.GetClassName ()` - Standar VTK class methods.
- `int = obj.IsA (string name)` - Standar VTK class methods.
- `vtkLogoWidget = obj.NewInstance ()` - Standar VTK class methods.

- `vtkLogoWidget = obj.SafeDownCast (vtkObject o)` - Standar VTK class methods.
- `obj.SetRepresentation (vtkLogoRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.61 vtkOrientationMarkerWidget

42.61.1 Usage

This class provides support for interactively manipulating the position, size, and apparent orientation of a prop that represents an orientation marker. This class works by adding its internal renderer to an external "parent" renderer on a different layer. The input orientation marker is rendered as an overlay on the parent renderer and, thus, appears superposed over all props in the parent's scene. The camera view of the orientation the marker is made to match that of the parent's by means of an observer mechanism, giving the illusion that the orientation of the marker reflects that of the prop(s) in the parent's scene.

The widget listens to left mouse button and mouse movement events. It will change the cursor shape based on its location. If the cursor is over the overlay renderer, it will change the cursor shape to a SIZEALL shape or to a resize corner shape (e.g., SIZENW) if the cursor is near a corner. If the left mouse button is pressed and held down while moving, the overlay renderer, and hence, the orientation marker, is resized or moved. I the case of a resize operation, releasing the left mouse button causes the widget to enforce its renderer to be square. The diagonally opposite corner to the one moved is repositioned such that all edges of the renderer have the same length: the minimum.

To use this object, there are two key steps: 1) invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor, and 2) invoke SetOrientationMarker with an instance of vtkProp (see caveats below). Specifically, vtkAxesActor and vtkAnnotatedCubeActor are two classes designed to work with this class. A composite orientation marker can be generated by adding instances of vtkAxesActor and vtkAnnotatedCubeActor to a vtkPropAssembly, which can then be set as the input orientation marker. The widget can be also be set up in a non-interactive fashion by setting Ineractive to Off and sizing/placing the overlay renderer in its parent renderer by calling the widget's SetViewport method.

To create an instance of class vtkOrientationMarkerWidget, simply invoke its constructor as follows

```
obj = vtkOrientationMarkerWidget
```

42.61.2 Methods

The class vtkOrientationMarkerWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOrientationMarkerWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOrientationMarkerWidget = obj.NewInstance ()`
- `vtkOrientationMarkerWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetOrientationMarker (vtkProp prop)` - Set/get the orientation marker to be displayed in this widget.
- `vtkProp = obj.GetOrientationMarker ()` - Set/get the orientation marker to be displayed in this widget.
- `obj.SetEnabled (int )` - Enable/disable the widget. Default is 0 (disabled).

- `obj.SetInteractive (int state)` - Set/get whether to allow this widget to be interactively moved/scaled. Default is On.
- `int = obj.GetInteractive ()` - Set/get whether to allow this widget to be interactively moved/scaled. Default is On.
- `obj.InteractiveOn ()` - Set/get whether to allow this widget to be interactively moved/scaled. Default is On.
- `obj.InteractiveOff ()` - Set/get whether to allow this widget to be interactively moved/scaled. Default is On.
- `obj.SetOutlineColor (double r, double g, double b)` - Set/get the color of the outline of this widget. The outline is visible when (in interactive mode) the cursor is over this widget. Default is white (1,1,1).
- `obj.SetViewport (double minX, double minY, double maxX, double maxY)` - Set/get the viewport to position/size this widget. Default is bottom left corner (0,0,0.2,0.2).
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).

42.62 vtkOrientedGlyphContourRepresentation

42.62.1 Usage

This class provides the default concrete representation for the vtkContourWidget. It works in conjunction with the vtkContourLineInterpolator and vtkPointPlacer. See vtkContourWidget for details.

To create an instance of class vtkOrientedGlyphContourRepresentation, simply invoke its constructor as follows

```
obj = vtkOrientedGlyphContourRepresentation
```

42.62.2 Methods

The class vtkOrientedGlyphContourRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOrientedGlyphContourRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkOrientedGlyphContourRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.

- `vtkOrientedGlyphContourRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetCursorShape (vtkPolyData cursorShape)` - Specify the cursor shape. Keep in mind that the shape will be aligned with the constraining plane by orienting it such that the x axis of the geometry lies along the normal of the plane.
- `vtkPolyData = obj.GetCursorShape ()` - Specify the cursor shape. Keep in mind that the shape will be aligned with the constraining plane by orienting it such that the x axis of the geometry lies along the normal of the plane.
- `obj.SetActiveCursorShape (vtkPolyData activeShape)` - Specify the shape of the cursor (handle) when it is active. This is the geometry that will be used when the mouse is close to the handle or if the user is manipulating the handle.
- `vtkPolyData = obj.GetActiveCursorShape ()` - Specify the shape of the cursor (handle) when it is active. This is the geometry that will be used when the mouse is close to the handle or if the user is manipulating the handle.
- `vtkProperty = obj.GetProperty ()` - This is the property used when the handle is not active (the mouse is not near the handle)
- `vtkProperty = obj.GetActiveProperty ()` - This is the property used when the user is interacting with the handle.
- `vtkProperty = obj.GetLinesProperty ()` - This is the property used by the lines.
- `obj.SetRenderer (vtkRenderer ren)` - Subclasses of vtkOrientedGlyphContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.BuildRepresentation ()` - Subclasses of vtkOrientedGlyphContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses of vtkOrientedGlyphContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses of vtkOrientedGlyphContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `int = obj.ComputeInteractionState (int X, int Y, int modified)` - Subclasses of vtkOrientedGlyphContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.GetActors (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.

- `vtkPolyData = obj.GetContourRepresentationAsPolyData ()` - Get the points in this contour as a vtkPolyData.
- `obj.SetAlwaysOnTop (int )` - Controls whether the contour widget should always appear on top of other actors in the scene. (In effect, this will disable OpenGL Depth buffer tests while rendering the contour). Default is to set it to false.
- `int = obj.GetAlwaysOnTop ()` - Controls whether the contour widget should always appear on top of other actors in the scene. (In effect, this will disable OpenGL Depth buffer tests while rendering the contour). Default is to set it to false.
- `obj.AlwaysOnTopOn ()` - Controls whether the contour widget should always appear on top of other actors in the scene. (In effect, this will disable OpenGL Depth buffer tests while rendering the contour). Default is to set it to false.
- `obj.AlwaysOnTopOff ()` - Controls whether the contour widget should always appear on top of other actors in the scene. (In effect, this will disable OpenGL Depth buffer tests while rendering the contour). Default is to set it to false.
- `obj.SetLineColor (double r, double g, double b)` - Convenience method to set the line color. Ideally one should use GetLinesProperty()-¿SetColor().
- `obj.SetShowSelectedNodes (int )` - A flag to indicate whether to show the Selected nodes Default is to set it to false.

42.63 vtkOrientedGlyphFocalPlaneContourRepresentation

42.63.1 Usage

This class is used to represent a contour drawn on the focal plane (usually overlayed on top of an image or volume widget). The class was written in order to be able to draw contours on a volume widget and have the contours overlayed on the focal plane in order to do contour segmentation.

To create an instance of class vtkOrientedGlyphFocalPlaneContourRepresentation, simply invoke its constructor as follows

```
obj = vtkOrientedGlyphFocalPlaneContourRepresentation
```

42.63.2 Methods

The class vtkOrientedGlyphFocalPlaneContourRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOrientedGlyphFocalPlaneContourRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkOrientedGlyphFocalPlaneContourRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkOrientedGlyphFocalPlaneContourRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetCursorShape (vtkPolyData cursorShape)` - Specify the cursor shape. Keep in mind that the shape will be aligned with the constraining plane by orienting it such that the x axis of the geometry lies along the normal of the plane.

- `vtkPolyData = obj.GetCursorShape ()` - Specify the cursor shape. Keep in mind that the shape will be aligned with the constraining plane by orienting it such that the x axis of the geometry lies along the normal of the plane.
- `obj.SetActiveCursorShape (vtkPolyData activeShape)` - Specify the shape of the cursor (handle) when it is active. This is the geometry that will be used when the mouse is close to the handle or if the user is manipulating the handle.
- `vtkPolyData = obj.GetActiveCursorShape ()` - Specify the shape of the cursor (handle) when it is active. This is the geometry that will be used when the mouse is close to the handle or if the user is manipulating the handle.
- `vtkProperty2D = obj.GetProperty ()` - This is the property used when the handle is not active (the mouse is not near the handle)
- `vtkProperty2D = obj.GetActiveProperty ()` - This is the property used when the user is interacting with the handle.
- `vtkProperty2D = obj.GetLinesProperty ()` - This is the property used by the lines.
- `obj.SetRenderer (vtkRenderer ren)` - Subclasses of vtkOrientedGlyphFocalPlaneContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.BuildRepresentation ()` - Subclasses of vtkOrientedGlyphFocalPlaneContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses of vtkOrientedGlyphFocalPlaneContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses of vtkOrientedGlyphFocalPlaneContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `int = obj.ComputeInteractionState (int X, int Y, int modified)` - Subclasses of vtkOrientedGlyphFocalPlaneContourRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.GetActors2D (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.
- `vtkPolyData = obj.GetContourRepresentationAsPolyData ()` - Get the points in this contour as a vtkPolyData.
- `vtkMatrix4x4 = obj.GetContourPlaneDirectionCosines (double origin[3])` - Direction cosines of the plane on which the contour lies on in world co-ordinates. This would be the same matrix that would be set in vtkImageReslice or vtkImagePlaneWidget if there were a plane passing through the contour points. The origin must be the origin of the data under the contour.

42.64 vtkOrientedPolygonalHandleRepresentation3D

42.64.1 Usage

This class serves as the geometrical representation of a vtkHandleWidget. The handle can be represented by an arbitrary polygonal data (vtkPolyData), set via SetHandle(vtkPolyData *). The actual position of the handle will be initially assumed to be (0,0,0). You can specify an offset from this position if desired. This class differs from vtkPolygonalHandleRepresentation3D in that the handle will always remain front facing, ie it maintains a fixed orientation with respect to the camera. This is done by using vtkFollowers internally to render the actors.

To create an instance of class vtkOrientedPolygonalHandleRepresentation3D, simply invoke its constructor as follows

```
obj = vtkOrientedPolygonalHandleRepresentation3D
```

42.64.2 Methods

The class vtkOrientedPolygonalHandleRepresentation3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOrientedPolygonalHandleRepresentation3D class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkOrientedPolygonalHandleRepresentation3D = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkOrientedPolygonalHandleRepresentation3D = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.

42.65 vtkParallelopipedRepresentation

42.65.1 Usage

This class provides the default geometrical representation for vtkParallelopipedWidget. As a result of interactions of the widget, this representation can take on of the following shapes: ¡p¿1) A parallelopiped. (8 handles, 6 faces) ¡p¿2) Paralleopiped with a chair depression on any one handle. (A chair is a depression on one of the handles that carves inwards so as to allow the user to visualize cuts in the volume). (14 handles, 9 faces).

To create an instance of class vtkParallelopipedRepresentation, simply invoke its constructor as follows

```
obj = vtkParallelopipedRepresentation
```

42.65.2 Methods

The class vtkParallelopipedRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelopipedRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkParallelopipedRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.

- `vtkParallelopipedRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.GetActors (vtkPropCollection pc)` - Methods to satisfy the superclass.
- `obj.PlaceWidget (double bounds[6])` - Place the widget in the scene. You can use either of the two APIs : 1) PlaceWidget(double bounds[6]) Creates a cuboid conforming to the said bounds. 2) PlaceWidget(double corners[8][3]) Creates a parallelopiped with corners specified. The order in which corners are specified must obey the following rule: Corner 0 - 1 - 2 - 3 - 0 forms a face Corner 4 - 5 - 6 - 7 - 4 forms a face Corner 0 - 4 - 5 - 1 - 0 forms a face Corner 1 - 5 - 6 - 2 - 1 forms a face Corner 2 - 6 - 7 - 3 - 2 forms a face Corner 3 - 7 - 4 - 0 - 3 forms a face
- `obj.SetInteractionState (int )` - The interaction state may be set from a widget (e.g., PointWidget) or other object. This controls how the interaction with the widget proceeds.
- `obj.GetBoundingPlanes (vtkPlaneCollection pc)` - Get the bounding planes of the object. The first 6 planes will be bounding planes of the parallelopiped. If in chair mode, three additional planes will be present. The last three planes will be those of the chair. The normals of all the planes will point into the object.
- `obj.GetPolyData (vtkPolyData pd)` - The parallelopiped polydata.
- `double = obj.GetBounds ()` - The parallelopiped polydata.
- `obj.SetHandleProperty (vtkProperty )` - Set/Get the handle properties.
- `obj.SetHoveredHandleProperty (vtkProperty )` - Set/Get the handle properties.
- `obj.SetSelectedHandleProperty (vtkProperty )` - Set/Get the handle properties.
- `vtkProperty = obj.GetHandleProperty ()` - Set/Get the handle properties.
- `vtkProperty = obj.GetHoveredHandleProperty ()` - Set/Get the handle properties.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Set/Get the handle properties.
- `obj.SetHandleRepresentation (vtkHandleRepresentation handle)`
- `vtkHandleRepresentation = obj.GetHandleRepresentation (int index)`
- `obj.HandlesOn ()` - Turns the visibility of the handles on/off. Sometimes they may get in the way of visualization.
- `obj.HandlesOff ()` - Turns the visibility of the handles on/off. Sometimes they may get in the way of visualization.
- `vtkProperty = obj.GetFaceProperty ()` - Get the face properties. When a face is being translated, the face gets highlighted with the SelectedFaceProperty.
- `vtkProperty = obj.GetSelectedFaceProperty ()` - Get the face properties. When a face is being translated, the face gets highlighted with the SelectedFaceProperty.
- `vtkProperty = obj.GetOutlineProperty ()` - Get the outline properties. These are the properties with which the parallelopiped wireframe is rendered.
- `vtkProperty = obj.GetSelectedOutlineProperty ()` - Get the outline properties. These are the properties with which the parallelopiped wireframe is rendered.
- `obj.BuildRepresentation ()` - This actually constructs the geometry of the widget from the various data parameters.
- `obj.ReleaseGraphicsResources (vtkWindow w)` - Methods required by vtkProp superclass.

- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods required by vtkProp superclass.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Given and x-y display coordinate, compute the interaction state of the widget.
- `obj.Translate (double translation[3])`
- `obj.Translate (int X, int Y)`
- `obj.Scale (int X, int Y)`
- `obj.PositionHandles ()` - Synchronize the parallelopiped handle positions with the Polygonal datastructure.
- `obj.SetMinimumThickness (double )` - Minimum thickness for the parallelopiped. User interactions cannot make any individual axis of the parallopiped thinner than this value. Default is 0.05 expressed as a fraction of the diagonal of the bounding box used in the PlaceWidget() invocation.
- `double = obj.GetMinimumThickness ()` - Minimum thickness for the parallelopiped. User interactions cannot make any individual axis of the parallopiped thinner than this value. Default is 0.05 expressed as a fraction of the diagonal of the bounding box used in the PlaceWidget() invocation.

42.66 vtkParallelopipedWidget

42.66.1 Usage

This widget was designed with the aim of visualizing / probing cuts on a skewed image data / structured grid.

.SECTION Interaction The widget allows you to create a parallelopiped (defined by 8 handles). The widget is initially placed by using the "PlaceWidget" method in the representation class. After the widget has been created, the following interactions may be used to manipulate it : 1) Click on a handle and drag it around moves the handle in space, while keeping the same axis alignment of the parallelopiped 2) Dragging a handle with the shift button pressed resizes the piped along an axis. 3) Control-click on a handle creates a chair at that position. (A chair is a depression in the piped that allows you to visualize cuts in the volume). 4) Clicking on a chair and dragging it around moves the chair within the piped. 5) Shift-click on the piped enables you to translate it.

To create an instance of class vtkParallelopipedWidget, simply invoke its constructor as follows

```
obj = vtkParallelopipedWidget
```

42.66.2 Methods

The class vtkParallelopipedWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParallelopipedWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParallelopipedWidget = obj.NewInstance ()`
- `vtkParallelopipedWidget = obj.SafeDownCast (vtkObject o)`

- `obj.SetEnabled (int )` - Override the superclass method. This is a composite widget, (it internally consists of handle widgets). We will override the superclass method, so that we can pass the enabled state to the internal widgets as well.
- `obj.SetRepresentation (vtkParallelopipedRepresentation r)` - Enable/disable the creation of a chair on this widget. If off, chairs cannot be created.
- `obj.SetEnableChairCreation (int )` - Enable/disable the creation of a chair on this widget. If off, chairs cannot be created.
- `int = obj.GetEnableChairCreation ()` - Enable/disable the creation of a chair on this widget. If off, chairs cannot be created.
- `obj.EnableChairCreationOn ()` - Enable/disable the creation of a chair on this widget. If off, chairs cannot be created.
- `obj.EnableChairCreationOff ()` - Enable/disable the creation of a chair on this widget. If off, chairs cannot be created.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Overridden to pass the state to component widgets.

42.67 vtkPlaneWidget

42.67.1 Usage

This 3D widget defines a finite (bounded) plane that can be interactively placed in a scene. The plane has four handles (at its corner vertices), a normal vector, and the plane itself. The handles are used to resize the plane; the normal vector to rotate it, and the plane can be picked and translated. Selecting the plane while pressing CTRL makes it spin around the normal. A nice feature of the object is that the vtkPlaneWidget, like any 3D widget, will work with the current interactor style. That is, if vtkPlaneWidget does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkPlaneWidget will terminate the processing of the event that it handles.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. If the "i" key (for "interactor") is pressed, the vtkPlaneWidget will appear. (See superclass documentation for information about changing this behavior.) By grabbing the one of the four handles (use the left mouse button), the plane can be resized. By grabbing the plane itself, the entire plane can be arbitrarily translated. Pressing CTRL while grabbing the plane will spin the plane around the normal. If you select the normal vector, the plane can be arbitrarily rotated. Selecting any part of the widget with the middle mouse button enables translation of the plane along its normal. (Once selected using middle mouse, moving the mouse in the direction of the normal translates the plane in the direction of the normal; moving in the direction opposite the normal translates the plane in the direction opposite the normal.) Scaling (about the center of the plane) is achieved by using the right mouse button. By moving the mouse "up" the render window the plane will be made bigger; by moving "down" the render window the widget will be made smaller. Events that occur outside of the widget (i.e., no part of the widget is picked) are propagated to any other registered obsevers (such as the interaction style). Turn off the widget by pressing the "i" key again (or invoke the Off() method).

The vtkPlaneWidget has several methods that can be used in conjunction with other VTK objects. The Set/GetResolution() methods control the number of subdivisions of the plane; the GetPolyData() method can be used to get the polygonal representation and can be used for things like seeding stream lines. GetPlane() can be used to update a vtkPlane implicit function. Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (either left or right button).

Some additional features of this class include the ability to control the properties of the widget. You can set the properties of the selected and unselected representations of the plane. For example, you can set the property for the handles and plane. In addition there are methods to constrain the plane so that it is perpendicular to the x-y-z axes.

To create an instance of class vtkPlaneWidget, simply invoke its constructor as follows

```
obj = vtkPlaneWidget
```

42.67.2 Methods

The class vtkPlaneWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlaneWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPlaneWidget = obj.NewInstance ()`
- `vtkPlaneWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set/Get the resolution (number of subdivisions) of the plane.
- `obj.SetResolution (int r)` - Set/Get the resolution (number of subdivisions) of the plane.
- `int = obj.GetResolution ()` - Set/Get the resolution (number of subdivisions) of the plane.
- `obj.SetOrigin (double x, double y, double z)` - Set/Get the origin of the plane.
- `obj.SetOrigin (double x[3])` - Set/Get the origin of the plane.
- `double = obj.GetOrigin ()` - Set/Get the origin of the plane.
- `obj.GetOrigin (double xyz[3])` - Set/Get the origin of the plane.
- `obj.SetPoint1 (double x, double y, double z)` - Set/Get the position of the point defining the first axis of the plane.
- `obj.SetPoint1 (double x[3])` - Set/Get the position of the point defining the first axis of the plane.
- `double = obj.GetPoint1 ()` - Set/Get the position of the point defining the first axis of the plane.
- `obj.GetPoint1 (double xyz[3])` - Set/Get the position of the point defining the first axis of the plane.
- `obj.SetPoint2 (double x, double y, double z)` - Set/Get the position of the point defining the second axis of the plane.
- `obj.SetPoint2 (double x[3])` - Set/Get the position of the point defining the second axis of the plane.
- `double = obj.GetPoint2 ()` - Set/Get the position of the point defining the second axis of the plane.

- `obj.GetPoint2 (double xyz[3])` - Set/Get the position of the point defining the second axis of the plane.
- `obj.SetCenter (double x, double y, double z)` - Get the center of the plane.
- `obj.SetCenter (double x[3])` - Get the center of the plane.
- `double = obj.GetCenter ()` - Get the center of the plane.
- `obj.GetCenter (double xyz[3])` - Get the center of the plane.
- `obj.SetNormal (double x, double y, double z)` - Get the normal to the plane.
- `obj.SetNormal (double x[3])` - Get the normal to the plane.
- `double = obj.GetNormal ()` - Get the normal to the plane.
- `obj.GetNormal (double xyz[3])` - Get the normal to the plane.
- `obj.SetRepresentation (int )` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `int = obj.GetRepresentationMinValue ()` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `int = obj.GetRepresentationMaxValue ()` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `int = obj.GetRepresentation ()` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `obj.SetRepresentationToOff ()` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `obj.SetRepresentationToOutline ()` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `obj.SetRepresentationToWireframe ()` - Control how the plane appears when GetPolyData() is invoked. If the mode is "outline", then just the outline of the plane is shown. If the mode is "wireframe" then the plane is drawn with the outline plus the interior mesh (corresponding to the resolution specified). If the mode is "surface" then the plane is drawn as a surface.
- `obj.SetRepresentationToSurface ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToXAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.

- `int = obj.GetNormalToXAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToXAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToXAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToYAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToYAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToYAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToYAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.SetNormalToZAxis (int )` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `int = obj.GetNormalToZAxis ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToZAxisOn ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.NormalToZAxisOff ()` - Force the plane widget to be aligned with one of the x-y-z axes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the plane to the axes if it is orginally not aligned.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the plane. The polydata consists of (res+1)*(res+1) points, and res*res quadrilateral polygons, where res is the resolution of the plane. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polyplane are added to it.
- `obj.GetPlane (vtkPlane plane)` - Get the planes describing the implicit function defined by the plane widget. The user must provide the instance of the class vtkPlane. Note that vtkPlane is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data.
- `vtkPolyDataAlgorithm = obj.GetPolyDataAlgorithm ()` - Satisfies superclass API. This returns a pointer to the underlying PolyData. Make changes to this before calling the initial PlaceWidget() to have the initial placement follow suit. Or, make changes after the widget has been initialised and call UpdatePlacement() to realise.

- `obj.UpdatePlacement (void )` - Satisfies superclass API. This will change the state of the widget to match changes that have been made to the underlying PolyDataSource
- `vtkProperty = obj.GetHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be manipulated.
- `obj.SetPlaneProperty (vtkProperty )` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.
- `vtkProperty = obj.GetPlaneProperty ()` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedPlaneProperty ()` - Get the plane properties. The properties of the plane when selected and unselected can be manipulated.

42.68 vtkPlaybackRepresentation

42.68.1 Usage

This class is used to represent the vtkPlaybackWidget. Besides defining geometry, this class defines a series of virtual method stubs that are meant to be subclassed by applications for controlling playback.

To create an instance of class vtkPlaybackRepresentation, simply invoke its constructor as follows

```
obj = vtkPlaybackRepresentation
```

42.68.2 Methods

The class vtkPlaybackRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlaybackRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK class methods.
- `int = obj.IsA (string name)` - Standard VTK class methods.
- `vtkPlaybackRepresentation = obj.NewInstance ()` - Standard VTK class methods.
- `vtkPlaybackRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK class methods.
- `vtkProperty2D = obj.GetProperty ()` - By obtaining this property you can specify the properties of the representation.
- `obj.Play ()` - Virtual callbacks that subclasses should implement.
- `obj.Stop ()` - Virtual callbacks that subclasses should implement.
- `obj.ForwardOneFrame ()` - Virtual callbacks that subclasses should implement.
- `obj.BackwardOneFrame ()` - Virtual callbacks that subclasses should implement.
- `obj.JumpToBeginning ()` - Virtual callbacks that subclasses should implement.
- `obj.JumpToEnd ()` - Satisfy the superclasses' API.
- `obj.BuildRepresentation ()` - Satisfy the superclasses' API.

- `obj.GetSize (double size[2])` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.GetActors2D (vtkPropCollection )` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - These methods are necessary to make this representation behave as a vtkProp.

42.69 vtkPlaybackWidget

42.69.1 Usage

This class provides support for interactively controlling the playback of a serial stream of information (e.g., animation sequence, video, etc.). Controls for play, stop, advance one step forward, advance one step backward, jump to beginning, and jump to end are available.

To create an instance of class vtkPlaybackWidget, simply invoke its constructor as follows

```
obj = vtkPlaybackWidget
```

42.69.2 Methods

The class vtkPlaybackWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlaybackWidget class.

- `string = obj.GetClassName ()` - Standar VTK class methods.
- `int = obj.IsA (string name)` - Standar VTK class methods.
- `vtkPlaybackWidget = obj.NewInstance ()` - Standar VTK class methods.
- `vtkPlaybackWidget = obj.SafeDownCast (vtkObject o)` - Standar VTK class methods.
- `obj.SetRepresentation (vtkPlaybackRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.70 vtkPointHandleRepresentation2D

42.70.1 Usage

This class is used to represent a vtkHandleWidget. It represents a position in 2D world coordinates using a x-y cursor (the cursor defined by an instance of vtkPolyData and generated by a vtkPolyDataAlgorithm).

To create an instance of class vtkPointHandleRepresentation2D, simply invoke its constructor as follows

```
obj = vtkPointHandleRepresentation2D
```

42.70.2 Methods

The class vtkPointHandleRepresentation2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointHandleRepresentation2D class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPointHandleRepresentation2D = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPointHandleRepresentation2D = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetCursorShape (vtkPolyData cursorShape)` - Specify the cursor shape with an instance of vtkPolyData. Note that shape is assumed to be defined in the display coordinate system. By default a vtkCursor2D shape is used.
- `vtkPolyData = obj.GetCursorShape ()` - Specify the cursor shape with an instance of vtkPolyData. Note that shape is assumed to be defined in the display coordinate system. By default a vtkCursor2D shape is used.
- `obj.SetDisplayPosition (double xyz[3])` - Set/Get the position of the point in display coordinates. This overloads the superclasses SetDisplayPosition in order to set the focal point of the cursor.
- `obj.SetProperty (vtkProperty2D )` - Set/Get the handle properties when unselected and selected.
- `obj.SetSelectedProperty (vtkProperty2D )` - Set/Get the handle properties when unselected and selected.
- `vtkProperty2D = obj.GetProperty ()` - Set/Get the handle properties when unselected and selected.
- `vtkProperty2D = obj.GetSelectedProperty ()` - Set/Get the handle properties when unselected and selected.
- `double = obj.GetBounds ()` - Subclasses of vtkPointHandleRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.BuildRepresentation ()` - Subclasses of vtkPointHandleRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses of vtkPointHandleRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses of vtkPointHandleRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Subclasses of vtkPointHandleRepresentation2D must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.DeepCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.

- `obj.GetActors2D (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.

42.71 vtkPointHandleRepresentation3D

42.71.1 Usage

This class is used to represent a vtkHandleWidget. It represents a position in 3D world coordinates using a x-y-z cursor. The cursor can be configured to show a bounding box and/or shadows.

To create an instance of class vtkPointHandleRepresentation3D, simply invoke its constructor as follows

```
obj = vtkPointHandleRepresentation3D
```

42.71.2 Methods

The class vtkPointHandleRepresentation3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointHandleRepresentation3D class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPointHandleRepresentation3D = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPointHandleRepresentation3D = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetWorldPosition (double p[3])` - Set the position of the point in world and display coordinates. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box. This method overloads the superclasses' SetWorldPosition() and SetDisplayPosition() in order to set the focal point of the cursor properly.
- `obj.SetDisplayPosition (double p[3])` - Set the position of the point in world and display coordinates. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box. This method overloads the superclasses' SetWorldPosition() and SetDisplayPosition() in order to set the focal point of the cursor properly.
- `obj.SetOutline (int o)` - Turn on/off the wireframe bounding box.
- `int = obj.GetOutline ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOn ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOff ()` - Turn on/off the wireframe x-shadows.
- `obj.SetXShadows (int o)` - Turn on/off the wireframe x-shadows.
- `int = obj.GetXShadows ()` - Turn on/off the wireframe x-shadows.
- `obj.XShadowsOn ()` - Turn on/off the wireframe x-shadows.
- `obj.XShadowsOff ()` - Turn on/off the wireframe y-shadows.
- `obj.SetYShadows (int o)` - Turn on/off the wireframe y-shadows.

- `int = obj.GetYShadows ()` - Turn on/off the wireframe y-shadows.
- `obj.YShadowsOn ()` - Turn on/off the wireframe y-shadows.
- `obj.YShadowsOff ()` - Turn on/off the wireframe z-shadows.
- `obj.SetZShadows (int o)` - Turn on/off the wireframe z-shadows.
- `int = obj.GetZShadows ()` - Turn on/off the wireframe z-shadows.
- `obj.ZShadowsOn ()` - Turn on/off the wireframe z-shadows.
- `obj.ZShadowsOff ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated and sized simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). If translation mode is off, the cursor does not scale itself (based on the specified handle size), and the bounding box and shadows do not move or size themselves as the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button, and the bounds can be manually set with the SetBounds() method.)
- `obj.SetTranslationMode (int )` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated and sized simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). If translation mode is off, the cursor does not scale itself (based on the specified handle size), and the bounding box and shadows do not move or size themselves as the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button, and the bounds can be manually set with the SetBounds() method.)
- `int = obj.GetTranslationMode ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated and sized simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). If translation mode is off, the cursor does not scale itself (based on the specified handle size), and the bounding box and shadows do not move or size themselves as the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button, and the bounds can be manually set with the SetBounds() method.)
- `obj.TranslationModeOn ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated and sized simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). If translation mode is off, the cursor does not scale itself (based on the specified handle size), and the bounding box and shadows do not move or size themselves as the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button, and the bounds can be manually set with the SetBounds() method.)
- `obj.TranslationModeOff ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated and sized simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). If translation mode is off, the cursor does not scale itself (based on the specified handle size), and the bounding box and shadows do not move or size themselves as the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button, and the bounds can be manually set with the SetBounds() method.)
- `obj.AllOn ()` - Convenience methods to turn outline and shadows on and off.
- `obj.AllOff ()` - Set/Get the handle properties when unselected and selected.
- `obj.SetProperty (vtkProperty )` - Set/Get the handle properties when unselected and selected.

- `obj.SetSelectedProperty (vtkProperty )` - Set/Get the handle properties when unselected and selected.
- `vtkProperty = obj.GetProperty ()` - Set/Get the handle properties when unselected and selected.
- `vtkProperty = obj.GetSelectedProperty ()` - Set/Get the handle properties when unselected and selected.
- `obj.SetHotSpotSize (double )` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSizeMinValue ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSizeMaxValue ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSize ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `obj.SetHandleSize (double size)` - Overload the superclasses SetHandleSize() method to update internal variables.
- `double = obj.GetBounds ()` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.BuildRepresentation ()` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.WidgetInteraction (double eventPos[2])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.PlaceWidget (double bounds[6])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.GetActors (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.

42.72 vtkPointPlacer

42.72.1 Usage

Most widgets in VTK have a need to translate of 2D display coordinates (as reported by the RenderWindowInteractor) to 3D world coordinates. This class is an abstraction of this functionality. A few subclasses are listed below: ¡p¿1) vtkFocalPlanePointPlacer: This class converts 2D display positions to world positions such that they lie on the focal plane. ¡p¿2) vtkPolygonalSurfacePointPlacer: Converts 2D display positions to world positions such that they lie on the surface of one or more specified polydatas. ¡p¿3) vtkImageActorPointPlacer: Converts 2D display positions to world positions such that they lie on an ImageActor ¡p¿4) vtkBoundedPlanePointPlacer: Converts 2D display positions to world positions such that they lie within a set of specified bounding planes. ¡p¿5) vtkTerrainDataPointPlacer: Converts 2D display positions to world positions such that they lie on a height field. ¡p¿ Point placers provide an extensible framework to specify constraints on points. The methods ComputeWorldPosition, ValidateDisplayPosition and ValidateWorldPosition may be overridden to dictate whether a world or display position is allowed. These classes are currently used by the HandleWidget and the ContourWidget to allow various constraints to be enforced on the placement of their handles.

To create an instance of class vtkPointPlacer, simply invoke its constructor as follows

```
obj = vtkPointPlacer
```

42.72.2 Methods

The class vtkPointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given a renderer and a display position in pixel coordinates, compute the world position and orientation where this point will be placed. This method is typically used by the representation to place the point initially. A return value of 1 indicates that constraints of the placer are met.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[3], doubl` - Given a renderer, a display position, and a reference world position, compute the new world position and orientation of this point. This method is typically used by the representation to move the point. A return value of 1 indicates that constraints of the placer are met.
- `int = obj.ValidateWorldPosition (double worldPos[3])` - Given a world position check the validity of this position according to the constraints of the placer.
- `int = obj.ValidateDisplayPosition (vtkRenderer , double displayPos[2])` - Given a display position, check the validity of this position.
- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])` - Given a world position and a world orientation, validate it according to the constraints of the placer.
- `int = obj.UpdateWorldPosition (vtkRenderer ren, double worldPos[3], double worldOrient[9])` - Given a current renderer, world position and orientation, update them according to the constraints of the placer. This method is typically used when UpdateContour is called on the representation, which must be called after changes are made to the constraints in the placer. A return value of 1 indicates

that the point has been updated. A return value of 0 indicates that the point could not be updated and was left alone. By default this is a no-op - leaving the point as is.

- `int = obj.UpdateInternalState ()` - Set/get the tolerance used when performing computations in display coordinates.
- `obj.SetPixelTolerance (int )` - Set/get the tolerance used when performing computations in display coordinates.
- `int = obj.GetPixelToleranceMinValue ()` - Set/get the tolerance used when performing computations in display coordinates.
- `int = obj.GetPixelToleranceMaxValue ()` - Set/get the tolerance used when performing computations in display coordinates.
- `int = obj.GetPixelTolerance ()` - Set/get the tolerance used when performing computations in display coordinates.
- `obj.SetWorldTolerance (double )` - Set/get the tolerance used when performing computations in world coordinates.
- `double = obj.GetWorldToleranceMinValue ()` - Set/get the tolerance used when performing computations in world coordinates.
- `double = obj.GetWorldToleranceMaxValue ()` - Set/get the tolerance used when performing computations in world coordinates.
- `double = obj.GetWorldTolerance ()` - Set/get the tolerance used when performing computations in world coordinates.

42.73 vtkPointWidget

42.73.1 Usage

This 3D widget allows the user to position a point in 3D space using a 3D cursor. The cursor has an outline bounding box, axes-aligned cross-hairs, and axes shadows. (The outline and shadows can be turned off.) Any of these can be turned off. A nice feature of the object is that the vtkPointWidget, like any 3D widget, will work with the current interactor style. That is, if vtkPointWidget does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkPointWidget will terminate the processing of the event that it handles.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. The interactor will act normally until the "i" key (for "interactor") is pressed, at which point the vtkPointWidget will appear. (See superclass documentation for information about changing this behavior.) To move the point, the user can grab (left mouse) on any widget line and "slide" the point into position. Scaling is achieved by using the right mouse button "up" the render window (makes the widget bigger) or "down" the render window (makes the widget smaller). To translate the widget use the middle mouse button. (Note: all of the translation interactions can be constrained to one of the x-y-z axes by using the "shift" key.) The vtkPointWidget produces as output a polydata with a single point and a vertex cell.

Some additional features of this class include the ability to control the rendered properties of the widget. You can set the properties of the selected and unselected representations of the parts of the widget. For example, you can set the property of the 3D cursor in its normal and selected states.

To create an instance of class vtkPointWidget, simply invoke its constructor as follows

```
obj = vtkPointWidget
```

42.73.2 Methods

The class vtkPointWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointWidget = obj.NewInstance ()`
- `vtkPointWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Grab the polydata (including points) that defines the point. A single point and a vertex compose the vtkPolyData.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the point. A single point and a vertex compose the vtkPolyData.
- `obj.SetPosition (double x, double y, double z)` - Set/Get the position of the point. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box.
- `obj.SetPosition (double x[3])` - Set/Get the position of the point. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box.
- `double = obj.GetPosition ()` - Set/Get the position of the point. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box.
- `obj.GetPosition (double xyz[3])` - Turn on/off the wireframe bounding box.
- `obj.SetOutline (int o)` - Turn on/off the wireframe bounding box.
- `int = obj.GetOutline ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOn ()` - Turn on/off the wireframe bounding box.
- `obj.OutlineOff ()` - Turn on/off the wireframe x-shadows.
- `obj.SetXShadows (int o)` - Turn on/off the wireframe x-shadows.
- `int = obj.GetXShadows ()` - Turn on/off the wireframe x-shadows.
- `obj.XShadowsOn ()` - Turn on/off the wireframe x-shadows.
- `obj.XShadowsOff ()` - Turn on/off the wireframe y-shadows.
- `obj.SetYShadows (int o)` - Turn on/off the wireframe y-shadows.
- `int = obj.GetYShadows ()` - Turn on/off the wireframe y-shadows.
- `obj.YShadowsOn ()` - Turn on/off the wireframe y-shadows.
- `obj.YShadowsOff ()` - Turn on/off the wireframe z-shadows.

- `obj.SetZShadows (int o)` - Turn on/off the wireframe z-shadows.
- `int = obj.GetZShadows ()` - Turn on/off the wireframe z-shadows.
- `obj.ZShadowsOn ()` - Turn on/off the wireframe z-shadows.
- `obj.ZShadowsOff ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves.
- `obj.SetTranslationMode (int mode)` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves.
- `int = obj.GetTranslationMode ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves.
- `obj.TranslationModeOn ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves.
- `obj.TranslationModeOff ()` - Convenience methods to turn outline and shadows on and off.
- `obj.AllOn ()` - Convenience methods to turn outline and shadows on and off.
- `obj.AllOff ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be set.
- `vtkProperty = obj.GetProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be set.
- `vtkProperty = obj.GetSelectedProperty ()` - Get the handle properties (the little balls are the handles). The properties of the handles when selected and normal can be set.
- `obj.SetHotSpotSize (double )` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSizeMinValue ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSizeMaxValue ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSize ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.

42.74 vtkPolyDataContourLineInterpolator

42.74.1 Usage

vtkPolyDataContourLineInterpolator is an abstract base class for contour line interpolators that interpolate on polygonal data.

To create an instance of class vtkPolyDataContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkPolyDataContourLineInterpolator
```

42.74.2 Methods

The class vtkPolyDataContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPolyDataContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPolyDataContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)` - Subclasses that wish to interpolate a line segment must implement this. For instance vtkBezierContourLineInterpolator adds nodes between idx1 and idx2, that allow the contour to adhere to a bezier curve.
- `int = obj.UpdateNode (vtkRenderer , vtkContourRepresentation , double , int )` - The interpolator is given a chance to update the node. vtkImageContourLineInterpolator updates the idx'th node in the contour, so it automatically sticks to edges in the vicinity as the user constructs the contour. Returns 0 if the node (world position) is unchanged.
- `vtkPolyDataCollection = obj.GetPolys ()` - Be sure to add polydata on which you wish to place points to this list or they will not be considered for placement.

42.75 vtkPolyDataPointPlacer

42.75.1 Usage

vtkPolyDataPointPlacer is a base class to place points on the surface of polygonal data.

.SECTION Usage The actors that render polygonal data and wish to be considered for placement by this placer are added to the list as

```
placer->AddProp( polyDataActor );
```

To create an instance of class vtkPolyDataPointPlacer, simply invoke its constructor as follows

```
obj = vtkPolyDataPointPlacer
```

42.75.2 Methods

The class vtkPolyDataPointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataPointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPolyDataPointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPolyDataPointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.

- `obj.AddProp (vtkProp )`
- `obj.RemoveViewProp (vtkProp prop)`
- `obj.RemoveAllProps ()`
- `int = obj.HasProp (vtkProp )`
- `int = obj.GetNumberOfProps ()`
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given a renderer and a display position in pixel coordinates, compute the world position and orientation where this point will be placed. This method is typically used by the representation to place the point initially. For the Terrain point placer this computes world points that lie at the specified height above the terrain.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[3], doubl` - Given a renderer, a display position, and a reference world position, compute the new world position and orientation of this point. This method is typically used by the representation to move the point.
- `int = obj.ValidateWorldPosition (double worldPos[3])` - Given a world position check the validity of this position according to the constraints of the placer
- `int = obj.ValidateDisplayPosition (vtkRenderer , double displayPos[2])` - Given a display position, check the validity of this position.
- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])` - Given a world position and a world orientation, validate it according to the constraints of the placer.
- `vtkPropPicker = obj.GetPropPicker ()` - Get the Prop picker.

42.76 vtkPolyDataSourceWidget

42.76.1 Usage

This abstract class serves as parent to 3D widgets that have simple vtkPolyDataSource instances defining their geometry.

In addition to what is offered by the vtk3DWidget parent, this class makes it possible to manipulate the underlying polydatasource and to PlaceWidget() according to that, instead of having to make use of SetInput() or SetProp3D().

Implementors of child classes HAVE to implement their PlaceWidget(bounds) to check for the existence of Input and Prop3D FIRST. If these don't exist, place according to the underlying PolyDataSource. Child classes also have to imprement UpdatePlacement(), which updates the widget according to the geometry of the underlying PolyDataSource.

To create an instance of class vtkPolyDataSourceWidget, simply invoke its constructor as follows

```
obj = vtkPolyDataSourceWidget
```

42.76.2 Methods

The class vtkPolyDataSourceWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataSourceWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkPolyDataSourceWidget = obj.NewInstance ()`
- `vtkPolyDataSourceWidget = obj.SafeDownCast (vtkObject o)`
- `obj.PlaceWidget ()` - Overrides vtk3DWidget PlaceWidget() so that it doesn't complain if there's no Input and no Prop3D.
- `obj.PlaceWidget (double bounds[6])` - We have to redeclare this abstract, PlaceWidget() requires it. You HAVE to override this in your concrete child classes. If there's no Prop3D and no Input, your PlaceWidget must make use of the underlying PolyDataSource to do its work.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Returns underlying vtkPolyDataSource that determines geometry. This can be modified after which PlaceWidget() or UpdatePlacement() can be called. UpdatePlacement() will always update the planewidget according to the geometry of the underlying PolyDataSource. PlaceWidget() will only make use of this geometry if there is no Input and no Prop3D set.
- `vtkPolyDataSource = obj.GetPolyDataSource ()` - Returns underlying vtkPolyDataSource that determines geometry. This can be modified after which PlaceWidget() or UpdatePlacement() can be called. UpdatePlacement() will always update the planewidget according to the geometry of the underlying PolyDataSource. PlaceWidget() will only make use of this geometry if there is no Input and no Prop3D set.
- `vtkPolyDataAlgorithm = obj.GetPolyDataAlgorithm ()` - Returns underlying vtkPolyDataSource that determines geometry. This can be modified after which PlaceWidget() or UpdatePlacement() can be called. UpdatePlacement() will always update the planewidget according to the geometry of the underlying PolyDataSource. PlaceWidget() will only make use of this geometry if there is no Input and no Prop3D set.
- `obj.UpdatePlacement ()` - If you've made changes to the underlying vtkPolyDataSource AFTER your initial call to PlaceWidget(), use this method to realise the changes in the widget.

42.77 vtkPolygonalHandleRepresentation3D

42.77.1 Usage

This class serves as the geometrical representation of a vtkHandleWidget. The handle can be represented by an arbitrary polygonal data (vtkPolyData), set via SetHandle(vtkPolyData *). The actual position of the handle will be initially assumed to be (0,0,0). You can specify an offset from this position if desired.

To create an instance of class vtkPolygonalHandleRepresentation3D, simply invoke its constructor as follows

```
obj = vtkPolygonalHandleRepresentation3D
```

42.77.2 Methods

The class vtkPolygonalHandleRepresentation3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolygonalHandleRepresentation3D class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPolygonalHandleRepresentation3D = obj.NewInstance ()` - Standard methods for instances of this class.

- `vtkPolygonalHandleRepresentation3D = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetWorldPosition (double p[3])` - Set the position of the point in world and display coordinates.
- `obj.SetOffset (double , double , double )` - Set/get the offset of the handle position with respect to the handle center, assumed to be the origin.
- `obj.SetOffset (double a[3])` - Set/get the offset of the handle position with respect to the handle center, assumed to be the origin.
- `double = obj. GetOffset ()` - Set/get the offset of the handle position with respect to the handle center, assumed to be the origin.

42.78 vtkPolygonalSurfaceContourLineInterpolator

42.78.1 Usage

vtkPolygonalSurfaceContourLineInterpolator interpolates and places contour points on polygonal surfaces. The class interpolates nodes by computing a *graph* geodesic lying on the polygonal data. By *graph* Geodesic, we mean that the line interpolating the two end points traverses along on the mesh edges so as to form the shortest path. A Dijkstra algorithm is used to compute the path. See vtkDijkstraGraphGeodesicPath.

The class is mean to be used in conjunction with vtkPolygonalSurfacePointPlacer. The reason for this weak coupling is a performance issue, both classes need to perform a cell pick, and coupling avoids multiple cell picks (cell picks are slow).

To create an instance of class vtkPolygonalSurfaceContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkPolygonalSurfaceContourLineInterpolator
```

42.78.2 Methods

The class vtkPolygonalSurfaceContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolygonalSurfaceContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPolygonalSurfaceContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPolygonalSurfaceContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)` - Subclasses that wish to interpolate a line segment must implement this. For instance vtkBezierContourLineInterpolator adds nodes between idx1 and idx2, that allow the contour to adhere to a bezier curve.
- `int = obj.UpdateNode (vtkRenderer , vtkContourRepresentation , double , int )` - The interpolator is given a chance to update the node. vtkImageContourLineInterpolator updates the idx'th node in the contour, so it automatically sticks to edges in the vicinity as the user constructs the contour. Returns 0 if the node (world position) is unchanged.

- `obj.SetDistanceOffset (double )` - Height offset at which points may be placed on the polygonal surface. If you specify a non-zero value here, be sure to have computed vertex normals on your input polygonal data. (easily done with vtkPolyDataNormals).
- `double = obj.GetDistanceOffset ()` - Height offset at which points may be placed on the polygonal surface. If you specify a non-zero value here, be sure to have computed vertex normals on your input polygonal data. (easily done with vtkPolyDataNormals).

42.79 vtkPolygonalSurfacePointPlacer

42.79.1 Usage

vtkPolygonalSurfacePointPlacer places points on polygonal data and is meant to be used in conjunction with vtkPolygonalSurfaceContourLineInterpolator.

.SECTION Usage

To create an instance of class vtkPolygonalSurfacePointPlacer, simply invoke its constructor as follows

```
obj = vtkPolygonalSurfacePointPlacer
```

42.79.2 Methods

The class vtkPolygonalSurfacePointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolygonalSurfacePointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkPolygonalSurfacePointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkPolygonalSurfacePointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.AddProp (vtkProp )`
- `obj.RemoveViewProp (vtkProp prop)`
- `obj.RemoveAllProps ()`
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given a renderer and a display position in pixel coordinates, compute the world position and orientation where this point will be placed. This method is typically used by the representation to place the point initially. For the Terrain point placer this computes world points that lie at the specified height above the terrain.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[3], doubl` - Given a renderer, a display position, and a reference world position, compute the new world position and orientation of this point. This method is typically used by the representation to move the point.
- `int = obj.ValidateWorldPosition (double worldPos[3])` - Given a world position check the validity of this position according to the constraints of the placer
- `int = obj.ValidateDisplayPosition (vtkRenderer , double displayPos[2])` - Given a display position, check the validity of this position.

- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])` - Given a world position and a world orientation, validate it according to the constraints of the placer.
- `vtkCellPicker = obj.GetCellPicker ()` - Get the Prop picker.
- `vtkPolyDataCollection = obj.GetPolys ()` - Be sure to add polydata on which you wish to place points to this list or they will not be considered for placement.
- `obj.SetDistanceOffset (double )` - Height offset at which points may be placed on the polygonal surface. If you specify a non-zero value here, be sure to compute cell normals on your input polygonal data (easily done with vtkPolyDataNormals).
- `double = obj.GetDistanceOffset ()` - Height offset at which points may be placed on the polygonal surface. If you specify a non-zero value here, be sure to compute cell normals on your input polygonal data (easily done with vtkPolyDataNormals).

42.80 vtkRectilinearWipeRepresentation

42.80.1 Usage

This class is used to represent and render a vtkRectilinearWipeWidget. To use this class, you need to specify an instance of a vtkImageRectilinearWipe and vtkImageActor. This provides the information for this representation to construct and place itself.

The class may be subclassed so that alternative representations can be created. The class defines an API and a default implementation that the vtkRectilinearWipeWidget interacts with to render itself in the scene.

To create an instance of class vtkRectilinearWipeRepresentation, simply invoke its constructor as follows

```
obj = vtkRectilinearWipeRepresentation
```

42.80.2 Methods

The class vtkRectilinearWipeRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearWipeRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkRectilinearWipeRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkRectilinearWipeRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetRectilinearWipe (vtkImageRectilinearWipe wipe)` - Specify an instance of vtkImageRectilinearWipe to manipulate.
- `vtkImageRectilinearWipe = obj.GetRectilinearWipe ()` - Specify an instance of vtkImageRectilinearWipe to manipulate.
- `obj.SetImageActor (vtkImageActor imageActor)` - Specify an instance of vtkImageActor to decorate.
- `vtkImageActor = obj.GetImageActor ()` - Specify an instance of vtkImageActor to decorate.
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).

- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered to be on the widget, or on a widget feature (e.g., a corner point or edge).
- `vtkProperty2D = obj.GetProperty ()` - Get the properties for the widget. This can be manipulated to set different colors, line widths, etc.
- `obj.BuildRepresentation ()` - Subclasses of vtkRectilinearWipeRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.StartWidgetInteraction (double eventPos[2])` - Subclasses of vtkRectilinearWipeRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.WidgetInteraction (double eventPos[2])` - Subclasses of vtkRectilinearWipeRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Subclasses of vtkRectilinearWipeRepresentation must implement these methods. These are the methods that the widget and its representation use to communicate with each other.
- `obj.GetActors2D (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.

42.81 vtkRectilinearWipeWidget

42.81.1 Usage

The vtkRectilinearWipeWidget is used to interactively control an instance of vtkImageRectilinearWipe (and an associated vtkImageActor used to display the rectilinear wipe). A rectilinear wipe is a 2x2 checkerboard pattern created by combining two separate images, where various combinations of the checker squares are possible. Using this widget, the user can adjust the layout of the checker pattern, such as moving the center point, moving the horizontal separator, or moving the vertical separator. These capabilities are particularly useful for comparing two images.

To use this widget, specify its representation (by default the representation is an instance of vtkRectilinearWipeProp). The representation generally requires that you specify an instance of vtkImageRectilinearWipe and an instance of vtkImageActor. Other instance variables may also be required to be set – see the documentation for vtkRectilinearWipeProp (or appropriate subclass).

By default, the widget responds to the following events:

```
Selecting the center point, horizontal separator, and verticel separator:
  LeftButtonPressEvent - move the separators
  LeftButtonReleaseEvent - release the separators
  MouseMoveEvent - move the separators
```

Selecting the center point allows you to move the horizontal and vertical separators simultaneously. Otherwise only horizontal or vertical motion is possible/

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkRectilinearWipeWidget's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for motion has been invoked
```

In turn, when these widget events are processed, the vtkRectilinearWipeWidget invokes the following VTK events (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkRectilinearWipeWidget, simply invoke its constructor as follows

```
obj = vtkRectilinearWipeWidget
```

42.81.2 Methods

The class vtkRectilinearWipeWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearWipeWidget class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkRectilinearWipeWidget = obj.NewInstance ()` - Standard macros.
- `vtkRectilinearWipeWidget = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetRepresentation (vtkRectilinearWipeRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.82 vtkScalarBarRepresentation

42.82.1 Usage

This class represents a scalar bar for a vtkScalarBarWidget. This class provides support for interactively placing a scalar bar on the 2D overlay plane. The scalar bar is defined by an instance of vtkScalarBarActor.

One specialty of this class is that if the scalar bar is moved near enough to an edge, it's orientation is flipped to match that edge.

To create an instance of class vtkScalarBarRepresentation, simply invoke its constructor as follows

```
obj = vtkScalarBarRepresentation
```

42.82.2 Methods

The class vtkScalarBarRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScalarBarRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScalarBarRepresentation = obj.NewInstance ()`
- `vtkScalarBarRepresentation = obj.SafeDownCast (vtkObject o)`
- `vtkScalarBarActor = obj.GetScalarBarActor ()` - The prop that is placed in the renderer.
- `obj.SetScalarBarActor (vtkScalarBarActor )` - The prop that is placed in the renderer.
- `obj.BuildRepresentation ()` - Satisfy the superclass' API.
- `obj.WidgetInteraction (double eventPos[2])` - Satisfy the superclass' API.
- `obj.GetSize (double size[2])` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.GetActors2D (vtkPropCollection collection)` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow window)` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.SetOrientation (int orient)` - Get/Set the orientation.
- `int = obj.GetOrientation ()` - Get/Set the orientation.

42.83 vtkScalarBarWidget

42.83.1 Usage

This class provides support for interactively manipulating the position, size, and orientation of a scalar bar. It listens to Left mouse events and mouse movement. It also listens to Right mouse events and notifies any observers of Right mouse events on this object when they occur. It will change the cursor shape based on its location. If the cursor is over an edge of the scalar bar it will change the cursor shape to a resize edge shape. If the position of a scalar bar is moved to be close to the center of one of the four edges of the viewport, then the scalar bar will change its orientation to align with that edge. This orientation is sticky in that it will stay that orientation until the position is moved close to another edge.

To create an instance of class vtkScalarBarWidget, simply invoke its constructor as follows

```
obj = vtkScalarBarWidget
```

42.83.2 Methods

The class vtkScalarBarWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScalarBarWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScalarBarWidget = obj.NewInstance ()`
- `vtkScalarBarWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetRepresentation (vtkScalarBarRepresentation rep)` - Specify an instance of vtkWidgetRepresentation used to represent this widget in the scene. Note that the representation is a subclass of vtkProp so it can be added to the renderer independent of the widget.
- `vtkScalarBarRepresentation = obj.GetScalarBarRepresentation ()` - Get the ScalarBar used by this Widget. One is created automatically.
- `obj.SetScalarBarActor (vtkScalarBarActor actor)` - Get the ScalarBar used by this Widget. One is created automatically.
- `vtkScalarBarActor = obj.GetScalarBarActor ()` - Get the ScalarBar used by this Widget. One is created automatically.
- `obj.SetRepositionable (int )` - Can the widget be moved. On by default. If off, the widget cannot be moved around.

  TODO: This functionality should probably be moved to the superclass.
- `int = obj.GetRepositionable ()` - Can the widget be moved. On by default. If off, the widget cannot be moved around.

  TODO: This functionality should probably be moved to the superclass.
- `obj.RepositionableOn ()` - Can the widget be moved. On by default. If off, the widget cannot be moved around.

  TODO: This functionality should probably be moved to the superclass.
- `obj.RepositionableOff ()` - Can the widget be moved. On by default. If off, the widget cannot be moved around.

  TODO: This functionality should probably be moved to the superclass.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.84 vtkSeedRepresentation

42.84.1 Usage

The vtkSeedRepresentation is a superclass for classes representing the vtkSeedWidget. This representation consists of one or more handles (vtkHandleRepresentation) which are used to place and manipulate the points defining the collection of seeds.

To create an instance of class vtkSeedRepresentation, simply invoke its constructor as follows

```
obj = vtkSeedRepresentation
```

42.84.2 Methods

The class vtkSeedRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSeedRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkSeedRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkSeedRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `obj.GetSeedWorldPosition (int seedNum, double pos[3])` - Methods to Set/Get the coordinates of seed points defining this representation. Note that methods are available for both display and world coordinates. The seeds are accessed by a seed number.
- `obj.SetSeedDisplayPosition (int seedNum, double pos[3])` - Methods to Set/Get the coordinates of seed points defining this representation. Note that methods are available for both display and world coordinates. The seeds are accessed by a seed number.
- `obj.GetSeedDisplayPosition (int seedNum, double pos[3])` - Methods to Set/Get the coordinates of seed points defining this representation. Note that methods are available for both display and world coordinates. The seeds are accessed by a seed number.
- `int = obj.GetNumberOfSeeds ()` - Return the number of seeds (or handles) that have been created.
- `obj.SetHandleRepresentation (vtkHandleRepresentation handle)` - This method is used to specify the type of handle representation to use for the internal vtkHandleWidgets within vtkSeedWidget. To use this method, create a dummy vtkHandleWidget (or subclass), and then invoke this method with this dummy. Then the vtkSeedRepresentation uses this dummy to clone vtkHandleWidgets of the same type. Make sure you set the handle representation before the widget is enabled.
- `vtkHandleRepresentation = obj.GetHandleRepresentation (int num)` - Get the handle representations used for a particular seed. A side effect of this method is that it will create a handle representation in the list of representations if one has not yet been created.
- `vtkHandleRepresentation = obj.GetHandleRepresentation ()` - Returns the model HandleRepresentation.
- `obj.SetTolerance (int )` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.
- `int = obj.GetToleranceMinValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.
- `int = obj.GetToleranceMaxValue ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.
- `int = obj.GetTolerance ()` - The tolerance representing the distance to the widget (in pixels) in which the cursor is considered near enough to the end points of the widget to be active.
- `int = obj.GetActiveHandle ()` - These are methods specific to vtkSeedRepresentation and which are invoked from vtkSeedWidget.
- `int = obj.CreateHandle (double e[2])` - These are methods specific to vtkSeedRepresentation and which are invoked from vtkSeedWidget.

- `obj.RemoveLastHandle ()` - These are methods specific to vtkSeedRepresentation and which are invoked from vtkSeedWidget.
- `obj.RemoveActiveHandle ()` - These are methods specific to vtkSeedRepresentation and which are invoked from vtkSeedWidget.
- `obj.RemoveHandle (int n)` - Remove the nth handle.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API.

42.85 vtkSeedWidget

42.85.1 Usage

The vtkSeedWidget is used to placed multiple seed points in the scene. The seed points can be used for operations like connectivity, segmentation, and region growing.

To use this widget, specify an instance of vtkSeedWidget and a representation (a subclass of vtkSeedRepresentation). The widget is implemented using multiple instances of vtkHandleWidget which can be used to position the seed points (after they are initially placed). The representations for these handle widgets are provided by the vtkSeedRepresentation.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
LeftButtonPressEvent - add a point or select a handle (i.e., seed)
RightButtonPressEvent - finish adding the seeds
MouseMoveEvent - move a handle (i.e., seed)
LeftButtonReleaseEvent - release the selected handle (seed)
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkSeedWidget's widget events:

```
vtkWidgetEvent::AddPoint -- add one point; depending on the state
                            it may the first or second point added. Or,
                            if near handle, select handle.
vtkWidgetEvent::Completed -- finished adding seeds.
vtkWidgetEvent::Move -- move the second point or handle depending on the state.
vtkWidgetEvent::EndSelect -- the handle manipulation process has completed.
```

This widget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (beginning to interact)
vtkCommand::EndInteractionEvent (completing interaction)
vtkCommand::InteractionEvent (moving after selecting something)
vtkCommand::PlacePointEvent (after point is positioned;
                             call data includes handle id (0,1))
```

To create an instance of class vtkSeedWidget, simply invoke its constructor as follows

```
obj = vtkSeedWidget
```

42.85.2 Methods

The class vtkSeedWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSeedWidget class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkSeedWidget = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkSeedWidget = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - The method for activiating and deactiviating this widget. This method must be overridden because it is a composite widget and does more than its superclasses' vtkAbstractWidget::SetEnabled() method.
- `obj.SetCurrentRenderer (vtkRenderer )` - Set the current renderer. This method also propagates to all the child handle widgets, if any exist
- `obj.SetInteractor (vtkRenderWindowInteractor )` - Set the interactor. This method also propagates to all the child handle widgets, if any exist
- `obj.SetRepresentation (vtkSeedRepresentation rep)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `obj.SetProcessEvents (int )` - Methods to change the whether the widget responds to interaction. Overridden to pass the state to component widgets.
- `obj.CompleteInteraction ()` - Method to be called when the seed widget should stop responding to the place point interaction. The seed widget, when defined allows you place seeds by clicking on the render window. Use this method to indicate that you would like to stop placing seeds interactively. If you'd like the widget to stop responding to *any* user interaction simply disable event processing by the widget by calling widget-¿ProcessEventsOff()
- `obj.RestartInteraction ()` - Method to be called when the seed widget should start responding to the interaction.
- `vtkHandleWidget = obj.CreateNewHandle ()` - Use this method to programmatically create a new handle. In interactive mode, (when the widget is in the PlacingSeeds state) this method is automatically invoked. The method returns the handle created. A valid seed representation must exist for the widget to create a new handle.
- `obj.DeleteSeed (int n)` - Delete the nth seed.
- `vtkHandleWidget = obj.GetSeed (int n)` - Get the nth seed

42.86 vtkSliderRepresentation

42.86.1 Usage

This abstract class is used to specify how the vtkSliderWidget should interact with representations of the vtkSliderWidget. This class may be subclassed so that alternative representations can be created. The class defines an API, and a default implementation, that the vtkSliderWidget interacts with to render itself in the scene.

To create an instance of class vtkSliderRepresentation, simply invoke its constructor as follows

```
obj = vtkSliderRepresentation
```

42.86.2 Methods

The class vtkSliderRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSliderRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkSliderRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkSliderRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `obj.SetValue (double value)` - Specify the current value for the widget. The value should lie between the minimum and maximum values.
- `double = obj.GetValue ()` - Specify the current value for the widget. The value should lie between the minimum and maximum values.
- `obj.SetMinimumValue (double value)` - Set the current minimum value that the slider can take. Setting the minimum value greater than the maximum value will cause the maximum value to grow to (minimum value + 1).
- `double = obj.GetMinimumValue ()` - Set the current minimum value that the slider can take. Setting the minimum value greater than the maximum value will cause the maximum value to grow to (minimum value + 1).
- `obj.SetMaximumValue (double value)` - Set the current maximum value that the slider can take. Setting the maximum value less than the minimum value will cause the minimum value to change to (maximum value - 1).
- `double = obj.GetMaximumValue ()` - Set the current maximum value that the slider can take. Setting the maximum value less than the minimum value will cause the minimum value to change to (maximum value - 1).
- `obj.SetSliderLength (double )` - Specify the length of the slider shape (in normalized display coordinates [0.01,0.5]). The slider length by default is 0.05.
- `double = obj.GetSliderLengthMinValue ()` - Specify the length of the slider shape (in normalized display coordinates [0.01,0.5]). The slider length by default is 0.05.
- `double = obj.GetSliderLengthMaxValue ()` - Specify the length of the slider shape (in normalized display coordinates [0.01,0.5]). The slider length by default is 0.05.
- `double = obj.GetSliderLength ()` - Specify the length of the slider shape (in normalized display coordinates [0.01,0.5]). The slider length by default is 0.05.
- `obj.SetSliderWidth (double )` - Set the width of the slider in the directions orthogonal to the slider axis. Using this it is possible to create ellipsoidal and hockey puck sliders (in some subclasses). By default the width is 0.05.
- `double = obj.GetSliderWidthMinValue ()` - Set the width of the slider in the directions orthogonal to the slider axis. Using this it is possible to create ellipsoidal and hockey puck sliders (in some subclasses). By default the width is 0.05.
- `double = obj.GetSliderWidthMaxValue ()` - Set the width of the slider in the directions orthogonal to the slider axis. Using this it is possible to create ellipsoidal and hockey puck sliders (in some subclasses). By default the width is 0.05.

- `double = obj.GetSliderWidth ()` - Set the width of the slider in the directions orthogonal to the slider axis. Using this it is possible to create ellipsoidal and hockey puck sliders (in some subclasses). By default the width is 0.05.
- `obj.SetTubeWidth (double )` - Set the width of the tube (in normalized display coordinates) on which the slider moves. By default the width is 0.05.
- `double = obj.GetTubeWidthMinValue ()` - Set the width of the tube (in normalized display coordinates) on which the slider moves. By default the width is 0.05.
- `double = obj.GetTubeWidthMaxValue ()` - Set the width of the tube (in normalized display coordinates) on which the slider moves. By default the width is 0.05.
- `double = obj.GetTubeWidth ()` - Set the width of the tube (in normalized display coordinates) on which the slider moves. By default the width is 0.05.
- `obj.SetEndCapLength (double )` - Specify the length of each end cap (in normalized coordinates [0.0,0.25]). By default the length is 0.025. If the end cap length is set to 0.0, then the end cap will not display at all.
- `double = obj.GetEndCapLengthMinValue ()` - Specify the length of each end cap (in normalized coordinates [0.0,0.25]). By default the length is 0.025. If the end cap length is set to 0.0, then the end cap will not display at all.
- `double = obj.GetEndCapLengthMaxValue ()` - Specify the length of each end cap (in normalized coordinates [0.0,0.25]). By default the length is 0.025. If the end cap length is set to 0.0, then the end cap will not display at all.
- `double = obj.GetEndCapLength ()` - Specify the length of each end cap (in normalized coordinates [0.0,0.25]). By default the length is 0.025. If the end cap length is set to 0.0, then the end cap will not display at all.
- `obj.SetEndCapWidth (double )` - Specify the width of each end cap (in normalized coordinates [0.0,0.25]). By default the width is twice the tube width.
- `double = obj.GetEndCapWidthMinValue ()` - Specify the width of each end cap (in normalized coordinates [0.0,0.25]). By default the width is twice the tube width.
- `double = obj.GetEndCapWidthMaxValue ()` - Specify the width of each end cap (in normalized coordinates [0.0,0.25]). By default the width is twice the tube width.
- `double = obj.GetEndCapWidth ()` - Specify the width of each end cap (in normalized coordinates [0.0,0.25]). By default the width is twice the tube width.
- `obj.SetTitleText (string )` - Specify the label text for this widget. If the value is not set, or set to the empty string "", then the label text is not displayed.
- `string = obj.GetTitleText ()` - Set/Get the format with which to print the slider value.
- `obj.SetLabelFormat (string )` - Set/Get the format with which to print the slider value.
- `string = obj.GetLabelFormat ()` - Set/Get the format with which to print the slider value.
- `obj.SetLabelHeight (double )` - Specify the relative height of the label as compared to the length of the slider.
- `double = obj.GetLabelHeightMinValue ()` - Specify the relative height of the label as compared to the length of the slider.
- `double = obj.GetLabelHeightMaxValue ()` - Specify the relative height of the label as compared to the length of the slider.

- `double = obj.GetLabelHeight ()` - Specify the relative height of the label as compared to the length of the slider.
- `obj.SetTitleHeight (double )` - Specify the relative height of the title as compared to the length of the slider.
- `double = obj.GetTitleHeightMinValue ()` - Specify the relative height of the title as compared to the length of the slider.
- `double = obj.GetTitleHeightMaxValue ()` - Specify the relative height of the title as compared to the length of the slider.
- `double = obj.GetTitleHeight ()` - Specify the relative height of the title as compared to the length of the slider.
- `obj.SetShowSliderLabel (int )` - Indicate whether the slider text label should be displayed. This is a number corresponding to the current Value of this widget.
- `int = obj.GetShowSliderLabel ()` - Indicate whether the slider text label should be displayed. This is a number corresponding to the current Value of this widget.
- `obj.ShowSliderLabelOn ()` - Indicate whether the slider text label should be displayed. This is a number corresponding to the current Value of this widget.
- `obj.ShowSliderLabelOff ()` - Indicate whether the slider text label should be displayed. This is a number corresponding to the current Value of this widget.
- `double = obj.GetCurrentT ()` - Methods to interface with the vtkSliderWidget. Subclasses of this class actually do something.
- `double = obj.GetPickedT ()`

42.87 vtkSliderRepresentation2D

42.87.1 Usage

This class is used to represent and render a vtkSliderWidget. To use this class, you must at a minimum specify the end points of the slider. Optional instance variable can be used to modify the appearance of the widget.

To create an instance of class vtkSliderRepresentation2D, simply invoke its constructor as follows

```
obj = vtkSliderRepresentation2D
```

42.87.2 Methods

The class vtkSliderRepresentation2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSliderRepresentation2D class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkSliderRepresentation2D = obj.NewInstance ()` - Standard methods for the class.
- `vtkSliderRepresentation2D = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.

- `vtkCoordinate = obj.GetPoint1Coordinate ()` - Position the first end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point1Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.

- `vtkCoordinate = obj.GetPoint2Coordinate ()` - Position the second end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point2Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.

- `obj.SetTitleText (string )` - Specify the label text for this widget. If the value is not set, or set to the empty string "", then the label text is not displayed.

- `string = obj.GetTitleText ()` - Specify the label text for this widget. If the value is not set, or set to the empty string "", then the label text is not displayed.

- `vtkProperty2D = obj.GetSliderProperty ()` - Get the slider properties. The properties of the slider when selected and unselected can be manipulated.

- `vtkProperty2D = obj.GetTubeProperty ()` - Get the properties for the tube and end caps.

- `vtkProperty2D = obj.GetCapProperty ()` - Get the properties for the tube and end caps.

- `vtkProperty2D = obj.GetSelectedProperty ()` - Get the selection property. This property is used to modify the appearance of selected objects (e.g., the slider).

- `vtkTextProperty = obj.GetLabelProperty ()` - Set/Get the properties for the label and title text.

- `vtkTextProperty = obj.GetTitleProperty ()` - Set/Get the properties for the label and title text.

- `obj.PlaceWidget (double bounds[6])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.

- `obj.BuildRepresentation ()` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.

- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.

- `obj.WidgetInteraction (double newEventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.

- `obj.Highlight (int )` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.

- `obj.GetActors2D (vtkPropCollection )`

- `obj.ReleaseGraphicsResources (vtkWindow )`

- `int = obj.RenderOverlay (vtkViewport )`

- `int = obj.RenderOpaqueGeometry (vtkViewport )`

42.88 vtkSliderRepresentation3D

42.88.1 Usage

This class is used to represent and render a vtkSliderWidget. To use this class, you must at a minimum specify the end points of the slider. Optional instance variable can be used to modify the appearance of the widget.

To create an instance of class vtkSliderRepresentation3D, simply invoke its constructor as follows

```
obj = vtkSliderRepresentation3D
```

42.88.2 Methods

The class vtkSliderRepresentation3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSliderRepresentation3D class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkSliderRepresentation3D = obj.NewInstance ()` - Standard methods for the class.
- `vtkSliderRepresentation3D = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `vtkCoordinate = obj.GetPoint1Coordinate ()` - Position the first end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point1Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `obj.SetPoint1InWorldCoordinates (double x, double y, double z)` - Position the first end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point1Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `vtkCoordinate = obj.GetPoint2Coordinate ()` - Position the second end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point2Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `obj.SetPoint2InWorldCoordinates (double x, double y, double z)` - Position the second end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point2Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `obj.SetTitleText (string )` - Specify the title text for this widget. If the value is not set, or set to the empty string "", then the title text is not displayed.
- `string = obj.GetTitleText ()` - Specify the title text for this widget. If the value is not set, or set to the empty string "", then the title text is not displayed.
- `obj.SetSliderShape (int )` - Specify whether to use a sphere or cylinder slider shape. By default, a sphere shape is used.

- `int = obj.GetSliderShapeMinValue ()` - Specify whether to use a sphere or cylinder slider shape. By default, a sphere shape is used.
- `int = obj.GetSliderShapeMaxValue ()` - Specify whether to use a sphere or cylinder slider shape. By default, a sphere shape is used.
- `int = obj.GetSliderShape ()` - Specify whether to use a sphere or cylinder slider shape. By default, a sphere shape is used.
- `obj.SetSliderShapeToSphere ()` - Specify whether to use a sphere or cylinder slider shape. By default, a sphere shape is used.
- `obj.SetSliderShapeToCylinder ()` - Set the rotation of the slider widget around the axis of the widget. This is used to control which way the widget is initially oriented. (This is especially important for the label and title.)
- `obj.SetRotation (double )` - Set the rotation of the slider widget around the axis of the widget. This is used to control which way the widget is initially oriented. (This is especially important for the label and title.)
- `double = obj.GetRotation ()` - Set the rotation of the slider widget around the axis of the widget. This is used to control which way the widget is initially oriented. (This is especially important for the label and title.)
- `vtkProperty = obj.GetSliderProperty ()` - Get the slider properties. The properties of the slider when selected and unselected can be manipulated.
- `vtkProperty = obj.GetTubeProperty ()` - Get the properties for the tube and end caps.
- `vtkProperty = obj.GetCapProperty ()` - Get the properties for the tube and end caps.
- `vtkProperty = obj.GetSelectedProperty ()` - Get the selection property. This property is used to modify the appearance of selected objects (e.g., the slider).
- `obj.PlaceWidget (double bounds[6])` - Methods to interface with the vtkSliderWidget.
- `obj.BuildRepresentation ()` - Methods to interface with the vtkSliderWidget.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget.
- `obj.WidgetInteraction (double newEventPos[2])` - Methods to interface with the vtkSliderWidget.
- `obj.Highlight (int )` - Methods to interface with the vtkSliderWidget.
- `double = obj.GetBounds ()`
- `obj.GetActors (vtkPropCollection )`
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `int = obj.RenderOpaqueGeometry (vtkViewport )`
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )`
- `int = obj.HasTranslucentPolygonalGeometry ()`
- `long = obj.GetMTime ()` - Override GetMTime to include point coordinates

42.89 vtkSliderWidget

42.89.1 Usage

The vtkSliderWidget is used to set a scalar value in an application. This class assumes that a slider is moved along a 1D parameter space (e.g., a spherical bead that can be moved along a tube). Moving the slider modifies the value of the widget, which can be used to set parameters on other objects. Note that the actual appearance of the widget depends on the specific representation for the widget.

To use this widget, set the widget representation. The representation is assumed to consist of a tube, two end caps, and a slider (the details may vary depending on the particulars of the representation). Then in the representation you will typically set minimum and maximum value, as well as the current value. The position of the slider must also be set, as well as various properties.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
If the slider bead is selected:
  LeftButtonPressEvent - select slider (if on slider)
  LeftButtonReleaseEvent - release slider (if selected)
  MouseMoveEvent - move slider
If the end caps or slider tube are selected:
  LeftButtonPressEvent - move (or animate) to cap or point on tube;
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkSliderWidget's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for slider motion has been invoked
```

In turn, when these widget events are processed, the vtkSliderWidget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkSliderWidget, simply invoke its constructor as follows

```
obj = vtkSliderWidget
```

42.89.2 Methods

The class vtkSliderWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSliderWidget class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkSliderWidget = obj.NewInstance ()` - Standard macros.
- `vtkSliderWidget = obj.SafeDownCast (vtkObject o)` - Standard macros.

- `obj.SetRepresentation (vtkSliderRepresentation r)` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `obj.SetAnimationMode (int )` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `int = obj.GetAnimationModeMinValue ()` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `int = obj.GetAnimationModeMaxValue ()` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `int = obj.GetAnimationMode ()` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `obj.SetAnimationModeToOff ()` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `obj.SetAnimationModeToJump ()` - Control the behavior of the slider when selecting the tube or caps. If Jump, then selecting the tube, left cap, or right cap causes the slider to jump to the selection point. If the mode is Animate, the slider moves towards the selection point in NumberOfAnimationSteps number of steps. If Off, then the slider does not move.
- `obj.SetAnimationModeToAnimate ()` - Specify the number of animation steps to take if the animation mode is set to animate.
- `obj.SetNumberOfAnimationSteps (int )` - Specify the number of animation steps to take if the animation mode is set to animate.
- `int = obj.GetNumberOfAnimationStepsMinValue ()` - Specify the number of animation steps to take if the animation mode is set to animate.
- `int = obj.GetNumberOfAnimationStepsMaxValue ()` - Specify the number of animation steps to take if the animation mode is set to animate.
- `int = obj.GetNumberOfAnimationSteps ()` - Specify the number of animation steps to take if the animation mode is set to animate.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.90 vtkSphereHandleRepresentation

42.90.1 Usage

This class is a concrete implementation of vtkHandleRepresentation. It renders handles as spherical blobs in 3D space.

To create an instance of class vtkSphereHandleRepresentation, simply invoke its constructor as follows

```
obj = vtkSphereHandleRepresentation
```

42.90.2 Methods

The class vtkSphereHandleRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphereHandleRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkSphereHandleRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkSphereHandleRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetWorldPosition (double p[3])` - Set the position of the point in world and display coordinates. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box. This method overloads the superclasses' SetWorldPosition() and SetDisplayPosition() in order to set the focal point of the cursor properly.
- `obj.SetDisplayPosition (double p[3])` - Set the position of the point in world and display coordinates. Note that if the position is set outside of the bounding box, it will be clamped to the boundary of the bounding box. This method overloads the superclasses' SetWorldPosition() and SetDisplayPosition() in order to set the focal point of the cursor properly.
- `obj.SetTranslationMode (int )` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). Otherwise, only the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button.)
- `int = obj.GetTranslationMode ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). Otherwise, only the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button.)
- `obj.TranslationModeOn ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). Otherwise, only the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button.)
- `obj.TranslationModeOff ()` - If translation mode is on, as the widget is moved the bounding box, shadows, and cursor are all translated simultaneously as the point moves (i.e., the left and middle mouse buttons act the same). Otherwise, only the cursor focal point moves, which is constrained by the bounds of the point representation. (Note that the bounds can be scaled up using the right mouse button.)
- `obj.SetSphereRadius (double )`
- `double = obj.GetSphereRadius ()`
- `obj.SetProperty (vtkProperty )` - Set/Get the handle properties when unselected and selected.

- `obj.SetSelectedProperty (vtkProperty )` - Set/Get the handle properties when unselected and selected.
- `vtkProperty = obj.GetProperty ()` - Set/Get the handle properties when unselected and selected.
- `vtkProperty = obj.GetSelectedProperty ()` - Set/Get the handle properties when unselected and selected.
- `obj.SetHotSpotSize (double )` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSizeMinValue ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSizeMaxValue ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `double = obj.GetHotSpotSize ()` - Set the "hot spot" size; i.e., the region around the focus, in which the motion vector is used to control the constrained sliding action. Note the size is specified as a fraction of the length of the diagonal of the point widget's bounding box.
- `obj.SetHandleSize (double size)` - Overload the superclasses SetHandleSize() method to update internal variables.
- `double = obj.GetBounds ()` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.BuildRepresentation ()` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.WidgetInteraction (double eventPos[2])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.PlaceWidget (double bounds[6])` - Methods to make this class properly act like a vtkWidgetRepresentation.
- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.DeepCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp.
- `obj.GetActors (vtkPropCollection )` - Methods to make this class behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Methods to make this class behave as a vtkProp.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods to make this class behave as a vtkProp.

42.91 vtkSphereRepresentation

42.91.1 Usage

This class is a concrete representation for the vtkSphereWidget2. It represents a sphere with an optional handle. Through interaction with the widget, the sphere can be arbitrarily positioned and scaled in 3D space; and the handle can be moved on the surface of the sphere. Typically the vtkSphereWidget2/vtkSphereRepresentation are used to position a sphere for the purpose of extracting, cutting or clipping data; or the handle is moved on the sphere to position a light or camera.

To use this representation, you normally use the PlaceWidget() method to position the widget at a specified region in space. It is also possible to set the center of the sphere, a radius, and/or a handle position.

To create an instance of class vtkSphereRepresentation, simply invoke its constructor as follows

```
obj = vtkSphereRepresentation
```

42.91.2 Methods

The class vtkSphereRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphereRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for type information and to print out the contents of the class.
- `int = obj.IsA (string name)` - Standard methods for type information and to print out the contents of the class.
- `vtkSphereRepresentation = obj.NewInstance ()` - Standard methods for type information and to print out the contents of the class.
- `vtkSphereRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for type information and to print out the contents of the class.
- `obj.SetRepresentation (int )` - Set the representation (i.e., appearance) of the sphere. Different representations are useful depending on the application.
- `int = obj.GetRepresentationMinValue ()` - Set the representation (i.e., appearance) of the sphere. Different representations are useful depending on the application.
- `int = obj.GetRepresentationMaxValue ()` - Set the representation (i.e., appearance) of the sphere. Different representations are useful depending on the application.
- `int = obj.GetRepresentation ()` - Set the representation (i.e., appearance) of the sphere. Different representations are useful depending on the application.
- `obj.SetRepresentationToOff ()` - Set the representation (i.e., appearance) of the sphere. Different representations are useful depending on the application.
- `obj.SetRepresentationToWireframe ()` - Set the representation (i.e., appearance) of the sphere. Different representations are useful depending on the application.
- `obj.SetRepresentationToSurface ()` - Set/Get the resolution of the sphere in the theta direction.
- `obj.SetThetaResolution (int r)` - Set/Get the resolution of the sphere in the theta direction.
- `int = obj.GetThetaResolution ()` - Set/Get the resolution of the sphere in the phi direction.
- `obj.SetPhiResolution (int r)` - Set/Get the resolution of the sphere in the phi direction.

- `int = obj.GetPhiResolution ()` - Set/Get the center position of the sphere. Note that this may adjust the direction from the handle to the center, as well as the radius of the sphere.
- `obj.SetCenter (double c[3])` - Set/Get the center position of the sphere. Note that this may adjust the direction from the handle to the center, as well as the radius of the sphere.
- `obj.SetCenter (double x, double y, double z)` - Set/Get the center position of the sphere. Note that this may adjust the direction from the handle to the center, as well as the radius of the sphere.
- `double = obj.GetCenter ()` - Set/Get the center position of the sphere. Note that this may adjust the direction from the handle to the center, as well as the radius of the sphere.
- `obj.GetCenter (double xyz[3])` - Set/Get the radius of sphere. Default is 0.5. Note that this may modify the position of the handle based on the handle direction.
- `obj.SetRadius (double r)` - Set/Get the radius of sphere. Default is 0.5. Note that this may modify the position of the handle based on the handle direction.
- `double = obj.GetRadius ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.SetHandleVisibility (int )` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `int = obj.GetHandleVisibility ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.HandleVisibilityOn ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.HandleVisibilityOff ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.SetHandlePosition (double handle[3])` - Set/Get the position of the handle. Note that this may adjust the radius of the sphere and the handle direction.
- `obj.SetHandlePosition (double x, double y, double z)` - Set/Get the position of the handle. Note that this may adjust the radius of the sphere and the handle direction.
- `double = obj. GetHandlePosition ()` - Set/Get the position of the handle. Note that this may adjust the radius of the sphere and the handle direction.
- `obj.SetHandleDirection (double dir[3])` - Set/Get the direction vector of the handle relative to the center of the sphere. This may affect the position of the handle and the radius of the sphere.
- `obj.SetHandleDirection (double dx, double dy, double dz)` - Set/Get the direction vector of the handle relative to the center of the sphere. This may affect the position of the handle and the radius of the sphere.
- `double = obj. GetHandleDirection ()` - Set/Get the direction vector of the handle relative to the center of the sphere. This may affect the position of the handle and the radius of the sphere.
- `obj.SetHandleText (int )` - Enable/disable a label that displays the location of the handle in spherical coordinates (radius,theta,phi). The two angles, theta and phi, are displayed in degrees. Note that phi is measured from the north pole down towards the equator; and theta is the angle around the north/south axis.

- `int = obj.GetHandleText ()` - Enable/disable a label that displays the location of the handle in spherical coordinates (radius,theta,phi). The two angles, theta and phi, are displayed in degrees. Note that phi is measured from the north pole down towards the equator; and theta is the angle around the north/south axis.
- `obj.HandleTextOn ()` - Enable/disable a label that displays the location of the handle in spherical coordinates (radius,theta,phi). The two angles, theta and phi, are displayed in degrees. Note that phi is measured from the north pole down towards the equator; and theta is the angle around the north/south axis.
- `obj.HandleTextOff ()` - Enable/disable a label that displays the location of the handle in spherical coordinates (radius,theta,phi). The two angles, theta and phi, are displayed in degrees. Note that phi is measured from the north pole down towards the equator; and theta is the angle around the north/south axis.
- `obj.SetRadialLine (int )` - Enable/disable a radial line segment that joins the center of the outer sphere and the handle.
- `int = obj.GetRadialLine ()` - Enable/disable a radial line segment that joins the center of the outer sphere and the handle.
- `obj.RadialLineOn ()` - Enable/disable a radial line segment that joins the center of the outer sphere and the handle.
- `obj.RadialLineOff ()` - Enable/disable a radial line segment that joins the center of the outer sphere and the handle.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the sphere. The polydata consists of n+1 points, where n is the resolution of the sphere. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polysphere are added to it.
- `obj.GetSphere (vtkSphere sphere)` - Get the spherical implicit function defined by this widget. Note that vtkSphere is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data.
- `vtkProperty = obj.GetSphereProperty ()` - Get the sphere properties. The properties of the sphere when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedSphereProperty ()` - Get the sphere properties. The properties of the sphere when selected and unselected can be manipulated.
- `vtkProperty = obj.GetHandleProperty ()` - Get the handle properties (the little ball on the sphere is the handle). The properties of the handle when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Get the handle properties (the little ball on the sphere is the handle). The properties of the handle when selected and unselected can be manipulated.
- `vtkTextProperty = obj.GetHandleTextProperty ()` - Get the handle text property. This can be used to control the appearance of the handle text.
- `vtkProperty = obj.GetRadialLineProperty ()` - Get the property of the radial line. This can be used to control the appearance of the optional line connecting the center to the handle.
- `obj.SetInteractionState (int state)` - The interaction state may be set from a widget (e.g., vtkSphereWidget2) or other object. This controls how the interaction with the widget proceeds. Normally this method is used as part of a handshaking process with the widget: First ComputeInteractionState() is invoked that returns a state based on geometric considerations (i.e., cursor near a widget feature), then based on events, the widget may modify this further.

- `obj.PlaceWidget (double bounds[6])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.PlaceWidget (double center[3], double handlePosition[3])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods supporting, and required by, the rendering process.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Methods supporting, and required by, the rendering process.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Methods supporting, and required by, the rendering process.
- `int = obj.RenderOverlay (vtkViewport )` - Methods supporting, and required by, the rendering process.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods supporting, and required by, the rendering process.

42.92 vtkSphereWidget

42.92.1 Usage

This 3D widget defines a sphere that can be interactively placed in a scene.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. The interactor will act normally until the "i" key (for "interactor") is pressed, at which point the vtkSphereWidget will appear. (See superclass documentation for information about changing this behavior.) Events that occur outside of the widget (i.e., no part of the widget is picked) are propagated to any other registered obsevers (such as the interaction style). Turn off the widget by pressing the "i" key again (or invoke the Off() method).

The vtkSphereWidget has several methods that can be used in conjunction with other VTK objects. The Set/GetThetaResolution() and Set/GetPhiResolution() methods control the number of subdivisions of the sphere in the theta and phi directions; the GetPolyData() method can be used to get the polygonal representation and can be used for things like seeding streamlines. The GetSphere() method returns a sphere implicit function that can be used for cutting and clipping. Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (any mouse button).

Some additional features of this class include the ability to control the properties of the widget. You can set the properties of the selected and unselected representations of the sphere.

To create an instance of class vtkSphereWidget, simply invoke its constructor as follows

```
obj = vtkSphereWidget
```

42.92.2 Methods

The class vtkSphereWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphereWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSphereWidget = obj.NewInstance ()`
- `vtkSphereWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `obj.SetRepresentation (int )` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `int = obj.GetRepresentationMinValue ()` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `int = obj.GetRepresentationMaxValue ()` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `int = obj.GetRepresentation ()` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `obj.SetRepresentationToOff ()` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `obj.SetRepresentationToWireframe ()` - Set the representation of the sphere. Different representations are useful depending on the application. The default is VTK_SPHERE_WIREFRAME.
- `obj.SetRepresentationToSurface ()` - Set/Get the resolution of the sphere in the Theta direction. The default is 16.
- `obj.SetThetaResolution (int r)` - Set/Get the resolution of the sphere in the Theta direction. The default is 16.
- `int = obj.GetThetaResolution ()` - Set/Get the resolution of the sphere in the Phi direction. The default is 8.
- `obj.SetPhiResolution (int r)` - Set/Get the resolution of the sphere in the Phi direction. The default is 8.
- `int = obj.GetPhiResolution ()` - Set/Get the radius of sphere. Default is .5.
- `obj.SetRadius (double r)` - Set/Get the radius of sphere. Default is .5.
- `double = obj.GetRadius ()` - Set/Get the center of the sphere.
- `obj.SetCenter (double x, double y, double z)` - Set/Get the center of the sphere.

- `obj.SetCenter (double x[3])` - Set/Get the center of the sphere.
- `double = obj.GetCenter ()` - Set/Get the center of the sphere.
- `obj.GetCenter (double xyz[3])` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.SetTranslation (int )` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `int = obj.GetTranslation ()` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.TranslationOn ()` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.TranslationOff ()` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.SetScale (int )` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `int = obj.GetScale ()` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.ScaleOn ()` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.ScaleOff ()` - Enable translation and scaling of the widget. By default, the widget can be translated and rotated.
- `obj.SetHandleVisibility (int )` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `int = obj.GetHandleVisibility ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.HandleVisibilityOn ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.HandleVisibilityOff ()` - The handle sits on the surface of the sphere and may be moved around the surface by picking (left mouse) and then moving. The position of the handle can be retrieved, this is useful for positioning cameras and lights. By default, the handle is turned off.
- `obj.SetHandleDirection (double , double , double )` - Set/Get the direction vector of the handle relative to the center of the sphere. The direction of the handle is from the sphere center to the handle position.
- `obj.SetHandleDirection (double  a[3])` - Set/Get the direction vector of the handle relative to the center of the sphere. The direction of the handle is from the sphere center to the handle position.
- `double = obj. GetHandleDirection ()` - Set/Get the direction vector of the handle relative to the center of the sphere. The direction of the handle is from the sphere center to the handle position.
- `double = obj. GetHandlePosition ()` - Get the position of the handle.

- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the sphere. The polydata consists of n+1 points, where n is the resolution of the sphere. These point values are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polysphere are added to it.
- `obj.GetSphere (vtkSphere sphere)` - Get the spherical implicit function defined by this widget. Note that vtkSphere is a subclass of vtkImplicitFunction, meaning that it can be used by a variety of filters to perform clipping, cutting, and selection of data.
- `vtkProperty = obj.GetSphereProperty ()` - Get the sphere properties. The properties of the sphere when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedSphereProperty ()` - Get the sphere properties. The properties of the sphere when selected and unselected can be manipulated.
- `vtkProperty = obj.GetHandleProperty ()` - Get the handle properties (the little ball on the sphere is the handle). The properties of the handle when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Get the handle properties (the little ball on the sphere is the handle). The properties of the handle when selected and unselected can be manipulated.

42.93 vtkSphereWidget2

42.93.1 Usage

This 3D widget interacts with a vtkSphereRepresentation class (i.e., it handles the events that drive its corresponding representation). It can be used to position a point on a sphere (for example, to place a light or camera), or to position a sphere in a scene, including translating and scaling the sphere.

A nice feature of vtkSphereWidget2, like any 3D widget, is that it will work in combination with the current interactor style (or any other interactor observer). That is, if vtkSphereWidget2 does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkSphereWidget2 will terminate the processing of the event that it handles.

To use this widget, you generally pair it with a vtkSphereRepresentation (or a subclass). Variuos options are available in the representation for controlling how the widget appears, and how the widget functions.

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
If the handle or sphere are selected:
  LeftButtonPressEvent - select the handle or sphere
  LeftButtonReleaseEvent - release the handle ot sphere
  MouseMoveEvent - move the handle or translate the sphere
In all the cases, independent of what is picked, the widget responds to the
following VTK events:
  MiddleButtonPressEvent - translate the representation
  MiddleButtonReleaseEvent - stop translating the representation
  RightButtonPressEvent - scale the widget's representation
  RightButtonReleaseEvent - stop scaling the representation
  MouseMoveEvent - scale (if right button) or move (if middle button) the widget
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkSphereWidget2's widget events:

```
  vtkWidgetEvent::Select -- some part of the widget has been selected
  vtkWidgetEvent::EndSelect -- the selection process has completed
  vtkWidgetEvent::Scale -- some part of the widget has been selected
```

```
vtkWidgetEvent::EndScale -- the selection process has completed
vtkWidgetEvent::Translate -- some part of the widget has been selected
vtkWidgetEvent::EndTranslate -- the selection process has completed
vtkWidgetEvent::Move -- a request for motion has been invoked
```

In turn, when these widget events are processed, the vtkSphereWidget2 invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkSphereWidget2, simply invoke its constructor as follows

```
obj = vtkSphereWidget2
```

42.93.2 Methods

The class vtkSphereWidget2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphereWidget2 class.

- `string = obj.GetClassName ()` - Standard class methods for type information and printing.
- `int = obj.IsA (string name)` - Standard class methods for type information and printing.
- `vtkSphereWidget2 = obj.NewInstance ()` - Standard class methods for type information and printing.
- `vtkSphereWidget2 = obj.SafeDownCast (vtkObject o)` - Standard class methods for type information and printing.
- `obj.SetRepresentation (vtkSphereRepresentation r)` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.SetTranslationEnabled (int )` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `int = obj.GetTranslationEnabled ()` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.TranslationEnabledOn ()` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.TranslationEnabledOff ()` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.SetScalingEnabled (int )` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `int = obj.GetScalingEnabled ()` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.ScalingEnabledOn ()` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.ScalingEnabledOff ()` - Control the behavior of the widget (i.e., how it processes events). Translation, and scaling can all be enabled and disabled.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set. By default, this is an instance of the vtkSphereRepresentation class.

42.94 vtkSplineRepresentation

42.94.1 Usage

vtkSplineRepresentation is a vtkWidgetRepresentation for a spline. This 3D widget defines a spline that can be interactively placed in a scene. The spline has handles, the number of which can be changed, plus it can be picked on the spline itself to translate or rotate it in the scene. This is based on vtkSplineWidget.

To create an instance of class vtkSplineRepresentation, simply invoke its constructor as follows

```
obj = vtkSplineRepresentation
```

42.94.2 Methods

The class vtkSplineRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplineRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSplineRepresentation = obj.NewInstance ()`
- `vtkSplineRepresentation = obj.SafeDownCast (vtkObject o)`
- `obj.SetInteractionState (int )`
- `obj.SetProjectToPlane (int )` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the InteractionState changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `int = obj.GetProjectToPlane ()` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the InteractionState changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.ProjectToPlaneOn ()` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the InteractionState changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.ProjectToPlaneOff ()` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the InteractionState changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.SetPlaneSource (vtkPlaneSource plane)` - Set up a reference to a vtkPlaneSource that could be from another widget object, e.g. a vtkPolyDataSourceWidget.
- `obj.SetProjectionNormal (int )`
- `int = obj.GetProjectionNormalMinValue ()`
- `int = obj.GetProjectionNormalMaxValue ()`

- `int = obj.GetProjectionNormal ()`
- `obj.SetProjectionNormalToXAxes ()`
- `obj.SetProjectionNormalToYAxes ()`
- `obj.SetProjectionNormalToZAxes ()`
- `obj.SetProjectionNormalToOblique ()` - Set the position of spline handles and points in terms of a plane's position. i.e., if ProjectionNormal is 0, all of the x-coordinate values of the points are set to position. Any value can be passed (and is ignored) to update the spline points when Projection normal is set to 3 for arbritrary plane orientations.
- `obj.SetProjectionPosition (double position)` - Set the position of spline handles and points in terms of a plane's position. i.e., if ProjectionNormal is 0, all of the x-coordinate values of the points are set to position. Any value can be passed (and is ignored) to update the spline points when Projection normal is set to 3 for arbritrary plane orientations.
- `double = obj.GetProjectionPosition ()` - Set the position of spline handles and points in terms of a plane's position. i.e., if ProjectionNormal is 0, all of the x-coordinate values of the points are set to position. Any value can be passed (and is ignored) to update the spline points when Projection normal is set to 3 for arbritrary plane orientations.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the spline. The polydata consists of points and line segments numbering Resolution + 1 and Resoltuion, respectively. Points are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polyline are added to it.
- `vtkProperty = obj.GetHandleProperty ()` - Set/Get the handle properties (the spheres are the handles). The properties of the handles when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Set/Get the handle properties (the spheres are the handles). The properties of the handles when selected and unselected can be manipulated.
- `vtkProperty = obj.GetLineProperty ()` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedLineProperty ()` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `obj.SetNumberOfHandles (int npts)` - Set/Get the number of handles for this widget.
- `int = obj.GetNumberOfHandles ()` - Set/Get the number of handles for this widget.
- `obj.SetResolution (int resolution)` - Set/Get the number of line segments representing the spline for this widget.
- `int = obj.GetResolution ()` - Set/Get the number of line segments representing the spline for this widget.
- `obj.SetParametricSpline (vtkParametricSpline )` - Set the parametric spline object. Through vtkParametricSpline's API, the user can supply and configure one of currently two types of spline: vtkCardinalSpline, vtkKochanekSpline. The widget controls the open or closed configuration of the spline. WARNING: The widget does not enforce internal consistency so that all three are of the same type.
- `vtkParametricSpline = obj.GetParametricSpline ()` - Set the parametric spline object. Through vtkParametricSpline's API, the user can supply and configure one of currently two types of spline: vtkCardinalSpline, vtkKochanekSpline. The widget controls the open or closed configuration of the spline. WARNING: The widget does not enforce internal consistency so that all three are of the same type.

- `obj.SetHandlePosition (int handle, double x, double y, double z)` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.
- `obj.SetHandlePosition (int handle, double xyz[3])` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.
- `obj.GetHandlePosition (int handle, double xyz[3])` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.
- `vtkDoubleArray = obj.GetHandlePositions ()` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.
- `obj.SetClosed (int closed)` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.
- `int = obj.GetClosed ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.
- `obj.ClosedOn ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.
- `obj.ClosedOff ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.
- `int = obj.IsClosed ()` - Convenience method to determine whether the spline is closed in a geometric sense. The widget may be set "closed" but still be geometrically open (e.g., a straight line).
- `double = obj.GetSummedLength ()` - Get the approximate vs. the true arc length of the spline. Calculated as the summed lengths of the individual straight line segments. Use SetResolution to control the accuracy.
- `obj.InitializeHandles (vtkPoints points)` - Convenience method to allocate and set the handles from a vtkPoints instance. If the first and last points are the same, the spline sets Closed to the on InteractionState and disregards the last point, otherwise Closed remains unchanged.
- `obj.BuildRepresentation ()` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.StartWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.WidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.
- `obj.EndWidgetInteraction (double e[2])` - These are methods that satisfy vtkWidgetRepresentation's API. Note that a version of place widget is available where the center and handle position are specified.

- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods supporting, and required by, the rendering process.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Methods supporting, and required by, the rendering process.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Methods supporting, and required by, the rendering process.
- `int = obj.RenderOverlay (vtkViewport )` - Methods supporting, and required by, the rendering process.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Methods supporting, and required by, the rendering process.
- `obj.SetLineColor (double r, double g, double b)` - Convenience method to set the line color. Ideally one should use GetLineProperty()-¿SetColor().

42.95 vtkSplineWidget

42.95.1 Usage

This 3D widget defines a spline that can be interactively placed in a scene. The spline has handles, the number of which can be changed, plus it can be picked on the spline itself to translate or rotate it in the scene. A nice feature of the object is that the vtkSplineWidget, like any 3D widget, will work with the current interactor style. That is, if vtkSplineWidget does not handle an event, then all other registered observers (including the interactor style) have an opportunity to process the event. Otherwise, the vtkSplineWidget will terminate the processing of the event that it handles.

To use this object, just invoke SetInteractor() with the argument of the method a vtkRenderWindowInteractor. You may also wish to invoke "PlaceWidget()" to initially position the widget. The interactor will act normally until the "i" key (for "interactor") is pressed, at which point the vtkSplineWidget will appear. (See superclass documentation for information about changing this behavior.) Events that occur outside of the widget (i.e., no part of the widget is picked) are propagated to any other registered obsevers (such as the interaction style). Turn off the widget by pressing the "i" key again (or invoke the Off() method).

The button actions and key modifiers are as follows for controlling the widget: 1) left button down on and drag one of the spherical handles to change the shape of the spline: the handles act as "control points". 2) left button or middle button down on a line segment forming the spline allows uniform translation of the widget. 3) ctrl + middle button down on the widget enables spinning of the widget about its center. 4) right button down on the widget enables scaling of the widget. By moving the mouse "up" the render window the spline will be made bigger; by moving "down" the render window the widget will be made smaller. 5) ctrl key + right button down on any handle will erase it providing there will be two or more points remaining to form a spline. 6) shift key + right button down on any line segment will insert a handle onto the spline at the cursor position.

The vtkSplineWidget has several methods that can be used in conjunction with other VTK objects. The Set/GetResolution() methods control the number of subdivisions of the spline; the GetPolyData() method can be used to get the polygonal representation and can be used for things like seeding streamlines or probing other data sets. Typical usage of the widget is to make use of the StartInteractionEvent, InteractionEvent, and EndInteractionEvent events. The InteractionEvent is called on mouse motion; the other two events are called on button down and button up (either left or right button).

Some additional features of this class include the ability to control the properties of the widget. You can set the properties of the selected and unselected representations of the spline. For example, you can set the property for the handles and spline. In addition there are methods to constrain the spline so that it is aligned with a plane. Note that a simple ruler widget can be derived by setting the resolution to 1, the number of handles to 2, and calling the GetSummedLength method!

To create an instance of class vtkSplineWidget, simply invoke its constructor as follows

```
obj = vtkSplineWidget
```

42.95.2 Methods

The class vtkSplineWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplineWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSplineWidget = obj.NewInstance ()`
- `vtkSplineWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetEnabled (int )` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double bounds[6])` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget ()` - Methods that satisfy the superclass' API.
- `obj.PlaceWidget (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.SetProjectToPlane (int )` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `int = obj.GetProjectToPlane ()` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.ProjectToPlaneOn ()` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.ProjectToPlaneOff ()` - Force the spline widget to be projected onto one of the orthogonal planes. Remember that when the state changes, a ModifiedEvent is invoked. This can be used to snap the spline to the plane if it is orginally not aligned. The normal in SetProjectionNormal is 0,1,2 for YZ,XZ,XY planes respectively and 3 for arbitrary oblique planes when the widget is tied to a vtkPlaneSource.
- `obj.SetPlaneSource (vtkPlaneSource plane)` - Set up a reference to a vtkPlaneSource that could be from another widget object, e.g. a vtkPolyDataSourceWidget.
- `obj.SetProjectionNormal (int )`
- `int = obj.GetProjectionNormalMinValue ()`
- `int = obj.GetProjectionNormalMaxValue ()`
- `int = obj.GetProjectionNormal ()`

- `obj.SetProjectionNormalToXAxes ()`
- `obj.SetProjectionNormalToYAxes ()`
- `obj.SetProjectionNormalToZAxes ()`
- `obj.SetProjectionNormalToOblique ()` - Set the position of spline handles and points in terms of a plane's position. i.e., if ProjectionNormal is 0, all of the x-coordinate values of the points are set to position. Any value can be passed (and is ignored) to update the spline points when Projection normal is set to 3 for arbritrary plane orientations.
- `obj.SetProjectionPosition (double position)` - Set the position of spline handles and points in terms of a plane's position. i.e., if ProjectionNormal is 0, all of the x-coordinate values of the points are set to position. Any value can be passed (and is ignored) to update the spline points when Projection normal is set to 3 for arbritrary plane orientations.
- `double = obj.GetProjectionPosition ()` - Set the position of spline handles and points in terms of a plane's position. i.e., if ProjectionNormal is 0, all of the x-coordinate values of the points are set to position. Any value can be passed (and is ignored) to update the spline points when Projection normal is set to 3 for arbritrary plane orientations.
- `obj.GetPolyData (vtkPolyData pd)` - Grab the polydata (including points) that defines the spline. The polydata consists of points and line segments numbering Resolution + 1 and Resoltuion, respectively. Points are guaranteed to be up-to-date when either the InteractionEvent or EndInteraction events are invoked. The user provides the vtkPolyData and the points and polyline are added to it.
- `obj.SetHandleProperty (vtkProperty )` - Set/Get the handle properties (the spheres are the handles). The properties of the handles when selected and unselected can be manipulated.
- `vtkProperty = obj.GetHandleProperty ()` - Set/Get the handle properties (the spheres are the handles). The properties of the handles when selected and unselected can be manipulated.
- `obj.SetSelectedHandleProperty (vtkProperty )` - Set/Get the handle properties (the spheres are the handles). The properties of the handles when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedHandleProperty ()` - Set/Get the handle properties (the spheres are the handles). The properties of the handles when selected and unselected can be manipulated.
- `obj.SetLineProperty (vtkProperty )` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetLineProperty ()` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `obj.SetSelectedLineProperty (vtkProperty )` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `vtkProperty = obj.GetSelectedLineProperty ()` - Set/Get the line properties. The properties of the line when selected and unselected can be manipulated.
- `obj.SetNumberOfHandles (int npts)` - Set/Get the number of handles for this widget.
- `int = obj.GetNumberOfHandles ()` - Set/Get the number of handles for this widget.
- `obj.SetResolution (int resolution)` - Set/Get the number of line segments representing the spline for this widget.
- `int = obj.GetResolution ()` - Set/Get the number of line segments representing the spline for this widget.

- `obj.SetParametricSpline (vtkParametricSpline )` - Set the parametric spline object. Through vtkParametricSpline's API, the user can supply and configure one of currently two types of spline: vtkCardinalSpline, vtkKochanekSpline. The widget controls the open or closed configuration of the spline. WARNING: The widget does not enforce internal consistency so that all three are of the same type.

- `vtkParametricSpline = obj.GetParametricSpline ()` - Set the parametric spline object. Through vtkParametricSpline's API, the user can supply and configure one of currently two types of spline: vtkCardinalSpline, vtkKochanekSpline. The widget controls the open or closed configuration of the spline. WARNING: The widget does not enforce internal consistency so that all three are of the same type.

- `obj.SetHandlePosition (int handle, double x, double y, double z)` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.

- `obj.SetHandlePosition (int handle, double xyz[3])` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.

- `obj.GetHandlePosition (int handle, double xyz[3])` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.

- `double = obj.GetHandlePosition (int handle)` - Set/Get the position of the spline handles. Call GetNumberOfHandles to determine the valid range of handle indices.

- `obj.SetClosed (int closed)` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.

- `int = obj.GetClosed ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.

- `obj.ClosedOn ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.

- `obj.ClosedOff ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous. A minimum of 3 handles are required to form a closed loop. This method enforces consistency with user supplied subclasses of vtkSpline.

- `int = obj.IsClosed ()` - Convenience method to determine whether the spline is closed in a geometric sense. The widget may be set "closed" but still be geometrically open (e.g., a straight line).

- `double = obj.GetSummedLength ()` - Get the approximate vs. the true arc length of the spline. Calculated as the summed lengths of the individual straight line segments. Use SetResolution to control the accuracy.

- `obj.InitializeHandles (vtkPoints points)` - Convenience method to allocate and set the handles from a vtkPoints instance. If the first and last points are the same, the spline sets Closed to the on state and disregards the last point, otherwise Closed remains unchanged.

42.96 vtkSplineWidget2

42.96.1 Usage

vtkSplineWidget2 is the vtkAbstractWidget subclass for vtkSplineRepresentation which manages the interactions with vtkSplineRepresentation. This is based on vtkSplineWidget.

To create an instance of class vtkSplineWidget2, simply invoke its constructor as follows

```
obj = vtkSplineWidget2
```

42.96.2 Methods

The class vtkSplineWidget2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSplineWidget2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSplineWidget2 = obj.NewInstance ()`
- `vtkSplineWidget2 = obj.SafeDownCast (vtkObject o)`
- `obj.SetRepresentation (vtkSplineRepresentation r)` - Create the default widget representation if one is not set. By default, this is an instance of the vtkSplineRepresentation class.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set. By default, this is an instance of the vtkSplineRepresentation class.

42.97 vtkTensorProbeRepresentation

42.97.1 Usage

The class serves as an abstract geometrical representation for the vtkTensorProbeWidget. It is left to the concrete implementation to render the tensors as it desires. For instance, vtkEllipsoidTensorProbeRepresentation renders the tensors as ellipsoids.

To create an instance of class vtkTensorProbeRepresentation, simply invoke its constructor as follows

```
obj = vtkTensorProbeRepresentation
```

42.97.2 Methods

The class vtkTensorProbeRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTensorProbeRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkTensorProbeRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkTensorProbeRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.

- `obj.BuildRepresentation ()` - See vtkWidgetRepresentation for details.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - See vtkWidgetRepresentation for details.
- `obj.SetProbePosition (double , double , double )` - Set the position of the Tensor probe.
- `obj.SetProbePosition (double a[3])` - Set the position of the Tensor probe.
- `double = obj. GetProbePosition ()` - Set the position of the Tensor probe.
- `obj.SetProbeCellId (vtkIdType )` - Set the position of the Tensor probe.
- `vtkIdType = obj.GetProbeCellId ()` - Set the position of the Tensor probe.
- `obj.SetTrajectory (vtkPolyData )` - Set the trajectory that we are trying to probe tensors on
- `obj.Initialize ()` - Set the probe position to a reasonable location on the trajectory.
- `int = obj.SelectProbe (int pos[2])` - This method is invoked by the widget during user interaction. Can we pick the tensor glyph at the current cursor pos
- `int = obj.Move (double motionVector[2])` - INTERNAL - Do not use This method is invoked by the widget during user interaction. Move probe based on the position and the motion vector.
- `obj.GetActors (vtkPropCollection )` - See vtkProp for details.
- `obj.ReleaseGraphicsResources (vtkWindow )` - See vtkProp for details.

42.98 vtkTensorProbeWidget

42.98.1 Usage

The class is used to probe tensors on a trajectory. The representation (vtkTensorProbeRepresentation) is free to choose its own method of rendering the tensors. For instance vtkEllipsoidTensorProbeRepresentation renders the tensors as ellipsoids. The interactions of the widget are controlled by the left mouse button. A left click on the tensor selects it. It can dragged around the trajectory to probe the tensors on it.

For instance dragging the ellipsoid around with vtkEllipsoidTensorProbeRepresentation will manifest itself with the ellipsoid shape changing as needed along the trajectory.

To create an instance of class vtkTensorProbeWidget, simply invoke its constructor as follows

```
obj = vtkTensorProbeWidget
```

42.98.2 Methods

The class vtkTensorProbeWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTensorProbeWidget class.

- `string = obj.GetClassName ()` - Standard VTK class macros.
- `int = obj.IsA (string name)` - Standard VTK class macros.
- `vtkTensorProbeWidget = obj.NewInstance ()` - Standard VTK class macros.
- `vtkTensorProbeWidget = obj.SafeDownCast (vtkObject o)` - Standard VTK class macros.
- `obj.SetRepresentation (vtkTensorProbeRepresentation r)` - See vtkWidgetRepresentation for details.
- `obj.CreateDefaultRepresentation ()` - See vtkWidgetRepresentation for details.

42.99 vtkTerrainContourLineInterpolator

42.99.1 Usage

vtkTerrainContourLineInterpolator interpolates nodes on height field data. The class is meant to be used in conjunciton with a vtkContourWidget, enabling you to draw paths on terrain data. The class internally uses a vtkProjectedTerrainPath. Users can set kind of interpolation desired between two node points by setting the modes of the this filter. For instance:

```
contourRepresentation->SetLineInterpolator(interpolator);
interpolator->SetImageData( demDataFile );
interpolator->GetProjector()->SetProjectionModeToHug();
interpolator->SetHeightOffset(25.0);
```

You are required to set the ImageData to this class as the height-field image.
To create an instance of class vtkTerrainContourLineInterpolator, simply invoke its constructor as follows

```
obj = vtkTerrainContourLineInterpolator
```

42.99.2 Methods

The class vtkTerrainContourLineInterpolator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTerrainContourLineInterpolator class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkTerrainContourLineInterpolator = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkTerrainContourLineInterpolator = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `int = obj.InterpolateLine (vtkRenderer ren, vtkContourRepresentation rep, int idx1, int idx2)` - Interpolate to create lines between contour nodes idx1 and idx2. Depending on the projection mode, the interpolated line may either hug the terrain, just connect the two points with a straight line or a non-occluded interpolation. Used internally by vtkContourRepresentation.
- `int = obj.UpdateNode (vtkRenderer , vtkContourRepresentation , double , int )` - The interpolator is given a chance to update the node. Used internally by vtkContourRepresentation Returns 0 if the node (world position) is unchanged.
- `obj.SetImageData (vtkImageData )` - Set the height field data. The height field data is a 2D image. The scalars in the image represent the height field. This must be set.
- `vtkImageData = obj.GetImageData ()` - Set the height field data. The height field data is a 2D image. The scalars in the image represent the height field. This must be set.
- `vtkProjectedTerrainPath = obj.GetProjector ()` - Get the vtkProjectedTerrainPath operator used to project the terrain onto the data. This operator has several modes, See the documentation of vtkProjectedTerrainPath. The default mode is to hug the terrain data at 0 height offset.

42.100 vtkTerrainDataPointPlacer

42.100.1 Usage

vtkTerrainDataPointPlacer dictates the placement of points on height field data. The class takes as input the list of props that represent the terrain in a rendered scene. A height offset can be specified to dicatate the placement of points at a certain height above the surface.

.SECTION Usage A typical usage of this class is as follows:

```
pointPlacer->AddProp(demActor);    // the actor(s) containing the terrain.
rep->SetPointPlacer(pointPlacer);
pointPlacer->SetHeightOffset( 100 );
```

To create an instance of class vtkTerrainDataPointPlacer, simply invoke its constructor as follows

```
obj = vtkTerrainDataPointPlacer
```

42.100.2 Methods

The class vtkTerrainDataPointPlacer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTerrainDataPointPlacer class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkTerrainDataPointPlacer = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkTerrainDataPointPlacer = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.AddProp (vtkProp )`
- `obj.RemoveAllProps ()`
- `obj.SetHeightOffset (double )` - This is the height above (or below) the terrain that the dictated point should be placed. Positive values indicate distances above the terrain; negative values indicate distances below the terrain. The default is 0.0.
- `double = obj.GetHeightOffset ()` - This is the height above (or below) the terrain that the dictated point should be placed. Positive values indicate distances above the terrain; negative values indicate distances below the terrain. The default is 0.0.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double worldPos[3], double w` - Given a renderer and a display position in pixel coordinates, compute the world position and orientation where this point will be placed. This method is typically used by the representation to place the point initially. For the Terrain point placer this computes world points that lie at the specified height above the terrain.
- `int = obj.ComputeWorldPosition (vtkRenderer ren, double displayPos[2], double refWorldPos[3], doubl` - Given a renderer, a display position, and a reference world position, compute the new world position and orientation of this point. This method is typically used by the representation to move the point.
- `int = obj.ValidateWorldPosition (double worldPos[3])` - Given a world position check the validity of this position according to the constraints of the placer
- `int = obj.ValidateDisplayPosition (vtkRenderer , double displayPos[2])` - Given a display position, check the validity of this position.

- `int = obj.ValidateWorldPosition (double worldPos[3], double worldOrient[9])` - Given a world position and a world orientation, validate it according to the constraints of the placer.
- `vtkPropPicker = obj.GetPropPicker ()` - Get the Prop picker.

42.101 vtkTextRepresentation

42.101.1 Usage

This class represents text for a vtkTextWidget. This class provides support for interactively placing text on the 2D overlay plane. The text is defined by an instance of vtkTextActor.

To create an instance of class vtkTextRepresentation, simply invoke its constructor as follows

```
obj = vtkTextRepresentation
```

42.101.2 Methods

The class vtkTextRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextRepresentation class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkTextRepresentation = obj.NewInstance ()` - Standard VTK methods.
- `vtkTextRepresentation = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `obj.SetTextActor (vtkTextActor textActor)` - Specify the vtkTextActor to manage. If not specified, then one is automatically created.
- `vtkTextActor = obj.GetTextActor ()` - Specify the vtkTextActor to manage. If not specified, then one is automatically created.
- `obj.SetText (string text)` - Get/Set the text string display by this representation.
- `string = obj.GetText ()` - Get/Set the text string display by this representation.
- `obj.BuildRepresentation ()` - Satisfy the superclasses API.
- `obj.GetSize (double size[2])` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.GetActors2D (vtkPropCollection )` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.ReleaseGraphicsResources (vtkWindow )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOverlay (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderOpaqueGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - These methods are necessary to make this representation behave as a vtkProp.

- `int = obj.HasTranslucentPolygonalGeometry ()` - These methods are necessary to make this representation behave as a vtkProp.
- `obj.SetWindowLocation (int enumLocation)` - Set the text position, by enumeration (AnyLocation = 0, LowerLeftCorner, LowerRightCorner, LowerCenter, UpperLeftCorner, UpperRightCorner, UpperCenter) related to the render window
- `int = obj.GetWindowLocation ()` - Set the text position, by enumeration (AnyLocation = 0, LowerLeftCorner, LowerRightCorner, LowerCenter, UpperLeftCorner, UpperRightCorner, UpperCenter) related to the render window
- `obj.SetPosition (double x, double y)` - Set the text position, by overiding the same function of vtkBorderRepresentation so that the Modified() will be called.
- `obj.SetPosition (double pos[2])` - Set the text position, by overiding the same function of vtkBorderRepresentation so that the Modified() will be called.

42.102 vtkTextWidget

42.102.1 Usage

This class provides support for interactively placing text on the 2D overlay plane. The text is defined by an instance of vtkTextActor. It uses the event bindings of its superclass (vtkBorderWidget). In addition, when the text is selected, the widget emits a WidgetActivateEvent that observers can watch for. This is useful for opening GUI dialogues to adjust font characteristics, etc. (Please see the superclass for a description of event bindings.)

To create an instance of class vtkTextWidget, simply invoke its constructor as follows

```
obj = vtkTextWidget
```

42.102.2 Methods

The class vtkTextWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTextWidget class.

- `string = obj.GetClassName ()` - Standard VTK methods.
- `int = obj.IsA (string name)` - Standard VTK methods.
- `vtkTextWidget = obj.NewInstance ()` - Standard VTK methods.
- `vtkTextWidget = obj.SafeDownCast (vtkObject o)` - Standard VTK methods.
- `obj.SetRepresentation (vtkTextRepresentation r)` - Specify a vtkTextActor to manage. This is a convenient, alternative method to specify the representation for the widget (i.e., used instead of SetRepresentation()). It internally creates a vtkTextRepresentation and then invokes vtkTextRepresentation::SetTextActor().
- `obj.SetTextActor (vtkTextActor textActor)` - Specify a vtkTextActor to manage. This is a convenient, alternative method to specify the representation for the widget (i.e., used instead of SetRepresentation()). It internally creates a vtkTextRepresentation and then invokes vtkTextRepresentation::SetTextActor().
- `vtkTextActor = obj.GetTextActor ()` - Specify a vtkTextActor to manage. This is a convenient, alternative method to specify the representation for the widget (i.e., used instead of SetRepresentation()). It internally creates a vtkTextRepresentation and then invokes vtkTextRepresentation::SetTextActor().
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.

42.103 vtkWidgetCallbackMapper

42.103.1 Usage

vtkWidgetCallbackMapper maps widget events (defined in vtkWidgetEvent.h) into static class methods, and provides facilities to invoke the methods. This class is templated and meant to be used as an internal helper class by the widget classes. The class works in combination with the class vtkWidgetEventTranslator, which translates VTK events into widget events.

To create an instance of class vtkWidgetCallbackMapper, simply invoke its constructor as follows

```
obj = vtkWidgetCallbackMapper
```

42.103.2 Methods

The class vtkWidgetCallbackMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWidgetCallbackMapper class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkWidgetCallbackMapper = obj.NewInstance ()` - Standard macros.
- `vtkWidgetCallbackMapper = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetEventTranslator (vtkWidgetEventTranslator t)` - Specify the vtkWidgetEventTranslator to coordinate with.
- `vtkWidgetEventTranslator = obj.GetEventTranslator ()` - Specify the vtkWidgetEventTranslator to coordinate with.
- `obj.InvokeCallback (long widgetEvent)` - This method invokes the callback given a widget event. A non-zero value is returned if the listed event is registered.

42.104 vtkWidgetEvent

42.104.1 Usage

vtkWidgetEvent defines widget events. These events are processed by subclasses of vtkInteractorObserver.

To create an instance of class vtkWidgetEvent, simply invoke its constructor as follows

```
obj = vtkWidgetEvent
```

42.104.2 Methods

The class vtkWidgetEvent has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWidgetEvent class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkWidgetEvent = obj.NewInstance ()` - Standard macros.
- `vtkWidgetEvent = obj.SafeDownCast (vtkObject o)` - Standard macros.

42.105 vtkWidgetEventTranslator

42.105.1 Usage

vtkWidgetEventTranslator maps VTK events (defined on vtkCommand) into widget events (defined in vtkWidgetEvent.h). This class is typically used in combination with vtkWidgetCallbackMapper, which is responsible for translating widget events into method callbacks, and then invoking the callbacks.

This class can be used to define different mappings of VTK events into the widget events. Thus widgets can be reconfigured to use different event bindings.

To create an instance of class vtkWidgetEventTranslator, simply invoke its constructor as follows

```
obj = vtkWidgetEventTranslator
```

42.105.2 Methods

The class vtkWidgetEventTranslator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWidgetEventTranslator class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkWidgetEventTranslator = obj.NewInstance ()` - Standard macros.
- `vtkWidgetEventTranslator = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetTranslation (long VTKEvent, long widgetEvent)` - Use these methods to create the translation from a VTK event to a widget event. Specifying vtkWidgetEvent::NoEvent or an empty string for the (toEvent) erases the mapping for the event.
- `obj.SetTranslation (string VTKEvent, string widgetEvent)` - Use these methods to create the translation from a VTK event to a widget event. Specifying vtkWidgetEvent::NoEvent or an empty string for the (toEvent) erases the mapping for the event.
- `obj.SetTranslation (long VTKEvent, int modifier, char keyCode, int repeatCount, string keySym, long` - Use these methods to create the translation from a VTK event to a widget event. Specifying vtkWidgetEvent::NoEvent or an empty string for the (toEvent) erases the mapping for the event.
- `obj.SetTranslation (vtkEvent VTKevent, long widgetEvent)` - Use these methods to create the translation from a VTK event to a widget event. Specifying vtkWidgetEvent::NoEvent or an empty string for the (toEvent) erases the mapping for the event.
- `long = obj.GetTranslation (long VTKEvent)` - Translate a VTK event into a widget event. If no event mapping is found, then the methods return vtkWidgetEvent::NoEvent or a NULL string.
- `string = obj.GetTranslation (string VTKEvent)` - Translate a VTK event into a widget event. If no event mapping is found, then the methods return vtkWidgetEvent::NoEvent or a NULL string.
- `long = obj.GetTranslation (long VTKEvent, int modifier, char keyCode, int repeatCount, string keySy` - Translate a VTK event into a widget event. If no event mapping is found, then the methods return vtkWidgetEvent::NoEvent or a NULL string.
- `long = obj.GetTranslation (vtkEvent VTKEvent)` - Translate a VTK event into a widget event. If no event mapping is found, then the methods return vtkWidgetEvent::NoEvent or a NULL string.
- `int = obj.RemoveTranslation (long VTKEvent, int modifier, char keyCode, int repeatCount, string key` - Remove translations for a binding. Returns the number of translations removed.

- `int = obj.RemoveTranslation (vtkEvent e)` - Remove translations for a binding. Returns the number of translations removed.
- `int = obj.RemoveTranslation (long VTKEvent)` - Remove translations for a binding. Returns the number of translations removed.
- `obj.ClearEvents ()` - Clear all events from the translator (i.e., no events will be translated).

42.106 vtkWidgetRepresentation

42.106.1 Usage

This class is used to define the API for, and partially implement, a representation for different types of widgets. Note that the widget representation (i.e., subclasses of vtkWidgetRepresentation) are a type of vtkProp; meaning that they can be associated with a vtkRenderer end embedded in a scene like any other vtkActor. However, vtkWidgetRepresentation also defines an API that enables it to be paired with a subclass vtkAbstractWidget, meaning that it can be driven by a widget, serving to represent the widget as the widget responds to registered events.

The API defined here should be regarded as a guideline for implementing widgets and widget representations. Widget behavior is complex, as is the way the representation responds to the registered widget events, so the API may vary from widget to widget to reflect this complexity.

To create an instance of class vtkWidgetRepresentation, simply invoke its constructor as follows

```
obj = vtkWidgetRepresentation
```

42.106.2 Methods

The class vtkWidgetRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWidgetRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for instances of this class.
- `int = obj.IsA (string name)` - Standard methods for instances of this class.
- `vtkWidgetRepresentation = obj.NewInstance ()` - Standard methods for instances of this class.
- `vtkWidgetRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for instances of this class.
- `obj.SetRenderer (vtkRenderer ren)` - Subclasses of vtkWidgetRepresentation must implement these methods. This is considered the minimum API for a widget representation.

  ```
  SetRenderer() - the renderer in which the widget is to appear must be set.
  BuildRepresentation() - update the geometry of the widget based on its
                          current state.
  ```

  WARNING: The renderer is NOT reference counted by the representation, in order to avoid reference loops. Be sure that the representation lifetime does not extend beyond the renderer lifetime.

- `vtkRenderer = obj.GetRenderer ()` - Subclasses of vtkWidgetRepresentation must implement these methods. This is considered the minimum API for a widget representation.

  ```
  SetRenderer() - the renderer in which the widget is to appear must be set.
  BuildRepresentation() - update the geometry of the widget based on its
                          current state.
  ```

WARNING: The renderer is NOT reference counted by the representation, in order to avoid reference loops. Be sure that the representation lifetime does not extend beyond the renderer lifetime.

- `obj.BuildRepresentation ()` - Subclasses of vtkWidgetRepresentation must implement these methods. This is considered the minimum API for a widget representation.

```
SetRenderer() - the renderer in which the widget is to appear must be set.
BuildRepresentation() - update the geometry of the widget based on its
                        current state.
```

WARNING: The renderer is NOT reference counted by the representation, in order to avoid reference loops. Be sure that the representation lifetime does not extend beyond the renderer lifetime.

- `obj.PlaceWidget (double )` - The following is a suggested API for widget representations. These methods define the communication between the widget and its representation. These methods are only suggestions because widgets take on so many different forms that a universal API is not deemed practical. However, these methods should be implemented when possible to insure that the VTK widget hierarchy remains self-consistent.

```
PlaceWidget() - given a bounding box (xmin,xmax,ymin,ymax,zmin,zmax), place
                the widget inside of it. The current orientation of the widget
                is preserved, only scaling and translation is performed.
StartWidgetInteraction() - generally corresponds to a initial event (e.g.,
                           mouse down) that starts the interaction process
                           with the widget.
WidgetInteraction() - invoked when an event causes the widget to change
                      appearance.
EndWidgetInteraction() - generally corresponds to a final event (e.g., mouse up)
                         and completes the interaction sequence.
ComputeInteractionState() - given (X,Y) display coordinates in a renderer, with a
                            possible flag that modifies the computation,
                            what is the state of the widget?
GetInteractionState() - return the current state of the widget. Note that the
                        value of ''0'' typically refers to ''outside''. The
                        interaction state is strictly a function of the
                        representation, and the widget/represent must agree
                        on what they mean.
Highlight() - turn on or off any highlights associated with the widget.
              Highlights are generally turned on when the widget is selected.
```

Note that subclasses may ignore some of these methods and implement their own depending on the specifics of the widget.

- `obj.StartWidgetInteraction (double eventPos[2])` - The following is a suggested API for widget representations. These methods define the communication between the widget and its representation. These methods are only suggestions because widgets take on so many different forms that a universal API is not deemed practical. However, these methods should be implemented when possible to insure that the VTK widget hierarchy remains self-consistent.

```
PlaceWidget() - given a bounding box (xmin,xmax,ymin,ymax,zmin,zmax), place
                the widget inside of it. The current orientation of the widget
                is preserved, only scaling and translation is performed.
StartWidgetInteraction() - generally corresponds to a initial event (e.g.,
```

```
                            mouse down) that starts the interaction process
                            with the widget.
WidgetInteraction() - invoked when an event causes the widget to change
                      appearance.
EndWidgetInteraction() - generally corresponds to a final event (e.g., mouse up)
                         and completes the interaction sequence.
ComputeInteractionState() - given (X,Y) display coordinates in a renderer, with a
                            possible flag that modifies the computation,
                            what is the state of the widget?
GetInteractionState() - return the current state of the widget. Note that the
                        value of ''0'' typically refers to ''outside''. The
                        interaction state is strictly a function of the
                        representation, and the widget/represent must agree
                        on what they mean.
Highlight() - turn on or off any highlights associated with the widget.
              Highlights are generally turned on when the widget is selected.
```

Note that subclasses may ignore some of these methods and implement their own depending on the specifics of the widget.

- `obj.WidgetInteraction (double newEventPos[2])` - The following is a suggested API for widget representations. These methods define the communication between the widget and its representation. These methods are only suggestions because widgets take on so many different forms that a universal API is not deemed practical. However, these methods should be implemented when possible to insure that the VTK widget hierarchy remains self-consistent.

```
PlaceWidget() - given a bounding box (xmin,xmax,ymin,ymax,zmin,zmax), place
                the widget inside of it. The current orientation of the widget
                is preserved, only scaling and translation is performed.
StartWidgetInteraction() - generally corresponds to a initial event (e.g.,
                           mouse down) that starts the interaction process
                           with the widget.
WidgetInteraction() - invoked when an event causes the widget to change
                      appearance.
EndWidgetInteraction() - generally corresponds to a final event (e.g., mouse up)
                         and completes the interaction sequence.
ComputeInteractionState() - given (X,Y) display coordinates in a renderer, with a
                            possible flag that modifies the computation,
                            what is the state of the widget?
GetInteractionState() - return the current state of the widget. Note that the
                        value of ''0'' typically refers to ''outside''. The
                        interaction state is strictly a function of the
                        representation, and the widget/represent must agree
                        on what they mean.
Highlight() - turn on or off any highlights associated with the widget.
              Highlights are generally turned on when the widget is selected.
```

Note that subclasses may ignore some of these methods and implement their own depending on the specifics of the widget.

- `obj.EndWidgetInteraction (double newEventPos[2])` - The following is a suggested API for widget representations. These methods define the communication between the widget and its representation. These methods are only suggestions because widgets take on so many different forms that a universal

API is not deemed practical. However, these methods should be implemented when possible to insure that the VTK widget hierarchy remains self-consistent.

```
PlaceWidget() - given a bounding box (xmin,xmax,ymin,ymax,zmin,zmax), place
                the widget inside of it. The current orientation of the widget
                is preserved, only scaling and translation is performed.
StartWidgetInteraction() - generally corresponds to a initial event (e.g.,
                           mouse down) that starts the interaction process
                           with the widget.
WidgetInteraction() - invoked when an event causes the widget to change
                      appearance.
EndWidgetInteraction() - generally corresponds to a final event (e.g., mouse up)
                         and completes the interaction sequence.
ComputeInteractionState() - given (X,Y) display coordinates in a renderer, with a
                            possible flag that modifies the computation,
                            what is the state of the widget?
GetInteractionState() - return the current state of the widget. Note that the
                        value of ''0'' typically refers to ''outside''. The
                        interaction state is strictly a function of the
                        representation, and the widget/represent must agree
                        on what they mean.
Highlight() - turn on or off any highlights associated with the widget.
              Highlights are generally turned on when the widget is selected.
```

Note that subclasses may ignore some of these methods and implement their own depending on the specifics of the widget.

- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - The following is a suggested API for widget representations. These methods define the communication between the widget and its representation. These methods are only suggestions because widgets take on so many different forms that a universal API is not deemed practical. However, these methods should be implemented when possible to insure that the VTK widget hierarchy remains self-consistent.

```
PlaceWidget() - given a bounding box (xmin,xmax,ymin,ymax,zmin,zmax), place
                the widget inside of it. The current orientation of the widget
                is preserved, only scaling and translation is performed.
StartWidgetInteraction() - generally corresponds to a initial event (e.g.,
                           mouse down) that starts the interaction process
                           with the widget.
WidgetInteraction() - invoked when an event causes the widget to change
                      appearance.
EndWidgetInteraction() - generally corresponds to a final event (e.g., mouse up)
                         and completes the interaction sequence.
ComputeInteractionState() - given (X,Y) display coordinates in a renderer, with a
                            possible flag that modifies the computation,
                            what is the state of the widget?
GetInteractionState() - return the current state of the widget. Note that the
                        value of ''0'' typically refers to ''outside''. The
                        interaction state is strictly a function of the
                        representation, and the widget/represent must agree
                        on what they mean.
Highlight() - turn on or off any highlights associated with the widget.
              Highlights are generally turned on when the widget is selected.
```

Note that subclasses may ignore some of these methods and implement their own depending on the specifics of the widget.

- `int = obj.GetInteractionState ()` - The following is a suggested API for widget representations. These methods define the communication between the widget and its representation. These methods are only suggestions because widgets take on so many different forms that a universal API is not deemed practical. However, these methods should be implemented when possible to insure that the VTK widget hierarchy remains self-consistent.

```
PlaceWidget() - given a bounding box (xmin,xmax,ymin,ymax,zmin,zmax), place
                the widget inside of it. The current orientation of the widget
                is preserved, only scaling and translation is performed.
StartWidgetInteraction() - generally corresponds to a initial event (e.g.,
                           mouse down) that starts the interaction process
                           with the widget.
WidgetInteraction() - invoked when an event causes the widget to change
                      appearance.
EndWidgetInteraction() - generally corresponds to a final event (e.g., mouse up)
                         and completes the interaction sequence.
ComputeInteractionState() - given (X,Y) display coordinates in a renderer, with a
                            possible flag that modifies the computation,
                            what is the state of the widget?
GetInteractionState() - return the current state of the widget. Note that the
                        value of ''0'' typically refers to ''outside''. The
                        interaction state is strictly a function of the
                        representation, and the widget/represent must agree
                        on what they mean.
Highlight() - turn on or off any highlights associated with the widget.
              Highlights are generally turned on when the widget is selected.
```

Note that subclasses may ignore some of these methods and implement their own depending on the specifics of the widget.

- `obj.Highlight (int )` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `obj.SetPlaceFactor (double )` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `double = obj.GetPlaceFactorMinValue ()` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `double = obj.GetPlaceFactorMaxValue ()` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `double = obj.GetPlaceFactor ()` - Set/Get a factor representing the scaling of the widget upon placement (via the PlaceWidget() method). Normally the widget is placed so that it just fits within

the bounding box defined in PlaceWidget(bounds). The PlaceFactor will make the widget larger (PlaceFactor ¿ 1) or smaller (PlaceFactor ¡ 1). By default, PlaceFactor is set to 0.5.

- `obj.SetHandleSize (double )` - Set/Get the factor that controls the size of the handles that appear as part of the widget (if any). These handles (like spheres, etc.) are used to manipulate the widget. The HandleSize data member allows you to change the relative size of the handles. Note that while the handle size is typically expressed in pixels, some subclasses may use a relative size with respect to the viewport. (As a corollary, the value of this ivar is often set by subclasses of this class during instance instantiation.)

- `double = obj.GetHandleSizeMinValue ()` - Set/Get the factor that controls the size of the handles that appear as part of the widget (if any). These handles (like spheres, etc.) are used to manipulate the widget. The HandleSize data member allows you to change the relative size of the handles. Note that while the handle size is typically expressed in pixels, some subclasses may use a relative size with respect to the viewport. (As a corollary, the value of this ivar is often set by subclasses of this class during instance instantiation.)

- `double = obj.GetHandleSizeMaxValue ()` - Set/Get the factor that controls the size of the handles that appear as part of the widget (if any). These handles (like spheres, etc.) are used to manipulate the widget. The HandleSize data member allows you to change the relative size of the handles. Note that while the handle size is typically expressed in pixels, some subclasses may use a relative size with respect to the viewport. (As a corollary, the value of this ivar is often set by subclasses of this class during instance instantiation.)

- `double = obj.GetHandleSize ()` - Set/Get the factor that controls the size of the handles that appear as part of the widget (if any). These handles (like spheres, etc.) are used to manipulate the widget. The HandleSize data member allows you to change the relative size of the handles. Note that while the handle size is typically expressed in pixels, some subclasses may use a relative size with respect to the viewport. (As a corollary, the value of this ivar is often set by subclasses of this class during instance instantiation.)

- `int = obj.GetNeedToRender ()` - Some subclasses use this data member to keep track of whether to render or not (i.e., to minimize the total number of renders).

- `obj.SetNeedToRender (int )` - Some subclasses use this data member to keep track of whether to render or not (i.e., to minimize the total number of renders).

- `int = obj.GetNeedToRenderMinValue ()` - Some subclasses use this data member to keep track of whether to render or not (i.e., to minimize the total number of renders).

- `int = obj.GetNeedToRenderMaxValue ()` - Some subclasses use this data member to keep track of whether to render or not (i.e., to minimize the total number of renders).

- `obj.NeedToRenderOn ()` - Some subclasses use this data member to keep track of whether to render or not (i.e., to minimize the total number of renders).

- `obj.NeedToRenderOff ()` - Some subclasses use this data member to keep track of whether to render or not (i.e., to minimize the total number of renders).

- `double = obj.GetBounds ()` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `obj.ShallowCopy (vtkProp prop)` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e.,

not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `obj.GetActors (vtkPropCollection )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `obj.GetActors2D (vtkPropCollection )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `obj.GetVolumes (vtkPropCollection )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `obj.ReleaseGraphicsResources (vtkWindow )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `int = obj.RenderOverlay (vtkViewport )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `int = obj.RenderOpaqueGeometry (vtkViewport )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `int = obj.RenderVolumetricGeometry (vtkViewport )` - Methods to make this class behave as a vtkProp. They are repeated here (from the vtkProp superclass) as a reminder to the widget implementor. Failure to implement these methods properly may result in the representation not appearing in the scene (i.e., not implementing the Render() methods properly) or leaking graphics resources (i.e., not implementing ReleaseGraphicsResources() properly).

- `int = obj.HasTranslucentPolygonalGeometry ()`

42.107 vtkWidgetSet

42.107.1 Usage

The class synchronizes a set of vtkAbstractWidget(s). Widgets typically invoke "Actions" that drive the geometry/behaviour of their representations in response to interactor events. Interactor interactions on a render window are mapped into "Callbacks" by the widget, from which "Actions" are dispatched to the entire set. This architecture allows us to tie widgets existing in different render windows together. For instance a HandleWidget might exist on the sagittal view. Moving it around should update the representations of the corresponding handle widget that lies on the axial and coronal and volume views as well.

.SECTION User API A user would use this class as follows.

```
vtkWidgetSet *set = vtkWidgetSet::New();
vtkParallelopipedWidget *w1 = vtkParallelopipedWidget::New();
set->AddWidget(w1);
w1->SetInteractor(axialRenderWindow->GetInteractor());
vtkParallelopipedWidget *w2 = vtkParallelopipedWidget::New();
set->AddWidget(w2);
w2->SetInteractor(coronalRenderWindow->GetInteractor());
vtkParallelopipedWidget *w3 = vtkParallelopipedWidget::New();
set->AddWidget(w3);
w3->SetInteractor(sagittalRenderWindow->GetInteractor());
set->SetEnabled(1);
```

.SECTION Motivation The motivation for this class is really to provide a usable API to tie together multiple widgets of the same kind. To enable this, subclasses of vtkAbstractWidget, must be written as follows: They will generally have callback methods mapped to some user interaction such as:

```
this->CallbackMapper->SetCallbackMethod(vtkCommand::LeftButtonPressEvent,
                        vtkEvent::NoModifier, 0, 0, NULL,
                        vtkPaintbrushWidget::BeginDrawStrokeEvent,
                        this, vtkPaintbrushWidget::BeginDrawCallback);
```

The callback invoked when the left button is pressed looks like:

```
void vtkPaintbrushWidget::BeginDrawCallback(vtkAbstractWidget *w)
{
  vtkPaintbrushWidget *self = vtkPaintbrushWidget::SafeDownCast(w);
  self->WidgetSet->DispatchAction(self, \&vtkPaintbrushWidget::BeginDrawAction);
}
```

The actual code for handling the drawing is written in the BeginDrawAction method.

```
void vtkPaintbrushWidget::BeginDrawAction( vtkPaintbrushWidget *dispatcher)
{
// Do stuff to draw...
// Here dispatcher is the widget that was interacted with, the one that
// dispatched an action to all the other widgets in its group. You may, if
// necessary find it helpful to get parameters from it.
//   For instance for a ResizeAction:
//     if (this != dispatcher)
//       {
//       double *newsize = dispatcher->GetRepresentation()->GetSize();
//       this->WidgetRep->SetSize(newsize);
```

```
//       }
//     else
//       {
//       this->WidgetRep->IncrementSizeByDelta();
//       }
}
```

To create an instance of class vtkWidgetSet, simply invoke its constructor as follows

```
obj = vtkWidgetSet
```

42.107.2 Methods

The class vtkWidgetSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWidgetSet class.

- `string = obj.GetClassName ()` - Standard methods for a VTK class.
- `int = obj.IsA (string name)` - Standard methods for a VTK class.
- `vtkWidgetSet = obj.NewInstance ()` - Standard methods for a VTK class.
- `vtkWidgetSet = obj.SafeDownCast (vtkObject o)` - Standard methods for a VTK class.
- `obj.SetEnabled (int )` - Method for activiating and deactiviating all widgets in the group.
- `obj.EnabledOn ()` - Method for activiating and deactiviating all widgets in the group.
- `obj.EnabledOff ()` - Method for activiating and deactiviating all widgets in the group.
- `obj.AddWidget (vtkAbstractWidget )` - Add a widget to the set.
- `obj.RemoveWidget (vtkAbstractWidget )` - Remove a widget from the set
- `int = obj.GetNumberOfWidgets ()` - Get number of widgets in the set.
- `vtkAbstractWidget = obj.GetNthWidget (int )` - Get the Nth widget in the set.

42.108 vtkXYPlotWidget

42.108.1 Usage

This class provides support for interactively manipulating the position, size, and orientation of a XY Plot. It listens to Left mouse events and mouse movement. It will change the cursor shape based on its location. If the cursor is over an edge of thea XY plot it will change the cursor shape to a resize edge shape. If the position of a XY plot is moved to be close to the center of one of the four edges of the viewport, then the XY plot will change its orientation to align with that edge. This orientation is sticky in that it will stay that orientation until the position is moved close to another edge.

To create an instance of class vtkXYPlotWidget, simply invoke its constructor as follows

```
obj = vtkXYPlotWidget
```

42.108.2 Methods

The class vtkXYPlotWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXYPlotWidget class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXYPlotWidget = obj.NewInstance ()`
- `vtkXYPlotWidget = obj.SafeDownCast (vtkObject o)`
- `obj.SetXYPlotActor (vtkXYPlotActor )` - Get the XY plot used by this Widget. One is created automatically.
- `vtkXYPlotActor = obj.GetXYPlotActor ()` - Get the XY plot used by this Widget. One is created automatically.
- `obj.SetEnabled (int )` - Methods for turning the interactor observer on and off.
