Chapter 1

Introduction and Getting Started

1.1 INSTALL Installing FreeMat

1.1.1 General Instructions

Here are the general instructions for installing FreeMat. First, follow the instructions listed below for the platform of interest. Then, run the

```
-->pathtool
```

which brings up the path setup tool. More documentation on the GUI elements (and how to use them) will be forthcoming.

1.1.2 Linux

For Linux, FreeMat is now provided as a binary installation. To install it simply download the binary using your web browser, and then unpack it

```
tar xvfz FreeMat-<VERSION_NUMBER>-Linux-Binary.tar.gz
```

You can then run FreeMat directly without any additional effort

```
FreeMat-<VERSION_NUMBER>-Linux-Binary/Contents/bin/FreeMat
```

will start up FreeMat as an X application. If you want to run it as a command line application (to run from within an xterm), use the `nogui` flag

```
FreeMat-<VERSION_NUMBER>-Linux-Binary/Contents/bin/FreeMat -nogui
```

If you do not want FreeMat to use X at all (no graphics at all), use the `noX` flag

```
FreeMat-<VERSION_NUMBER>-Linux-Binary/Contents/bin/FreeMat -noX
```

For convenience, you may want to add FreeMat to your path. The exact mechanism for doing this depends on your shell. Assume that you have unpacked `FreeMat-<VERSION\_NUMBER>-Linux-Binary.tar.gz` into the directory `/home/myname`. Then if you use `csh` or its derivatives (like `tcsh`) you should add the following line to your `.cshrc` file:

```
set path=($path /home/myname/FreeMat-<VERSION_NUMBER>-Linux/Binary/Contents/bin)
```

If you use `bash`, then add the following line to your `.bash\_profile`

```
PATH=$PATH:/home/myname/FreeMat-<VERSION_NUMBER>-Linux/Binary/Contents/bin
```

If the prebuilt binary package does not work for your Linux distribution, you will need to build FreeMat from source (see the source section below). When you have FreeMat running, you can setup your path using the `pathtool`. Note that the `FREEMAT\_PATH` is no longer used by FreeMat. You must use the `pathtool` to adjust the path.

1.1.3 Windows

For Windows, FreeMat is installed via a binary installer program. To use it, simply download the setup program `FreeMat-<VERSION\_NUMBER>-Setup.exe`, and double click it. Follow the instructions to do the installation, then setup your path using `pathtool`.

1.1.4 Mac OS X

For Mac OS X, FreeMat is distributed as an application bundle. To install it, simply download the compressed disk image file `FreeMat-<VERSION\_NUMBER>.dmg`, double click to mount the disk image, and then copy the application `FreeMat-<VERSION\_NUMBER>` to some convenient place. To run FreeMat, simply double click on the application. Run `pathtool` to setup your FreeMat path.

1.1.5 Source Code

The source code build is a little more complicated than previous versions of FreeMat. Here are the current build instructions for all platforms.

1. Build and install Qt 4.3 or later - `http://trolltech.com/developer/downloads/opensource`
2. Install g77 or gfortran (use fink for Mac OS X, use `gcc-g77` package for MinGW)
3. Download the source code `FreeMat-<VERSION\_NUMBER>-src.tar.gz`.
4. Unpack the source code: `tar xvfz FreeMat-<VERSION\_NUMBER>-src.tar.gz`.
5. For Windows, you will need to install MSYS as well as MINGW to build FreeMat. You will also need unzip to unpack the enclosed matio.zip archive. Alternately, you can cross-build the WIndows version of FreeMat under Linux (this is how I build it now).
6. If you are extraordinarily lucky (or prepared), you can issue the usual ./configure, then the make and make install. This is not likely to work because of the somewhat esoteric dependencies of FreeMat. The configure step will probably fail and indicate what external dependencies are still needed.
7. I assume that you are familiar with the process of installing dependencies if you are trying to build FreeMat from source.

To build a binary distributable (app bundle on the Mac, setup installer on win32, and a binary distribution on Linux), you will need to run `make package` instead of `make install`.

Chapter 2

Variables and Arrays

2.1 CELL Cell Array Definitions

2.1.1 Usage

The cell array is a fairly powerful array type that is available in FreeMat. Generally speaking, a cell array is a heterogenous array type, meaning that different elements in the array can contain variables of different type (including other cell arrays). For those of you familiar with `C`, it is the equivalent to the `void *` array. The general syntax for their construction is

```
A = {row_def1;row_def2;...;row_defN}
```

where each row consists of one or more elements, seperated by commas

```
row_defi = element_i1,element_i2,...,element_iM
```

Each element can be any type of FreeMat variable, including matrices, arrays, cell-arrays, structures, strings, etc. The restriction on the definition is that each row must have the same number of elements in it.

2.1.2 Examples

Here is an example of a cell-array that contains a number, a string, and an array

```
--> A = {14,'hello',[1:10]}

A =
 [14] [hello] [1x10 double array]
```

Note that in the output, the number and string are explicitly printed, but the array is summarized. We can create a 2-dimensional cell-array by adding another row definition

```
--> B = {pi,i;e,-1}

B =
 [3.14159] [0+1i]
 [2.71828] [-1]
```

Finally, we create a new cell array by placing `A` and `B` together

```
--> C = {A,B}

C =
 [1x3 cell array] [2x2 cell array]
```

2.2 FUNCTIONHANDLES Function Handles

2.2.1 Usage

Starting with version 1.11, FreeMat now supports `function handles`, or `function pointers`. A `function handle` is an alias for a function or script that is stored in a variable. First, the way to assign a function handle is to use the notation

```
handle = @func
```

where `func` is the name to point to. The function `func` must exist at the time we make the call. It can be a local function (i.e., a subfunction). To use the `handle`, we can either pass it to `feval` via

```
[x,y] = feval(handle,arg1,arg2).
```

Alternately, you can the function directly using the notation

```
[x,y] = handle(arg1,arg2)
```

2.3 GLOBAL Global Variables

2.3.1 Usage

Global variables are shared variables that can be seen and modified from any function or script that declares them. The syntax for the `global` statement is

```
global variable_1 variable_2 ...
```

The `global` statement must occur before the variables appear.

2.3.2 Example

Here is an example of two functions that use a global variable to communicate an array between them. The first function sets the global variable.

```
    set_global.m
function set_global(x)
  global common_array
  common_array = x;
```

The second function retrieves the value from the global variable

```
    get_global.m
function x = get_global
  global common_array
  x = common_array;
```

Here we exercise the two functions

```
--> set_global('Hello')
--> get_global

ans =
Hello
```

2.4 INDEXING Indexing Expressions

2.4.1 Usage

There are three classes of indexing expressions available in FreeMat: `()`, `{}`, and `.` Each is explained below in some detail, and with its own example section.

2.4.2 Array Indexing

We start with array indexing `()`, which is the most general indexing expression, and can be used on any array. There are two general forms for the indexing expression - the N-dimensional form, for which the general syntax is

```
variable(index_1,index_2,...,index_n)
```

and the vector form, for which the general syntax is

```
variable(index)
```

Here each index expression is either a scalar, a range of integer values, or the special token `:`, which is shorthand for `1:end`. The keyword `end`, when included in an indexing expression, is assigned the length of the array in that dimension. The concept is easier to demonstrate than explain. Consider the following examples:

```
--> A = zeros(4)

A =
 0 0 0 0
 0 0 0 0
 0 0 0 0
 0 0 0 0

--> B = float(randn(2))

B =
   -0.1688    0.5183
    0.9485   -0.6864

--> A(2:3,2:3) = B

A =
         0         0         0         0
         0   -0.1688    0.5183         0
         0    0.9485   -0.6864         0
         0         0         0         0
```

Here the array indexing was used on the left hand side only. It can also be used for right hand side indexing, as in

```
--> C = A(2:3,1:end)

C =
         0   -0.1688    0.5183         0
         0    0.9485   -0.6864         0
```

Note that we used the `end` keyword to avoid having to know that `A` has 4 columns. Of course, we could also use the `:` token instead:

```
--> C = A(2:3,:)

C =
         0   -0.1688    0.5183         0
         0    0.9485   -0.6864         0
```

An extremely useful example of `:` with array indexing is for slicing. Suppose we have a 3-D array, that is `2 x 2 x 3`, and we want to set the middle slice:

```
--> D = zeros(2,2,3)

D =

(:,:,1) =
 0 0
 0 0

(:,:,2) =
 0 0
 0 0

(:,:,3) =
 0 0
 0 0

--> D(:,:,2) = int32(10*rand(2,2))

D =

(:,:,1) =
  0  0
  0  0

(:,:,2) =
  9 10
  5  8

(:,:,3) =
  0  0
  0  0
```

In another level of nuance, the assignment expression will automatically fill in the indexed rectangle on the left using data from the right hand side, as long as the lengths match. So we can take a vector and roll it into a matrix using this approach:

```
--> A = zeros(4)

A =
 0 0 0 0
 0 0 0 0
 0 0 0 0
 0 0 0 0

--> v = [1;2;3;4]

v =
 1
 2
 3
 4

--> A(2:3,2:3) = v

A =
```

```
 0 0 0 0
 0 1 3 0
 0 2 4 0
 0 0 0 0
```

The N-dimensional form of the variable index is limited to accessing only (hyper-) rectangular regions of the array. You cannot, for example, use it to access only the diagonal elements of the array. To do that, you use the second form of the array access (or a loop). The vector form treats an arbitrary N-dimensional array as though it were a column vector. You can then access arbitrary subsets of the arrays elements (for example, through a `find` expression) efficiently. Note that in vector form, the `end` keyword takes the meaning of the total length of the array (defined as the product of its dimensions), as opposed to the size along the first dimension.

2.4.3 Cell Indexing

The second form of indexing operates, to a large extent, in the same manner as the array indexing, but it is by no means interchangable. As the name implies, `cell`-indexing applies only to `cell` arrays. For those familiar with `C`, cell- indexing is equivalent to pointer derefencing in `C`. First, the syntax:

```
  variable{index_1,index_2,...,index_n}
```

and the vector form, for which the general syntax is

```
  variable{index}
```

The rules and interpretation for N-dimensional and vector indexing are identical to `()`, so we will describe only the differences. In simple terms, applying `()` to a cell-array returns another cell array that is a subset of the original array. On the other hand, applying `{}` to a cell-array returns the contents of that cell array. A simple example makes the difference quite clear:

```
--> A = {1, 'hello', [1:4]}

A =
 [1] [hello] [1x4 double array]

--> A(1:2)

ans =
 [1] [hello]

--> A{1:2}

ans =

1 of 2:
 1

2 of 2:
hello
```

You may be surprised by the response to the last line. The output is multiple assignments to `ans`!. The output of a cell-array dereference can be used anywhere a list of expressions is required. This includes arguments and returns for function calls, matrix construction, etc. Here is an example of using cell-arrays to pass parameters to a function:

```
--> A = {[1,3,0],[5,2,7]}

A =
 [1x3 double array] [1x3 double array]

--> max(A{1:end})

ans =
 5 3 7
```

And here, cell-arrays are used to capture the return.

```
--> [K{1:2}] = max(randn(1,4))
K =
 [0.779398] [4]
```

Here, cell-arrays are used in the matrix construction process:

```
--> C = [A{1};A{2}]

C =
 1 3 0
 5 2 7
```

Note that this form of indexing is used to implement variable length arguments to function. See `varargin` and `varargout` for more details.

2.4.4 Structure Indexing

The third form of indexing is structure indexing. It can only be applied to structure arrays, and has the general syntax

```
variable.fieldname
```

where `fieldname` is one of the fields on the structure. Note that in FreeMat, fields are allocated dynamically, so if you reference a field that does not exist in an assignment, it is created automatically for you. If variable is an array, then the result of the `.` reference is an expression list, exactly like the `{}` operator. Hence, we can use structure indexing in a simple fashion:

```
--> clear A
--> A.color = 'blue'

A =
    color: blue
--> B = A.color

B =
blue
```

Or in more complicated ways using expression lists for function arguments

```
--> clear A
--> A(1).maxargs = [1,6,7,3]

A =
    maxargs: 1x4 double array
--> A(2).maxargs = [5,2,9,0]
```

```
A =
1x2 struct array with fields:
    maxargs
--> max(A.maxargs)

ans =
 5 6 9 3
```

or to store function outputs

```
--> clear A
--> A(1).maxreturn = [];
--> A(2).maxreturn = [];
--> [A.maxreturn] = max(randn(1,4))
A =
1x2 struct array with fields:
    maxreturn
```

FreeMat now also supports the so called dynamic-field indexing expressions. In this mode, the fieldname is supplied through an expression instead of being explicitly provided. For example, suppose we have a set of structure indexed by color,

```
--> x.red = 430;
--> x.green = 240;
--> x.blue = 53;
--> x.yello = 105

x =
    red: 430
    green: 240
    blue: 53
    yello: 105
```

Then we can index into the structure `x` using a dynamic field reference:

```
--> y = 'green'

y =
green
--> a = x.(y)

a =
 240
```

Note that the indexing expression has to resolve to a string for dynamic field indexing to work.

2.4.5 Complex Indexing

The indexing expressions described above can be freely combined to affect complicated indexing expressions. Here is an example that exercises all three indexing expressions in one assignment.

```
--> Z{3}.foo(2) = pi

Z =
 [0] [0] [1x1 struct array]
```

From this statement, FreeMat infers that Z is a cell-array of length 3, that the third element is a structure array (with one element), and that this structure array contains a field named 'foo' with two double elements, the second of which is assigned a value of pi.

2.5 MATRIX Matrix Definitions

2.5.1 Usage

The matrix is the basic datatype of FreeMat. Matrices can be defined using the following syntax

```
A = [row_def1;row_def2;...,row_defN]
```

where each row consists of one or more elements, seperated by commas

```
row_defi = element_i1,element_i2,...,element_iM
```

Each element can either be a scalar value or another matrix, provided that the resulting matrix definition makes sense. In general this means that all of the elements belonging to a row have the same number of rows themselves, and that all of the row definitions have the same number of columns. Matrices are actually special cases of N-dimensional arrays where `N<=2`. Higher dimensional arrays cannot be constructed using the bracket notation described above. The type of a matrix defined in this way (using the bracket notation) is determined by examining the types of the elements. The resulting type is chosen so no information is lost on any of the elements (or equivalently, by choosing the highest order type from those present in the elements).

2.5.2 Examples

Here is an example of a matrix of `int32` elements (note that untyped integer constants default to type `int32`).

```
--> A = [1,2;5,8]

A =
 1 2
 5 8
```

Now we define a new matrix by adding a column to the right of `A`, and using float constants.

```
--> B = [A,[3.2f;5.1f]]

B =
    1.0000    2.0000    3.2000
    5.0000    8.0000    5.1000
```

Next, we add extend `B` by adding a row at the bottom. Note how the use of an untyped floating point constant forces the result to be of type `double`

```
--> C = [B;5.2,1.0,0.0]

C =
    1.0000    2.0000    3.2000
    5.0000    8.0000    5.1000
    5.2000    1.0000         0
```

If we instead add a row of `complex` values (recall that `i` is a `complex` constant, not a `dcomplex` constant)

```
--> D = [B;2.0f+3.0f*i,i,0.0f]

D =
   1.0000 +  0.0000i   2.0000 +  0.0000i   3.2000 +  0.0000i
   5.0000 +  0.0000i   8.0000 +  0.0000i   5.1000 +  0.0000i
   2.0000 +  3.0000i   0.0000 +  1.0000i        0
```

Likewise, but using `dcomplex` constants

```
--> E = [B;2.0+3.0*i,i,0.0]

E =
   1.0000 +  0.0000i   2.0000 +  0.0000i   3.2000 +  0.0000i
   5.0000 +  0.0000i   8.0000 +  0.0000i   5.1000 +  0.0000i
   2.0000 +  3.0000i   0.0000 +  1.0000i        0
```

Finally, in FreeMat, you can construct matrices with strings as contents, but you have to make sure that if the matrix has more than one row, that all the strings have the same length.

```
--> F = ['hello';'there']

F =
hello
there
```

2.6 PERSISTENT Persistent Variables

2.6.1 Usage

Persistent variables are variables whose value persists between calls to a function or script. The general syntax for its use is

```
persistent variable1 variable2 ... variableN
```

The `persistent` statement must occur before the variable is the tagged as persistent. Per the MATLAB API documentation an empty variable is created when the `persistent` statement is called.

2.6.2 Example

Here is an example of a function that counts how many times it has been called.

```
    count_calls.m
function count_calls
  persistent ccount
  if isempty(ccount); ccount = 0; end;
  ccount = ccount + 1;
  printf('Function has been called %d times\n',ccount);
```

We now call the function several times:

```
--> for i=1:10; count_calls; end
Function has been called 1 times
Function has been called 2 times
Function has been called 3 times
Function has been called 4 times
Function has been called 5 times
Function has been called 6 times
Function has been called 7 times
Function has been called 8 times
Function has been called 9 times
Function has been called 10 times
```

2.7 STRUCT Structure Array Constructor

2.7.1 Usage

Creates an array of structures from a set of field, value pairs. The syntax is

```
y = struct(n_1,v_1,n_2,v_2,...)
```

where `n\_i` are the names of the fields in the structure array, and `v\_i` are the values. The values `v\_i` must either all be scalars, or be cell-arrays of all the same dimensions. In the latter case, the output structure array will have dimensions dictated by this common size. Scalar entries for the `v\_i` are replicated to fill out their dimensions. An error is raised if the inputs are not properly matched (i.e., are not pairs of field names and values), or if the size of any two non-scalar values cell-arrays are different.

Another use of the `struct` function is to convert a class into a structure. This allows you to access the members of the class, directly but removes the class information from the object.

2.7.2 Example

This example creates a 3-element structure array with three fields, `foo` `bar` and `key`, where the contents of `foo` and `bar` are provided explicitly as cell arrays of the same size, and the contents of `bar` are replicated from a scalar.

```
--> y = struct('foo',{1,3,4},'bar',{'cheese','cola','beer'},'key',508)

y =
1x3 struct array with fields:
    foo
    bar
    key
--> y(1)

ans =
    foo: 1
    bar: cheese
    key: 508
--> y(2)

ans =
    foo: 3
    bar: cola
    key: 508
--> y(3)

ans =
    foo: 4
    bar: beer
    key: 508
```

An alternate way to create a structure array is to initialize the last element of each field of the structure

```
--> Test(2,3).Type = 'Beer';
--> Test(2,3).Ounces = 12;
--> Test(2,3).Container = 'Can';
--> Test(2,3)

ans =
    Type: Beer
```

```
    Ounces: 12
    Container: Can
--> Test(1,1)

ans =
    Type: 0
    Ounces: 0
    Container: 0
```

Chapter 3

Functions and Scripts

3.1 ANONYMOUS Anonymous Functions

3.1.1 Usage

Anonymous functions are simple, nameless functions that can be defined anywhere (in a script, function, or at the prompt). They are intended to supplant `inline` functions. The syntax for an anonymous function is simple:

```
y = @(arg1,arg2,...,argn) expression
```

where `arg1,arg2,...,argn` is a list of valid identifiers that define the arguments to the function, and `expression` is the expression to compute in the function. The returned value `y` is a function handle for the anonymous function that can then be used to evaluate the expression. Note that `y` will capture the value of variables that are not indicated in the argument list from the current scope or workspace at the time it is defined. So, for example, consider the simple anonymous function definition

```
y = @(x) a*(x+b)
```

In order for this definition to work, the variables `a` and `b` need to be defined in the current workspace. Whatever value they have is captured in the function handle `y`. To change the values of `a` and `b` in the anonymous function, you must recreate the handle using another call. See the examples section for more information. In order to use the anonymous function, you can use it just like any other function handle. For example,

```
p = y(3)
p = y()
p = feval(y,3)
```

are all examples of using the `y` anonymous function to perform a calculation.

3.1.2 Examples

Here are some examples of using an anonymous function

```
--> a = 2; b = 4;    % define a and b (slope and intercept)
--> y = @(x) a*x+b   % create the anonymous function

y =
 @(x)   a*x+b   % create the anonymous function
--> y(2)             % evaluate it for x = 2

ans =
```

```
 8

--> a = 5; b = 7;    % change a and b
--> y(2)             % the value did not change!  because a=2,b=4 are captured in y

ans =
 8

--> y = @(x) a*x+b   % recreate the function

y =
 @(x)   a*x+b   % recreate the function
--> y(2)             % now the new values are used

ans =
 17
```

3.2 FUNC2STR Function to String conversion

3.2.1 Usage

The `func2str` function converts a function pointer into a string. The syntax is

```
y = func2str(funcptr)
```

where `funcptr` is a function pointer. If `funcptr` is a pointer to a function, then `y` is the name of the function. On the other hand, if `funcptr` is an anonymous function then `func2str` returns the definition of the anonymous function.

3.2.2 Example

Here is a simple example of using `func2str`

```
--> y = @sin

y =
 @sin
--> x = func2str(y)

x =
sin
```

If we use an anonymous function, then `func2str` returns the definition of the anonymous function

```
--> y = @(x) x.^2

y =
 @(x)   x.^2
--> x = func2str(y)

x =
 @(x)   x.^2
```

3.3 FUNCTION Function Declarations

3.3.1 Usage

There are several forms for function declarations in FreeMat. The most general syntax for a function declaration is the following:

```
function [out_1,...,out_M,varargout] = fname(in_1,...,in_N,varargin)
```

where `out\_i` are the output parameters, `in\_i` are the input parameters, and `varargout` and `varargin` are special keywords used for functions that have variable inputs or outputs. For functions with a fixed number of input or output parameters, the syntax is somewhat simpler:

```
function [out_1,...,out_M] = fname(in_1,...,in_N)
```

Note that functions that have no return arguments can omit the return argument list (of `out\_i`) and the equals sign:

```
function fname(in_1,...,in_N)
```

Likewise, a function with no arguments can eliminate the list of parameters in the declaration:

```
function [out_1,...,out_M] = fname
```

Functions that return only a single value can omit the brackets

```
function out_1 = fname(in_1,...,in_N)
```

In the body of the function `in\_i` are initialized with the values passed when the function is called. Also, the function must assign values for `out\_i` to pass values to the caller. Note that by default, FreeMat passes arguments by value, meaning that if we modify the contents of `in\_i` inside the function, it has no effect on any variables used by the caller. Arguments can be passed by reference by prepending an ampersand `\&` before the name of the input, e.g.

```
function [out1,...,out_M] = fname(in_1,&in_2,in_3,...,in_N)
```

in which case `in\_2` is passed by reference and not by value. Also, FreeMat works like `C` in that the caller does not have to supply the full list of arguments. Also, when `keywords` (see help `keywords`) are used, an arbitrary subset of the parameters may be unspecified. To assist in deciphering the exact parameters that were passed, FreeMat also defines two variables inside the function context: `nargin` and `nargout`, which provide the number of input and output parameters of the caller, respectively. See help for `nargin` and `nargout` for more details. In some circumstances, it is necessary to have functions that take a variable number of arguments, or that return a variable number of results. In these cases, the last argument to the parameter list is the special argument `varargin`. Inside the function, `varargin` is a cell-array that contains all arguments passed to the function that have not already been accounted for. Similarly, the function can create a cell array named `varargout` for variable length output lists. See help `varargin` and `varargout` for more details.

The function name `fname` can be any legal FreeMat identifier. Functions are stored in files with the `.m` extension. Note that the name of the file (and not the function name `fname` used in the declaration) is how the function appears in FreeMat. So, for example, if the file is named `foo.m`, but the declaration uses `bar` for the name of the function, in FreeMat, it will still appear as function `foo`. Note that this is only true for the first function that appears in a `.m` file. Additional functions that appear after the first function are known as `helper functions` or `local` functions. These are functions that can only be called by other functions in the same `.m` file. Furthermore the names of these helper functions are determined by their declaration and not by the name of the `.m` file. An example of using helper functions is included in the examples.

Another important feature of functions, as opposed to, say `scripts`, is that they have their own `scope`. That means that variables defined or modified inside a function do not affect the scope of the caller. That means that a function can freely define and use variables without unintentionally using a variable name reserved elsewhere. The flip side of this fact is that functions are harder to debug than scripts without using the `keyboard` function, because the intermediate calculations used in the function are not available once the function exits.

3.3.2 Examples

Here is an example of a trivial function that adds its first argument to twice its second argument:

```
    addtest.m
function c = addtest(a,b)
  c = a + 2*b;

--> addtest(1,3)

ans =
 7

--> addtest(3,0)

ans =
 3
```

Suppose, however, we want to replace the value of the first argument by the computed sum. A first attempt at doing so has no effect:

```
    addtest2.m
function addtest2(a,b)
  a = a + 2*b;

--> arg1 = 1

arg1 =
 1

--> arg2 = 3

arg2 =
 3

--> addtest2(arg1,arg2)
--> arg1

ans =
 1

--> arg2

ans =
 3
```

The values of `arg1` and `arg2` are unchanged, because they are passed by value, so that any changes to `a` and `b` inside the function do not affect `arg1` and `arg2`. We can change that by passing the first argument by reference:

```
    addtest3.m
function addtest3(&a,b)
  a = a + 2*b
```

Note that it is now illegal to pass a literal value for `a` when calling `addtest3`:

```
--> addtest3(3,4)

a =
 11

Error: Must have lvalue in argument passed by reference
--> addtest3(arg1,arg2)

a =
 7

--> arg1

ans =
 7

--> arg2

ans =
 3
```

The first example fails because we cannot pass a literal like the number `3` by reference. However, the second call succeeds, and note that `arg1` has now changed. Note: please be careful when passing by reference - this feature is not available in MATLAB and you must be clear that you are using it.

As variable argument and return functions are covered elsewhere, as are keywords, we include one final example that demonstrates the use of helper functions, or local functions, where multiple function declarations occur in the same file.

```
    euclidlength.m
function y = foo(x,y)
  square_me(x);
  square_me(y);
  y = sqrt(x+y);

function square_me(&t)
  t = t^2;

--> euclidlength(3,4)

ans =
 5

--> euclidlength(2,0)

ans =
 2
```

3.4 KEYWORDS Function Keywords

3.4.1 Usage

A feature of IDL that FreeMat has adopted is a modified form of `keywords`. The purpose of `keywords` is to allow you to call a function with the arguments to the function specified in an arbitrary order. To specify the syntax of `keywords`, suppose there is a function with prototype

```
function [out_1,...,out_M] = foo(in_1,...,in_N)
```

Then the general syntax for calling function `foo` using keywords is

```
foo(val_1, val_2, /in_k=3)
```

which is exactly equivalent to

```
foo(val_1, val_2, [], [], ..., [], 3),
```

where the 3 is passed as the k-th argument, or alternately,

```
foo(val_1, val_2, /in_k)
```

which is exactly equivalent to

```
foo(val_1, val_2, [], [], ..., [], logical(1)),
```

Note that you can even pass reference arguments using keywords.

3.4.2 Example

The most common use of keywords is in controlling options for functions. For example, the following function takes a number of binary options that control its behavior. For example, consider the following function with two arguments and two options. The function has been written to properly use and handle keywords. The result is much cleaner than the MATLAB approach involving testing all possible values of `nargin`, and forcing explicit empty brackets for don't care parameters.

```
    keyfunc.m
function c = keyfunc(a,b,operation,printit)
  if (~isset('a') | ~isset('b'))
    error('keyfunc requires at least the first two 2 arguments');
  end;
  if (~isset('operation'))
    % user did not define the operation, default to '+'
    operation = '+';
  end
  if (~isset('printit'))
    % user did not specify the printit flag, default is false
    printit = 0;
  end
  % simple operation...
  eval(['c = a ' operation ' b;']);
  if (printit)
    printf('%f %s %f = %f\n',a,operation,b,c);
  end
```

Now some examples of how this function can be called using `keywords`.

```
--> keyfunc(1,3)               % specify a and b, defaults for the others

ans =
 4

--> keyfunc(1,3,/printit)      % specify printit is true
1.000000 + 3.000000 = 4.000000

ans =
 4
```

```
--> keyfunc(/operation='-',2,3) % assigns a=2, b=3

ans =
 -1

--> keyfunc(4,/operation='*',/printit) % error as b is unspecified
In /home/sbasu/Devel/FreeMat/help/tmp/keyfunc.m(keyfunc) at line 3
    In scratch() at line 1
    In base(base)
    In base()
    In global()
Error: keyfunc requires at least the first two 2 arguments
```

3.5 NARGIN Number of Input Arguments

3.5.1 Usage

The `nargin` function returns the number of arguments passed to a function when it was called. The general syntax for its use is

```
  y = nargin
```

FreeMat allows for fewer arguments to be passed to a function than were declared, and `nargin`, along with `isset` can be used to determine exactly what subset of the arguments were defined.

You can also use `nargin` on a function handle to return the number of input arguments expected by the function

```
  y = nargin(fun)
```

where `fun` is the name of the function (e.g. `'sin'`) or a function handle.

3.5.2 Example

Here is a function that is declared to take five arguments, and that simply prints the value of `nargin` each time it is called.

```
    nargintest.m
function nargintest(a1,a2,a3,a4,a5)
  printf('nargin = %d\n',nargin);

--> nargintest(3);
nargin = 1
--> nargintest(3,'h');
nargin = 2
--> nargintest(3,'h',1.34);
nargin = 3
--> nargintest(3,'h',1.34,pi,e);
nargin = 5
--> nargin('sin')

ans =
 1

--> y = @sin
```

```
y =
 @sin
--> nargin(y)

ans =
 1
```

3.6 NARGOUT Number of Output Arguments

3.6.1 Usage

The `nargout` function computes the number of return values requested from a function when it was called. The general syntax for its use

```
y = nargout
```

FreeMat allows for fewer return values to be requested from a function than were declared, and `nargout` can be used to determine exactly what subset of the functions outputs are required.

You can also use `nargout` on a function handle to return the number of input arguments expected by the function

```
y = nargout(fun)
```

where `fun` is the name of the function (e.g. `'sin'`) or a function handle.

3.6.2 Example

Here is a function that is declared to return five values, and that simply prints the value of `nargout` each time it is called.

```
    nargouttest.m
function [a1,a2,a3,a4,a5] = nargouttest
  printf('nargout = %d\n',nargout);
  a1 = 1; a2 = 2; a3 = 3; a4 = 4; a5 = 5;

--> a1 = nargouttest
nargout = 1

a1 =
 1

--> [a1,a2] = nargouttest
nargout = 2
a1 =
 1

a2 =
 2

--> [a1,a2,a3] = nargouttest
nargout = 3
a1 =
 1

a2 =
 2
```

```
a3 =
 3

--> [a1,a2,a3,a4,a5] = nargouttest
nargout = 5
a1 =
 1

a2 =
 2

a3 =
 3

a4 =
 4

a5 =
 5

--> nargout('sin')

ans =
 1

--> y = @sin

y =
 @sin
--> nargout(y)

ans =
 1
```

3.7 SCRIPT Script Files

3.7.1 Usage

A script is a sequence of FreeMat commands contained in a `.m` file. When the script is called (via the name of the file), the effect is the same as if the commands inside the script file were issued one at a time from the keyboard. Unlike `function` files (which have the same extension, but have a `function` declaration), script files share the same environment as their callers. Hence, assignments, etc, made inside a script are visible to the caller (which is not the case for functions.

3.7.2 Example

Here is an example of a script that makes some simple assignments and `printf` statements.

```
    tscript.m
a = 13;
printf('a is %d\n',a);
b = a + 32
```

If we execute the script and then look at the defined variables

```
--> tscript
a is 13

b =
 45

--> who
  Variable Name       Type   Flags             Size
              a    double                    [1x1]
            ans    double                    [0x0]
              b    double                    [1x1]
```

we see that `a` and `b` are defined appropriately.

3.8 SPECIAL Special Calling Syntax

3.8.1 Usage

To reduce the effort to call certain functions, FreeMat supports a special calling syntax for functions that take string arguments. In particular, the three following syntaxes are equivalent, with one caveat:

```
functionname('arg1','arg2',...,'argn')
```

or the parenthesis and commas can be removed

```
functionname 'arg1' 'arg2' ... 'argn'
```

The quotes are also optional (providing, of course, that the argument strings have no spaces in them)

```
functionname arg1 arg2 ... argn
```

This special syntax enables you to type `hold on` instead of the more cumbersome `hold('on')`. The caveat is that FreeMat currently only recognizes the special calling syntax as the first statement on a line of input. Thus, the following construction

```
for i=1:10; plot(vec(i)); hold on; end
```

would not work. This limitation may be removed in a future version.

3.8.2 Example

Here is a function that takes two string arguments and returns the concatenation of them.

```
    strcattest.m
function strcattest(str1,str2)
  str3 = [str1,str2];
  printf('str1 = %s, str2 = %s, str3 = %s\n',str1,str2,str3);
```

We call `strcattest` using all three syntaxes.

```
--> strcattest('hi','ho')
str1 = hi, str2 = ho, str3 = hiho
--> strcattest 'hi' 'ho'
str1 = hi, str2 = ho, str3 = hiho
--> strcattest hi ho
str1 = hi, str2 = ho, str3 = hiho
```

3.9 STR2FUNC String to Function conversion

3.9.1 Usage

The `str2func` function converts a function name into a function pointer. The syntax is

```
y = str2func('funcname')
```

where `funcname` is the name of the function. The return variable `y` is a function handle that points to the given function.

An alternate syntax is used to construct an anonymous function given an expression. They syntax is

```
y = str2func('anonymous def')
```

where `anonymous def` is an expression that defines an anonymous function, for example `'@(x) x.\^2'`.

3.9.2 Example

Here is a simple example of using `str2func`.

```
--> sin(.5)              % Calling the function directly

ans =
    0.4794

--> y = str2func('sin')  % Convert it into a function handle

y =
 @sin
--> y(.5)                % Calling 'sin' via the function handle

ans =
    0.4794
```

Here we use `str2func` to define an anonymous function

```
--> y = str2func('@(x) x.^2')

y =
 @(x)   x.^2
--> y(2)

ans =
 4
```

3.10 VARARGIN Variable Input Arguments

3.10.1 Usage

FreeMat functions can take a variable number of input arguments by setting the last argument in the argument list to `varargin`. This special keyword indicates that all arguments to the function (beyond the last non-`varargin` keyword) are assigned to a cell array named `varargin` available to the function. Variable argument functions are usually used when writing driver functions, i.e., functions that need to pass arguments to another function. The general syntax for a function that takes a variable number of arguments is

```
function [out_1,...,out_M] = fname(in_1,..,in_M,varargin)
```

Inside the function body, `varargin` collects the arguments to `fname` that are not assigned to the `in\_k`.

3.10.2 Example

Here is a simple wrapper to `feval` that demonstrates the use of variable arguments functions.

```
    wrapcall.m
function wrapcall(fname,varargin)
  feval(fname,varargin{:});
```

Now we show a call of the `wrapcall` function with a number of arguments

```
--> wrapcall('printf','%f...%f\n',pi,e)
3.141593...2.718282
```

A more serious driver routine could, for example, optimize a one dimensional function that takes a number of auxilliary parameters that are passed through `varargin`.

3.11 VARARGOUT Variable Output Arguments

3.11.1 Usage

FreeMat functions can return a variable number of output arguments by setting the last argument in the argument list to `varargout`. This special keyword indicates that the number of return values is variable. The general syntax for a function that returns a variable number of outputs is

```
  function [out_1,...,out_M,varargout] = fname(in_1,...,in_M)
```

The function is responsible for ensuring that `varargout` is a cell array that contains the values to assign to the outputs beyond `out\_M`. Generally, variable output functions use `nargout` to figure out how many outputs have been requested.

3.11.2 Example

This is a function that returns a varying number of values depending on the value of the argument.

```
    varoutfunc.m
function [varargout] = varoutfunc
  switch(nargout)
    case 1
      varargout = {'one of one'};
    case 2
      varargout = {'one of two','two of two'};
    case 3
      varargout = {'one of three','two of three','three of three'};
  end
```

Here are some examples of exercising `varoutfunc`:

```
--> [c1] = varoutfunc
c1 =
one of one
--> [c1,c2] = varoutfunc
c1 =
one of two
c2 =
two of two
--> [c1,c2,c3] = varoutfunc
c1 =
one of three
```

```
c2 =
two of three
c3 =
three of three
```

Chapter 4

Mathematical Operators

4.1 COLON Index Generation Operator

4.1.1 Usage

There are two distinct syntaxes for the colon `:` operator - the two argument form

```
y = a : c
```

and the three argument form

```
y = a : b : c
```

The two argument form is exactly equivalent to `a:1:c`. The output `y` is the vector

$$y = [a, a+b, a+2b, \ldots, a+nb]$$

where `a+nb <= c`. There is a third form of the colon operator, the no-argument form used in indexing (see `indexing` for more details).

4.1.2 Function Internals

The colon operator turns out to be trickier to implement than one might believe at first, primarily because the floating point versions should do the right thing, which is not the obvious behavior. For example, suppose the user issues a three point colon command

```
y = a : b : c
```

The first question that one might need to answer is: how many points in this vector? If you answered

$$n = \frac{c-a}{b} + 1$$

then you would be doing the straighforward, but not correct thing. because a, b, and c are all floating point values, there are errors associated with each of the quantities that can lead to n not being an integer. A better way (and the way FreeMat currently does the calculation) is to compute the bounding values (for b positive)

$$n \in \left[\frac{(c-a) \rightarrow 0}{b \rightarrow \infty}, \frac{(c-a) \rightarrow \infty}{b \rightarrow 0} \right] + 1$$

where

$$x \rightarrow y$$

means we replace x by the floating point number that is closest to it in the direction of y. Once we have determined the number of points we have to compute the intermediate values

$$[a, a+b, a+2*b, \ldots, a+n*b]$$

but one can readily verify for themselves that this may *not* be the same as the vector

$$\text{fliplr}[c, c-b, c-2*b, \ldots, c-n*b]$$

even for the case where

$$c = a + n*b$$

for some n. The reason is that the roundoff in the calculations may be different depending on the nature of the sum. FreeMat uses the following strategy to compute the double-colon vector:

1. The value `n` is computed by taking the floor of the larger value in the interval defined above.
2. If `n` falls inside the interval defined above, then it is assumed that the user intended `c = a + n*b`, and the symmetric algorithm is used. Otherwise, the nonsymmetric algorithm is used.
3. The symmetric algorithm computes the vector via

   $$[a, a+b, a+2b, \ldots, c-2b, c-b, c]$$

   working symmetrically from both ends of the vector (hence the nomenclature), while the nonsymmetric algorithm computes

   $$[a, a+b, a+2b, \ldots, a+nb]$$

   In practice, the entries are computed by repeated accumulation instead of multiplying the step size by an integer.
4. The real interval calculation is modified so that we get the exact same result with `a:b:c` and `c:-b:a` (which basically means that instead of moving towards infinity, we move towards the signed infinity where the sign is inherited from `b`).

If you think this is all very obscure, it is. But without it, you will be confronted by mysterious vectors where the last entry is dropped, or where the values show progressively larger amounts of accumulated roundoff error.

4.1.3 Examples

Some simple examples of index generation.

```
--> y = 1:4

y =
 1 2 3 4
```

Now by half-steps:

```
--> y = 1:.5:4

y =
    1.0000    1.5000    2.0000    2.5000    3.0000    3.5000    4.0000
```

Now going backwards (negative steps)

```
--> y = 4:-.5:1

y =
    4.0000    3.5000    3.0000    2.5000    2.0000    1.5000    1.0000
```

If the endpoints are the same, one point is generated, regardless of the step size (middle argument)

```
--> y = 4:1:4

y =
 4
```

If the endpoints define an empty interval, the output is an empty matrix:

```
--> y = 5:4

y =
  Empty array 1x0
```

4.2 COMPARISONOPS Array Comparison Operators

4.2.1 Usage

There are a total of six comparison operators available in FreeMat, all of which are binary operators with the following syntax

```
y = a < b
y = a <= b
y = a > b
y = a >= b
y = a ~= b
y = a == b
```

where `a` and `b` are numerical arrays or scalars, and `y` is a `logical` array of the appropriate size. Each of the operators has three modes of operation, summarized in the following list:

1. `a` is a scalar, `b` is an n-dimensional array - the output is then the same size as `b`, and contains the result of comparing each element in `b` to the scalar `a`.
2. `a` is an n-dimensional array, `b` is a scalar - the output is the same size as `a`, and contains the result of comparing each element in `a` to the scalar `b`.
3. `a` and `b` are both n-dimensional arrays of the same size - the output is then the same size as both `a` and `b`, and contains the result of an element-wise comparison between `a` and `b`.

The operators behave the same way as in `C`, with unequal types being promoted using the standard type promotion rules prior to comparisons. The only difference is that in FreeMat, the not-equals operator is `~=` instead of `!=`.

4.2.2 Examples

Some simple examples of comparison operations. First a comparison with a scalar:

```
--> a = randn(1,5)

a =
   -0.0454   -0.1876    1.5987   -0.9136   -0.2120

--> a>0

ans =
 0 0 1 0 0
```

Next, we construct two vectors, and test for equality:

```
--> a = [1,2,5,7,3]

a =
 1 2 5 7 3

--> b = [2,2,5,9,4]

b =
 2 2 5 9 4

--> c = a == b

c =
 0 1 1 0 0
```

4.3 DOTLEFTDIVIDE Element-wise Left-Division Operator

4.3.1 Usage

Divides two numerical arrays (elementwise) - gets its name from the fact that the divisor is on the left. There are two forms for its use, both with the same general syntax:

```
y = a .\ b
```

where `a` and `b` are `n`-dimensional arrays of numerical type. In the first case, the two arguments are the same size, in which case, the output `y` is the same size as the inputs, and is the element-wise division of `b` by `a`. In the second case, either `a` or `b` is a scalar, in which case `y` is the same size as the larger argument, and is the division of the scalar with each element of the other argument.

The rules for manipulating types has changed in FreeMat 4.0. See `typerules` for more details.

4.3.2 Function Internals

There are three formulae for the dot-left-divide operator, depending on the sizes of the three arguments. In the most general case, in which the two arguments are the same size, the output is computed via:

$$y(m_1,\ldots,m_d) = \frac{b(m_1,\ldots,m_d)}{a(m_1,\ldots,m_d)}$$

If `a` is a scalar, then the output is computed via

$$y(m_1,\ldots,m_d) = \frac{b(m_1,\ldots,m_d)}{a}$$

On the other hand, if `b` is a scalar, then the output is computed via

$$y(m_1,\ldots,m_d) = \frac{b}{a(m_1,\ldots,m_d)}.$$

4.3.3 Examples

Here are some examples of using the dot-left-divide operator. First, a straight-forward usage of the `.\\` operator. The first example is straightforward:

```
--> 3 .\ 8

ans =
    2.6667
```

We can also divide complex arguments:

```
--> a = 3 + 4*i

a =
   3.0000 +  4.0000i

--> b = 5 + 8*i

b =
   5.0000 +  8.0000i

--> c = b .\ a

c =
   0.5281 -  0.0449i
```

We can also demonstrate the three forms of the dot-left-divide operator. First the element-wise version:

```
--> a = [1,2;3,4]

a =
 1 2
 3 4

--> b = [2,3;6,7]

b =
 2 3
 6 7

--> c = a .\ b

c =
    2.0000    1.5000
    2.0000    1.7500
```

Then the scalar versions

```
--> c = a .\ 3

c =
    3.0000    1.5000
    1.0000    0.7500

--> c = 3 .\ a

c =
    0.3333    0.6667
    1.0000    1.3333
```

4.4 DOTPOWER Element-wise Power Operator

4.4.1 Usage

Raises one numerical array to another array (elementwise). There are three operators all with the same general syntax:

```
y = a .^ b
```

The result `y` depends on which of the following three situations applies to the arguments `a` and `b`:

1. `a` is a scalar, `b` is an arbitrary `n`-dimensional numerical array, in which case the output is `a` raised to the power of each element of `b`, and the output is the same size as `b`.

2. `a` is an `n`-dimensional numerical array, and `b` is a scalar, then the output is the same size as `a`, and is defined by each element of `a` raised to the power `b`.

3. `a` and `b` are both `n`-dimensional numerical arrays of *the same size*. In this case, each element of the output is the corresponding element of `a` raised to the power defined by the corresponding element of `b`.

The rules for manipulating types has changed in FreeMat 4.0. See `typerules` for more details.

4.4.2 Function Internals

There are three formulae for this operator. For the first form

$$y(m_1, \ldots, m_d) = a^{b(m_1,\ldots,m_d)},$$

and the second form

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d)^b,$$

and in the third form

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d)^{b(m_1,\ldots,m_d)}.$$

4.4.3 Examples

We demonstrate the three forms of the dot-power operator using some simple examples. First, the case of a scalar raised to a series of values.

```
--> a = 2

a =
 2

--> b = 1:4

b =
 1 2 3 4

--> c = a.^b

c =
  2  4  8 16
```

The second case shows a vector raised to a scalar.

```
--> c = b.^a

c =
  1  4  9 16
```

The third case shows the most general use of the dot-power operator.

```
--> A = [1,2;3,2]

A =
 1 2
 3 2

--> B = [2,1.5;0.5,0.6]

B =
    2.0000    1.5000
    0.5000    0.6000

--> C = A.^B

C =
    1.0000    2.8284
    1.7321    1.5157
```

4.5 DOTRIGHTDIVIDE Element-wise Right-Division Operator

4.5.1 Usage

Divides two numerical arrays (elementwise). There are two forms for its use, both with the same general syntax:

```
y = a ./ b
```

where `a` and `b` are `n`-dimensional arrays of numerical type. In the first case, the two arguments are the same size, in which case, the output `y` is the same size as the inputs, and is the element-wise division of `b` by `a`. In the second case, either `a` or `b` is a scalar, in which case `y` is the same size as the larger argument, and is the division of the scalar with each element of the other argument.

The rules for manipulating types has changed in FreeMat 4.0. See `typerules` for more details.

4.5.2 Function Internals

There are three formulae for the dot-right-divide operator, depending on the sizes of the three arguments. In the most general case, in which the two arguments are the same size, the output is computed via:

$$y(m_1,\ldots,m_d) = \frac{a(m_1,\ldots,m_d)}{b(m_1,\ldots,m_d)}$$

If `a` is a scalar, then the output is computed via

$$y(m_1,\ldots,m_d) = \frac{a}{b(m_1,\ldots,m_d)}$$

On the other hand, if `b` is a scalar, then the output is computed via

$$y(m_1,\ldots,m_d) = \frac{a(m_1,\ldots,m_d)}{b}.$$

4.5.3 Examples

Here are some examples of using the dot-right-divide operator. First, a straight-forward usage of the `./` operator. The first example is straightforward:

```
--> 3 ./ 8

ans =
    0.3750
```

We can also divide complex arguments:

```
--> a = 3 + 4*i

a =
   3.0000 +  4.0000i

--> b = 5 + 8*i

b =
   5.0000 +  8.0000i

--> c = a ./ b

c =
   0.5281 -  0.0449i
```

We can also demonstrate the three forms of the dot-right-divide operator. First the element-wise version:

```
--> a = [1,2;3,4]

a =
 1 2
 3 4

--> b = [2,3;6,7]

b =
 2 3
 6 7

--> c = a ./ b

c =
    0.5000    0.6667
    0.5000    0.5714
```

Then the scalar versions

```
--> c = a ./ 3

c =
    0.3333    0.6667
    1.0000    1.3333

--> c = 3 ./ a

c =
    3.0000    1.5000
    1.0000    0.7500
```

4.6 DOTTIMES Element-wise Multiplication Operator

4.6.1 Usage

Multiplies two numerical arrays (elementwise). There are two forms for its use, both with the same general syntax:

```
y = a .* b
```

where `a` and `b` are `n`-dimensional arrays of numerical type. In the first case, the two arguments are the same size, in which case, the output `y` is the same size as the inputs, and is the element-wise product of `a` and `b`. In the second case, either `a` or `b` is a scalar, in which case `y` is the same size as the larger argument, and is the product of the scalar with each element of the other argument.

The rules for manipulating types has changed in FreeMat 4.0. See `typerules` for more details.

4.6.2 Function Internals

There are three formulae for the dot-times operator, depending on the sizes of the three arguments. In the most general case, in which the two arguments are the same size, the output is computed via:

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d) \times b(m_1, \ldots, m_d)$$

If `a` is a scalar, then the output is computed via

$$y(m_1, \ldots, m_d) = a \times b(m_1, \ldots, m_d).$$

On the other hand, if `b` is a scalar, then the output is computed via

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d) \times b.$$

4.6.3 Examples

Here are some examples of using the dottimes operator. First, a straight-forward usage of the `.*` operator. The first example is straightforward:

```
--> 3 .* 8

ans =
 24
```

Next, we multiply a scalar by a vector of values:

```
--> 3.1 .* [2,4,5,6,7]

ans =
    6.2000   12.4000   15.5000   18.6000   21.7000
```

With complex values

```
--> a = 3 + 4*i

a =
   3.0000 +  4.0000i

--> b = a .* 2

b =
   6.0000 +  8.0000i
```

Finally, the element-wise version:

```
--> a = [1,2;3,4]

a =
 1 2
 3 4

--> b = [2,3;6,7]

b =
 2 3
 6 7

--> c = a .* b

c =
  2  6
 18 28
```

4.7 HERMITIAN Matrix Hermitian (Conjugate Transpose) Operator

4.7.1 Usage

Computes the Hermitian of the argument (a 2D matrix). The syntax for its use is

```
y = a';
```

where `a` is a `M x N` numerical matrix. The output `y` is a numerical matrix of the same type of size `N x M`. This operator is the conjugating transpose, which is different from the transpose operator `.'` (which does not conjugate complex values).

4.7.2 Function Internals

The Hermitian operator is defined simply as

$$y_{i,j} = \overline{a_{j,i}}$$

where `y\_ij` is the element in the `i`th row and `j`th column of the output matrix `y`.

4.7.3 Examples

A simple transpose example:

```
--> A = [1,2,0;4,1,-1]

A =
  1  2  0
  4  1 -1

--> A'

ans =
  1  4
  2  1
  0 -1
```

Here, we use a complex matrix to demonstrate how the Hermitian operator conjugates the entries.

```
--> A = [1+i,2-i]

A =
   1.0000 +  1.0000i   2.0000 -  1.0000i

--> A.'

ans =
   1.0000 +  1.0000i
   2.0000 -  1.0000i
```

4.8 LEFTDIVIDE Matrix Equation Solver/Divide Operator

4.8.1 Usage

The divide operator \ is really a combination of three operators, all of which have the same general syntax:

```
Y = A \ B
```

where `A` and `B` are arrays of numerical type. The result `Y` depends on which of the following three situations applies to the arguments `A` and `B`:

1. `A` is a scalar, `B` is an arbitrary `n`-dimensional numerical array, in which case the output is each element of `B` divided by the scalar `A`.
2. `A,B` are matrices with the same number of rows, i.e., `A` is of size `M x K`, and `B` is of size `M x L`, in which case the output is of size `K x L`.

The output follows the standard type promotion rules, although in the first two cases, if `A` and `B` are integers, the output is an integer also, while in the third case if `A` and `B` are integers, the output is of type `double`.

A few additional words about the third version, in which `A` and `B` are matrices. Very loosely speaking, `Y` is the matrix that satisfies `A * Y = B`. In cases where such a matrix exists. If such a matrix does not exist, then a matrix `Y` is returned that approximates `A * Y pprox B`.

4.8.2 Function Internals

There are three formulae for the times operator. For the first form

$$Y(m_1,\ldots,m_d) = \frac{B(m_1,\ldots,m_d)}{A}.$$

In the second form, the calculation of the output depends on the size of `A`. Because each column of `B` is treated independantly, we can rewrite the equation `A Y = B` as

$$A[y_1, y_2, \ldots, y_l] = [b_1, b_2, \ldots, b_l]$$

where `y\_i` are the columns of `Y`, and `b\_i` are the columns of the matrix `B`. If `A` is a square matrix, then the LAPACK routine `*gesvx` (where the `*` is replaced with `sdcz` depending on the type of the arguments) is used, which uses an LU decomposition of `A` to solve the sequence of equations sequentially. If `A` is singular, then a warning is emitted.

On the other hand, if `A` is rectangular, then the LAPACK routine `*gelsy` is used. Note that these routines are designed to work with matrices `A` that are full rank - either full column rank or full row rank. If `A` fails to satisfy this assumption, a warning is emitted. If `A` has full column rank (and thus necessarily has more rows than columns), then theoretically, this operator finds the columns `y\_i` that satisfy:

$$y_i = \arg\min_y \|Ay - b_i\|_2$$

and each column is thus the Least Squares solution of `A y = b\_i`. On the other hand, if `A` has full row rank (and thus necessarily has more columns than rows), then theoretically, this operator finds the columns `y\_i` that satisfy

$$y_i = \arg \min_{Ay=b_i} \|y\|_2$$

and each column is thus the Minimum Norm vector `y\_i` that satisfies `A y\_i = b\_i`. In the event that the matrix `A` is neither full row rank nor full column rank, a solution is returned, that is the minimum norm least squares solution. The solution is computed using an orthogonal factorization technique that is documented in the LAPACK User's Guide (see the References section for details).

4.8.3 Examples

Here are some simple examples of the divide operator. We start with a simple example of a full rank, square matrix:

```
--> A = [1,1;0,1]

A =
 1 1
 0 1
```

Suppose we wish to solve

$$\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \end{bmatrix}$$

(which by inspection has the solution `y\_1 = 1`, `y\_2 = 2`). Thus we compute:

```
--> B = [3;2]

B =
 3
 2

--> Y = A\B

Y =
 1
 2
```

Suppose we wish to solve a trivial Least Squares (LS) problem. We want to find a simple scaling of the vector `[1;1]` that is closest to the point `[2,1]`. This is equivalent to solving

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} y = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

in a least squares sense. For fun, we can calculate the solution using calculus by hand. The error we wish to minimize is

$$\varepsilon(y) = (y-2)^2 + (y-1)^2.$$

Taking a derivative with respect to `y`, and setting to zero (which we must have for an extrema when `y` is unconstrained)

$$2(y-2) + 2(y-1) = 0$$

which we can simplify to `4y = 6` or `y = 3/2` (we must, technically, check to make sure this is a minimum, and not a maximum or an inflection point). Here is the same calculation performed using FreeMat:

```
--> A = [1;1]

A =
 1
 1

--> B = [2;1]

B =
 2
 1

--> A\B

ans =
    1.5000
```

which is the same solution.

4.9 LOGICALOPS Logical Array Operators

4.9.1 Usage

There are three Boolean operators available in FreeMat. The syntax for their use is:

```
y = ~x
y = a & b
y = a | b
```

where `x`, `a` and `b` are `logical` arrays. The operators are

- NOT (`~`) - output `y` is true if the corresponding element of `x` is false, and ouput `y` is false if the corresponding element of `x` is true.
- OR (—) - output `y` is true if corresponding element of `a` is true or if corresponding element of `b` is true (or if both are true).
- AND (`\&`) - output `y` is true only if both the corresponding elements of `a` and `b` are both true.

The binary operators AND and OR can take scalar arguments as well as vector arguments, in which case, the scalar is operated on with each element of the vector. As of version 1.10, FreeMat supports `shortcut` evaluation. This means that if we have two expressions

```
if (expr1 & expr2)
```

then if `expr1` evaluates to `false`, then `expr2` is not evaluated at all. Similarly, for the expression

```
if (expr1 | expr2)
```

then if `expr1` evaluates to `true`, then `expr2` is not evaluated at all. Shortcut evaluation is useful for doing a sequence of tests, each of which is not valid unless the prior test is successful. For example,

```
if isa(p,'string') & strcmp(p,'fro')
```

is not valid without shortcut evaluation (if `p` is an integer, for example, the first test returns false, and an attempt to evaluate the second expression would lead to an error). Note that shortcut evaluation only works with scalar expressions.

4.9.2 Examples

Some simple examples of logical operators. Suppose we want to calculate the exclusive-or (XOR) of two vectors of logical variables. First, we create a pair of vectors to perform the XOR operation on:

```
--> a = (randn(1,6)>0)

a =
 0 0 0 0 1 0

--> b = (randn(1,6)>0)

b =
 1 1 0 1 0 1
```

Next, we can compute the OR of `a` and `b`:

```
--> c = a | b

c =
 1 1 0 1 1 1
```

However, the XOR and OR operations differ on the fifth entry - the XOR would be false, since it is true if and only if exactly one of the two inputs is true. To isolate this case, we can AND the two vectors, to find exactly those entries that appear as true in both `a` and `b`:

```
--> d = a & b

d =
 0 0 0 0 0 0
```

At this point, we can modify the contents of `c` in two ways – the Boolean way is to AND `\sim d` with `c`, like so

```
--> xor = c & (~d)

xor =
 1 1 0 1 1 1
```

The other way to do this is simply force `c(d) = 0`, which uses the logical indexing mode of FreeMat (see the chapter on indexing for more details). This, however, will cause `c` to become an `int32` type, as opposed to a logical type.

```
--> c(d) = 0

c =
 1 1 0 1 1 1
```

4.10 MATRIXPOWER Matrix Power Operator

4.10.1 Usage

The power operator for scalars and square matrices. This operator is really a combination of two operators, both of which have the same general syntax:

```
  y = a ^ b
```

The exact action taken by this operator, and the size and type of the output, depends on which of the two configurations of `a` and `b` is present:

1. a is a scalar, b is a square matrix
2. a is a square matrix, b is a scalar

4.10.2 Function Internals

In the first case that a is a scalar, and b is a square matrix, the matrix power is defined in terms of the eigenvalue decomposition of b. Let b have the following eigen-decomposition (problems arise with non-symmetric matrices b, so let us assume that b is symmetric):

$$b = E \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & \lambda_n \end{bmatrix} E^{-1}$$

Then a raised to the power b is defined as

$$a^b = E \begin{bmatrix} a^{\lambda_1} & 0 & \cdots & 0 \\ 0 & a^{\lambda_2} & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & a^{\lambda_n} \end{bmatrix} E^{-1}$$

Similarly, if a is a square matrix, then a has the following eigen-decomposition (again, suppose a is symmetric):

$$a = E \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & \lambda_n \end{bmatrix} E^{-1}$$

Then a raised to the power b is defined as

$$a^b = E \begin{bmatrix} \lambda_1^b & 0 & \cdots & 0 \\ 0 & \lambda_2^b & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & \lambda_n^b \end{bmatrix} E^{-1}$$

4.10.3 Examples

We first define a simple 2 x 2 symmetric matrix

```
--> A = 1.5

A =
    1.5000

--> B = [1,.2;.2,1]

B =
    1.0000    0.2000
    0.2000    1.0000
```

First, we raise B to the (scalar power) A:

```
--> C = B^A

C =
    1.0150    0.2995
    0.2995    1.0150
```

Next, we raise `A` to the matrix power `B`:

```
--> C = A^B

C =
    1.5049    0.1218
    0.1218    1.5049
```

4.11 MINUS Subtraction Operator

4.11.1 Usage

Subtracts two numerical arrays (elementwise). There are two forms for its use, both with the same general syntax:

```
y = a - b
```

where `a` and `b` are `n`-dimensional arrays of numerical type. In the first case, the two arguments are the same size, in which case, the output `y` is the same size as the inputs, and is the element-wise difference of `a` and `b`. In the second case, either `a` or `b` is a scalar, in which case `y` is the same size as the larger argument, and is the difference of the scalar to each element of the other argument.

The rules for manipulating types has changed in FreeMat 4.0. See `typerules` for more details.

4.11.2 Function Internals

There are three formulae for the subtraction operator, depending on the sizes of the three arguments. In the most general case, in which the two arguments are the same size, the output is computed via:

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d) - b(m_1, \ldots, m_d)$$

If `a` is a scalar, then the output is computed via

$$y(m_1, \ldots, m_d) = a - b(m_1, \ldots, m_d).$$

On the other hand, if `b` is a scalar, then the output is computed via

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d) - b.$$

4.11.3 Examples

Here are some examples of using the subtraction operator. First, a straight-forward usage of the minus operator. The first example is straightforward:

```
--> 3 - 8

ans =
 -5
```

Next, we subtract a vector of values from a scalar:

```
--> 3.1 - [2,4,5,6,7]

ans =
    1.1000   -0.9000   -1.9000   -2.9000   -3.9000
```

With complex values

```
--> a = 3 - 4*i

a =
   3.0000 -  4.0000i

--> b = a - 2

b =
   1.0000 -  4.0000i
```

Finally, the element-wise version:

```
--> a = [1,2;3,4]

a =
 1 2
 3 4

--> b = [2,3;6,7]

b =
 2 3
 6 7

--> c = a - b

c =
 -1 -1
 -3 -3
```

4.12 PLUS Addition Operator

4.12.1 Usage

Adds two numerical arrays (elementwise) together. There are two forms for its use, both with the same general syntax:

```
y = a + b
```

where `a` and `b` are `n`-dimensional arrays of numerical type. In the first case, the two arguments are the same size, in which case, the output `y` is the same size as the inputs, and is the element-wise the sum of `a` and `b`. In the second case, either `a` or `b` is a scalar, in which case `y` is the same size as the larger argument, and is the sum of the scalar added to each element of the other argument.

The rules for manipulating types has changed in FreeMat 4.0. See `typerules` for more details.

4.12.2 Function Internals

There are three formulae for the addition operator, depending on the sizes of the three arguments. In the most general case, in which the two arguments are the same size, the output is computed via:

$$y(m_1,\ldots,m_d) = a(m_1,\ldots,m_d) + b(m_1,\ldots,m_d)$$

If `a` is a scalar, then the output is computed via

$$y(m_1, \ldots, m_d) = a + b(m_1, \ldots, m_d).$$

On the other hand, if `b` is a scalar, then the output is computed via

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d) + b.$$

4.12.3 Examples

Here are some examples of using the addition operator. First, a straight-forward usage of the plus operator. The first example is straightforward:

```
--> 3 + 8

ans =
 11
```

Next, we add a scalar to a vector of values:

```
--> 3.1 + [2,4,5,6,7]

ans =
    5.1000    7.1000    8.1000    9.1000   10.1000
```

With complex values

```
--> a = 3 + 4*i

a =
   3.0000 +  4.0000i

--> b = a + 2

b =
   5.0000 +  4.0000i
```

Finally, the element-wise version:

```
--> a = [1,2;3,4]

a =
 1 2
 3 4

--> b = [2,3;6,7]

b =
 2 3
 6 7

--> c = a + b

c =
  3  5
  9 11
```

4.13 RIGHTDIVIDE Matrix Equation Solver/Divide Operator

4.13.1 Usage

The divide operator `/` is really a combination of three operators, all of which have the same general syntax:

```
Y = A / B
```

where `A` and `B` are arrays of numerical type. The result `Y` depends on which of the following three situations applies to the arguments `A` and `B`:

1. `A` is a scalar, `B` is an arbitrary `n`-dimensional numerical array, in which case the output is the scalar `A` divided into each element of `B`.

2. `B` is a scalar, `A` is an arbitrary `n`-dimensional numerical array, in which case the output is each element of `A` divided by the scalar `B`.

3. `A,B` are matrices with the same number of columns, i.e., `A` is of size `K x M`, and `B` is of size `L x M`, in which case the output is of size `K x L`.

The output follows the standard type promotion rules, although in the first two cases, if `A` and `B` are integers, the output is an integer also, while in the third case if `A` and `B` are integers, the output is of type `double`.

4.13.2 Function Internals

There are three formulae for the times operator. For the first form

$$Y(m_1,\ldots,m_d) = \frac{A}{B(m_1,\ldots,m_d)},$$

and the second form

$$Y(m_1,\ldots,m_d) = \frac{A(m_1,\ldots,m_d)}{B}.$$

In the third form, the output is defined as:

$$Y = (B'\backslash A')'$$

and is used in the equation `Y B = A`.

4.13.3 Examples

The right-divide operator is much less frequently used than the left-divide operator, but the concepts are similar. It can be used to find least-squares and minimum norm solutions. It can also be used to solve systems of equations in much the same way. Here's a simple example:

```
--> B = [1,1;0,1];
--> A = [4,5]

A =
 4 5

--> A/B

ans =
 4 1
```

4.14 TIMES Matrix Multiply Operator

4.14.1 Usage

Multiplies two numerical arrays. This operator is really a combination of three operators, all of which have the same general syntax:

```
y = a * b
```

where `a` and `b` are arrays of numerical type. The result `y` depends on which of the following three situations applies to the arguments `a` and `b`:

1. `a` is a scalar, `b` is an arbitrary `n`-dimensional numerical array, in which case the output is the element-wise product of `b` with the scalar `a`.

2. `b` is a scalar, `a` is an arbitrary `n`-dimensional numerical array, in which case the output is the element-wise product of `a` with the scalar `b`.

3. `a,b` are conformant matrices, i.e., `a` is of size `M x K`, and `b` is of size `K x N`, in which case the output is of size `M x N` and is the matrix product of `a`, and `b`.

Matrix multiplication is only defined for matrices of type `double` and `single`.

4.14.2 Function Internals

There are three formulae for the times operator. For the first form

$$y(m_1, \ldots, m_d) = a \times b(m_1, \ldots, m_d),$$

and the second form

$$y(m_1, \ldots, m_d) = a(m_1, \ldots, m_d) \times b.$$

In the third form, the output is the matrix product of the arguments

$$y(m, n) = \sum_{k=1}^{K} a(m, k) b(k, n)$$

4.14.3 Examples

Here are some examples of using the matrix multiplication operator. First, the scalar examples (types 1 and 2 from the list above):

```
--> a = [1,3,4;0,2,1]

a =
 1 3 4
 0 2 1

--> b = a * 2

b =
 2 6 8
 0 4 2
```

The matrix form, where the first argument is `2 x 3`, and the second argument is `3 x 1`, so that the product is size `2 x 1`.

```
--> a = [1,2,0;4,2,3]

a =
 1 2 0
 4 2 3

--> b = [5;3;1]

b =
 5
 3
 1

--> c = a*b

c =
 11
 29
```

Note that the output is double precision.

4.15 TRANSPOSE Matrix Transpose Operator

4.15.1 Usage

Performs a transpose of the argument (a 2D matrix). The syntax for its use is

```
  y = a.';
```

where `a` is a `M x N` numerical matrix. The output `y` is a numerical matrix of the same type of size `N x M`. This operator is the non-conjugating transpose, which is different from the Hermitian operator `'` (which conjugates complex values).

4.15.2 Function Internals

The transpose operator is defined simply as

$$y_{i,j} = a_{j,i}$$

where `y\_ij` is the element in the `i`th row and `j`th column of the output matrix `y`.

4.15.3 Examples

A simple transpose example:

```
--> A = [1,2,0;4,1,-1]

A =
  1  2  0
  4  1 -1

--> A.'

ans =
  1  4
  2  1
  0 -1
```

Here, we use a complex matrix to demonstrate how the transpose does *not* conjugate the entries.

```
--> A = [1+i,2-i]

A =
   1.0000 +  1.0000i   2.0000 -  1.0000i

--> A.'

ans =
   1.0000 +  1.0000i
   2.0000 -  1.0000i
```

4.16 TYPERULES Type Rules for Operators

4.16.1 Usage

Starting with FreeMat 4.0, the type of `y` is determined according to the same rules as Matlab. These are the rules:

1. Integer types of the same class can be combined. The answer is the same type as the inputs, and the operation is performed using saturating arithmetic. Integer types can also be combined with double precision values (again, the result is of the integer type).
2. Single precision floating point values can be combined with double precision, logical and character array classes. The result is of class single.
3. Double precision floating point values can be combined with all other types. Except as noted above, the output is of double precision.

These rules look strange, and they are. In general, computations are done in double precision in almost all cases. When single precision values are involved, the computations take place in single precision.

Chapter 5

Flow Control

5.1 BREAK Exit Execution In Loop

5.1.1 Usage

The `break` statement is used to exit a loop prematurely. It can be used inside a `for` loop or a `while` loop. The syntax for its use is

```
   break
```

inside the body of the loop. The `break` statement forces execution to exit the loop immediately.

5.1.2 Example

Here is a simple example of how `break` exits the loop. We have a loop that sums integers from `1` to `10`, but that stops prematurely at `5` using a `break`. We will use a `while` loop.

```
    break_ex.m
function accum = break_ex
  accum = 0;
  i = 1;
  while (i<=10)
    accum = accum + i;
    if (i == 5)
      break;
    end
    i = i + 1;
  end
```

The function is exercised here:

```
--> break_ex

ans =
 15

--> sum(1:5)

ans =
 15
```

5.2 CONTINUE Continue Execution In Loop

5.2.1 Usage

The `continue` statement is used to change the order of execution within a loop. The `continue` statement can be used inside a `for` loop or a `while` loop. The syntax for its use is

```
continue
```

inside the body of the loop. The `continue` statement forces execution to start at the top of the loop with the next iteration. The examples section shows how the `continue` statement works.

5.2.2 Example

Here is a simple example of using a `continue` statement. We want to sum the integers from `1` to `10`, but not the number `5`. We will use a `for` loop and a continue statement.

```
    continue_ex.m
function accum = continue_ex
  accum = 0;
  for i=1:10
    if (i==5)
      continue;
    end
    accum = accum + 1; %skipped if i == 5!
  end
```

The function is exercised here:

```
--> continue_ex

ans =
 9

--> sum([1:4,6:10])

ans =
 50
```

5.3 ERROR Causes an Error Condition Raised

5.3.1 Usage

The `error` function causes an error condition (exception to be raised). The general syntax for its use is

```
error(s),
```

where `s` is the string message describing the error. The `error` function is usually used in conjunction with `try` and `catch` to provide error handling. If the string `s`, then (to conform to the MATLAB API), `error` does nothing.

5.3.2 Example

Here is a simple example of an `error` being issued by a function `evenoddtest`:

```
    evenoddtest.m
function evenoddtest(n)
  if (n==0)
    error('zero is neither even nor odd');
  elseif ( n ~= fix(n) )
    error('expecting integer argument');
  end;
  if (n==int32(n/2)*2)
    printf('%d is even\n',n);
  else
    printf('%d is odd\n',n);
  end
```

The normal command line prompt `-->` simply prints the error that occured.

```
--> evenoddtest(4)
4 is even
--> evenoddtest(5)
5 is odd
--> evenoddtest(0)
In /home/sbasu/Devel/FreeMat/help/tmp/evenoddtest.m(evenoddtest) at line 3
    In scratch() at line 1
    In base(base)
    In base()
    In global()
Error: zero is neither even nor odd
--> evenoddtest(pi)
In /home/sbasu/Devel/FreeMat/help/tmp/evenoddtest.m(evenoddtest) at line 5
    In scratch() at line 1
    In base(base)
    In base()
    In global()
Error: expecting integer argument
```

5.4 FOR For Loop

5.4.1 Usage

The `for` loop executes a set of statements with an index variable looping through each element in a vector. The syntax of a `for` loop is one of the following:

```
  for (variable=expression)
     statements
  end
```

Alternately, the parenthesis can be eliminated

```
  for variable=expression
     statements
  end
```

or alternately, the index variable can be pre-initialized with the vector of values it is going to take:

```
  for variable
     statements
  end
```

The third form is essentially equivalent to `for variable=variable`, where `variable` is both the index variable and the set of values over which the for loop executes. See the examples section for an example of this form of the `for` loop.

5.4.2 Examples

Here we write `for` loops to add all the integers from `1` to `100`. We will use all three forms of the `for` statement.

```
--> accum = 0;
--> for (i=1:100); accum = accum + i; end
--> accum

ans =
 5050
```

The second form is functionally the same, without the extra parenthesis

```
--> accum = 0;
--> for i=1:100; accum = accum + i; end
--> accum

ans =
 5050
```

In the third example, we pre-initialize the loop variable with the values it is to take

5.5 IF-ELSEIF-ELSE Conditional Statements

5.5.1 Usage

The `if` and `else` statements form a control structure for conditional execution. The general syntax involves an `if` test, followed by zero or more `elseif` clauses, and finally an optional `else` clause:

```
  if conditional_expression_1
    statements_1
  elseif conditional_expression_2
    statements_2
  elseif conditional_expresiion_3
    statements_3
  ...
  else
    statements_N
  end
```

Note that a conditional expression is considered true if the real part of the result of the expression contains any non-zero elements (this strange convention is adopted for compatibility with MATLAB).

5.5.2 Examples

Here is an example of a function that uses an `if` statement

```
    if_test.m
function c = if_test(a)
  if (a == 1)
```

```
    c = 'one';
  elseif (a==2)
    c = 'two';
  elseif (a==3)
    c = 'three';
  else
    c = 'something else';
  end
```

Some examples of `if\_test` in action:

```
--> if_test(1)

ans =
one
--> if_test(2)

ans =
two
--> if_test(3)

ans =
three
--> if_test(pi)

ans =
something else
```

5.6 KEYBOARD Initiate Interactive Debug Session

5.6.1 Usage

The `keyboard` statement is used to initiate an interactive session at a specific point in a function. The general syntax for the `keyboard` statement is

```
keyboard
```

A `keyboard` statement can be issued in a `script`, in a `function`, or from within another `keyboard` session. The result of a `keyboard` statement is that execution of the program is halted, and you are given a prompt of the form:

```
[scope,n] -->
```

where `scope` is the current scope of execution (either the name of the function we are executing, or `base` otherwise). And `n` is the depth of the `keyboard` session. If, for example, we are in a `keyboard` session, and we call a function that issues another `keyboard` session, the depth of that second session will be one higher. Put another way, `n` is the number of `return` statements you have to issue to get back to the base workspace. Incidentally, a `return` is how you exit the `keyboard` session and resume execution of the program from where it left off. A `retall` can be used to shortcut execution and return to the base workspace.

The `keyboard` statement is an excellent tool for debugging FreeMat code, and along with `eval` provide a unique set of capabilities not usually found in compiled environments. Indeed, the `keyboard` statement is equivalent to a debugger breakpoint in more traditional environments, but with significantly more inspection power.

5.6.2 Example

Here we demonstrate a two-level `keyboard` situation. We have a simple function that calls `keyboard` internally:

```
    key_one.m
function c = key_one(a,b)
c = a + b;
keyboard
```

Now, we execute the function from the base workspace, and at the `keyboard` prompt, we call it again. This action puts us at depth 2. We can confirm that we are in the second invocation of the function by examining the arguments. We then issue two `return` statements to return to the base workspace.

```
--> key_one(1,2)
[key_one,3]--> key_one(5,7)
[key_one,3]--> a

ans =
 5

[key_one,3]--> b

ans =
 7

[key_one,3]--> c

ans =
 12

[key_one,3]--> return

ans =
 12

[key_one,3]--> a

ans =
 1

[key_one,3]--> b

ans =
 2

[key_one,3]--> c

ans =
 3

[key_one,3]--> return

ans =
 3
```

5.7 LASTERR Retrieve Last Error Message

5.7.1 Usage

Either returns or sets the last error message. The general syntax for its use is either

```
msg = lasterr
```

which returns the last error message that occured, or

```
lasterr(msg)
```

which sets the contents of the last error message.

5.7.2 Example

Here is an example of using the `error` function to set the last error, and then retrieving it using lasterr.

```
--> try; error('Test error message'); catch; end;
--> lasterr

ans =
Test error message
```

Or equivalently, using the second form:

```
--> lasterr('Test message');
--> lasterr

ans =
Test message
```

5.8 RETALL Return From All Keyboard Sessions

5.8.1 Usage

The `retall` statement is used to return to the base workspace from a nested `keyboard` session. It is equivalent to forcing execution to return to the main prompt, regardless of the level of nesting of `keyboard` sessions, or which functions are running. The syntax is simple

```
retall
```

The `retall` is a convenient way to stop debugging. In the process of debugging a complex program or set of functions, you may find yourself 5 function calls down into the program only to discover the problem. After fixing it, issueing a `retall` effectively forces FreeMat to exit your program and return to the interactive prompt.

5.8.2 Example

Here we demonstrate an extreme example of `retall`. We are debugging a recursive function `self` to calculate the sum of the first N integers. When the function is called, a `keyboard` session is initiated after the function has called itself N times. At this `keyboard` prompt, we issue another call to `self` and get another `keyboard` prompt, this time with a depth of 2. A `retall` statement returns us to the top level without executing the remainder of either the first or second call to `self`:

```
    self.m
function y = self(n)
  if (n>1)
    y = n + self(n-1);
    printf('y is %d\n',y);
  else
    y = 1;
    printf('y is initialized to one\n');
    keyboard
  end
```

```
--> self(4)
y is initialized to one
[self,8]--> self(6)
y is initialized to one
[self,8]--> retall
```

5.9 RETURN Return From Function

5.9.1 Usage

The `return` statement is used to immediately return from a function, or to return from a `keyboard` session. The syntax for its use is

```
  return
```

Inside a function, a `return` statement causes FreeMat to exit the function immediately. When a `keyboard` session is active, the `return` statement causes execution to resume where the `keyboard` session started.

5.9.2 Example

In the first example, we define a function that uses a `return` to exit the function if a certain test condition is satisfied.

```
    return_func.m
function ret = return_func(a,b)
  ret = 'a is greater';
  if (a > b)
    return;
  end
  ret = 'b is greater';
  printf('finishing up...\n');
```

Next we exercise the function with a few simple test cases:

```
--> return_func(1,3)
finishing up...

ans =
b is greater
--> return_func(5,2)

ans =
a is greater
```

In the second example, we take the function and rewrite it to use a `keyboard` statement inside the `if` statement.

```
    return_func2.m
function ret = return_func2(a,b)
  if (a > b)
     ret = 'a is greater';
     keyboard;
  else
     ret = 'b is greater';
  end
  printf('finishing up...\n');
```

Now, we call the function with a larger first argument, which triggers the `keyboard` session. After verifying a few values inside the `keyboard` session, we issue a `return` statement to resume execution.

```
--> return_func2(2,4)
finishing up...

ans =
b is greater
--> return_func2(5,1)
[return_func2,4]--> ret

ans =
a is greater
[return_func2,4]--> a

ans =
 5

[return_func2,4]--> b

ans =
 1

[return_func2,4]--> return
finishing up...

ans =
a is greater
```

5.10 SWITCH Switch statement

5.10.1 Usage

The `switch` statement is used to selective execute code based on the value of either scalar value or a string. The general syntax for a `switch` statement is

```
  switch(expression)
    case test_expression_1
      statements
    case test_expression_2
      statements
    otherwise
      statements
  end
```

The `otherwise` clause is optional. Note that each test expression can either be a scalar value, a string to test against (if the switch expression is a string), or a `cell-array` of expressions to test against. Note that unlike `C` `switch` statements, the FreeMat `switch` does not have fall-through, meaning that the statements associated with the first matching case are executed, and then the `switch` ends. Also, if the `switch` expression matches multiple `case` expressions, only the first one is executed.

5.10.2 Examples

Here is an example of a `switch` expression that tests against a string input:

```
    switch_test.m
function c = switch_test(a)
  switch(a)
    case {'lima beans','root beer'}
      c = 'food';
    case {'red','green','blue'}
      c = 'color';
    otherwise
      c = 'not sure';
  end
```

Now we exercise the switch statements

```
--> switch_test('root beer')

ans =
food
--> switch_test('red')

ans =
color
--> switch_test('carpet')

ans =
not sure
```

5.11 TRY-CATCH Try and Catch Statement

5.11.1 Usage

The `try` and `catch` statements are used for error handling and control. A concept present in `C++`, the `try` and `catch` statements are used with two statement blocks as follows

```
   try
     statements_1
   catch
     statements_2
   end
```

The meaning of this construction is: try to execute `statements\_1`, and if any errors occur during the execution, then execute the code in `statements\_2`. An error can either be a FreeMat generated error (such as a syntax error in the use of a built in function), or an error raised with the `error` command.

5.11.2 Examples

Here is an example of a function that uses error control via `try` and `catch` to check for failures in `fopen`.

```
    read_file.m
function c = read_file(filename)
try
   fp = fopen(filename,'r');
   c = fgetline(fp);
   fclose(fp);
catch
   c = ['could not open file because of error :' lasterr]
end
```

Now we try it on an example file - first one that does not exist, and then on one that we create (so that we know it exists).

```
--> read_file('this_filename_is_invalid')

c =
could not open file because of error :Invalid handle!

ans =
could not open file because of error :Invalid handle!
--> fp = fopen('test_text.txt','w');
--> fprintf(fp,'a line of text\n');
--> fclose(fp);
--> read_file('test_text.txt')

ans =
a line of text
```

5.12 WARNING Emits a Warning Message

5.12.1 Usage

The `warning` function causes a warning message to be sent to the user. The general syntax for its use is

```
warning(s)
```

where `s` is the string message containing the warning.

The `warning` function can also be used to turn off warnings, and to retrieve the current state of the warning flag. To turn off warnings use the syntax

```
warning off
```

at which point, warnings will not be displayed. To turn on warnings use the syntax

```
warning on
```

In both cases, you can also retrieve the current state of the warnings flag

```
y = warning('on')
y = warning('off')
```

5.13 WHILE While Loop

5.13.1 Usage

The `while` loop executes a set of statements as long as a the test condition remains `true`. The syntax of a `while` loop is

```
  while test_expression
     statements
  end
```

Note that a conditional expression is considered true if the real part of the result of the expression contains any non-zero elements (this strange convention is adopted for compatibility with MATLAB).

5.13.2 Examples

Here is a `while` loop that adds the integers from `1` to `100`:

```
--> accum = 0;
--> k=1;
--> while (k<=100), accum = accum + k; k = k + 1; end
--> accum

ans =
 5050
```

Chapter 6

FreeMat Functions

6.1 ADDPATH Add

6.1.1 Usage

The `addpath` routine adds a set of directories to the current path. The first form takes a single directory and adds it to the beginning or top of the path:

```
addpath('directory')
```

The second form add several directories to the top of the path:

```
addpath('dir1','dir2',...,'dirn')
```

Finally, you can provide a flag to control where the directories get added to the path

```
addpath('dir1','dir2',...,'dirn','-flag')
```

where if `flag` is either `'-0'` or `'-begin'`, the directories are added to the top of the path, and if the `flag` is either `'-1'` or `'-end'` the directories are added to the bottom (or end) of the path.

6.2 ASSIGNIN Assign Variable in Workspace

6.2.1 Usage

The `assignin` function allows you to assign a value to a variable in either the callers work space or the base work space. The syntax for `assignin` is

```
assignin(workspace,variablename,value)
```

The argument `workspace` must be either 'caller' or 'base'. If it is 'caller' then the variable is assigned in the caller's work space. That does not mean the caller of `assignin`, but the caller of the current function or script. On the other hand if the argument is 'base', then the assignment is done in the base work space. Note that the variable is created if it does not already exist.

6.3 BLASLIB Select BLAS library

6.3.1 Usage

The `blaslib` function allows you to select the FreeMat blas library. It has two modes of operation. The first is to select blas library:

```
blaslib LIB_NAME
```

If you want to see current blas library selected issue a `blaslib` command with no arguments.

```
blaslib
```

the returned list of libraries will include an asterix next to the library currently selected. If no library is selected, FreeMat will use its internal (reference) BLAS implementation, which is slow, but portable.

Location of the optimized library is specified in blas.ini file which is installed in the binary directory (i.e. directory where FreeMat executable is located).

The format of blas.ini file is following:

```
 [Linux64]
ATLAS64\libname=/usr/lib64/atlas/libblas.so
ATLAS64\capfnames=false
ATLAS64\prefix=
ATLAS64\suffix=_
ATLAS64\desc="ATLAS BLAS. Optimized."
```

Where Linux64 is the OS flavor for the blas library described below it. Other options are [Win32], [Linux32], [OSX]. Note that Linux is our name for all unix platforms.

- `ATLAS64` - name of the library as it will appear in the list when you type blaslib command in FreeMat.
- `ATLAS64bname` - path to the library. It has to be a shared library (Linux), DLL (Windows), Bundle (? OSX). This library has to be a Fortran BLAS library, not cblas!
- `ATLAS64\capfnames` - does the library use capital letters for function names (usually false).
- `ATLAS64refix` - prefix (characters that are put in front of) for all blas functions in the library (e.g. `ATL\_` or `AMD\_`).
- `ATLAS64\suffix` - suffix (characters that are put after) for all blas function in the library (e.g. `\_`)
- `ATLAS64\desc` - text description of the library.

On FreeMat startup it looks at the blas.ini file, and tries to load each library described in the section for the given OS flavor. FreeMat will use the first library it can successfully load. If you want to switch the BLAS libraries dynamically in the running FreeMat session you need to use blaslib command.

If FreeMat can't load any library it will default to using built in BLAS.

You should be a careful when using non-default BLAS libraries. Some libraries do not implement all the BLAS functions correctly. You should run FreeMat test suite (type `run\_tests()`) and use common sense when evaluating the results of numerical computations.

6.4 BUILTIN Evaulate Builtin Function

6.4.1 Usage

The `builtin` function evaluates a built in function with the given name, bypassing any overloaded functions. The syntax of `builtin` is

```
[y1,y2,...,yn] = builtin(fname,x1,x2,...,xm)
```

where `fname` is the name of the function to call. Apart from the fact that `fname` must be a string, and that `builtin` always calls the non-overloaded method, it operates exactly like `feval`. Note that unlike MATLAB, `builtin` does not force evaluation to an actual compiled function. It simply subverts the activation of overloaded method calls.

6.5 CLC Clear Dislplay

6.5.1 Usage

The `clc` function clears the current display. The syntax for its use is

```
clc
```

6.6 CLOCK Get Current Time

6.6.1 Usage

Returns the current date and time as a vector. The syntax for its use is

```
y = clock
```

where `y` has the following format:

```
y = [year month day hour minute seconds]
```

6.6.2 Example

Here is the time that this manual was last built:

```
--> clock

ans =

   1.0e+03 *
    2.0110    0.0070    0.0100    0.0200    0.0110    0.0457
```

6.7 CLOCKTOTIME Convert Clock Vector to Epoch Time

6.7.1 Usage

Given the output of the `clock` command, this function computes the epoch time, i.e, the time in seconds since January 1,1970 at 00:00:00 UTC. This function is most useful for calculating elapsed times using the clock, and should be accurate to less than a millisecond (although the true accuracy depends on accuracy of the argument vector). The usage for `clocktotime` is

```
y = clocktotime(x)
```

where `x` must be in the form of the output of `clock`, that is

```
x = [year month day hour minute seconds]
```

6.7.2 Example

Here is an example of using `clocktotime` to time a delay of 1 second

```
--> x = clock

x =

   1.0e+03 *
    2.0110    0.0070    0.0100    0.0200    0.0110    0.0457

--> sleep(1)
```

```
--> y = clock

y =

   1.0e+03 *
    2.0110    0.0070    0.0100    0.0200    0.0110    0.0467

--> clocktotime(y) - clocktotime(x)

ans =
 1
```

6.8 COMPUTER Computer System FreeMat is Running On

6.8.1 Usage

Returns a string describing the name of the system FreeMat is running on. The exact value of this string is subject to change, although the `'MAC'` and `'PCWIN'` values are probably fixed.

```
str = computer
```

Currently, the following return values are defined

- `'PCWIN'` - MS Windows
- `'MAC'` - Mac OS X
- `'UNIX'` - All others

6.9 DIARY Create a Log File of Console

6.9.1 Usage

The `diary` function controls the creation of a log file that duplicates the text that would normally appear on the console. The simplest syntax for the command is simply:

```
diary
```

which toggles the current state of the diary command. You can also explicitly set the state of the diary command via the syntax

```
diary off
```

or

```
diary on
```

To specify a filename for the log (other than the default of `diary`), you can use the form:

```
diary filename
```

or

```
diary('filename')
```

which activates the diary with an output filename of `filename`. Note that the `diary` command is thread specific, but that the output is appended to a given file. That means that if you call `diary` with the same filename on multiple threads, their outputs will be intermingled in the log file (just as on the console). Because the `diary` state is tied to individual threads, you cannot retrieve the current diary state using the `get(0,'Diary')` syntax from MATLAB. Instead, you must call the `diary` function with no inputs and one output:

```
state = diary
```

which returns a logical `1` if the output of the current thread is currently going to a diary, and a logical `0` if not.

6.10 DOCLI Start a Command Line Interface

6.10.1 Usage

The `docli` function is the main function that you interact with when you run FreeMat. I am not sure why you would want to use it, but hey - its there if you want to use it.

6.11 EDIT Open Editor Window

6.11.1 Usage

Brings up the editor window. The arguments of `edit` function are names of files for editing:

```
edit file1 file2 file3
```

6.12 EDITOR Open Editor Window

6.12.1 Usage

Brings up the editor window. The `editor` function takes no arguments:

```
editor
```

6.13 ERRORCOUNT Retrieve the Error Counter for the Interpreter

6.13.1 Usage

This routine retrieves the internal counter for the interpreter, and resets it to zero. The general syntax for its use is

```
count = errorcount
```

6.14 ETIME Elapsed Time Function

6.14.1 Usage

The `etime` calculates the elapsed time between two `clock` vectors `x1` and `x2`. The syntax for its use is

```
y = etime(x1,x2)
```

where `x1` and `x2` are in the `clock` output format

```
x = [year month day hour minute seconds]
```

6.14.2 Example

Here we use `etime` as a substitute for `tic` and `toc`

```
--> x1 = clock;
--> sleep(1);
--> x2 = clock;
--> etime(x2,x1);
```

6.15 EVAL Evaluate a String

6.15.1 Usage

The `eval` function evaluates a string. The general syntax for its use is

```
eval(s)
```

where `s` is the string to evaluate. If `s` is an expression (instead of a set of statements), you can assign the output of the `eval` call to one or more variables, via

```
x = eval(s)
[x,y,z] = eval(s)
```

Another form of `eval` allows you to specify an expression or set of statements to execute if an error occurs. In this form, the syntax for `eval` is

```
eval(try_clause,catch_clause),
```

or with return values,

```
x = eval(try_clause,catch_clause)
[x,y,z] = eval(try_clause,catch_clause)
```

These later forms are useful for specifying defaults. Note that both the `try\_clause` and `catch\_clause` must be expressions, as the equivalent code is

```
try
  [x,y,z] = try_clause
catch
  [x,y,z] = catch_clause
end
```

so that the assignment must make sense in both cases.

6.15.2 Example

Here are some examples of `eval` being used.

```
--> eval('a = 32')

a =
 32

--> b = eval('a')

b =
 32
```

The primary use of the `eval` statement is to enable construction of expressions at run time.

```
--> s = ['b = a' ' + 2']

s =
b = a + 2
--> eval(s)

b =
 34
```

Here we demonstrate the use of the catch-clause to provide a default value

```
--> a = 32

a =
 32

--> b = eval('a','1')

b =
 32

--> b = eval('z','a+1')

b =
 33
```

Note that in the second case, `b` takes the value of 33, indicating that the evaluation of the first expression failed (because `z` is not defined).

6.16 EVALIN Evaluate a String in Workspace

6.16.1 Usage

The `evalin` function is similar to the `eval` function, with an additional argument up front that indicates the workspace that the expressions are to be evaluated in. The various syntaxes for `evalin` are:

```
evalin(workspace,expression)
x = evalin(workspace,expression)
[x,y,z] = evalin(workspace,expression)
evalin(workspace,try_clause,catch_clause)
x = evalin(workspace,try_clause,catch_clause)
[x,y,z] = evalin(workspace,try_clause,catch_clause)
```

The argument `workspace` must be either 'caller' or 'base'. If it is 'caller', then the expression is evaluated in the caller's work space. That does not mean the caller of `evalin`, but the caller of the current function or script. On the other hand if the argument is 'base', then the expression is evaluated in the base work space. See `eval` for details on the use of each variation.

6.17 EXIT Exit Program

6.17.1 Usage

The usage is

```
exit
```

Quits FreeMat. This script is a simple synonym for `quit`.

6.18 FEVAL Evaluate a Function

6.18.1 Usage

The `feval` function executes a function using its name. The syntax of `feval` is

```
[y1,y2,...,yn] = feval(f,x1,x2,...,xm)
```

where `f` is the name of the function to evaluate, and `xi` are the arguments to the function, and `yi` are the return values.

Alternately, `f` can be a function handle to a function (see the section on `function handles` for more information).

Finally, FreeMat also supports `f` being a user defined class in which case it will atttempt to invoke the `subsref` method of the class.

6.18.2 Example

Here is an example of using `feval` to call the `cos` function indirectly.

```
--> feval('cos',pi/4)

ans =
    0.7071
```

Now, we call it through a function handle

```
--> c = @cos

c =
 @cos
--> feval(c,pi/4)

ans =
    0.7071
```

Here we construct an inline object (which is a user-defined class) and use `feval` to call it

```
--> afunc = inline('cos(t)+sin(t)','t')

afunc =
  inline function object
  f(t) = cos(t)+sin(t)
--> feval(afunc,pi)

ans =
   -1.0000

--> afunc(pi)

ans =
   -1.0000
```

In both cases, (the `feval` call and the direct invokation), FreeMat calls the `subsref` method of the class, which computes the requested function.

6.19 FILESEP Directory Separation Character

6.19.1 Usage

The `filesep` routine returns the character used to separate directory names on the current platform (basically, a forward slash for Windows, and a backward slash for all other OSes). The syntax is simple:

```
  x = filesep
```

6.20 HELP Help

6.20.1 Usage

Displays help on a function available in FreeMat. The help function takes one argument:

```
help topic
```

where `topic` is the topic to look for help on. For scripts, the result of running `help` is the contents of the comments at the top of the file. If FreeMat finds no comments, then it simply displays the function declaration.

6.21 HELPWIN Online Help Window

6.21.1 Usage

Brings up the online help window with the FreeMat manual. The `helpwin` function takes no arguments:

```
helpwin
helpwin FunctionName
```

6.22 JITCONTROL Control the Just In Time Compiler

6.22.1 Usage

The `jitcontrol` functionality in FreeMat allows you to control the use of the Just In Time (JIT) compiler. Starting in FreeMat version 4, the JIT compiler is enabled by default on all platforms where it is successfully built. The JIT compiler should significantly improve the performance of loop intensive, scalar code. As development progresses, more and more functionality will be enabled under the JIT. In the mean time (if you use the GUI version of FreeMat) you can use the JIT chat window to get information on why your code was JIT compiled (or not).

6.23 MFILENAME Name of Current Function

6.23.1 Usage

Returns a string describing the name of the current function. For M-files this string will be the complete filename of the function. This is true even for subfunctions. The syntax for its use is

```
y = mfilename
```

6.24 PATH Get or Set FreeMat Path

6.24.1 Usage

The `path` routine has one of the following syntaxes. In the first form

```
x = path
```

`path` simply returns the current path. In the second, the current path is replaced by the argument string `'thepath'`

```
path('thepath')
```

In the third form, a new path is appended to the current search path

```
path(path,'newpath')
```

In the fourth form, a new path is prepended to the current search path

```
path('newpath',path)
```

In the final form, the path command prints out the current path

```
path
```

6.25 PATHSEP Path Directories Separation Character

6.25.1 Usage

The `pathsep` routine returns the character used to separate multiple directories on a path string for the current platform (basically, a semicolon for Windows, and a regular colon for all other OSes). The syntax is simple:

```
x = pathsep
```

6.26 PATHTOOL Open Path Setting Tool

6.26.1 Usage

Brings up the pathtool dialog. The `pathtool` function takes no arguments:

```
pathtool
```

6.27 PCODE Convert a Script or Function to P-Code

6.27.1 Usage

Writes out a script or function as a P-code function. The general syntax for its use is:

```
pcode fun1 fun2 ...
```

The compiled functions are written to the current directory.

6.28 PROFILER Control Profiling

6.28.1 Usage

The `profile` function allows you to control the FreeMat profiler. It has two modes of operation. The first is to enable-disable the profiler. To turn on profiling:

```
profiler on
```

to turn off profiling, use

```
profiler off
```

Note that regardless of the state of the profiler, only functions and scripts are profiled. Commands entered on the command line are not profiled. To see information that has accumulated in a profile, you use the variant of the command:

```
profiler list
```

which lists current sorted profiling resuls. You can use this form to obtain profiler results as a cell array

```
r=profiler('list')
```

If you want to see current profile status issue a `profile` command with no arguments.

```
profiler
```

6.29 QUIET Control the Verbosity of the Interpreter

6.29.1 Usage

The `quiet` function controls how verbose the interpreter is when executing code. The syntax for the function is

```
quiet flag
```

where `flag` is one of

- `'normal'` - normal output from the interpreter
- `'quiet'` - only intentional output (e.g. `printf` calls and `disp` calls) is printed. The output of expressions that are not terminated in semicolons are not printed.
- `'silent'` - nothing is printed to the output.

The `quiet` command also returns the current quiet flag.

6.30 QUIT Quit Program

6.30.1 Usage

The `quit` statement is used to immediately exit the FreeMat application. The syntax for its use is

```
quit
```

6.31 REHASH Rehash Directory Caches

6.31.1 Usage

Usually, FreeMat will automatically determine when M Files have changed, and pick up changes you have made to M files. Sometimes, you have to force a refresh. Use the `rehash` command for this purpose. The syntax for its use is

```
rehash
```

6.32 RESCAN Rescan M Files for Changes

6.32.1 Usage

Usually, FreeMat will automatically determine when M Files have changed, and pick up changes you have made to M files. Sometimes, you have to force a refresh. Use the `rescan` command for this purpose. The syntax for its use is

```
rescan
```

6.33 ROOTPATH Set FreeMat Root Path

6.33.1 Usage

In order to function properly, FreeMat needs to know where to find the `toolbox` directory as well as the `help` directory. These directories are located on what is known as the `root path`. Normally, FreeMat should know where these directories are located. However under some circumstances (usually when FreeMat is installed into a non-default location), it may be necessary to indicate a different root path location, or to specify a particular one. Note that on the Mac OS platform, FreeMat is installed as a bundle, and will use the toolbox

that is installed in the bundle regardless of the setting for `rootpath`. For Linux, FreeMat will typically use `/usr/local/share/FreeMat-<Version>/` for the root path. Installations from source code will generally work, but binary installations (e.g., from an `RPM`) may need to have the rootpath set.

The `rootpath` function has two forms. The first form takes no arguments and returns the current root path

```
rootpath
```

The second form will set a rootpath directly from the command line

```
rootpath(path)
```

where `path` is the full path to where the `toolbox` and `help` directories are located. For example, `rootpath('/usr/share/Freel`
The third form enables the GUI form

```
rootpath gui
```

which activates a dialog box to pick a directory that is the root directory of the FreeMat installation (e.g., where `help` and `toolbox` are located. Changes to `rootpath` are persistent (you do not need to run it every time you start FreeMat).

6.34 SIMKEYS Simulate Keypresses from the User

6.34.1 Usage

This routine simulates keystrokes from the user on FreeMat. The general syntax for its use is

```
otext = simkeys(text)
```

where `text` is a string to simulate as input to the console. The output of the commands are captured and returned in the string `otext`. This is primarily used by the testing infrastructure.

6.35 SLEEP Sleep For Specified Number of Seconds

6.35.1 Usage

Suspends execution of FreeMat for the specified number of seconds. The general syntax for its use is

```
sleep(n),
```

where `n` is the number of seconds to wait.

6.36 SOURCE Execute an Arbitrary File

6.36.1 Usage

The `source` function executes the contents of the given filename one line at a time (as if it had been typed at the `-->` prompt). The `source` function syntax is

```
source(filename)
```

where `filename` is a `string` containing the name of the file to process.

6.36.2 Example

First, we write some commands to a file (note that it does not end in the usual `.m` extension):

```
    source_test
a = 32;
b = a;
printf('a is %d and b is %d\n',a,b);
```

Now we source the resulting file.

```
--> clear a b
--> source source_test
a is 32 and b is 32
```

6.37 STARTUP Startup Script

6.37.1 Usage

Upon starting, FreeMat searches for a script names `startup.m`, and if it finds it, it executes it. This script can be in the current directory, or on the FreeMat path (set using `setpath`). The contents of startup.m must be a valid script (not a function).

6.38 TIC Start Stopwatch Timer

6.38.1 Usage

Starts the stopwatch timer, which can be used to time tasks in FreeMat. The `tic` takes no arguments, and returns no outputs. You must use `toc` to get the elapsed time. The usage is

```
  tic
```

6.38.2 Example

Here is an example of timing the solution of a large matrix equation.

```
--> A = rand(100);
--> b = rand(100,1);
--> tic; c = A\b; toc

ans =
    0.0020
```

6.39 TOC Stop Stopwatch Timer

6.39.1 Usage

Stop the stopwatch timer, which can be used to time tasks in FreeMat. The `toc` function takes no arguments, and returns no outputs. You must use `toc` to get the elapsed time. The usage is

```
  toc
```

6.39.2 Example

Here is an example of timing the solution of a large matrix equation.

```
--> A = rand(100);
--> b = rand(100,1);
--> tic; c = A\b; toc

ans =
    0.0010
```

6.40 VERSION The Current Version Number

6.40.1 Usage

The `version` function returns the current version number for FreeMat (as a string). The general syntax for its use is

```
v = version
```

6.40.2 Example

The current version of FreeMat is

```
--> version

ans =
4.1
```

6.41 VERSTRING The Current Version String

6.41.1 Usage

The `verstring` function returns the current version string for FreeMat. The general syntax for its use is

```
version = verstring
```

6.41.2 Example

The current version of FreeMat is

```
--> verstring

ans =
FreeMat v4.1
```

Chapter 7

Debugging FreeMat Code

7.1 DBAUTO Control Dbauto Functionality

7.1.1 Usage

The dbauto functionality in FreeMat allows you to debug your FreeMat programs. When `dbauto` is `on`, then any error that occurs while the program is running causes FreeMat to stop execution at that point and return you to the command line (just as if you had placed a `keyboard` command there). You can then examine variables, modify them, and resume execution using `return`. Alternately, you can exit out of all running routines via a `retall` statement. Note that errors that occur inside of `try/catch` blocks do not (by design) cause auto breakpoints. The `dbauto` function toggles the dbauto state of FreeMat. The syntax for its use is

```
dbauto(state)
```

where `state` is either

```
dbauto('on')
```

to activate dbauto, or

```
dbauto('off')
```

to deactivate dbauto. Alternately, you can use FreeMat's string-syntax equivalence and enter

```
dbauto on
```

or

```
dbauto off
```

to turn dbauto on or off (respectively). Entering `dbauto` with no arguments returns the current state (either 'on' or 'off').

7.2 DBDELETE Delete a Breakpoint

7.2.1 Usage

The `dbdelete` function deletes a breakpoint. The syntax for the `dbdelete` function is

```
dbdelete(num)
```

where `num` is the number of the breakpoint to delete.

7.3 DBDown Move Down One Debug Level

7.3.1 Usage

The `dbdown` function moves up one level in the debug hierarchy. The syntax for the `dbdown` function is

```
dbdown
```

7.4 DBLIST List Breakpoints

7.4.1 Usage

List the current set of breakpoints. The syntax for the `dblist` is simply

```
dblist
```

7.5 DBSTEP Step N Statements

7.5.1 Usage

Step `N` statements during debug mode. The synax for this is either

```
dbstep(N)
```

to step `N` statements, or

```
dbstep
```

to step one statement.

7.6 DBSTOP

7.6.1 Usage

Set a breakpoint. The syntax for this is:

```
dbstop(funcname,linenumber)
```

where `funcname` is the name of the function where we want to set the breakpoint, and `linenumber` is the line number.

7.7 DBUP Move Up One Debug Level

7.7.1 Usage

The `dbup` function moves up one level in the debug hierarchy. The syntax for the `dbup` function is

```
dbup
```

7.8 FDUMP Dump Information on Function

7.8.1 Usage

Dumps information about a function (diagnostic information only)

```
fdump fname
```

Chapter 8

Sparse Matrix Support

8.1 EIGS Sparse Matrix Eigendecomposition

8.1.1 Usage

Computes the eigendecomsition of a sparse square matrix. The `eigs` function has several forms. The most general form is

```
[V,D] = eigs(A,k,sigma)
```

where `A` is the matrix to analyze, `k` is the number of eigenvalues to compute and `sigma` determines which eigenvallues to solve for. Valid values for `sigma` are 'lm' - largest magnitude 'sm' - smallest magnitude 'la' - largest algebraic (for real symmetric problems) 'sa' - smallest algebraic (for real symmetric problems) 'be' - both ends (for real symmetric problems) 'lr' - largest real part 'sr' - smallest real part 'li' - largest imaginary part 'si' - smallest imaginary part scalar - find the eigenvalues closest to `sigma`. The returned matrix `V` contains the eigenvectors, and `D` stores the eigenvalues. The related form

```
d = eigs(A,k,sigma)
```

computes only the eigenvalues and not the eigenvectors. If `sigma` is omitted, as in the forms

```
[V,D] = eigs(A,k)
```

and

```
d = eigs(A,k)
```

then `eigs` returns the largest magnitude eigenvalues (and optionally the associated eigenvectors). As an even simpler form, the forms

```
[V,D] = eigs(A)
```

and

```
d = eigs(A)
```

then `eigs` returns the six largest magnitude eigenvalues of `A` and optionally the eigenvectors. The `eigs` function uses ARPACK to compute the eigenvectors and/or eigenvalues. Note that due to a limitation in the interface into ARPACK from FreeMat, the number of eigenvalues that are to be computed must be strictly smaller than the number of columns (or rows) in the matrix.

8.1.2 Example

Here is an example of using `eigs` to calculate eigenvalues of a matrix, and a comparison of the results with `eig`

```
--> a = sparse(rand(9));
--> eigs(a)

ans =
   4.1831 +  0.0000i
   0.3249 -  0.5504i
   0.3249 +  0.5504i
   0.5932 -  0.1774i
   0.5932 +  0.1774i
  -0.5572 +  0.0000i

--> eig(full(a))

ans =
   4.1831 +  0.0000i
   0.5932 +  0.1774i
   0.5932 -  0.1774i
   0.3249 +  0.5504i
   0.3249 -  0.5504i
  -0.5572 +  0.0000i
  -0.1285 +  0.0901i
  -0.1285 -  0.0901i
  -0.3219 +  0.0000i
```

Next, we exercise some of the variants of `eigs`:

```
--> eigs(a,4,'sm')

ans =
  -0.1285 +  0.0901i
  -0.1285 -  0.0901i
  -0.3219 +  0.0000i
  -0.5572 +  0.0000i

--> eigs(a,4,'lr')

ans =
   4.1831 +  0.0000i
   0.5932 +  0.1774i
   0.5932 -  0.1774i
   0.3249 +  0.5504i

--> eigs(a,4,'sr')

ans =
  -0.5572 +  0.0000i
  -0.3219 +  0.0000i
  -0.1285 +  0.0901i
  -0.1285 -  0.0901i
```

8.2 FULL Convert Sparse Matrix to Full Matrix

8.2.1 Usage

Converts a sparse matrix to a full matrix. The syntax for its use is

```
y = full(x)
```

The type of `x` is preserved. Be careful with the function. As a general rule of thumb, if you can work with the `full` representation of a function, you probably do not need the sparse representation.

8.2.2 Example

Here we convert a full matrix to a sparse one, and back again.

```
--> a = [1,0,4,2,0;0,0,0,0,0;0,1,0,0,2]

a =
 1 0 4 2 0
 0 0 0 0 0
 0 1 0 0 2

--> A = sparse(a)

A =
 1 1 1
 3 2 1
 1 3 4
 1 4 2
 3 5 2
--> full(A)

ans =
 1 0 4 2 0
 0 0 0 0 0
 0 1 0 0 2
```

8.3 SPARSE Construct a Sparse Matrix

8.3.1 Usage

Creates a sparse matrix using one of several formats. The first creates a sparse matrix from a full matrix

```
y = sparse(x).
```

The second form creates a sparse matrix containing all zeros that is of the specified size (the sparse equivalent of `zeros`).

```
y = sparse(m,n)
```

where `m` and `n` are integers. Just like the `zeros` function, the sparse matrix returned is of type `float`. The third form constructs a sparse matrix from the IJV syntax. It has two forms. The first version autosizes the sparse matrix

```
y = sparse(i,j,v)
```

while the second version uses an explicit size specification

```
y = sparse(i,j,v,m,n)
```

8.4 SPEYE Sparse Identity Matrix

8.4.1 Usage

Creates a sparse identity matrix of the given size. The syntax for its use is

```
y = speye(m,n)
```

which forms an `m x n` sparse matrix with ones on the main diagonal, or

```
y = speye(n)
```

which forms an `n x n` sparse matrix with ones on the main diagonal. The matrix type is a `float` single precision matrix.

8.4.2 Example

The following creates a 5000 by 5000 identity matrix, which would be difficult to do using `sparse(eye(5000))` because of the large amount of intermediate storage required.

```
--> I = speye(5000);
--> who I
  Variable Name       Type   Flags             Size
              I    double   sparse           [5000x5000]
--> full(I(1:10,1:10))

ans =
 1 0 0 0 0 0 0 0 0 0
 0 1 0 0 0 0 0 0 0 0
 0 0 1 0 0 0 0 0 0 0
 0 0 0 1 0 0 0 0 0 0
 0 0 0 0 1 0 0 0 0 0
 0 0 0 0 0 1 0 0 0 0
 0 0 0 0 0 0 1 0 0 0
 0 0 0 0 0 0 0 1 0 0
 0 0 0 0 0 0 0 0 1 0
 0 0 0 0 0 0 0 0 0 1
```

8.5 SPONES Sparse Ones Function

8.5.1 Usage

Returns a sparse `float` matrix with ones where the argument matrix has nonzero values. The general syntax for it is

```
y = spones(x)
```

where `x` is a matrix (it may be full or sparse). The output matrix `y` is the same size as `x`, has type `float`, and contains ones in the nonzero positions of `x`.

8.5.2 Examples

Here are some examples of the `spones` function

```
--> a = [1,0,3,0,5;0,0,2,3,0;1,0,0,0,1]

a =
```

```
 1 0 3 0 5
 0 0 2 3 0
 1 0 0 0 1

--> b = spones(a)

b =
 1 1 1
 1 2 1
 1 3 1
 1 4 1
 1 5 1
--> full(b)

ans =
 1 1 1 1 1
 0 0 0 0 0
 0 0 0 0 0
```

8.6 SPRAND Sparse Uniform Random Matrix

8.6.1 Usage

Creates a sparse matrix with uniformly distributed random entries (on [0,1]). The syntax for its use is

```
y = sprand(x)
```

where `x` is a sparse matrix, where `y` is a sparse matrix that has random entries where `x` is nonzero. The second form specifies the size of the matrix and the density

```
y = sprand(m,n,density)
```

where `m` is the number of rows in the output, `n` is the number of columns in the output, and `density` (which is between 0 and 1) is the density of nonzeros in the resulting matrix. Note that for very high densities the actual density of the output matrix may differ from the density you specify. This difference is a result of the way the random entries into the matrix are generated. If you need a very dense random matrix, it is better to generate a full matrix and zero out the entries you do not need.

8.6.2 Examples

Here we seed `sprand` with a full matrix (to demonstrate how the structure of the output is determined by the input matrix when using the first form).

```
--> x = [1,0,0;0,0,1;1,0,0]

x =
 1 0 0
 0 0 1
 1 0 0

--> y = sprand(x)

y =
 1 1 0.171364
 3 1 0.245464
 2 3 0.0426635
```

```
--> full(y)

ans =
    0.1714         0         0
         0         0    0.0427
    0.2455         0         0
```

The more generic version with a density of `0.001`. On many systems the following is impossible using full matrices

```
--> y = sprand(10000,10000,.001);
--> nnz(y)/10000^2

ans =
 9.9946e-04
```

8.7 SPRANDN Sparse Normal Random Matrix

8.7.1 Usage

Creates a sparse matrix with normally distributed random entries (mean 0, sigma 1). The syntax for its use is

```
  y = sprandn(x)
```

where `x` is a sparse matrix, where `y` is a sparse matrix that has random entries where `x` is nonzero. The second form specifies the size of the matrix and the density

```
  y = sprandn(m,n,density)
```

where `m` is the number of rows in the output, `n` is the number of columns in the output, and `density` (which is between 0 and 1) is the density of nonzeros in the resulting matrix. Note that for very high densities the actual density of the output matrix may differ from the density you specify. This difference is a result of the way the random entries into the matrix are generated. If you need a very dense random matrix, it is better to generate a full matrix and zero out the entries you do not need.

8.7.2 Examples

Here we seed `sprandn` with a full matrix (to demonstrate how the structure of the output is determined by the input matrix when using the first form).

```
--> x = [1,0,0;0,0,1;1,0,0]

x =
 1 0 0
 0 0 1
 1 0 0

--> y = sprandn(x)

y =
 1 1 -0.498012
 3 1 0.813313
 2 3 -1.10282
--> full(y)
```

```
ans =
   -0.4980         0         0
         0         0   -1.1028
    0.8133         0         0
```

The more generic version with a density of `0.001`. On many systems the following is impossible using full matrices

```
--> y = sprandn(10000,10000,.001);
--> nnz(y)/10000^2

ans =
 9.9952e-04
```

8.8 SPY Visualize Sparsity Pattern of a Sparse Matrix

8.8.1 Usage

Plots the sparsity pattern of a sparse matrix. The syntax for its use is

```
spy(x)
```

which uses a default color and symbol. Alternately, you can use

```
spy(x,colspec)
```

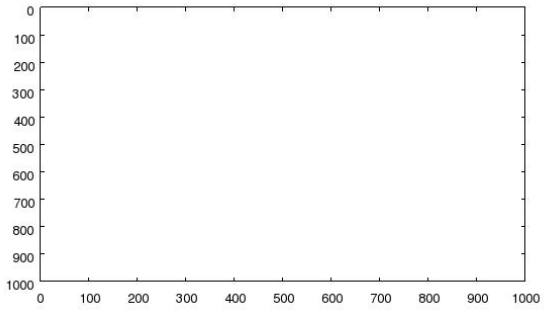
where `colspec` is any valid color and symbol spec accepted by `plot`.

8.8.2 Example

First, an example of a random sparse matrix.

```
--> y = sprand(1000,1000,.001);
--> spy(y,'ro')
```

which is shown here



Here is a sparse matrix with a little more structure. First we build a sparse matrix with block diagonal structure, and then use `spy` to visualize the structure.

```
--> A = sparse(1000,1000);
--> for i=1:25; A((1:40) + 40*(i-1),(1:40) + 40*(i-1)) = 1; end;
--> spy(A,'gx')
```

with the result shown here

Chapter 9

Mathematical Functions

9.1 ACOS Inverse Trigonometric Arccosine Function

9.1.1 Usage

Computes the `acos` function for its argument. The general syntax for its use is

```
y = acos(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `acos` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.1.2 Function Internals

Mathematically, the `acos` function is defined for all arguments `x` as

$$\text{acos}x \equiv \frac{pi}{2} + i \log\left(ix + \sqrt{1 - x^2}\right).$$

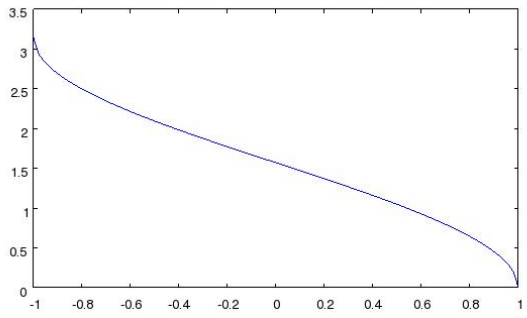
For real valued variables `x` in the range `[-1,1]`, the function is computed directly using the standard C library's numerical `acos` function. For both real and complex arguments `x`, note that generally

$$\text{acos}(\cos(x)) \neq x,$$

9.1.3 Example

The following code demonstates the `acos` function over the range `[-1,1]`.

```
--> t = linspace(-1,1);
--> plot(t,acos(t))
```



9.2 ACOSD Inverse Cosine Degrees Function

9.2.1 Usage

Computes the inverse cosine of the argument, but returns the argument in degrees instead of radians (as is the case for `acos`. The syntax for its use is

```
y = acosd(x)
```

9.2.2 Examples

The inverse cosine of `sqrt(2)/2` should be 45 degrees:

```
--> acosd(sqrt(2)/2)

ans =
  45.0000 +  0.0000i
```

and the inverse cosine of `0.5` should be 60 degrees:

```
--> acosd(0.5)

ans =
  60.0000 +  0.0000i
```

9.3 ACOSH Inverse Hyperbolic Cosine Function

9.3.1 Usage

Computes the inverse hyperbolic cosine of its argument. The general syntax for its use is

```
y = acosh(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.3.2 Function Internals

The `acosh` function is computed from the formula

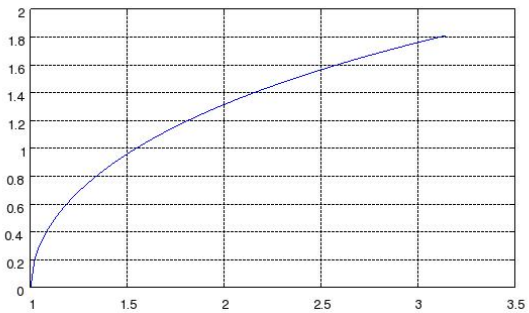
$$\cosh^{-1}(x) = \log\left(x + (x^2 - 1)^0.5\right)$$

where the `log` (and square root) is taken in its most general sense.

9.3.3 Examples

Here is a simple plot of the inverse hyperbolic cosine function

```
--> x = linspace(1,pi);
--> plot(x,acosh(x)); grid('on');
```



9.4 ACOT Inverse Cotangent Function

9.4.1 Usage

Computes the inverse cotangent of its argument. The general syntax for its use is

```
y = acot(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.4.2 Function Internals

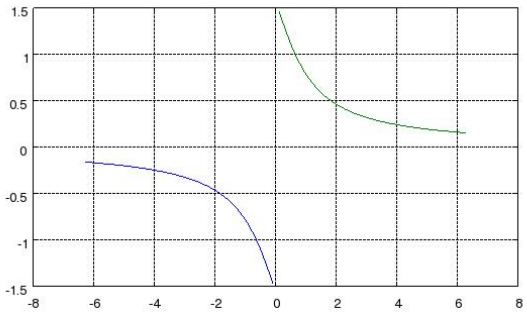
The `acot` function is computed from the formula

$$\cot^{-1}(x) = \tan^{-1}\left(\frac{1}{x}\right)$$

9.4.3 Examples

Here is a simple plot of the inverse cotangent function

```
--> x1 = -2*pi:pi/30:-0.1;
--> x2 = 0.1:pi/30:2*pi;
--> plot(x1,acot(x1),x2,acot(x2)); grid('on');
```



9.5 ACOTD Inverse Cotangent Degrees Function

9.5.1 Usage

Computes the inverse cotangent of its argument in degrees. The general syntax for its use is

```
y = acotd(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.6 ACOTH Inverse Hyperbolic Cotangent Function

9.6.1 Usage

Computes the inverse hyperbolic cotangent of its argument. The general syntax for its use is

```
y = acoth(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.6.2 Function Internals

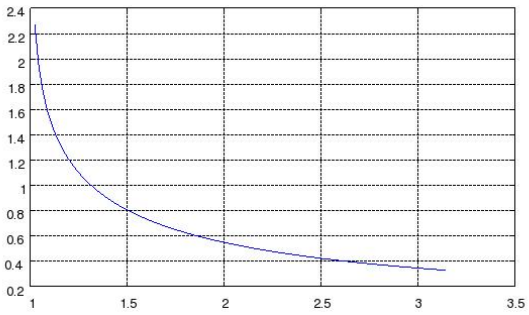
The `acoth` function is computed from the formula

$$\coth^{-1}(x) = \tanh^{-1}\left(\frac{1}{x}\right)$$

9.6.3 Examples

Here is a simple plot of the inverse hyperbolic cotangent function

```
--> x = linspace(1,pi);
--> plot(x,acoth(x)); grid('on');
```



9.7 ACSC Inverse Cosecant Function

9.7.1 Usage

Computes the inverse cosecant of its argument. The general syntax for its use is

```
y = acsc(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.7.2 Function Internals

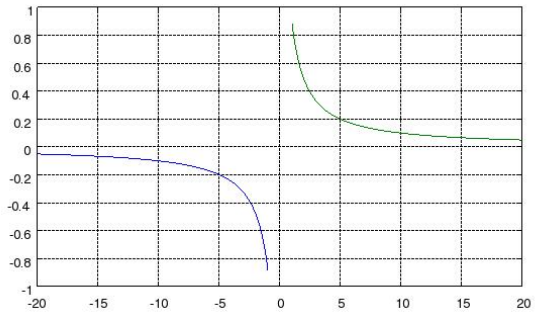
The `acosh` function is computed from the formula

$$\csc^{-1}(x) = \sin^{-1}\left(\frac{1}{x}\right)$$

9.7.3 Examples

Here is a simple plot of the inverse cosecant function

```
--> x1 = -10:.01:-1.01;
--> x2 = 1.01:.01:10;
--> plot(x1,acsc(x1),x2,acsc(x2)); grid('on');
```



9.8 ACSCD Inverse Cosecant Degrees Function

9.8.1 Usage

Computes the inverse cosecant of the argument, but returns the argument in degrees instead of radians (as is the case for `acsc`. The syntax for its use is

```
y = acscd(x)
```

9.8.2 Examples

The inverse cosecant of `2/sqrt(2)` should be 45 degrees:

```
--> acscd(2/sqrt(2))

ans =
   45.0000
```

and the inverse cosecant of `2` should be 30 degrees:

```
--> acscd(0.5)

ans =
  90.0000 - 75.4561i
```

9.9 ACSCH Inverse Hyperbolic Cosecant Function

9.9.1 Usage

Computes the inverse hyperbolic cosecant of its argument. The general syntax for its use is

```
y = acsch(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.9.2 Function Internals

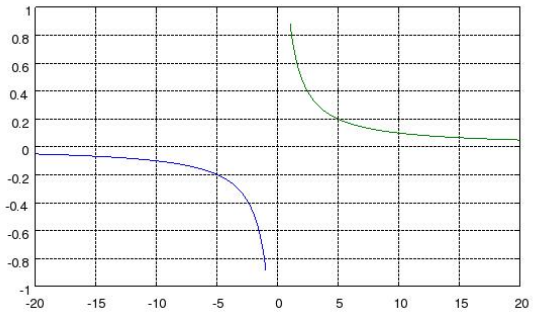
The `acsch` function is computed from the formula

$$\operatorname{csch}^{-1}(x) = \sinh^{-1}\left(\frac{1}{x}\right)$$

9.9.3 Examples

Here is a simple plot of the inverse hyperbolic cosecant function

```
--> x1 = -20:.01:-1;
--> x2 = 1:.01:20;
--> plot(x1,acsch(x1),x2,acsch(x2)); grid('on');
```



9.10 ANGLE Phase Angle Function

9.10.1 Usage

Compute the phase angle in radians of a complex matrix. The general syntax for its use is

```
p = angle(c)
```

where `c` is an `n`-dimensional array of numerical type.

9.10.2 Function Internals

For a complex number `x`, its polar representation is given by

$$x = |x|e^{j\theta}$$

and we can compute

$$\theta = \text{atan2}(\Im x, \Re x)$$

9.10.3 Example

Here are some examples of the use of `angle` in the polar decomposition of a complex number.

```
--> x = 3+4*i

x =
   3.0000 +  4.0000i

--> a = abs(x)

a =
 5

--> t = angle(x)

t =
    0.9273
```

```
--> a*exp(i*t)

ans =
   3.0000 +  4.0000i
```

M version contributor: M.W. Vogel 01-30-06

9.11 ASEC Inverse Secant Function

9.11.1 Usage

Computes the inverse secant of its argument. The general syntax for its use is

```
y = asec(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.11.2 Function Internals

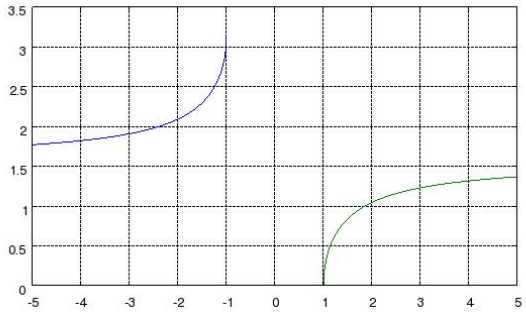
The `acosh` function is computed from the formula

$$\sec^{-1}(x) = \cos^{-1}\left(\frac{1}{x}\right)$$

9.11.3 Examples

Here is a simple plot of the inverse secant function

```
--> x1 = -5:.01:-1;
--> x2 = 1:.01:5;
--> plot(x1,asec(x1),x2,asec(x2)); grid('on');
```



9.12 ASECD Inverse Secant Degrees Function

9.12.1 Usage

Computes the inverse secant of the argument, but returns the argument in degrees instead of radians (as is the case for `asec`. The syntax for its use is

```
y = asecd(x)
```

9.12.2 Examples

The inverse secant of `2/sqrt(2)` should be 45 degrees:

```
--> asecd(2/sqrt(2))

ans =
  45.0000 +  0.0000i
```

and the inverse secant of `2` should be 60 degrees:

```
--> asecd(2)

ans =
  60.0000 +  0.0000i
```

9.13 ASECH Inverse Hyperbolic Secant Function

9.13.1 Usage

Computes the inverse hyperbolic secant of its argument. The general syntax for its use is

```
y = asech(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.13.2 Function Internals

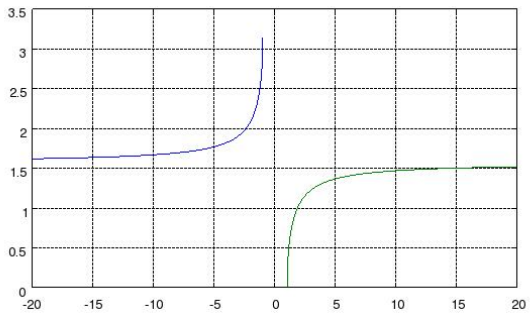
The `asech` function is computed from the formula

$$\operatorname{sech}^{-1}(x) = \cosh^{-1}\left(\frac{1}{x}\right)$$

9.13.3 Examples

Here is a simple plot of the inverse hyperbolic secant function

```
--> x1 = -20:.01:-1;
--> x2 = 1:.01:20;
--> plot(x1,imag(asech(x1)),x2,imag(asech(x2))); grid('on');
```



9.14 ASIN Inverse Trigonometric Arcsine Function

9.14.1 Usage

Computes the `asin` function for its argument. The general syntax for its use is

```
y = asin(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `asin` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.14.2 Function Internals

Mathematically, the `asin` function is defined for all arguments `x` as

$$\text{asin}x \equiv -i \log\left(ix + \sqrt{1-x^2}\right).$$

For real valued variables `x` in the range `[-1,1]`, the function is computed directly using the standard C library's numerical `asin` function. For both real and complex arguments `x`, note that generally

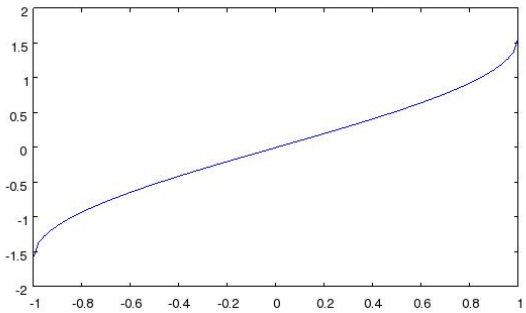
$$\text{asin}(\sin(x)) \neq x,$$

due to the periodicity of `sin(x)`.

9.14.3 Example

The following code demonstates the `asin` function over the range `[-1,1]`.

```
--> t = linspace(-1,1);
--> plot(t,asin(t))
```



9.15 ASIND Inverse Sine Degrees Function

9.15.1 Usage

Computes the inverse sine of the argument, but returns the argument in degrees instead of radians (as is the case for `asin`). The syntax for its use is

```
y = asind(x)
```

9.15.2 Examples

The inverse sine of `sqrt(2)/2` should be 45 degrees:

```
--> asind(sqrt(2)/2)

ans =
   45.0000
```

and the inverse sine of `0.5` should be 30 degrees:

```
--> asind(0.5)

ans =
   30.0000
```

9.16 ASINH Inverse Hyperbolic Sine Function

9.16.1 Usage

Computes the inverse hyperbolic sine of its argument. The general syntax for its use is

```
y = asinh(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.16.2 Function Internals

The `asinh` function is computed from the formula

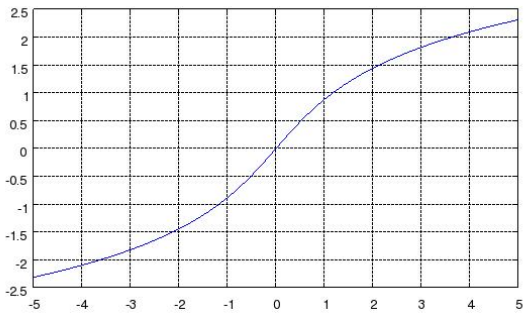
$$\sinh^{-1}(x) = \log\left(x + (x^2+1)^0.5\right)$$

where the `log` (and square root) is taken in its most general sense.

9.16.3 Examples

Here is a simple plot of the inverse hyperbolic sine function

```
--> x = -5:.01:5;
--> plot(x,asinh(x)); grid('on');
```



9.17 ATAN Inverse Trigonometric Arctangent Function

9.17.1 Usage

Computes the `atan` function for its argument. The general syntax for its use is

```
y = atan(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `atan` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.17.2 Function Internals

Mathematically, the `atan` function is defined for all arguments `x` as

$$\text{atan}x \equiv \frac{i}{2}\left(\log(1-ix) - \log(ix+1)\right).$$

For real valued variables `x`, the function is computed directly using the standard C library's numerical `atan` function. For both real and complex arguments `x`, note that generally

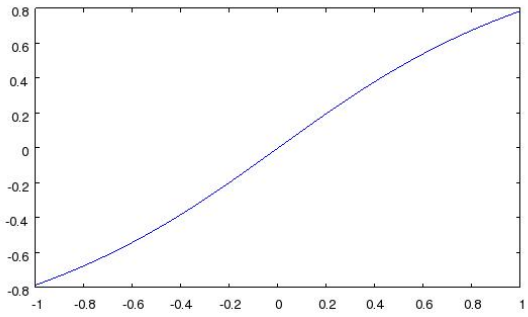
$$\text{atan}(\tan(x)) \neq x,$$

due to the periodicity of `tan(x)`.

9.17.3 Example

The following code demonstates the `atan` function over the range `[-1,1]`.

```
--> t = linspace(-1,1);
--> plot(t,atan(t))
```



9.18 ATAN2 Inverse Trigonometric 4-Quadrant Arctangent Function

9.18.1 Usage

Computes the `atan2` function for its argument. The general syntax for its use is

```
z = atan2(y,x)
```

where `x` and `y` are `n`-dimensional arrays of numerical type. Integer types are promoted to the `double` type prior to calculation of the `atan2` function. The size of the output depends on the size of `x` and `y`. If `x` is a scalar, then `z` is the same size as `y`, and if `y` is a scalar, then `z` is the same size as `x`. The type of the output is equal to the type of —y/x—.

9.18.2 Function Internals

The function is defined (for real values) to return an angle between `-pi` and `pi`. The signs of `x` and `y` are used to find the correct quadrant for the solution. For complex arguments, the two-argument arctangent is computed via

$$\text{atan2}(y,x) \equiv -i \log\left(\frac{x+iy}{\sqrt{x^2+y^2}}\right)$$

For real valued arguments `x,y`, the function is computed directly using the standard C library's numerical `atan2` function. For both real and complex arguments `x`, note that generally

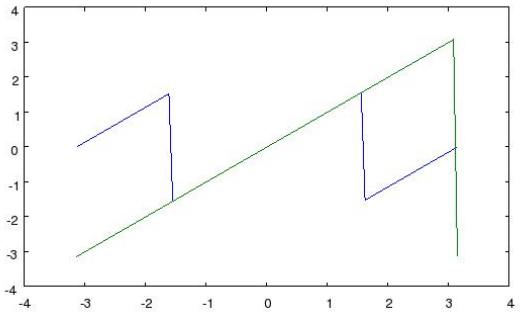
$$\text{atan2}(\sin(x),\cos(x)) \neq x,$$

due to the periodicities of `cos(x)` and `sin(x)`.

9.18.3 Example

The following code demonstates the difference between the `atan2` function and the `atan` function over the range `[-pi,pi]`.

```
--> x = linspace(-pi,pi);
--> sx = sin(x); cx = cos(x);
--> plot(x,atan(sx./cx),x,atan2(sx,cx))
```



Note how the two-argument `atan2` function (green line) correctly "unwraps" the phase of the angle, while the `atan` function (red line) wraps the angle to the interval `[-i/2,i/2]`.

9.19 ATAND Inverse Tangent Degrees Function

9.19.1 Usage

Computes the inverse tangent of the argument, but returns the argument in degrees instead of radians (as is the case for `atan`. The syntax for its use is

```
y = atand(x)
```

9.19.2 Examples

The inverse tangent of `1` should be 45 degrees:

```
--> atand(1)

ans =
 45
```

9.20 ATANH Inverse Hyperbolic Tangent Function

9.20.1 Usage

Computes the inverse hyperbolic tangent of its argument. The general syntax for its use is

```
y = atanh(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.20.2 Function Internals

The `atanh` function is computed from the formula

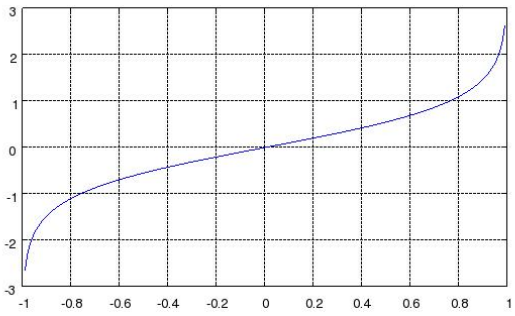
$$\tanh^{-1}(x) = \frac{1}{2}\log\left(\frac{1+x}{1-x}\right)$$

where the `log` (and square root) is taken in its most general sense.

9.20.3 Examples

Here is a simple plot of the inverse hyperbolic tangent function

```
--> x = -0.99:.01:0.99;
--> plot(x,atanh(x)); grid('on');
```



9.21 BETAINC Incomplete Beta Function

9.21.1 Usage

Computes the incomplete beta function. The `betainc` function takes 3 or 4 arguments

```
A = betainc(X,Y,Z)
```

```
A = betainc(X,Y,Z,tail)
```

where `X` is either a `float` or `double` array with elements in [0,1] interval, `Y` and `Z` are real non-negative arrays. `tail` specifies the tail of the incomplete beta function. If `tail` is 'lower' (default) than the integral from 0 to x is computed. If `tail` is 'upper' than the integral from x to 1 is computed. All arrays must be the same size or be scalar. The output vector `A` is the same size (and type) as input arrays.

9.21.2 Function Internals

The incomplete beta function is defined by the integral:

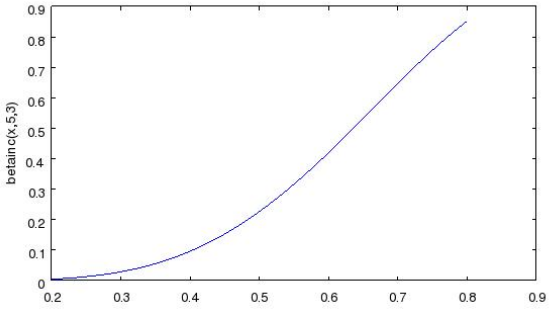
$$BetaI_x(a,b) = B_x(a,b)/B(a,b) where B_x(a,b) = \int_0^x t^{a-1}(1-t)^{b-1}dt for 0 <= x <= 1. For a > 0, b > 0$$

9.21.3 Example

Here is a plot of the betainc function over the range `[.2,.8]`.

```
--> x=.2:.01:.8;
--> y = betainc(x,5,3);
--> plot(x,y); xlabel('x'); ylabel('betainc(x,5,3)');
```

which results in the following plot.



9.22 COS Trigonometric Cosine Function

9.22.1 Usage

Computes the `cos` function for its argument. The general syntax for its use is

```
y = cos(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `cos` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.22.2 Function Internals

Mathematically, the `cos` function is defined for all real valued arguments `x` by the infinite summation

$$\cos x \equiv \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!}.$$

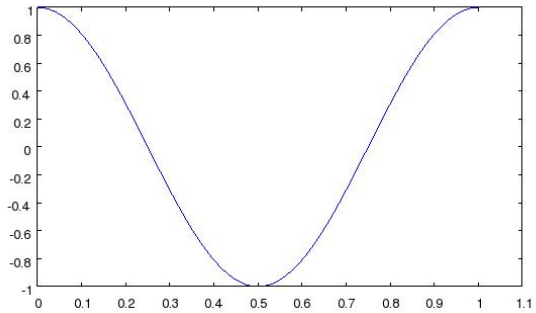
For complex valued arguments `z`, the cosine is computed via

$$\cos z \equiv \cos \Re z \cosh \Im z - \sin \Re z \sinh \Im z.$$

9.22.3 Example

The following piece of code plots the real-valued `cos(2 pi x)` function over one period of `[0,1]`:

```
--> x = linspace(0,1);
--> plot(x,cos(2*pi*x))
```



9.23 COSD Cosine Degrees Function

9.23.1 Usage

Computes the cosine of the argument, but takes the argument in degrees instead of radians (as is the case for `cos`). The syntax for its use is

```
y = cosd(x)
```

9.23.2 Examples

The cosine of 45 degrees should be `sqrt(2)/2`

```
--> cosd(45)

ans =
    0.7071
```

and the cosine of `60` degrees should be 0.5:

```
--> cosd(60)

ans =
    0.5000
```

9.24 COSH Hyperbolic Cosine Function

9.24.1 Usage

Computes the hyperbolic cosine of the argument. The syntax for its use is

```
y = cosh(x)
```

9.24.2 Function Internals

The `cosh` function is computed from the formula

$$\cosh(x) = \frac{e^x + e^{-x}}{2}$$

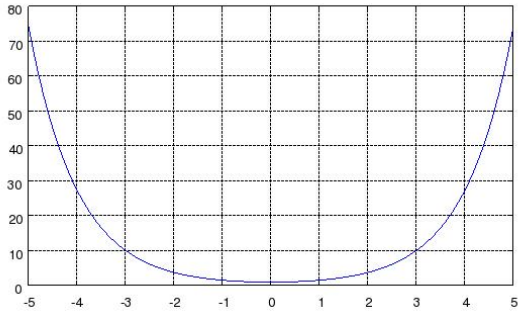
For `x` complex, it follows that

$$\cosh(a + i * b) = \frac{e^a(\cos(b) + i * \sin(b)) + e^{-a}(\cos(-b) + i * \sin(-b))}{2}$$

9.24.3 Examples

Here is a simple plot of the hyperbolic cosine function

```
--> x = linspace(-5,5);
--> plot(x,cosh(x)); grid('on');
```



9.25 COT Trigonometric Cotangent Function

9.25.1 Usage

Computes the `cot` function for its argument. The general syntax for its use is

```
y = cot(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `cot` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.25.2 Function Internals

Mathematically, the `cot` function is defined for all arguments `x` as

$$\cot x \equiv \frac{\cos x}{\sin x}$$

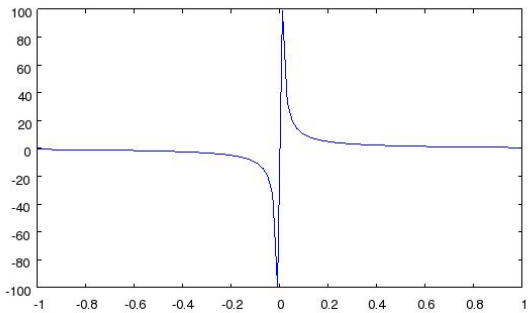
For complex valued arguments `z`, the cotangent is computed via

$$\cot z \equiv \frac{\cos 2\Re z + \cosh 2\Im z}{\sin 2\Re z + i \sinh 2\Im z}.$$

9.25.3 Example

The following piece of code plots the real-valued `cot(x)` function over the interval `[-1,1]`:

```
--> t = linspace(-1,1);
--> plot(t,cot(t))
```



9.26 COTD Cotangent Degrees Function

9.26.1 Usage

Computes the cotangent of the argument, but takes the argument in degrees instead of radians (as is the case for `cot`). The syntax for its use is

```
y = cotd(x)
```

9.26.2 Examples

The cotangent of 45 degrees should be 1.

```
--> cotd(45)

ans =
    1.0000
```

9.27 COTH Hyperbolic Cotangent Function

9.27.1 Usage

Computes the hyperbolic cotangent of the argument. The syntax for its use is

```
y = coth(x)
```

9.27.2 Function Internals

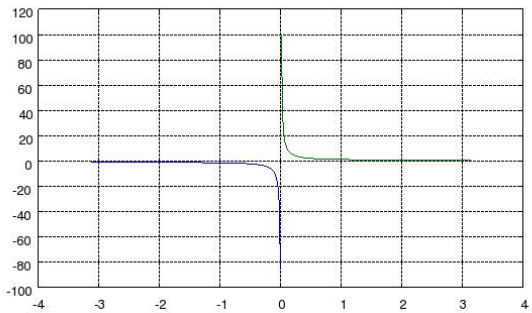
The `coth` function is computed from the formula

$$\coth(x) = \frac{1}{\tanh(x)}$$

9.27.3 Examples

Here is a simple plot of the hyperbolic cotangent function

```
--> x1 = -pi+.01:.01:-.01;
--> x2 = .01:.01:pi-.01;
--> plot(x1,coth(x1),x2,coth(x2)); grid('on');
```



9.28 CROSS Cross Product of Two Vectors

9.28.1 Usage

Computes the cross product of two vectors. The general syntax for its use is

```
c = cross(a,b)
```

where `a` and `b` are 3-element vectors.

9.29 CSC Trigonometric Cosecant Function

9.29.1 Usage

Computes the `csc` function for its argument. The general syntax for its use is

```
y = csc(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `csc` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.29.2 Function Internals

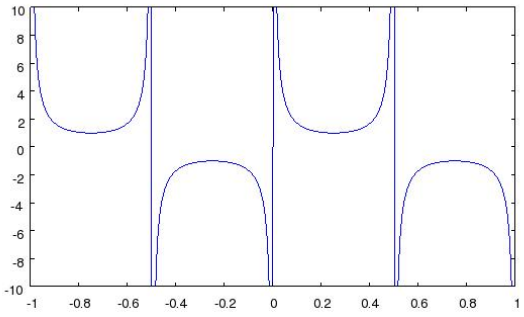
Mathematically, the `csc` function is defined for all arguments as

$$\csc x \equiv \frac{1}{\sin x}.$$

9.29.3 Example

The following piece of code plots the real-valued `csc(2 pi x)` function over the interval of `[-1,1]`:

```
--> t = linspace(-1,1,1000);
--> plot(t,csc(2*pi*t))
--> axis([-1,1,-10,10]);
```



9.30 CSCD Cosecant Degrees Function

9.30.1 Usage

Computes the cosecant of the argument, but takes the argument in degrees instead of radians (as is the case for `csc`). The syntax for its use is

```
y = cscd(x)
```

9.31 CSCH Hyperbolic Cosecant Function

9.31.1 Usage

Computes the hyperbolic cosecant of the argument. The syntax for its use is

```
y = csch(x)
```

9.31.2 Function Internals

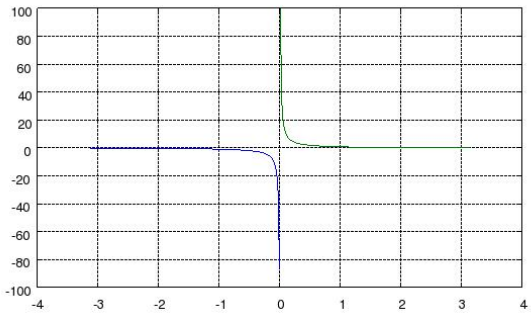
The `csch` function is computed from the formula

$$\mathrm{csch}(x) = \frac{1}{\sinh(x)}$$

9.31.3 Examples

Here is a simple plot of the hyperbolic cosecant function

```
--> x1 = -pi+.01:.01:-.01;
--> x2 = .01:.01:pi-.01;
--> plot(x1,csch(x1),x2,csch(x2)); grid('on');
```



9.32 DEG2RAD Convert From Degrees To Radians

9.32.1 Usage

Converts the argument from degrees to radians. The syntax for its use is

```
y = deg2rad(x)
```

where `x` is a numeric array. Conversion is done by simply multiplying `x` by `pi/180`.

9.32.2 Example

How many radians in a circle:

```
--> deg2rad(360) - 2*pi

ans =
 0
```

9.33 ERF Error Function

9.33.1 Usage

Computes the error function for real arguments. The `erf` function takes only a single argument

```
y = erf(x)
```

where `x` is either a `float` or `double` array. The output vector `y` is the same size (and type) as `x`.

9.33.2 Function Internals

The erf function is defined by the integral:

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2}\, dt,$$

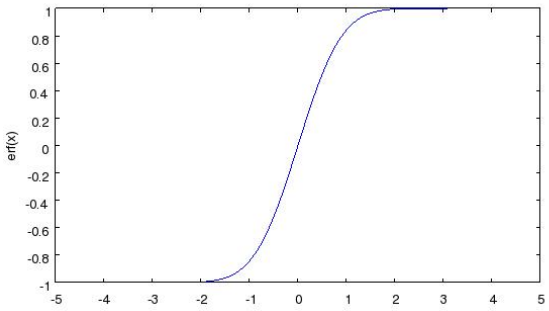
and is the integral of the normal distribution.

9.33.3 Example

Here is a plot of the erf function over the range `[-5,5]`.

```
--> x = linspace(-5,5);
--> y = erf(x);
--> plot(x,y); xlabel('x'); ylabel('erf(x)');
```

which results in the following plot.



9.34 ERFC Complimentary Error Function

9.34.1 Usage

Computes the complimentary error function for real arguments. The `erfc` function takes only a single argument

```
y = erfc(x)
```

where `x` is either a `float` or `double` array. The output vector `y` is the same size (and type) as `x`.

9.34.2 Function Internals

The erfc function is defined by the integral:

$$\mathrm{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2}\, dt,$$

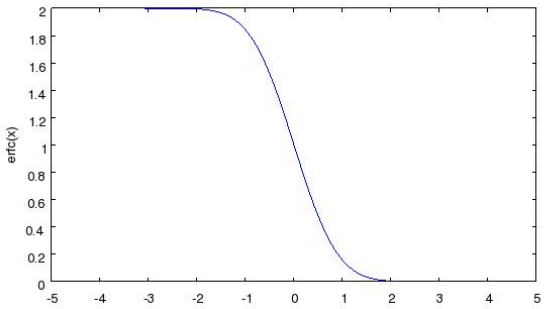
and is the integral of the normal distribution.

9.34.3 Example

Here is a plot of the `erfc` function over the range `[-5,5]`.

```
--> x = linspace(-5,5);
--> y = erfc(x);
--> plot(x,y); xlabel('x'); ylabel('erfc(x)');
```

which results in the following plot.



9.35 ERFINV Inverse Error Function

9.35.1 Usage

Computes the inverse error function for each element of x. The `erf` function takes only a single argument

```
y = erfinv(x)
```

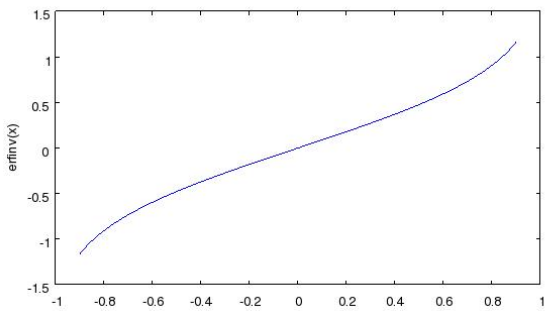
where `x` is either a `float` or `double` array. The output vector `y` is the same size (and type) as `x`. For values outside the interval [-1, 1] function returns NaN.

9.35.2 Example

Here is a plot of the erf function over the range `[-.9,.9]`.

```
--> x = linspace(-.9,.9,100);
--> y = erfinv(x);
--> plot(x,y); xlabel('x'); ylabel('erfinv(x)');
```

which results in the following plot.



9.36 EXP Exponential Function

9.36.1 Usage

Computes the `exp` function for its argument. The general syntax for its use is

```
y = exp(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `exp` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.36.2 Function Internals

Mathematically, the `exp` function is defined for all real valued arguments `x` as

$$\exp x \equiv e^x,$$

where

$$e = \sum_0^\infty \frac{1}{k!}$$

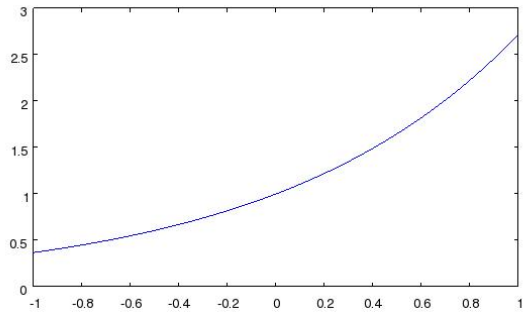
and is approximately `2.718281828459045` (returned by the function `e`). For complex values `z`, the famous Euler formula is used to calculate the exponential

$$e^z = e^{|z|}\left[\cos \Re z + i \sin \Re z\right]$$

9.36.3 Example

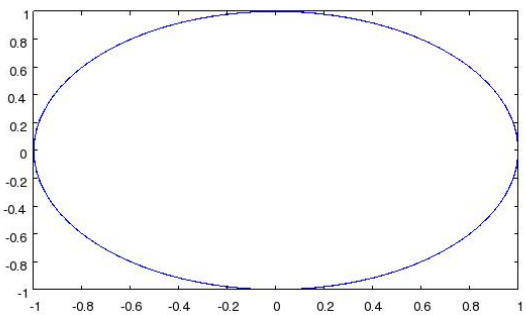
The following piece of code plots the real-valued `exp` function over the interval `[-1,1]`:

```
--> x = linspace(-1,1);
--> plot(x,exp(x))
```



In the second example, we plot the unit circle in the complex plane `e\^{i 2 pi x}` for `x in [-1,1]`.

```
--> x = linspace(-1,1);
--> plot(exp(-i*x*2*pi))
```



9.37 EXPM1 Exponential Minus One Function

9.37.1 Usage

Computes `exp(x)-1` function accurately for `x` small. The syntax for its use is

```
y = expm1(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.38 FIX Round Towards Zero

9.38.1 Usage

Rounds the argument array towards zero. The syntax for its use is

```
y = fix(x)
```

where `x` is a numeric array. For positive elements of `x`, the output is the largest integer smaller than `x`. For negative elements of `x` the output is the smallest integer larger than `x`. For complex `x`, the operation is applied seperately to the real and imaginary parts.

9.38.2 Example

Here is a simple example of the `fix` operation on some values

```
--> a = [-1.8,pi,8,-pi,-0.001,2.3+0.3i]

a =
  -1.8000 +  0.0000i   3.1416 +  0.0000i   8.0000 +  0.0000i  -3.1416 +  0.0000i  -0.0010 +  0.0000i   1

--> fix(a)

ans =
  -1.0000 +  0.0000i   3.0000 +  0.0000i   8.0000 +  0.0000i  -3.0000 +  0.0000i        0             2
```

9.39 GAMMA Gamma Function

9.39.1 Usage

Computes the gamma function for real arguments. The `gamma` function takes only a single argument

```
y = gamma(x)
```

where `x` is either a `float` or `double` array. The output vector `y` is the same size (and type) as `x`.

9.39.2 Function Internals

The gamma function is defined by the integral:

$$\Gamma(x) = \int_0^\infty e^{-t} t^{x-1}\, dt$$

The gamma function obeys the interesting relationship

$$\Gamma(x) = (x-1)\Gamma(x-1),$$

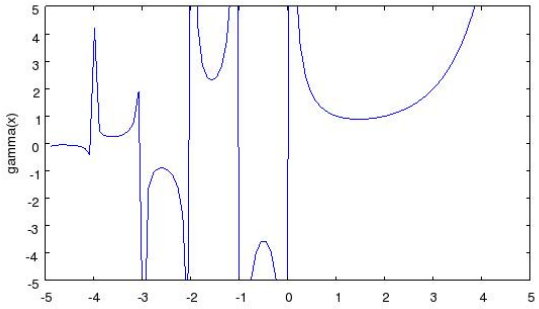
and for integer arguments, is equivalent to the factorial function.

9.39.3 Example

Here is a plot of the gamma function over the range `[-5,5]`.

```
--> x = linspace(-5,5);
--> y = gamma(x);
--> plot(x,y); xlabel('x'); ylabel('gamma(x)');
--> axis([-5,5,-5,5]);
```

which results in the following plot.



9.40 GAMMALN Log Gamma Function

9.40.1 Usage

Computes the natural log of the gamma function for real arguments. The `gammaln` function takes only a single argument

```
y = gammaln(x)
```

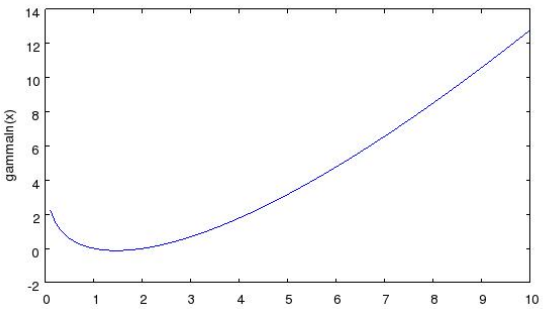
where `x` is either a `float` or `double` array. The output vector `y` is the same size (and type) as `x`.

9.40.2 Example

Here is a plot of the `gammaln` function over the range `[-5,5]`.

```
--> x = linspace(0,10);
--> y = gammaln(x);
--> plot(x,y); xlabel('x'); ylabel('gammaln(x)');
```

which results in the following plot.



9.41 IDIV Integer Division Operation

9.41.1 Usage

Computes the integer division of two arrays. The syntax for its use is

```
y = idiv(a,b)
```

where `a` and `b` are arrays or scalars. The effect of the `idiv` is to compute the integer division of `b` into `a`.

9.41.2 Example

The following examples show some uses of `idiv` arrays.

```
--> idiv(27,6)

ans =
 4

--> idiv(4,-2)

ans =
 -2

--> idiv(15,3)

ans =
 5
```

9.42 LEGENDRE Associated Legendre Polynomial

9.42.1 Usage

Computes the associated Legendre function of degree n.

```
y = legendre(n,x)
```

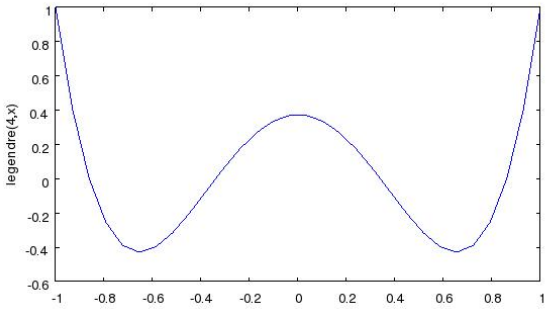
where `x` is either a `float` or `double` array in range `[-1,1]`, `n` is integer scalar. The output vector `y` is the same size (and type) as `x`.

9.42.2 Example

Here is a plot of the `legendre` function over the range `[-1,1]`.

```
--> x = linspace(-1,1,30);
--> y = legendre(4,x);
--> plot(x,y); xlabel('x'); ylabel('legendre(4,x)');
```

which results in the following plot.



9.43 LOG Natural Logarithm Function

9.43.1 Usage

Computes the `log` function for its argument. The general syntax for its use is

```
y = log(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `log` function. Output `y` is of the same size as the input `x`. For strictly positive, real inputs, the output type is the same as the input. For negative and complex arguments, the output is complex.

9.43.2 Function Internals

Mathematically, the `log` function is defined for all real valued arguments `x` by the integral

$$\log x \equiv \int_1^x \frac{d\,t}{t}.$$

For complex-valued arguments, `z`, the complex logarithm is defined as

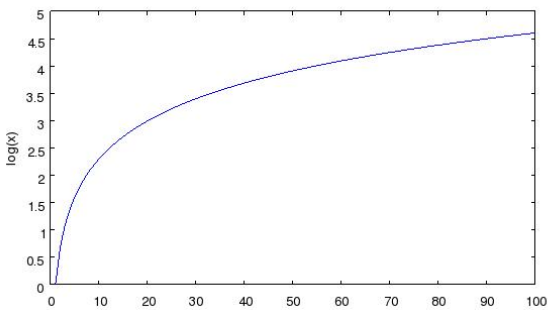
$$\log z \equiv \log |z| + i \arg z,$$

where `arg` is the complex argument of `z`.

9.43.3 Example

The following piece of code plots the real-valued `log` function over the interval `[1,100]`:

```
--> x = linspace(1,100);
--> plot(x,log(x))
--> xlabel('x');
--> ylabel('log(x)');
```



9.44 LOG10 Base-10 Logarithm Function

9.44.1 Usage

Computes the `log10` function for its argument. The general syntax for its use is

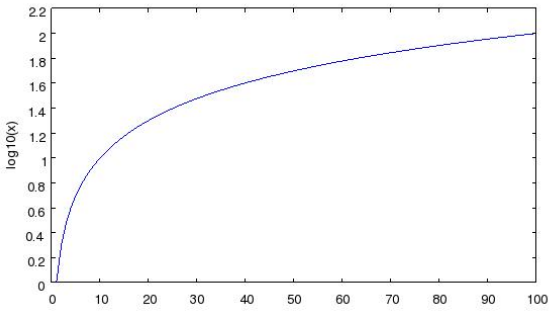
```
y = log10(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `log10` function. Output `y` is of the same size as the input `x`. For strictly positive, real inputs, the output type is the same as the input. For negative and complex arguments, the output is complex.

9.44.2 Example

The following piece of code plots the real-valued `log10` function over the interval `[1,100]`:

```
--> x = linspace(1,100);
--> plot(x,log10(x))
--> xlabel('x');
--> ylabel('log10(x)');
```



9.45 LOG1P Natural Logarithm of 1+P Function

9.45.1 Usage

Computes the `log` function for one plus its argument. The general syntax for its use is

```
y = log1p(x)
```

where `x` is an `n`-dimensional array of numerical type.

9.46 LOG2 Base-2 Logarithm Function

9.46.1 Usage

Computes the `log2` function for its argument. The general syntax for its use is

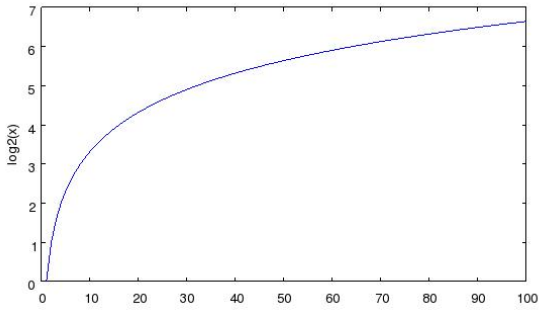
```
y = log2(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `log2` function. Output `y` is of the same size as the input `x`. For strictly positive, real inputs, the output type is the same as the input. For negative and complex arguments, the output is complex.

9.46.2 Example

The following piece of code plots the real-valued `log2` function over the interval `[1,100]`:

```
--> x = linspace(1,100);
--> plot(x,log2(x))
--> xlabel('x');
--> ylabel('log2(x)');
```



9.47 MOD Modulus Operation

9.47.1 Usage

Computes the modulus of an array. The syntax for its use is

```
y = mod(x,n)
```

where `x` is matrix, and `n` is the base of the modulus. The effect of the `mod` operator is to add or subtract multiples of `n` to the vector `x` so that each element `x\_i` is between `0` and `n` (strictly). Note that `n` does not have to be an integer. Also, `n` can either be a scalar (same base for all elements of `x`), or a vector (different base for each element of `x`).

Note that the following are defined behaviors:

1. `mod(x,0) = x`@
2. `mod(x,x) = 0`@
3. `mod(x,n)`@ has the same sign as `n` for all other cases.

9.47.2 Example

The following examples show some uses of `mod` arrays.

```
--> mod(18,12)

ans =
 6

--> mod(6,5)

ans =
 1

--> mod(2*pi,pi)

ans =
 0
```

Here is an example of using `mod` to determine if integers are even or odd:

```
--> mod([1,3,5,2],2)

ans =
 1 1 1 0
```

Here we use the second form of `mod`, with each element using a separate base.

```
--> mod([9 3 2 0],[1 0 2 2])

ans =
 0 3 0 0
```

9.48 MPOWER Matrix Power Function

9.48.1 Usage

Computes the matrix power operator for two arrays. It is an M-file version of the `\^` operator. The syntax for its use is

```
y = mpower(a,b)
```

where `y=a\^b`. See the `matrixpower` documentation for more details on what this function actually does.

9.49 POWER Element-wise Power Function

9.49.1 Usage

Computes the element-wise power operator for two arrays. It is an M-file version of the `.\^` operator. The syntax for its use is

```
y = power(a,b)
```

where `y=a.\^b`. See the `dotpower` documentation for more details on what this function actually does.

9.50 RAD2DEG Radians To Degrees Conversion Function

9.50.1 Usage

Converts the argument array from radians to degrees. The general syntax for its use is

```
y = rad2deg(x)
```

Note that the output type will be the same as the input type, and that complex arguments are allowed. The output is not wrapped to `[0,360)`.

9.50.2 Examples

Some known conversion factors

```
--> rad2deg(1) % one radian is about 57 degrees

ans =
   57.2958

--> rad2deg(pi/4) % should be 45 degrees
```

```
ans =
 45

--> rad2deg(2*pi) % Note that this is 360 not 0 degrees

ans =
 360
```

9.51 REM Remainder After Division

9.51.1 Usage

Computes the remainder after division of an array. The syntax for its use is

```
y = rem(x,n)
```

where `x` is matrix, and `n` is the base of the modulus. The effect of the `rem` operator is to add or subtract multiples of `n` to the vector `x` so that each element `x\_i` is between `0` and `n` (strictly). Note that `n` does not have to be an integer. Also, `n` can either be a scalar (same base for all elements of `x`), or a vector (different base for each element of `x`).

Note that the following are defined behaviors:

1. `rem(x,0) = nan@`
2. `rem(x,x) = 0@` for nonzero `x`
3. `rem(x,n)@` has the same sign as `x` for all other cases.

Note that `rem` and `mod` return the same value if `x` and `n` are of the same sign. But differ by `n` if `x` and `y` have different signs.

9.51.2 Example

The following examples show some uses of `rem` arrays.

```
--> rem(18,12)

ans =
 6

--> rem(6,5)

ans =
 1

--> rem(2*pi,pi)

ans =
 0
```

Here is an example of using `rem` to determine if integers are even or odd:

```
--> rem([1,3,5,2],2)

ans =
 1 1 1 0
```

Here we use the second form of `rem`, with each element using a separate base.

```
--> rem([9 3 2 0],[1 0 2 2])

ans =
         0 NaN         0         0
```

9.52 SEC Trigonometric Secant Function

9.52.1 Usage

Computes the `sec` function for its argument. The general syntax for its use is

```
y = sec(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `sec` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.52.2 Function Internals

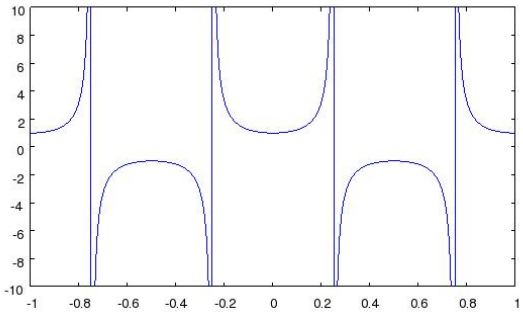
Mathematically, the `sec` function is defined for all arguments as

$$\sec x \equiv \frac{1}{\cos x}.$$

9.52.3 Example

The following piece of code plots the real-valued `sec(2 pi x)` function over the interval of `[-1,1]`:

```
--> t = linspace(-1,1,1000);
--> plot(t,sec(2*pi*t))
--> axis([-1,1,-10,10]);
```



9.53 SECD Secant Degrees Function

9.53.1 Usage

Computes the secant of the argument, but takes the argument in degrees instead of radians (as is the case for `sec`). The syntax for its use is

```
y = secd(x)
```

9.54 SECH Hyperbolic Secant Function

9.54.1 Usage

Computes the hyperbolic secant of the argument. The syntax for its use is

```
y = sech(x)
```

9.54.2 Function Internals

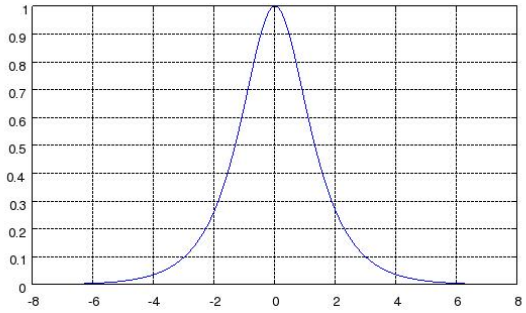
The `sech` function is computed from the formula

$$\operatorname{sech}(x) = \frac{1}{\cosh(x)}$$

9.54.3 Examples

Here is a simple plot of the hyperbolic secant function

```
--> x = -2*pi:.01:2*pi;
--> plot(x,sech(x)); grid('on');
```



9.55 SIN Trigonometric Sine Function

9.55.1 Usage

Computes the `sin` function for its argument. The general syntax for its use is

```
y = sin(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `sin` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.55.2 Function Internals

Mathematically, the `sin` function is defined for all real valued arguments `x` by the infinite summation

$$\sin x \equiv \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^{2n-1}}{(2n-1)!}.$$

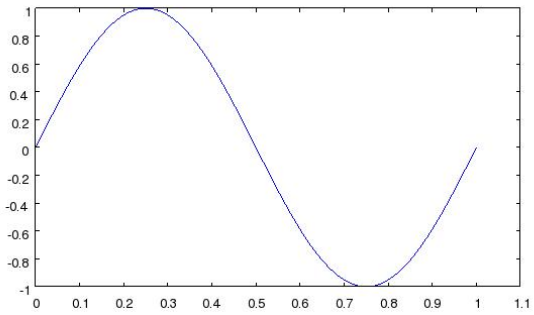
For complex valued arguments `z`, the sine is computed via

$$\sin z \equiv \sin \Re z \cosh \Im z - i \cos \Re z \sinh \Im z.$$

9.55.3 Example

The following piece of code plots the real-valued `sin(2 pi x)` function over one period of `[0,1]`:

```
--> x = linspace(0,1);
--> plot(x,sin(2*pi*x))
```



9.56 SIND Sine Degrees Function

9.56.1 Usage

Computes the sine of the argument, but takes the argument in degrees instead of radians (as is the case for `cos`). The syntax for its use is

```
y = sind(x)
```

9.56.2 Examples

The sine of 45 degrees should be `sqrt(2)/2`

```
--> sind(45)

ans =
    0.7071
```

and the sine of `30` degrees should be 0.5:

```
--> sind(30)

ans =
    0.5000
```

9.57 SINH Hyperbolic Sine Function

9.57.1 Usage

Computes the hyperbolic sine of the argument. The syntax for its use is

```
y = sinh(x)
```

9.57.2 Function Internals

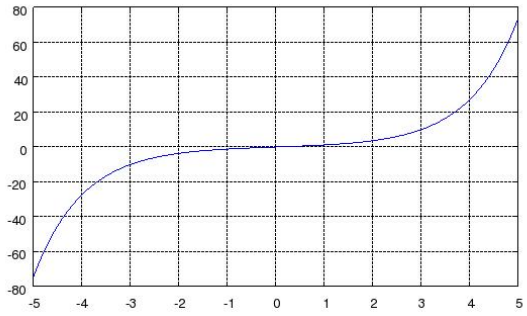
The `sinh` function is computed from the formula

$$\sinh(x) = \frac{e^x - e^{-x}}{2}$$

9.57.3 Examples

Here is a simple plot of the hyperbolic sine function

```
--> x = linspace(-5,5);
--> plot(x,sinh(x)); grid('on');
```



9.58 SQRT Square Root of an Array

9.58.1 Usage

Computes the square root of the argument matrix. The general syntax for its use is

```
y = sqrt(x)
```

where `x` is an N-dimensional numerical array.

9.58.2 Example

Here are some examples of using `sqrt`

```
--> sqrt(9)

ans =
 3

--> sqrt(i)

ans =
   0.7071 +  0.7071i

--> sqrt(-1)

ans =
   0.0000 +  1.0000i

--> x = rand(4)

x =
    0.4871    0.5309    0.3343    0.1123
    0.7049    0.6431    0.3320    0.7799
    0.5845    0.8331    0.9892    0.9155
    0.5407    0.9178    0.3408    0.2274
```

```
--> sqrt(x)

ans =
    0.6980    0.7286    0.5782    0.3352
    0.8396    0.8020    0.5762    0.8831
    0.7645    0.9127    0.9946    0.9568
    0.7354    0.9580    0.5838    0.4769
```

9.59 TAN Trigonometric Tangent Function

9.59.1 Usage

Computes the `tan` function for its argument. The general syntax for its use is

```
y = tan(x)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the `tan` function. Output `y` is of the same size and type as the input `x`, (unless `x` is an integer, in which case `y` is a `double` type).

9.59.2 Function Internals

Mathematically, the `tan` function is defined for all real valued arguments `x` by the infinite summation

$$\tan x \equiv x + \frac{x^3}{3} + \frac{2x^5}{15} + \cdots,$$

or alternately by the ratio

$$\tan x \equiv \frac{\sin x}{\cos x}$$

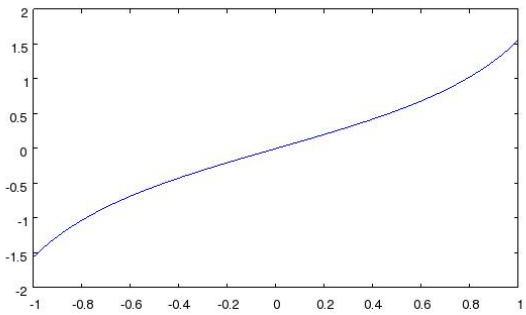
For complex valued arguments `z`, the tangent is computed via

$$\tan z \equiv \frac{\sin 2\Re z + i \sinh 2\Im z}{\cos 2\Re z + \cosh 2\Im z}.$$

9.59.3 Example

The following piece of code plots the real-valued `tan(x)` function over the interval `[-1,1]`:

```
--> t = linspace(-1,1);
--> plot(t,tan(t))
```



9.60 TAND Tangent Degrees Function

9.60.1 Usage

Computes the tangent of the argument, but takes the argument in degrees instead of radians (as is the case for `cos`). The syntax for its use is

```
y = tand(x)
```

9.60.2 Examples

The tangent of 45 degrees should be `1`

```
--> tand(45)

ans =
    1.0000
```

9.61 TANH Hyperbolic Tangent Function

9.61.1 Usage

Computes the hyperbolic tangent of the argument. The syntax for its use is

```
y = tanh(x)
```

9.61.2 Function Internals

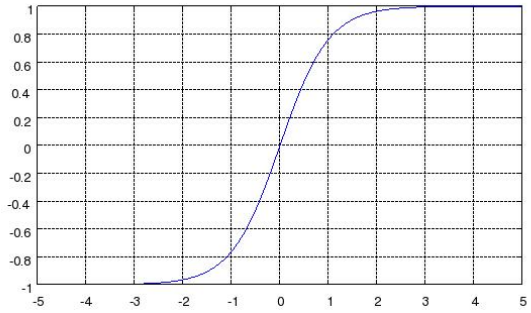
The `tanh` function is computed from the formula

$$\tanh(x) = \frac{\sinh(x)}{\cosh(x)}$$

9.61.3 Examples

Here is a simple plot of the hyperbolic tangent function

```
--> x = linspace(-5,5);
--> plot(x,tanh(x)); grid('on');
```



Chapter 10

Base Constants

10.1 E Euler Constant (Base of Natural Logarithm)

10.1.1 Usage

Returns a `double` (64-bit floating point number) value that represents Euler's constant, the base of the natural logarithm. Typical usage

```
y = e
```

This value is approximately 2.718281828459045.

10.1.2 Example

The following example demonstrates the use of the `e` function.

```
--> e

ans =
    2.7183

--> log(e)

ans =
 1
```

10.2 EPS Double Precision Floating Point Relative Machine Precision Epsilon

10.2.1 Usage

Returns `eps`, which quantifies the relative machine precision of floating point numbers (a machine specific quantity). The syntax for `eps` is:

```
y = eps
y = eps('double')
y = eps(X)
```

First form returns `eps` for `double` precision values. For most typical processors, this value is approximately `2\^-52`, or 2.2204e-16. Second form return `eps` for class `double` or `single`. Third form returns distance to the next value greater than X.

10.2.2 Example

The following example demonstrates the use of the `eps` function, and one of its numerical consequences.

```
--> eps

ans =
 2.2204e-16

--> 1.0+eps

ans =
    1.0000

--> eps(1000.)

ans =
 1.1369e-13
```

10.3 FALSE Logical False

10.3.1 Usage

Returns a logical 0. The syntax for its use is

```
y = false
```

You can also create an array of logical ones using the syntax

```
y = false(d1,d2,...,dn)
```

or the syntax

```
y = false([d1,d2,...,dn])
```

10.4 FEPS Single Precision Floating Point Relative Machine Precision Epsilon

10.4.1 Usage

Returns `feps`, which quantifies the relative machine precision of floating point numbers (a machine specific quantity). The syntax for `feps` is:

```
y = feps
```

which returns `feps` for `single` precision values. For most typical processors, this value is approximately `2\^-24`, or 5.9604e-8.

10.4.2 Example

The following example demonstrates the use of the `feps` function, and one of its numerical consequences.

```
--> feps

ans =
 1.1921e-07
```

```
--> 1.0f+eps

ans =
 1
```

10.5 I-J Square Root of Negative One

10.5.1 Usage

Returns a `complex` value that represents the square root of -1. There are two functions that return the same value:

```
y = i
```

and

```
y = j.
```

This allows either `i` or `j` to be used as loop indices. The returned value is a 32-bit complex value.

10.5.2 Example

The following examples demonstrate a few calculations with `i`.

```
--> i

ans =
   0.0000 +  1.0000i

--> i^2

ans =
  -1.0000 +  0.0000i
```

The same calculations with `j`:

```
--> j

ans =
   0.0000 +  1.0000i

--> j^2

ans =
  -1.0000 +  0.0000i
```

Here is an example of how `i` can be used as a loop index and then recovered as the square root of -1.

```
--> accum = 0; for i=1:100; accum = accum + i; end; accum

ans =
 5050

--> i

ans =
 100
```

```
--> clear i
--> i

ans =
   0.0000 +  1.0000i
```

10.6 INF Infinity Constant

10.6.1 Usage

Returns a value that represents positive infinity for both 32 and 64-bit floating point values. There are several forms for the `Inf` function. The first form returns a double precision `Inf`.

```
y = inf
```

The next form takes a class name that can be either `'double'`

```
y = inf('double')
```

or `'single'`:

```
y = inf('single')
```

With a single parameter it generates a square matrix of `inf`s.

```
y = inf(n)
```

Alternatively, you can specify the dimensions of the array via

```
y = inf(m,n,p,...)
```

or

```
y = inf([m,n,p,...])
```

Finally, you can add a classname of either `'single'` or `'double'`.

10.6.2 Function Internals

The infinity constant has several interesting properties. In particular:

$$\begin{aligned} \infty \times 0 &= \text{NaN} \\ \infty \times a &= \infty \,\text{forall}\, a > 0 \\ \infty \times a &= -\infty \,\text{forall}\, a < 0 \\ \infty / \infty &= \text{NaN} \\ \infty / 0 &= \infty \end{aligned}$$

Note that infinities are not preserved under type conversion to integer types (see the examples below).

10.6.3 Example

The following examples demonstrate the various properties of the infinity constant.

```
--> inf*0

ans =
 NaN
```

```
--> inf*2

ans =
 Inf

--> inf*-2

ans =
 -Inf

--> inf/inf

ans =
 NaN

--> inf/0

ans =
 Inf

--> inf/nan

ans =
 NaN
```

Note that infinities are preserved under type conversion to floating point types (i.e., `float`, `double`, `complex` and `dcomplex` types), but not integer types.

```
--> uint32(inf)

ans =
 4294967295

--> complex(inf)

ans =
 Inf
```

10.7 PI Constant Pi

10.7.1 Usage

Returns a `double` (64-bit floating point number) value that represents pi (ratio between the circumference and diameter of a circle...). Typical usage

```
y = pi
```

This value is approximately 3.141592653589793.

10.7.2 Example

The following example demonstrates the use of the `pi` function.

```
--> pi

ans =
```

```
    3.1416

--> cos(pi)

ans =
 -1
```

10.8 TEPS Type-based Epsilon Calculation

10.8.1 Usage

Returns `eps` for double precision arguments and `feps` for single precision arguments. The syntax for `teps` is

```
y = teps(x)
```

The `teps` function is most useful if you need to compute epsilon based on the type of the array.

10.8.2 Example

The following example demonstrates the use of the `teps` function, and one of its numerical consequences.

```
--> teps(float(3.4))

ans =
 1.1921e-07

--> teps(complex(3.4+i*2))

ans =
 2.2204e-16
```

10.9 TRUE Logical TRUE

10.9.1 Usage

Returns a logical 1. The syntax for its use is

```
y = true
```

You can also create an array of logical ones using the syntax

```
y = true(d1,d2,...,dn)
```

or the syntax

```
y = true([d1,d2,...,dn])
```

Chapter 11

Elementary Functions

11.1 ABS Absolute Value Function

11.1.1 Usage

Returns the absolute value of the input array for all elements. The general syntax for its use is

```
y = abs(x)
```

where `x` is an `n`-dimensional array of numerical type. The output is the same numerical type as the input, unless the input is `complex` or `dcomplex`. For `complex` inputs, the absolute value is a floating point array, so that the return type is `float`. For `dcomplex` inputs, the absolute value is a double precision floating point array, so that the return type is `double`.

11.1.2 Example

The following demonstrates the `abs` applied to a complex scalar.

```
--> abs(3+4*i)

ans =
 5
```

The `abs` function applied to integer and real values:

```
--> abs([-2,3,-4,5])

ans =
 2 3 4 5
```

For a double-precision complex array,

```
--> abs([2.0+3.0*i,i])

ans =
    3.6056    1.0000
```

11.2 ALL All True Function

11.2.1 Usage

Reduces a logical array along a given dimension by testing for all logical 1s. The general syntax for its use is

```
y = all(x,d)
```

where `x` is an `n`-dimensions array of `logical` type. The output is of `logical` type. The argument `d` is optional, and denotes the dimension along which to operate. The output `y` is the same size as `x`, except that it is singular along the operated direction. So, for example, if `x` is a `3 x 3 x 4` array, and we `all` operation along dimension `d=2`, then the output is of size `3 x 1 x 4`.

11.2.2 Function Internals

The output is computed via

$$y(m_1, \ldots, m_{d-1}, 1, m_{d+1}, \ldots, m_p) = \min_k x(m_1, \ldots, m_{d-1}, k, m_{d+1}, \ldots, m_p)$$

If `d` is omitted, then the minimum is taken over all elements of `x`.

11.2.3 Example

The following piece of code demonstrates various uses of the `all` function

```
--> A = [1,0,0;1,0,0;0,0,1]

A =
 1 0 0
 1 0 0
 0 0 1
```

We start by calling `all` without a dimension argument, in which case it defaults to testing all values of `A`

```
--> all(A)

ans =
 0 0 0
```

The `all` function is useful in expressions also.

```
--> all(A>=0)

ans =
 1 1 1
```

Next, we apply the `all` operation along the rows.

```
--> all(A,2)

ans =
 0
 0
 0
```

11.3 ANY Any True Function

11.3.1 Usage

Reduces a logical array along a given dimension by testing for any logical 1s. The general syntax for its use is

```
y = any(x,d)
```

where `x` is an `n`-dimensions array of `logical` type. The output is of `logical` type. The argument `d` is optional, and denotes the dimension along which to operate. The output `y` is the same size as `x`, except that it is singular along the operated direction. So, for example, if `x` is a `3 x 3 x 4` array, and we `any` operation along dimension `d=2`, then the output is of size `3 x 1 x 4`.

11.3.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \max_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

If `d` is omitted, then the summation is taken along the first non-singleton dimension of `x`.

11.3.3 Example

The following piece of code demonstrates various uses of the summation function

```
--> A = [1,0,0;1,0,0;0,0,1]

A =
 1 0 0
 1 0 0
 0 0 1
```

We start by calling `any` without a dimension argument, in which case it defaults to the first nonsingular dimension (in this case, along the columns or `d = 1`).

```
--> any(A)

ans =
 1 0 1
```

Next, we apply the `any` operation along the rows.

```
--> any(A,2)

ans =
 1
 1
 1
```

11.4 CEIL Ceiling Function

11.4.1 Usage

Computes the ceiling of an n-dimensional array elementwise. The ceiling of a number is defined as the smallest integer that is larger than or equal to that number. The general syntax for its use is

```
y = ceil(x)
```

where `x` is a multidimensional array of numerical type. The `ceil` function preserves the type of the argument. So integer arguments are not modified, and `float` arrays return `float` arrays as outputs, and similarly for `double` arrays. The `ceil` function is not defined for `complex` or `dcomplex` types.

11.4.2 Example

The following demonstrates the `ceil` function applied to various (numerical) arguments. For integer arguments, the ceil function has no effect:

```
--> ceil(3)

ans =
 3
```

```
--> ceil(-3)

ans =
 -3
```

Next, we take the `ceil` of a floating point value:

```
--> ceil(float(3.023))

ans =
 4

--> ceil(float(-2.341))

ans =
 -2
```

Note that the return type is a `float` also. Finally, for a `double` type:

```
--> ceil(4.312)

ans =
 5

--> ceil(-5.32)

ans =
 -5
```

11.5 CONJ Conjugate Function

11.5.1 Usage

Returns the complex conjugate of the input array for all elements. The general syntax for its use is

```
y = conj(x)
```

where `x` is an `n`-dimensional array of numerical type. The output is the same numerical type as the input. The `conj` function does nothing to real and integer types.

11.5.2 Example

The following demonstrates the complex conjugate applied to a complex scalar.

```
--> conj(3+4*i)

ans =
   3.0000 -  4.0000i
```

The `conj` function has no effect on real arguments:

```
--> conj([2,3,4])

ans =
 2 3 4
```

For a double-precision complex array,

```
--> conj([2.0+3.0*i,i])

ans =
   2.0000 -  3.0000i   0.0000 -  1.0000i
```

11.6 COV Covariance Matrix

11.6.1 Usage

Computes the covariance of a matrix or a vector. The general syntax for its use is

```
y = cov(x)
```

where `x` is a matrix or a vector. If `x` is a vector then `cov` returns the variance of `x`. If `x` is a matrix then `cov` returns the covariance matrix of the columns of `x`. You can also call `cov` with two arguments to compute the matrix of cross correlations. The syntax for this mode is

```
y = cov(x,z)
```

where `x` and `z` are matrices of the same size. Finally, you can provide a normalization flag `d` that is either `0` or `1`, which changes the normalization factor from `L-1` (for `d=0`) to `L` (for `d=1`) where `L` is the number of rows in the matrix `x`. In this case, the syntaxes are

```
y = cov(x,z,d)
```

for the two-argument case, and

```
y = cov(x,d)
```

for the one-argument case.

11.6.2 Example

The following demonstrates some uses of the `cov` function

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1

--> B = [4,-2,0;1,5,2;-2,0,1];
```

We start with the covariance matrix for `A`

```
--> cov(A)

ans =
    4.2222   -1.6667    1.5556
   -1.6667    0.6667   -0.6667
    1.5556   -0.6667    0.8889
```

and again with the (biased) normalization

```
--> cov(A,1)

ans =
    4.2222   -1.6667    1.5556
   -1.6667    0.6667   -0.6667
    1.5556   -0.6667    0.8889
```

Here we compute the cross covariance between `A` and `B`

```
--> cov(A,B)

ans =
    2.0988    1.6667
    1.6667    5.1111
```

and again with biased normalization

```
--> cov(A,B,1)

ans =
    2.0988    1.6667
    1.6667    5.1111
```

11.7 CUMPROD Cumulative Product Function

11.7.1 Usage

Computes the cumulative product of an n-dimensional array along a given dimension. The general syntax for its use is

```
  y = cumprod(x,d)
```

where `x` is a multidimensional array of numerical type, and `d` is the dimension along which to perform the cumulative product. The output `y` is the same size of `x`. Integer types are promoted to `int32`. If the dimension `d` is not specified, then the cumulative sum is applied along the first non-singular dimension.

11.7.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},j,m_{d+1},\ldots,m_p) = \prod_{k=1}^{j} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p).$$

11.7.3 Example

The default action is to perform the cumulative product along the first non-singular dimension.

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1

--> cumprod(A)

ans =
  5  1  3
 15  2  3
  0  6  3
```

To compute the cumulative product along the columns:

```
--> cumprod(A,2)

ans =
  5  5 15
  3  6  6
  0  0  0
```

The cumulative product also works along arbitrary dimensions

```
--> B(:,:,1) = [5,2;8,9];
--> B(:,:,2) = [1,0;3,0]

B =

(:,:,1) =
 5 2
 8 9

(:,:,2) =
 1 0
 3 0

--> cumprod(B,3)

ans =

(:,:,1) =
  5  2
  8  9

(:,:,2) =
  5  0
 24  0
```

11.8 CUMSUM Cumulative Summation Function

11.8.1 Usage

Computes the cumulative sum of an n-dimensional array along a given dimension. The general syntax for its use is

```
y = cumsum(x,d)
```

where `x` is a multidimensional array of numerical type, and `d` is the dimension along which to perform the cumulative sum. The output `y` is the same size of `x`. Integer types are promoted to `int32`. If the dimension `d` is not specified, then the cumulative sum is applied along the first non-singular dimension.

11.8.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},j,m_{d+1},\ldots,m_p) = \sum_{k=1}^{j} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p).$$

11.8.3 Example

The default action is to perform the cumulative sum along the first non-singular dimension.

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1

--> cumsum(A)

ans =
 5 1 3
 8 3 4
 8 6 5
```

To compute the cumulative sum along the columns:

```
--> cumsum(A,2)

ans =
 5 6 9
 3 5 6
 0 3 4
```

The cumulative sum also works along arbitrary dimensions

```
--> B(:,:,1) = [5,2;8,9];
--> B(:,:,2) = [1,0;3,0]

B =

(:,:,1) =
 5 2
 8 9

(:,:,2) =
 1 0
 3 0

--> cumsum(B,3)

ans =

(:,:,1) =
  5  2
  8  9

(:,:,2) =
  6  2
 11  9
```

11.9 DEAL Multiple Simultaneous Assignments

11.9.1 Usage

When making a function call, it is possible to assign multiple outputs in a single call, (see, e.g., `max` for an example). The `deal` call allows you to do the same thing with a simple assignment. The syntax for its use is

```
[a,b,c,...] = deal(expr)
```

where `expr` is an expression with multiple values. The simplest example is where `expr` is the dereference of a cell array, e.g. `expr <-- A{:}`. In this case, the `deal` call is equivalent to

```
a = A{1}; b = A{2}; C = A{3};
```

Other expressions which are multivalued are structure arrays with multiple entries (non-scalar), where field dereferencing has been applied.

11.10 DEC2HEX Convert Decimal Number to Hexadecimal

11.10.1 Usage

Converts an integer value into its hexadecimal representation. The syntax for its use is

```
y = dec2hex(x)
```

where `x` is an integer (and is promoted to a 64-bit integer if it is not). The returned value `y` is a string containing the hexadecimal representation of that integer. If you require a minimum length for the hexadecimal representation, you can specify an optional second argument

```
y = dec2hex(x,n)
```

where `n` indicates the minimum number of digits in the representation.

11.10.2 Example

Here are some simple examples:

```
--> dec2hex(1023)

ans =
3FF

--> dec2hex(58128493)

ans =
376F86D
```

11.11 DIFF Difference Function

11.11.1 Usage

```
y=diff(x)
y=diff(x,k)
y=diff(x,k,dim)
```

Produce difference of successive vector elements.

If `x` is a vector of length n, `diff (x)` is the vector of first differences

$$[x\_2 - x\_1, ..., x\_n - x\_n - 1].$$

If `x` is a matrix, `diff (x)` is the matrix of column differences along the first non-singleton dimension.

The second argument is optional. If supplied, `diff (x,k)`, where `k` is a nonnegative integer, returns the `k`-th differences. It is possible that `k` is larger than then first non-singleton dimension of the matrix. In this case, `diff` continues to take the differences along the next non-singleton dimension.

The dimension along which to take the difference can be explicitly stated with the optional variable `dim`. In this case the `k`-th order differences are calculated along this dimension. In the case where `k` exceeds `size (x, dim)` then an empty matrix is returned.

11.12 DOT Dot Product Function

11.12.1 Usage

Computes the scalar dot product of its two arguments. The general syntax for its use is

```
y = dot(x,z)
```

where `x` and `z` are numerical vectors of the same length. If `x` and `z` are multi-dimensional arrays of the same size, then the dot product is taken along the first non-singleton dimension. You can also specify the dimension to take the dot product along using the alternate form

```
y = dot(x,z,dim)
```

where `dim` specifies the dimension to take the dot product along.

11.13 FLOOR Floor Function

11.13.1 Usage

Computes the floor of an n-dimensional array elementwise. The floor of a number is defined as the smallest integer that is less than or equal to that number. The general syntax for its use is

```
y = floor(x)
```

where `x` is a multidimensional array of numerical type. The `floor` function preserves the type of the argument. So integer arguments are not modified, and `float` arrays return `float` arrays as outputs, and similarly for `double` arrays. The `floor` function is not defined for complex types.

11.13.2 Example

The following demonstrates the `floor` function applied to various (numerical) arguments. For integer arguments, the floor function has no effect:

```
--> floor(3)

ans =
 3

--> floor(-3)

ans =
 -3
```

Next, we take the `floor` of a floating point value:

```
--> floor(3.023)

ans =
 3

--> floor(-2.341)

ans =
 -3
```

11.14 GETFIELD Get Field Contents

11.14.1 Usage

Given a structure or structure array, returns the contents of the specified field. The first version is for scalar structures, and has the following syntax

```
y = getfield(x,'fieldname')
```

and is equivalent to `y = x.fieldname` where `x` is a scalar (1 x 1) structure. If `x` is not a scalar structure, then `y` is the first value, i.e., it is equivalent to `y = x(1).fieldname`. The second form allows you to specify a subindex into a structure array, and has the following syntax

```
y = getfield(x, {m,n}, 'fieldname')
```

and is equivalent to `y = x(m,n).fieldname`. You can chain multiple references together using this syntax.

11.15 HEX2DEC Convert Hexadecimal Numbers To Decimal

11.15.1 Usage

Converts a hexadecimal number (encoded as a string matrix) into integers. The syntax for its use is

```
y = hex2dec(x)
```

where `x` is a character matrix where each row represents an integer in hexadecimal form. The output is of type `Double`.

11.15.2 Examples

```
--> hex2dec('3ff')

ans =
 1023
```

Or for a more complex example

```
--> hex2dec(['0ff';'2de';'123'])

ans =
 255
 734
 291
```

11.16 IMAG Imaginary Function

11.16.1 Usage

Returns the imaginary part of the input array for all elements. The general syntax for its use is

```
y = imag(x)
```

where `x` is an `n`-dimensional array of numerical type. The output is the same numerical type as the input, unless the input is `complex` or `dcomplex`. For `complex` inputs, the imaginary part is a floating point array, so that the return type is `float`. For `dcomplex` inputs, the imaginary part is a double precision floating point array, so that the return type is `double`. The `imag` function returns zeros for real and integer types.

11.16.2 Example

The following demonstrates `imag` applied to a complex scalar.

```
--> imag(3+4*i)

ans =
 4
```

The imaginary part of real and integer arguments is a vector of zeros, the same type and size of the argument.

```
--> imag([2,4,5,6])

ans =
 0 0 0 0
```

For a double-precision complex array,

```
--> imag([2.0+3.0*i,i])

ans =
 3 1
```

11.17 IND2SUB Convert Linear Indexing To Multiple Indexing

11.17.1 Usage

The `ind2sub` function converts linear indexing expression into a multi-dimensional indexing expressionl The syntax for its use is

```
[d1, d2, ..., dn] = ind2sub(sizevec,index)
```

where `sizevec` is the size of the array being indexed into, index is the index value. Each `di` is a vector of the same length, containing index values.

11.17.2 Example

Suppose we have a simple `3 x 4` matrix `A` containing some random integer elements

```
--> A = randi(ones(3,4),10*ones(3,4))

A =
  6  6  9  6
 10  1  8  6
  9  1  6  2
```

```
--> [d1 d2] = ind2sub(size(A),7)
d1 =
 1

d2 =
 3

--> A(d1,d2)

ans =
 9
```

11.18 MAX Maximum Function

11.18.1 Usage

Computes the maximum of an array along a given dimension, or alternately, computes two arrays (entry-wise) and keeps the smaller value for each array. As a result, the `max` function has a number of syntaxes. The first one computes the maximum of an array along a given dimension. The first general syntax for its use is either

```
[y,n] = max(x,[],d)
```

where `x` is a multidimensional array of numerical type, in which case the output `y` is the maximum of `x` along dimension `d`. The second argument `n` is the index that results in the maximum. In the event that multiple maxima are present with the same value, the index of the first maximum is used. The second general syntax for the use of the `max` function is

```
[y,n] = max(x)
```

In this case, the maximum is taken along the first non-singleton dimension of `x`. For complex data types, the maximum is based on the magnitude of the numbers. NaNs are ignored in the calculations. The third general syntax for the use of the `max` function is as a comparison function for pairs of arrays. Here, the general syntax is

```
y = max(x,z)
```

where `x` and `z` are either both numerical arrays of the same dimensions, or one of the two is a scalar. In the first case, the output is the same size as both arrays, and is defined elementwise by the smaller of the two arrays. In the second case, the output is defined elementwise by the smaller of the array entries and the scalar.

11.18.2 Function Internals

In the general version of the `max` function which is applied to a single array (using the `max(x,[],d)` or `max(x)` syntaxes), The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \max_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p),$$

and the output array `n` of indices is calculated via

$$n(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \arg\max_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

In the two-array version (`max(x,z)`), the single output is computed as

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \begin{cases} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p) & x(\cdots) \leq z(\cdots) \\ z(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p) & z(\cdots) < x(\cdots). \end{cases}$$

11.18.3 Example

The following piece of code demonstrates various uses of the maximum function. We start with the one-array version.

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We first take the maximum along the columns, resulting in a row vector.

```
--> max(A)

ans =
 5 3 3
```

Next, we take the maximum along the rows, resulting in a column vector.

```
--> max(A,[],2)

ans =
 5
 3
 3
```

When the dimension argument is not supplied, `max` acts along the first non-singular dimension. For a row vector, this is the column direction:

```
--> max([5,3,2,9])

ans =
 9
```

For the two-argument version, we can compute the smaller of two arrays, as in this example:

```
--> a = int8(100*randn(4))

a =
  -16   65  -38  -45
  -33  -46  127  -14
 -110   18  -15  -11
  127 -128 -128 -120

--> b = int8(100*randn(4))

b =
  -60  127 -128   91
   71 -128  -36  -53
    8  127 -106 -128
 -128   47  -93  -34

--> max(a,b)

ans =
 -16 127 -38  91
```

```
  71 -46 127 -14
   8 127 -15 -11
 127  47 -93 -34
```

Or alternately, we can compare an array with a scalar

```
--> a = randn(2)

a =
   -0.0574    1.1346
   -1.3497   -2.3248

--> max(a,0)

ans =
         0    1.1346
         0         0
```

11.19 MEAN Mean Function

11.19.1 Usage

Computes the mean of an array along a given dimension. The general syntax for its use is

```
y = mean(x,d)
```

where `x` is an `n`-dimensions array of numerical type. The output is of the same numerical type as the input. The argument `d` is optional, and denotes the dimension along which to take the mean. The output `y` is the same size as `x`, except that it is singular along the mean direction. So, for example, if `x` is a `3 x 3 x 4` array, and we compute the mean along dimension `d=2`, then the output is of size `3 x 1 x 4`.

11.19.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \frac{1}{N}\sum_{k=1}^{N} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

If `d` is omitted, then the mean is taken along the first non-singleton dimension of `x`.

11.19.3 Example

The following piece of code demonstrates various uses of the mean function

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We start by calling `mean` without a dimension argument, in which case it defaults to the first nonsingular dimension (in this case, along the columns or `d = 1`).

```
--> mean(A)

ans =
    2.6667    2.0000    1.6667
```

Next, we take the mean along the rows.

```
--> mean(A,2)

ans =
    3.0000
    2.0000
    1.3333
```

11.20 MIN Minimum Function

11.20.1 Usage

Computes the minimum of an array along a given dimension, or alternately, computes two arrays (entry-wise) and keeps the smaller value for each array. As a result, the `min` function has a number of syntaxes. The first one computes the minimum of an array along a given dimension. The first general syntax for its use is either

```
[y,n] = min(x,[],d)
```

where `x` is a multidimensional array of numerical type, in which case the output `y` is the minimum of `x` along dimension `d`. The second argument `n` is the index that results in the minimum. In the event that multiple minima are present with the same value, the index of the first minimum is used. The second general syntax for the use of the `min` function is

```
[y,n] = min(x)
```

In this case, the minimum is taken along the first non-singleton dimension of `x`. For complex data types, the minimum is based on the magnitude of the numbers. NaNs are ignored in the calculations. The third general syntax for the use of the `min` function is as a comparison function for pairs of arrays. Here, the general syntax is

```
y = min(x,z)
```

where `x` and `z` are either both numerical arrays of the same dimensions, or one of the two is a scalar. In the first case, the output is the same size as both arrays, and is defined elementwise by the smaller of the two arrays. In the second case, the output is defined elementwise by the smaller of the array entries and the scalar.

11.20.2 Function Internals

In the general version of the `min` function which is applied to a single array (using the `min(x,[],d)` or `min(x)` syntaxes), The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \min_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p),$$

and the output array `n` of indices is calculated via

$$n(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \arg\min_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

In the two-array version (`min(x,z)`), the single output is computed as

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \begin{cases} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p) & x(\cdots) \le z(\cdots) \\ z(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p) & z(\cdots) < x(\cdots). \end{cases}$$

11.20.3 Example

The following piece of code demonstrates various uses of the minimum function. We start with the one-array version.

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We first take the minimum along the columns, resulting in a row vector.

```
--> min(A)

ans =
 0 1 1
```

Next, we take the minimum along the rows, resulting in a column vector.

```
--> min(A,[],2)

ans =
 1
 1
 0
```

When the dimension argument is not supplied, `min` acts along the first non-singular dimension. For a row vector, this is the column direction:

```
--> min([5,3,2,9])

ans =
 2
```

For the two-argument version, we can compute the smaller of two arrays, as in this example:

```
--> a = int8(100*randn(4))

a =
  -66  -74  -74   32
 -128  -14 -110 -128
  127  -96  -49   72
  127   50   83  120

--> b = int8(100*randn(4))

b =
  -94  108  -99  -35
  127   50 -100  113
  -98  -39 -127 -107
  -12  127  103  -44

--> min(a,b)

ans =
  -94  -74  -99  -35
```

```
 -128  -14 -110 -128
  -98  -96 -127 -107
  -12   50   83  -44
```

Or alternately, we can compare an array with a scalar

```
--> a = randn(2)

a =
    0.7713    0.6716
   -1.0581   -1.3734

--> min(a,0)

ans =
         0         0
   -1.0581   -1.3734
```

11.21 NUM2HEX Convert Numbers to IEEE Hex Strings

11.21.1 Usage

Converts single and double precision arrays to IEEE hex strings. The syntax for its use is

```
y = num2hex(x)
```

where `x` is either a `float` or `double` array. The output `y` is a `n-by-p` character array, where `n` is the number of elements in `x`, and `p` is 16 for `double` arrays, and 8 for `single` arrays.

11.21.2 Example

Some interesting numbers

```
--> num2hex([1 0 0.1 -pi inf nan])

ans =
3ff0000000000000
0000000000000000
3fb999999999999a
c00921fb54442d18
7ff0000000000000
fff8000000000000
```

The same in single precision

```
--> num2hex(float([1 0 0.1 -pi inf nan]))

ans =
3f800000
00000000
3dcccccd
c0490fdb
7f800000
fff80000
```

11.22 PROD Product Function

11.22.1 Usage

Computes the product of an array along a given dimension. The general syntax for its use is

```
y = prod(x,d)
```

where `x` is an `n`-dimensions array of numerical type. The output is of the same numerical type as the input, except for integer types, which are automatically promoted to `int32`. The argument `d` is optional, and denotes the dimension along which to take the product. The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \prod_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

If `d` is omitted, then the product is taken along the first non-singleton dimension of `x`. Note that by definition (starting with FreeMat 2.1) `prod([]) = 1`.

11.22.2 Example

The following piece of code demonstrates various uses of the product function

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We start by calling `prod` without a dimension argument, in which case it defaults to the first nonsingular dimension (in this case, along the columns or `d = 1`).

```
--> prod(A)

ans =
 0 6 3
```

Next, we take the product along the rows.

```
--> prod(A,2)

ans =
 15
  6
  0
```

11.23 REAL Real Function

11.23.1 Usage

Returns the real part of the input array for all elements. The general syntax for its use is

```
y = real(x)
```

where `x` is an `n`-dimensional array of numerical type. The output is the same numerical type as the input, unless the input is `complex` or `dcomplex`. For `complex` inputs, the real part is a floating point array, so that the return type is `float`. For `dcomplex` inputs, the real part is a double precision floating point array, so that the return type is `double`. The `real` function does nothing to real and integer types.

11.23.2 Example

The following demonstrates the `real` applied to a complex scalar.

```
--> real(3+4*i)

ans =
 3
```

The `real` function has no effect on real arguments:

```
--> real([2,3,4])

ans =
 2 3 4
```

For a double-precision complex array,

```
--> real([2.0+3.0*i,i])

ans =
 2 0
```

11.24 ROUND Round Function

11.24.1 Usage

Rounds an n-dimensional array to the nearest integer elementwise. The general syntax for its use is

```
y = round(x)
```

where `x` is a multidimensional array of numerical type. The `round` function preserves the type of the argument. So integer arguments are not modified, and `float` arrays return `float` arrays as outputs, and similarly for `double` arrays. The `round` function is not defined for `complex` or `dcomplex` types.

11.24.2 Example

The following demonstrates the `round` function applied to various (numerical) arguments. For integer arguments, the round function has no effect:

```
--> round(3)

ans =
 3

--> round(-3)

ans =
 -3
```

Next, we take the `round` of a floating point value:

```
--> round(3.023f)

ans =
 3

--> round(-2.341f)
```

```
ans =
 -2
```

Note that the return type is a `float` also. Finally, for a `double` type:

```
--> round(4.312)

ans =
 4

--> round(-5.32)

ans =
 -5
```

11.25 STD Standard Deviation Function

11.25.1 Usage

Computes the standard deviation of an array along a given dimension. The general syntax for its use is

```
  y = std(x,d)
```

where `x` is an `n`-dimensions array of numerical type. The output is of the same numerical type as the input. The argument `d` is optional, and denotes the dimension along which to take the variance. The output `y` is the same size as `x`, except that it is singular along the mean direction. So, for example, if `x` is a `3 x 3 x 4` array, and we compute the mean along dimension `d=2`, then the output is of size `3 x 1 x 4`.

11.25.2 Example

The following piece of code demonstrates various uses of the `std` function

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We start by calling `std` without a dimension argument, in which case it defaults to the first nonsingular dimension (in this case, along the columns or `d = 1`).

```
--> std(A)

ans =
    2.5166    1.0000    1.1547
```

Next, we take the variance along the rows.

```
--> std(A,2)

ans =
    2.0000
    1.0000
    1.5275
```

11.26 SUB2IND Convert Multiple Indexing To Linear Indexing

11.26.1 Usage

The `sub2ind` function converts a multi-dimensional indexing expression into a linear (or vector) indexing expression. The syntax for its use is

```
y = sub2ind(sizevec,d1,d2,...,dn)
```

where `sizevec` is the size of the array being indexed into, and each `di` is a vector of the same length, containing index values. The basic idea behind `sub2ind` is that it makes

```
[z(d1(1),d2(1),...,dn(1)),...,z(d1(n),d2(n),...,dn(n))]
```

equivalent to

```
z(sub2ind(size(z),d1,d2,...,dn))
```

where the later form is using vector indexing, and the former one is using native, multi-dimensional indexing.

11.26.2 Example

Suppose we have a simple `3 x 4` matrix `A` containing some random integer elements

```
--> A = randi(ones(3,4),10*ones(3,4))

A =
  2  3  2  3
 10  2  4  8
  5 10  1  2
```

We can extract the elements `(1,3),(2,3),(3,4)` of `A` via `sub2ind`. To calculate which elements of `A` this corresponds to, we can use `sub2ind` as

```
--> n = sub2ind(size(A),1:3,2:4)

n =
  4  8 12

--> A(n)

ans =
 3 4 2
```

11.27 SUM Sum Function

11.27.1 Usage

Computes the summation of an array along a given dimension. The general syntax for its use is

```
y = sum(x,d)
```

where `x` is an `n`-dimensions array of numerical type. The output is of the same numerical type as the input. The argument `d` is optional, and denotes the dimension along which to take the summation. The output `y` is the same size as `x`, except that it is singular along the summation direction. So, for example, if `x` is a `3 x 3 x 4` array, and we compute the summation along dimension `d=2`, then the output is of size `3 x 1 x 4`.

11.27.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \sum_k x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

If `d` is omitted, then the summation is taken along the first non-singleton dimension of `x`.

11.27.3 Example

The following piece of code demonstrates various uses of the summation function

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We start by calling `sum` without a dimension argument, in which case it defaults to the first nonsingular dimension (in this case, along the columns or `d = 1`).

```
--> sum(A)

ans =
 8 6 5
```

Next, we take the sum along the rows.

```
--> sum(A,2)

ans =
 9
 6
 4
```

11.28 TEST Test Function

11.28.1 Usage

Tests for the argument array to be all logical 1s. It is completely equivalent to the `all` function applied to a vectorized form of the input. The syntax for the `test` function is

```
y = test(x)
```

and the result is equivalent to `all(x(:))`.

11.29 VAR Variance Function

11.29.1 Usage

Computes the variance of an array along a given dimension. The general syntax for its use is

```
y = var(x,d)
```

where `x` is an `n`-dimensions array of numerical type. The output is of the same numerical type as the input. The argument `d` is optional, and denotes the dimension along which to take the variance. The output `y` is the same size as `x`, except that it is singular along the mean direction. So, for example, if `x` is a `3 x 3 x 4` array, and we compute the mean along dimension `d=2`, then the output is of size `3 x 1 x 4`.

11.29.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},1,m_{d+1},\ldots,m_p) = \frac{1}{N-1}\sum_{k=1}^{N}\left(x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p) - \bar{x}\right)^2,$$

where

$$\bar{x} = \frac{1}{N}\sum_{k=1}^{N} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)$$

If `d` is omitted, then the mean is taken along the first non-singleton dimension of `x`.

11.29.3 Example

The following piece of code demonstrates various uses of the var function

```
--> A = [5,1,3;3,2,1;0,3,1]

A =
 5 1 3
 3 2 1
 0 3 1
```

We start by calling `var` without a dimension argument, in which case it defaults to the first nonsingular dimension (in this case, along the columns or `d = 1`).

```
--> var(A)

ans =
    6.3333    1.0000    1.3333
```

Next, we take the variance along the rows.

```
--> var(A,2)

ans =
    4.0000
    1.0000
    2.3333
```

11.30 VEC Reshape to a Vector

11.30.1 Usage

Reshapes an n-dimensional array into a column vector. The general syntax for its use is

```
y = vec(x)
```

where `x` is an n-dimensional array (not necessarily numeric). This function is equivalent to the expression `y = x(:)`.

11.30.2 Example

A simple example of the `vec` operator reshaping a 2D matrix:

```
--> A = [1,2,4,3;2,3,4,5]

A =
 1 2 4 3
 2 3 4 5

--> vec(A)

ans =
 1
 2
 2
 3
 4
 4
 3
 5
```

Chapter 12

Inspection Functions

12.1 CLEAR Clear or Delete a Variable

12.1.1 Usage

Clears a set of variables from the current context, or alternately, delete all variables defined in the current context. There are several formats for the function call. The first is the explicit form in which a list of variables are provided:

```
clear a1 a2 ...
```

The variables can be persistent or global, and they will be deleted. The second form

```
clear 'all'
```

clears all variables and libraries from the current context. Alternately, you can use the form:

```
clear 'libs'
```

which will unload any libraries or DLLs that have been `import`ed. Optionally, you can specify that persistent variables should be cleared via:

```
clear 'persistent'
```

and similarly for global variables:

```
clear 'global'
```

You can use

```
clear 'classes'
```

to clear all definitions of user-defined classes. With no arguments, `clear` defaults to clearing `'all'`.

12.1.2 Example

Here is a simple example of using `clear` to delete a variable. First, we create a variable called `a`:

```
--> a = 53

a =
 53
```

Next, we clear `a` using the `clear` function, and verify that it is deleted.

```
--> clear a
--> a
Error: Undefined function or variable a
```

12.2 END End Function

12.2.1 Usage

Computes the size of a variable along a given dimension. The syntax for its use is

```
y = end(x,dim,subindexes)
```

where `x` is the array to be analyzed, `dim` is the dimension along which to compute the end, and `subindexes` indicates how many dimensions are involved in the `end` calculation.

12.3 EXIST Test for Existence

12.3.1 Usage

Tests for the existence of a variable, function, directory or file. The general syntax for its use is

```
y = exist(item,kind)
```

where `item` is a string containing the name of the item to look for, and `kind` is a string indicating the type of the search. The `kind` must be one of

- `'builtin'` checks for built-in functions
- `'dir'` checks for directories
- `'file'` checks for files
- `'var'` checks for variables
- `'all'` checks all possibilities (same as leaving out `kind`)

You can also leave the `kind` specification out, in which case the calling syntax is

```
y = exist(item)
```

The return code is one of the following:

- 0 - if `item` does not exist
- 1 - if `item` is a variable in the workspace
- 2 - if `item` is an M file on the search path, a full pathname to a file, or an ordinary file on your search path
- 5 - if `item` is a built-in FreeMat function
- 7 - if `item` is a directory

Note: previous to version `1.10`, `exist` used a different notion of existence for variables: a variable was said to exist if it was defined and non-empty. This test is now performed by `isset`.

12.3.2 Example

Some examples of the `exist` function. Note that generally `exist` is used in functions to test for keywords. For example,

```
function y = testfunc(a, b, c)
if (~exist('c'))
  % c was not defined, so establish a default
  c = 13;
end
y = a + b + c;
```

An example of exist in action.

```
--> a = randn(3,5,2)

a =

(:,:,1) =
    0.7785    0.6357    1.7582    1.5784   -0.8470
    0.7235    1.0468   -0.6919   -0.6796    0.4767
    0.2100    0.0865    1.5704   -0.1267    2.1381

(:,:,2) =
    1.5525   -0.2908   -1.4220    1.1076    0.2419
    0.1652   -0.5668   -0.8018   -0.5975    0.8483
    0.3147   -0.1109   -0.5203    0.5851    1.1503

--> b = []

b =
  []
--> who
  Variable Name       Type   Flags             Size
              a    double                    [3x5x2]
              b    double                    [0x0]
--> exist('a')

ans =
 1

--> exist('b')

ans =
 1

--> exist('c')

ans =
 0
```

12.4 FIELDNAMES Fieldnames of a Structure

12.4.1 Usage

Returns a cell array containing the names of the fields in a structure array. The syntax for its use is

```
x = fieldnames(y)
```

where y is a structure array of object array. The result is a cell array, with one entry per field in y.

12.4.2 Example

We define a simple structure array:

```
--> y.foo = 3; y.goo = 'hello';
--> x = fieldnames(y)
```

```
x =
 [foo]
 [goo]
```

12.5 ISA Test Type of Variable

12.5.1 Usage

Tests the type of a variable. The syntax for its use is

```
y = isa(x,type)
```

where `x` is the variable to test, and `type` is the type. Supported built-in types are

- `'cell'` for cell-arrays
- `'struct'` for structure-arrays
- `'logical'` for logical arrays
- `'uint8'` for unsigned 8-bit integers
- `'int8'` for signed 8-bit integers
- `'uint16'` for unsigned 16-bit integers
- `'int16'` for signed 16-bit integers
- `'uint32'` for unsigned 32-bit integers
- `'int32'` for signed 32-bit integers
- `'uint64'` for unsigned 64-bit integers
- `'int64'` for signed 64-bit integers
- `'single'` for 32-bit floating point numbers
- `'double'` for 64-bit floating point numbers
- `'char'` for string arrays

If the argument is a user-defined type (via the `class` function), then the name of that class is returned.

12.5.2 Examples

Here are some examples of the `isa` call.

```
--> a = {1}

a =
 [1]

--> isa(a,'char')

ans =
 0

--> isa(a,'cell')

ans =
 1
```

Here we use `isa` along with shortcut boolean evaluation to safely determine if a variable contains the string `'hello'`

```
--> a = 'hello'

a =
hello
--> isa(a,'char') && strcmp(a,'hello')

ans =
 1
```

12.6 ISCELL Test For Cell Array

12.6.1 Usage

The syntax for `iscell` is

```
x = iscell(y)
```

and it returns a logical 1 if the argument is a cell array and a logical 0 otherwise.

12.6.2 Example

Here are some examples of `iscell`

```
--> iscell('foo')

ans =
 0

--> iscell(2)

ans =
 0

--> iscell({1,2,3})

ans =
 1
```

12.7 ISCELLSTR Test For Cell Array of Strings

12.7.1 Usage

The syntax for `iscellstr` is

```
x = iscellstr(y)
```

and it returns a logical 1 if the argument is a cell array in which every cell is a character array (or is empty), and a logical 0 otherwise.

12.7.2 Example

Here is a simple example

```
--> A = {'Hello','Yellow';'Mellow','Othello'}

A =
 [Hello] [Yellow]
 [Mellow] [Othello]

--> iscellstr(A)

ans =
 1
```

12.8 ISCHAR Test For Character Array (string)

12.8.1 Usage

The syntax for `ischar` is

```
   x = ischar(y)
```

and it returns a logical 1 if the argument is a string and a logical 0 otherwise.

12.9 ISEMPTY Test For Variable Empty

12.9.1 Usage

The `isempty` function returns a boolean that indicates if the argument variable is empty or not. The general syntax for its use is

```
  y = isempty(x).
```

12.9.2 Examples

Here are some examples of the `isempty` function

```
--> a = []

a =
  []
--> isempty(a)

ans =
 1

--> b = 1:3

b =
 1 2 3

--> isempty(b)

ans =
 0
```

Note that if the variable is not defined, `isempty` does not return true.

```
--> clear x
--> isempty(x)
Error: Undefined function or variable x
```

12.10 ISEQUAL Test For Matrix Equality

12.10.1 Usage

Test two arrays for equality. The general format for its use is

```
y = isequal(a,b)
```

This function returns true if the two arrays are equal (compared element-wise). Unlike `issame` the `isequal` function will type convert where possible to do the comparison.

12.11 ISEQUALWITHEQUALNANS Test For Matrix Equality

12.11.1 Usage

Test two arrays for equality, with NaNs being equal. The general format for its use is

```
y = isequalwithequalnans(a,b)
```

This function returns true if the two arrays are equal (compared element-wise). Unlike `issame` the `isequalwithequalnans` function will type convert where possible to do the comparison.

12.12 ISFIELD Test for Existence of a Structure Field

12.12.1 Usage

Given a structure array, tests to see if that structure array contains a field with the given name. The syntax for its use is

```
y = isfield(x,field)
```

and returns a logical `1` if `x` has a field with the name `field` and a logical `0` if not. It also returns a logical `0` if the argument `x` is not a structure array.

12.12.2 Example

Here we define a simple struct, and then test for some fields

```
--> a.foo = 32

a =
    foo: 32
--> a.goo = 64

a =
    foo: 32
    goo: 64
--> isfield(a,'goo')

ans =
```

```
 1

--> isfield(a,'got')

ans =
 0

--> isfield(pi,'round')

ans =
 0
```

12.13 ISHANDLE Test for Graphics Handle

12.13.1 Usage

Given a constant, this routine will test to see if the constant is a valid graphics handle or not. The syntax for its use is

```
  y = ishandle(h,type)
```

and returns a logical `1` if `x` is a handle of type `type` and a logical `0` if not.

12.14 ISINF Test for infinities

12.14.1 Usage

Returns true for entries of an array that are infs (i.e., infinities). The usage is

```
   y = isinf(x)
```

The result is a logical array of the same size as `x`, which is true if `x` is not-a-number, and false otherwise. Note that for `complex` or `dcomplex` data types that the result is true if either the real or imaginary parts are infinite.

12.14.2 Example

Suppose we have an array of floats with one element that is `inf`:

```
--> a = [1.2 3.4 inf 5]

a =
    1.2000    3.4000 Inf    5.0000

--> isinf(a)

ans =
 0 0 1 0

--> b = 3./[2 5 0 3 1]

b =
    1.5000    0.6000 Inf    1.0000    3.0000
```

12.15 ISINTTYPE Test For Integer-type Array

12.15.1 Usage

The syntax for `isinttype` is

```
x = isinttype(y)
```

and it returns a logical 1 if the argument is an integer type and a logical 0 otherwise. Note that this function only tests the type of the variable, not the value. So if, for example, `y` is a `float` array containing all integer values, it will still return a logical 0.

12.16 ISLOGICAL Test for Logical Array

12.16.1 Usage

The syntax for `islogical` is

```
x = islogical(y)
```

and it returns a logical 1 if the argument is a logical array and a logical 0 otherwise.

12.17 ISMATRIX Test For a 2D Matrix

12.17.1 Usage

This function tests to see if the argument is a matrix. The syntax for `ismatrix` is

```
x = ismatrix(y)
```

and it returns a logical 1 if the argument is size `N x M` or `M x N` and a logical 0 otherwise.

12.18 ISNAN Test for Not-a-Numbers

12.18.1 Usage

Returns true for entries of an array that are NaN's (i.e., Not-a-Numbers). The usage is

```
y = isnan(x)
```

The result is a logical array of the same size as `x`, which is true if `x` is not-a-number, and false otherwise. Note that for complex data types that the result is true if either the real or imaginary parts are NaNs.

12.18.2 Example

Suppose we have an array of floats with one element that is `nan`:

```
--> a = [1.2 3.4 nan 5]

a =
    1.2000    3.4000 NaN    5.0000

--> isnan(a)

ans =
 0 0 1 0
```

12.19 ISNUMERIC Test for Numeric Array

12.19.1 Usage

The syntax for `isnumeric` is

```
x = isnumeric(y)
```

and it returns a logical 1 if the argument is a numeric (i.e., not a structure array, cell array, string or user defined class), and a logical 0 otherwise.

12.20 ISREAL Test For Real Array

12.20.1 Usage

The syntax for `isreal` is

```
x = isreal(y)
```

and it returns a logical 1 if the argument is real valued and a logical 0 otherwise.

12.21 ISSAME Test If Two Arrays Are Identical

12.21.1 Usage

Tests for two arrays to be identical. The syntax for its use is

```
y = issame(a,b)
```

where `a` and `b` are two arrays to compare. This comparison succeeds only if `a` and `b` are of the same data type, size, and contents. Unlike numerical equivalence tests, the `issame` function considers `NaN` to be equal in both arguments.

12.22 ISSCALAR Test For Scalar

12.22.1 Usage

The syntax for `isscalar` is

```
x = isscalar(y)
```

and it returns a logical 1 if the argument is a scalar, and a logical 0 otherwise.

12.23 ISSET Test If Variable Set

12.23.1 Usage

Tests for the existence and non-emptiness of a variable. the general syntax for its use is

```
y = isset('name')
```

where `name` is the name of the variable to test. This is functionally equivalent to

```
y = exist('name','var') & ~isempty(name)
```

It returns a `logical` 1 if the variable is defined in the current workspace, and is not empty, and returns a 0 otherwise.

12.23.2 Example

Some simple examples of using `isset`

```
--> who
  Variable Name       Type   Flags             Size
--> isset('a')

ans =
 0

--> a = [];
--> isset('a')

ans =
 0

--> a = 2;
--> isset('a')

ans =
 1
```

12.24 ISSPARSE Test for Sparse Matrix

12.24.1 Usage

Test a matrix to see if it is sparse or not. The general format for its use is

```
y = issparse(x)
```

This function returns true if `x` is encoded as a sparse matrix, and false otherwise.

12.24.2 Example

Here is an example of using `issparse`:

```
--> a = [1,0,0,5;0,3,2,0]

a =
 1 0 0 5
 0 3 2 0

--> issparse(a)

ans =
 0

--> A = sparse(a)

A =
 1 1 1
 2 2 3
 2 3 2
 1 4 5
--> issparse(A)
```

```
ans =
 1
```

12.25 ISSQUARE Test For a Square matrix

12.25.1 Usage

This function tests to see if the argument is a square matrix. The syntax for `issquare` is

```
x = issquare(y)
```

and it returns a logical 1 if the argument is size `N x N` logical 0 otherwise.

12.26 ISSTR Test For Character Array (string)

12.26.1 Usage

The syntax for `isstr` is

```
x = isstr(y)
```

and it returns a logical 1 if the argument is a string and a logical 0 otherwise.

12.27 ISSTRUCT Test For Structure Array

12.27.1 Usage

The syntax for `isstruct` is

```
x = isstruct(y)
```

and it returns a logical 1 if the argument is a structure array, and a logical 0 otherwise.

12.28 ISVECTOR Test For a Vector

12.28.1 Usage

This function tests to see if the argument is a vector. The syntax for `isvector` is

```
x = isvector(y)
```

and it returns a logical 1 if the argument is size `N x 1` or `1 x N` and a logical 0 otherwise.

12.29 LENGTH Length of an Array

12.29.1 Usage

Returns the length of an array `x`. The syntax for its use is

```
y = length(x)
```

and is defined as the maximum length of `x` along any of its dimensions, i.e., `max(size(x))`. If you want to determine the number of elements in `x`, use the `numel` function instead.

12.29.2 Example

For a `4 x 4 x 3` matrix, the length is `4`, not `48`, as you might expect.

```
--> x = rand(4,4,3);
--> length(x)

ans =
 4
```

12.30 MAXDIM Maximum Dimension in Array

12.30.1 Usage

The `maxdim` function returns the lowest order dimension along which an array is largest. The general syntax for its use is

```
  n = maxdim(x)
```

and is equivalent to min(find(size(x) == max(size(x)))).

12.31 NDIMS Number of Dimensions in Array

12.31.1 Usage

The `ndims` function returns the number of dimensions allocated in an array. The general syntax for its use is

```
  n = ndims(x)
```

and is equivalent to `length(size(x))`.

12.32 NNZ Number of Nonzeros

12.32.1 Usage

Returns the number of nonzero elements in a matrix. The general format for its use is

```
   y = nnz(x)
```

This function returns the number of nonzero elements in a matrix or array. This function works for both sparse and non-sparse arrays. For

12.32.2 Example

```
--> a = [1,0,0,5;0,3,2,0]

a =
 1 0 0 5
 0 3 2 0

--> nnz(a)

ans =
 4
```

```
--> A = sparse(a)

A =
 1 1 1
 2 2 3
 2 3 2
 1 4 5
--> nnz(A)

ans =
 4
```

12.33 NUMEL Number of Elements in an Array

12.33.1 Usage

Returns the number of elements in an array `x`, or in a subindex expression. The syntax for its use is either

```
y = numel(x)
```

or

```
y = numel(x,varargin)
```

Generally, `numel` returns `prod(size(x))`, the number of total elements in `x`. However, you can specify a number of indexing expressions for `varagin` such as `index1, index2, ..., indexm`. In that case, the output of `numel` is `prod(size(x(index1,...,indexm)))`.

12.33.2 Example

For a `4 x 4 x 3` matrix, the length is `4`, not `48`, as you might expect, but `numel` is `48`.

```
--> x = rand(4,4,3);
--> length(x)

ans =
 4

--> numel(x)

ans =
 48
```

Here is an example of using `numel` with indexing expressions.

```
--> numel(x,1:3,1:2,2)

ans =
 6
```

12.34 SIZE Size of a Variable

12.34.1 Usage

Returns the size of a variable. There are two syntaxes for its use. The first syntax returns the size of the array as a vector of integers, one integer for each dimension

```
[d1,d2,...,dn] = size(x)
```

The other format returns the size of `x` along a particular dimension:

```
d = size(x,n)
```

where `n` is the dimension along which to return the size.

12.34.2 Example

```
--> a = randn(23,12,5);
--> size(a)

ans =
 23 12  5
```

Here is an example of the second form of `size`.

```
--> size(a,2)

ans =
 12
```

12.35 TYPEOF Determine the Type of an Argument

12.35.1 Usage

Returns a string describing the type of an array. The syntax for its use is

```
y = typeof(x),
```

The returned string is one of

- `'cell'` for cell-arrays
- `'struct'` for structure-arrays
- `'logical'` for logical arrays
- `'uint8'` for unsigned 8-bit integers
- `'int8'` for signed 8-bit integers
- `'uint16'` for unsigned 16-bit integers
- `'int16'` for signed 16-bit integers
- `'uint32'` for unsigned 32-bit integers
- `'int32'` for signed 32-bit integers
- `'float'` for 32-bit floating point numbers
- `'double'` for 64-bit floating point numbers
- `'string'` for string arrays

12.35.2 Example

The following piece of code demonstrates the output of the `typeof` command for each possible type. The first example is with a simple cell array.

```
--> typeof({1})

ans =
cell
```

The next example uses the `struct` constructor to make a simple scalar struct.

```
--> typeof(struct('foo',3))

ans =
struct
```

The next example uses a comparison between two scalar integers to generate a scalar logical type.

```
--> typeof(3>5)

ans =
logical
```

For the integers, the typecast operations are used to generate the arguments.

```
--> typeof(uint8(3))

ans =
uint8
--> typeof(int8(8))

ans =
int8
--> typeof(uint16(3))

ans =
uint16
--> typeof(int16(8))

ans =
int16
--> typeof(uint32(3))

ans =
uint32
--> typeof(int32(3))

ans =
int32
--> typeof(uint64(3))

ans =
uint64
--> typeof(int64(3))

ans =
int64
```

Float, and double can be created using the suffixes.

```
--> typeof(1.0f)

ans =
single
--> typeof(1.0D)

ans =
double
--> typeof(1.0f+i)

ans =
single
--> typeof(1.0D+2.0D*i)

ans =
double
```

12.36 WHAT List FreeMat Files In Directory

12.36.1 Usage

Lists files in a directory (or the current directory if no argument is supplied) that are relevant to FreeMat. These are `M`-files, `MAT`-files, and class directories. There are several syntaxes for its use. The first is

```
what
```

which lists the aforementioned items. If you provide a path instead

```
what path-to-folder
```

then `what` will list the relevant FreeMat items in the specified directory.

12.37 WHERE Get Information on Program Stack

12.37.1 Usage

Returns information on the current stack. The usage is

```
where
```

The result is a kind of stack trace that indicates the state of the current call stack, and where you are relative to the stack.

12.37.2 Example

Suppose we have the following chain of functions.

```
    chain1.m
function chain1
  a = 32;
  b = a + 5;
  chain2(b)
```

```
    chain2.m
function chain2(d)
  d = d + 5;
  chain3
```

```
    chain3.m
function chain3
  g = 54;
  f = g + 1;
  keyboard
```

The execution of the `where` command shows the stack trace.

```
--> chain1
[chain3,4]--> where
In /home/sbasu/Devel/FreeMat/help/tmp/chain3.m(chain3) at line 4
    In /home/sbasu/Devel/FreeMat/help/tmp/chain2.m(chain2) at line 4
    In /home/sbasu/Devel/FreeMat/help/tmp/chain1.m(chain1) at line 4
    In scratch() at line 2
    In base(base)
    In base()
    In global()
[chain3,4]
```

12.38 WHICH Get Information on Function

12.38.1 Usage

Returns information on a function (if defined). The usage is

```
which(fname)
```

where `fname` is a `string` argument that contains the name of the function. For functions and scripts defined via `.m` files, the `which` command returns the location of the source file:

```
y = which(fname)
```

will return the filename for the `.m` file corresponding to the given function, and an empty string otherwise.

12.38.2 Example

First, we apply the `which` command to a built in function.

```
--> which fft
Function fft is a built in function
```

Next, we apply it to a function defined via a `.m` file.

```
--> which fliplr
Function fliplr, M-File function in file '/home/sbasu/Devel/FreeMat/src/toolbox/array/fliplr.m'
```

12.39 WHO Describe Currently Defined Variables

12.39.1 Usage

Reports information on either all variables in the current context or on a specified set of variables. For each variable, the `who` function indicates the size and type of the variable as well as if it is a global or persistent. There are two formats for the function call. The first is the explicit form, in which a list of variables are provided:

```
who a1 a2 ...
```

In the second form

```
who
```

the `who` function lists all variables defined in the current context (as well as global and persistent variables). Note that there are two alternate forms for calling the `who` function:

```
who 'a1' 'a2' ...
```

and

```
who('a1','a2',...)
```

12.39.2 Example

Here is an example of the general use of `who`, which lists all of the variables defined.

```
--> c = [1,2,3];
--> f = 'hello';
--> p = randn(1,256);
--> who
  Variable Name       Type   Flags             Size
              c    double                    [1x3]
              f      char                    [1x5]
              p    double                    [1x256]
```

In the second case, we examine only a specific variable:

```
--> who c
  Variable Name       Type   Flags             Size
              c    double                    [1x3]
--> who('c')
  Variable Name       Type   Flags             Size
              c    double                    [1x3]
```

12.40 WHOS Describe Currently Defined Variables With Memory Usage

12.40.1 Usage

Reports information on either all variables in the current context or on a specified set of variables. For each variable, the `who` function indicates the size and type of the variable as well as if it is a global or persistent. There are two formats for the function call. The first is the explicit form, in which a list of variables are provided:

```
whos a1 a2 ...
```

In the second form

```
whos
```

the `whos` function lists all variables defined in the current context (as well as global and persistent variables). Note that there are two alternate forms for calling the `whos` function:

```
whos 'a1' 'a2' ...
```

and

```
whos('a1','a2',...)
```

Chapter 13

Type Conversion Functions

13.1 BIN2DEC Convert Binary String to Decimal

13.1.1 USAGE

Converts a binary string to an integer. The syntax for its use is

```
y = bin2dec(x)
```

where `x` is a binary string. If `x` is a matrix, then the resulting `y` is a column vector.

13.1.2 Example

Here we convert some numbers to bits

```
--> bin2dec('101110')

ans =
 46

--> bin2dec('010')

ans =
 2
```

13.2 BIN2INT Convert Binary Arrays to Integer

13.2.1 Usage

Converts the binary decomposition of an integer array back to an integer array. The general syntax for its use is

```
y = bin2int(x)
```

where `x` is a multi-dimensional logical array, where the last dimension indexes the bit planes (see `int2bin` for an example). By default, the output of `bin2int` is unsigned `uint32`. To get a signed integer, it must be typecast correctly. A second form for `bin2int` takes a `'signed'` flag

```
y = bin2int(x,'signed')
```

in which case the output is signed.

13.2.2 Example

The following piece of code demonstrates various uses of the int2bin function. First the simplest example:

```
--> A = [2;5;6;2]

A =
 2
 5
 6
 2

--> B = int2bin(A,8)

B =
 0 0 0 0 0 0 1 0
 0 0 0 0 0 1 0 1
 0 0 0 0 0 1 1 0
 0 0 0 0 0 0 1 0

--> bin2int(B)

ans =
 2
 5
 6
 2

--> A = [1;2;-5;2]

A =
  1
  2
 -5
  2

--> B = int2bin(A,8)

B =
 0 0 0 0 0 0 0 1
 0 0 0 0 0 0 1 0
 1 1 1 1 1 0 1 1
 0 0 0 0 0 0 1 0

--> bin2int(B)

ans =
   1
   2
 251
   2

--> int32(bin2int(B))

ans =
```

```
  1
  2
251
  2
```

13.2.3 Tets

13.3 CAST Typecast Variable to Specified Type

13.3.1 Usage

The `cast` function allows you to typecast a variable from one type to another. The syntax for its use is

```
y = cast(x,toclass)
```

where `toclass` is the name of the class to cast `x` to. Note that the typecast must make sense, and that `toclass` must be one of the builtin types. The current list of supported types is

- `'cell'` for cell-arrays
- `'struct'` for structure-arrays
- `'logical'` for logical arrays
- `'uint8'` for unsigned 8-bit integers
- `'int8'` for signed 8-bit integers
- `'uint16'` for unsigned 16-bit integers
- `'int16'` for signed 16-bit integers
- `'uint32'` for unsigned 32-bit integers
- `'int32'` for signed 32-bit integers
- `'uint64'` for unsigned 64-bit integers
- `'int64'` for signed 64-bit integers
- `'float'` for 32-bit floating point numbers
- `'single'` is a synonym for `'float'`
- `'double'` for 64-bit floating point numbers
- `'char'` for string arrays

13.3.2 Example

Here is an example of a typecast from a float to an 8-bit integer

```
--> cast(pi,'uint8')

ans =
 3
```

and here we cast an array of arbitrary integers to a logical array

```
--> cast([1 0 3 0],'logical')

ans =
 1 0 1 0
```

13.4 CHAR Convert to character array or string

13.4.1 Usage

The `char` function can be used to convert an array into a string. It has several forms. The first form is

```
y = char(x)
```

where `x` is a numeric array containing character codes. FreeMat does not currently support Unicode, so the character codes must be in the range of `[0,255]`. The output is a string of the same size as `x`. A second form is

```
y = char(c)
```

where `c` is a cell array of strings, creates a matrix string where each row contains a string from the corresponding cell array. The third form is

```
y = char(s1, s2, s3, ...)
```

where `si` are a character arrays. The result is a matrix string where each row contains a string from the corresponding argument.

13.4.2 Example

Here is an example of the first technique being used to generate a string containing some ASCII characters

```
--> char([32:64;65:97])

ans =
 !"#$%&'()*+,-./0123456789:;<=>?@
ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_`a
```

In the next example, we form a character array from a set of strings in a cell array. Note that the character array is padded with spaces to make the rows all have the same length.

```
--> char({'hello','to','the','world'})

ans =
hello
to
the
world
```

In the last example, we pass the individual strings as explicit arguments to `char`

```
--> char('hello','to','the','world')

ans =
hello
to
the
world
```

13.5 COMPLEX Create a Complex Number

13.5.1 Usage

Converts the two real input arguments into the real and imaginary part (respectively) of a complex number. The syntax for its use is

```
y = complex(x,z)
```

where `x` and `z` are `n`-dimensional numerical arrays. The usual rules for binary operators apply (i.e., one of the arguments can be a scalar, if either is of type `single` the output is single, etc.).

13.6 DCOMPLEX Convert to Double Precision (deprecated)

13.6.1 Usage

The `dcomplex` function used to convert variables into 64-bit complex data types in prior versions of FreeMat. Starting with FreeMat 4, the type rules are the same as Matlab, hence, there is no distinction between a 64-bit complex type and and 64-bit real type. Thus, the `dcomplex` function is just a synonym for `double`.

13.7 DEC2BIN Convert Decimal to Binary String

13.7.1 USAGE

Converts an integer to a binary string. The syntax for its use is

```
y = dec2bin(x,n)
```

where `x` is the positive integer, and `n` is the number of bits to use in the representation. Alternately, if you leave `n` unspecified,

```
y = dec2bin(x)
```

the minimum number of bits needed to represent `x` are used. If `x` is a vector, then the resulting `y` is a character matrix.

13.7.2 Example

Here we convert some numbers to bits

```
--> dec2bin(56)

ans =
111000
--> dec2bin(1039456)

ans =
11111101110001100000
--> dec2bin([63,73,32],5)

ans =
11111
01001
00000
```

13.8 DOUBLE Convert to 64-bit Floating Point

13.8.1 Usage

Converts the argument to a 64-bit floating point number. The syntax for its use is

```
y = double(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the saturation rules. Note that both `NaN` and `Inf` are both preserved under type conversion.

13.8.2 Example

The following piece of code demonstrates several uses of `double`. First, we convert from an integer (the argument is an integer because no decimal is present):

```
--> double(200)

ans =
 200
```

In the next example, a single precision argument is passed in (the presence of the `f` suffix implies single precision).

```
--> double(400.0f)

ans =
 400
```

In the next example, a complex argument is passed in.

```
--> double(3.0+4.0*i)

ans =
   3.0000 +  4.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> double('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> double({4})
Error: Cannot perform type conversions with this type
```

13.9 FLOAT Convert to 32-bit Floating Point

13.9.1 Usage

Converts the argument to a 32-bit floating point number. The syntax for its use is

```
y = float(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the saturation rules. Note that both `NaN` and `Inf` are both preserved under type conversion.

13.9.2 Example

The following piece of code demonstrates several uses of `float`. First, we convert from an integer (the argument is an integer because no decimal is present):

```
--> float(200)

ans =
 200
```

In the next example, a double precision argument is passed in

```
--> float(400.0)

ans =
 400
```

In the next example, a complex argument is passed in.

```
--> float(3.0+4.0*i)

ans =
   3.0000 +  4.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> float('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> float({4})
Error: Cannot perform type conversions with this type
```

13.10 INT16 Convert to Signed 16-bit Integer

13.10.1 Usage

Converts the argument to an signed 16-bit Integer. The syntax for its use is

```
y = int16(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the saturation rules (e.g., if `x` is outside the normal range for a signed 16-bit integer of `[-32767,32767]`, it is truncated to that range). Note that both `NaN` and `Inf` both map to 0.

13.10.2 Example

The following piece of code demonstrates several uses of `int16`. First, the routine uses

```
--> int16(100)

ans =
 100

--> int16(-100)

ans =
 -100
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the range of the data type.

```
--> int16(40000)

ans =
 32767
```

In the next example, a positive double precision argument is passed in. The result is the signed integer that is closest to the argument.

```
--> int16(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the signed complex integer that is closest to the argument.

```
--> int16(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> int16('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> int16({4})
Error: Cannot perform type conversions with this type
```

13.11 INT2BIN Convert Integer Arrays to Binary

13.11.1 Usage

Computes the binary decomposition of an integer array to the specified number of bits. The general syntax for its use is

```
y = int2bin(x,n)
```

where `x` is a multi-dimensional integer array, and `n` is the number of bits to expand it to. The output array `y` has one extra dimension to it than the input. The bits are expanded along this extra dimension.

13.11.2 Example

The following piece of code demonstrates various uses of the int2bin function. First the simplest example:

```
--> A = [2;5;6;2]

A =
 2
 5
 6
 2

--> int2bin(A,8)

ans =
 0 0 0 0 0 0 1 0
 0 0 0 0 0 1 0 1
```

```
 0 0 0 0 0 1 1 0
 0 0 0 0 0 0 1 0

--> A = [1;2;-5;2]

A =
  1
  2
 -5
  2

--> int2bin(A,8)

ans =
 0 0 0 0 0 0 0 1
 0 0 0 0 0 0 1 0
 1 1 1 1 1 0 1 1
 0 0 0 0 0 0 1 0
```

13.12 INT32 Convert to Signed 32-bit Integer

13.12.1 Usage

Converts the argument to an signed 32-bit Integer. The syntax for its use is

```
y = int32(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the saturation rules (e.g., if `x` is outside the normal range for a signed 32-bit integer of `[-2147483647,2147483647]`, it is truncated to that range). Note that both `NaN` and `Inf` both map to 0.

13.12.2 Example

The following piece of code demonstrates several uses of `int32`. First, the routine uses

```
--> int32(100)

ans =
 100

--> int32(-100)

ans =
 -100
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the range of the data type.

```
--> int32(40e9)

ans =
 2147483647
```

In the next example, a positive double precision argument is passed in. The result is the signed integer that is closest to the argument.

```
--> int32(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the signed complex integer that is closest to the argument.

```
--> int32(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> int32('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> int32({4})
Error: Cannot perform type conversions with this type
```

13.13 INT64 Convert to Signed 64-bit Integer

13.13.1 Usage

Converts the argument to an signed 64-bit Integer. The syntax for its use is

```
y = int64(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the saturation rules (e.g., if `x` is outside the normal range for a signed 64-bit integer of `[-2\^63+1,2\^63-1]`, it is truncated to that range). Note that both `NaN` and `Inf` both map to 0.

13.13.2 Example

The following piece of code demonstrates several uses of `int64`. First, the routine uses

```
--> int64(100)

ans =
 100

--> int64(-100)

ans =
 -100
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the range of the data type.

```
--> int64(40e9)

ans =
 40000000000
```

In the next example, a positive double precision argument is passed in. The result is the signed integer that is closest to the argument.

```
--> int64(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the complex signed integer that is closest to the argument.

```
--> int64(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> int64('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> int64({4})
Error: Cannot perform type conversions with this type
```

13.14 INT8 Convert to Signed 8-bit Integer

13.14.1 Usage

Converts the argument to an signed 8-bit Integer. The syntax for its use is

```
y = int8(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the saturation rules (e.g., if `x` is outside the normal range for a signed 8-bit integer of `[-127,127]`, it is truncated to that range. Note that both `NaN` and `Inf` both map to 0.

13.14.2 Example

The following piece of code demonstrates several uses of `int8`. First, the routine uses

```
--> int8(100)

ans =
 100

--> int8(-100)

ans =
 -100
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the range of the type.

```
--> int8(400)

ans =
 127
```

In the next example, a positive double precision argument is passed in. The result is the signed integer that is closest to the argument.

```
--> int8(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the signed complex integer that is closest to the argument.

```
--> int8(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> int8('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> int8({4})
Error: Cannot perform type conversions with this type
```

13.15 LOGICAL Convert to Logical

13.15.1 Usage

Converts the argument to a logical array. The syntax for its use is

```
y = logical(x)
```

where `x` is an `n`-dimensional numerical array. Any nonzero element maps to a logical 1.

13.15.2 Example

Here we convert an integer array to `logical`:

```
--> logical([1,2,3,0,0,0,5,2,2])

ans =
 1 1 1 0 0 0 1 1 1
```

The same example with double precision values:

```
--> logical([pi,pi,0,e,0,-1])

ans =
 1 1 0 1 0 1
```

13.16 SINGLE Convert to 32-bit Floating Point

13.16.1 Usage

A synonym for the `float` function, converts the argument to a 32-bit floating point number. The syntax for its use is

```
y = single(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows the general C rules. Note that both `NaN` and `Inf` are both preserved under type conversion.

13.17 STRING Convert Array to String

13.17.1 Usage

Converts the argument array into a string. The syntax for its use is

```
y = string(x)
```

where `x` is an `n`-dimensional numerical array.

13.17.2 Example

Here we take an array containing ASCII codes for a string, and convert it into a string.

```
--> a = [104,101,108,108,111]

a =
 104 101 108 108 111

--> string(a)

ans =
hello
```

13.18 UINT16 Convert to Unsigned 16-bit Integer

13.18.1 Usage

Converts the argument to an unsigned 16-bit Integer. The syntax for its use is

```
y = uint16(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows saturation rules (e.g., if `x` is outside the normal range for an unsigned 16-bit integer of `[0,65535]`, it is truncated to that range. Note that both `NaN` and `Inf` both map to 0.

13.18.2 Example

The following piece of code demonstrates several uses of `uint16`.

```
--> uint16(200)

ans =
 200
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the maximum value of the data type.

```
--> uint16(99400)

ans =
 65535
```

In the next example, a negative integer is passed in. The result is truncated to zero.

```
--> uint16(-100)

ans =
 0
```

In the next example, a positive double precision argument is passed in. The result is the unsigned integer that is closest to the argument.

```
--> uint16(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the complex unsigned integer that is closest to the argument.

```
--> uint16(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> uint16('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> uint16({4})
Error: Cannot perform type conversions with this type
```

13.19 UINT32 Convert to Unsigned 32-bit Integer

13.19.1 Usage

Converts the argument to an unsigned 32-bit Integer. The syntax for its use is

```
y = uint32(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows saturation rules (e.g., if `x` is outside the normal range for an unsigned 32-bit integer of `[0,4294967295]`, it is truncated to that range. Note that both `NaN` and `Inf` both map to 0.

13.19.2 Example

The following piece of code demonstrates several uses of `uint32`.

```
--> uint32(200)

ans =
 200
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the maximum value of the data type.

```
--> uint32(40e9)

ans =
 4294967295
```

In the next example, a negative integer is passed in. The result is truncated to zero.

```
--> uint32(-100)

ans =
 0
```

In the next example, a positive double precision argument is passed in. The result is the unsigned integer that is closest to the argument.

```
--> uint32(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the complex unsigned integer that is closest to the argument.

```
--> uint32(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> uint32('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> uint32({4})
Error: Cannot perform type conversions with this type
```

13.20 UINT64 Convert to Unsigned 64-bit Integer

13.20.1 Usage

Converts the argument to an unsigned 64-bit Integer. The syntax for its use is

```
y = uint64(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows saturation rules (e.g., if `x` is outside the normal range for an unsigned 64-bit integer of `[0,2\^64-1]`, it is truncated to that range. Note that both `NaN` and `Inf` both map to 0.

13.20.2 Example

The following piece of code demonstrates several uses of `uint64`.

```
--> uint64(200)

ans =
 200
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the maximum value of the data type.

```
--> uint64(40e9)

ans =
 40000000000
```

In the next example, a negative integer is passed in. The result is zero.

```
--> uint64(-100)

ans =
 0
```

In the next example, a positive double precision argument is passed in. The result is the unsigned integer that is closest to the argument.

```
--> uint64(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is the complex unsigned integer that is closest to the argument.

```
--> uint64(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> uint64('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> uint64({4})
Error: Cannot perform type conversions with this type
```

13.21 UINT8 Convert to Unsigned 8-bit Integer

13.21.1 Usage

Converts the argument to an unsigned 8-bit Integer. The syntax for its use is

```
y = uint8(x)
```

where `x` is an `n`-dimensional numerical array. Conversion follows saturation rules (e.g., if `x` is outside the normal range for an unsigned 8-bit integer of `[0,255]`, it is truncated to that range. Note that both `NaN` and `Inf` both map to 0.

13.21.2 Example

The following piece of code demonstrates several uses of `uint8`.

```
--> uint8(200)

ans =
 200
```

In the next example, an integer outside the range of the type is passed in. The result is truncated to the maximum value of the data type.

```
--> uint8(400)

ans =
 255
```

In the next example, a negative integer is passed in. The result is trunated to zero.

```
--> uint8(-100)

ans =
 0
```

In the next example, a positive double precision argument is passed in. The result is the unsigned integer that is closest to the argument.

```
--> uint8(pi)

ans =
 3
```

In the next example, a complex argument is passed in. The result is complex unsigned integer that is closest to the argument.

```
--> uint8(5+2*i)

ans =
   5.0000 +  2.0000i
```

In the next example, a string argument is passed in. The string argument is converted into an integer array corresponding to the ASCII values of each character.

```
--> uint8('helo')

ans =
 104 101 108 111
```

In the last example, a cell-array is passed in. For cell-arrays and structure arrays, the result is an error.

```
--> uint8({4})
Error: Cannot perform type conversions with this type
```

Chapter 14

Array Generation and Manipulations

14.1 ARRAYFUN Apply a Function To Elements of an Array

14.1.1 Usage

The `arrayfun` function is used to apply a function handle to each element of an input array (or arrays), and to collect the outputs into an array. The general syntax for its use is

```
y = arrayfun(fun, x)
```

where `x` is an N-dimensional array. In this case, each element of the output `y\_i` is defined as `fun(x\_i)`. You can also supply multiple arguments to `arrayfun`, provided all of the arguments are the same size

```
y = arrayfun(fun, x, z,...)
```

in which case each output `y\_i = fun(x\_i,z\_i,...)`.

If the function returns multiple outputs, then `arrayfun` can be called with multiple outputs, in which case each output goes to a separate array output

```
[y1,y2,...] = arrayfun(fun, x, z, ...)
```

The assumption is that the output types for each call to `fun` is the same across the inputs.

Finally, some hints can be provided to `arrayfun` using the syntax

```
[y1,y2,...] = arrayfun(fun, x, z, ..., 'param', value, 'param', value)
```

where `param` and `value` take on the following possible values:

- `'UniformOutput'` - if the `value` is `true` then each output of `fun` must be a scalar, and the outputs are concatenated into an array the same size as the input arrays. If the `value` is `false` then the outputs are encapsulated into a cell array, with each entry in the cell array containing the call to `fun(x\_i,z\_i,...)`.
- `'ErrorHandler'` - in this case `value` is a function handle that gets called when `fun` throws an error. If `'ErrorHandler'` is not specified, then `arrayfun` allows the error to propogate (i.e., and exception is thrown).

14.2 ASSIGN Making assignments

14.2.1 Usage

FreeMat assignments take a number of different forms, depending on the type of the variable you want to make an assignment to. For numerical arrays and strings, the form of an assignment is either

```
a(ndx) = val
```

where `ndx` is a set of vector indexing coordinates. This means that the values `ndx` takes reference the elements of `a` in column order. So, if, for example `a` is an `N x M` matrix, the first column has vector indices `1,2,...,N`, and the second column has indices `N+1,N+2,...,2N`, and so on. Alternately, you can use multi-dimensional indexing to make an assignment:

```
a(ndx_1,ndx_2,..,ndx_m) = val
```

where each indexing expression `ndx\_i` corresponds to the `i-th` dimension of `a`. In both cases, (vector or multi-dimensional indexing), the right hand side `val` must either be a scalar, an empty matrix, or of the same size as the indices. If `val` is an empty matrix, the assignment acts like a delete. Note that the type of `a` may be modified by the assignment. So, for example, assigning a `double` value to an element of a `float` array `a` will cause the array `a` to become `double`.

For cell arrays, the above forms of assignment will still work, but only if `val` is also a cell array. If you want to assign the contents of a cell in a cell array, you must use one of the two following forms, either

```
a{ndx} = val
```

or

```
a{ndx_1,ndx_2,...,ndx_m} = val
```

which will modify the contents of the cell.

14.3 CELL Cell Array of Empty Matrices

14.3.1 Usage

Creates a cell array of empty matrix entres. Two seperate syntaxes are possible. The first syntax specifies the array dimensions as a sequence of scalar dimensions:

```
y = cell(d1,d2,...,dn).
```

The resulting array has the given dimensions, and is filled with all zeros. The type of `y` is `cell`, a cell array.

The second syntax specifies the array dimensions as a vector, where each element in the vector specifies a dimension length:

```
y = cell([d1,d2,...,dn]).
```

This syntax is more convenient for calling `zeros` using a variable for the argument. In both cases, specifying only one dimension results in a square matrix output.

14.3.2 Example

The following examples demonstrate generation of some zero arrays using the first form.

```
--> cell(2,3,2)

ans =

(:,:,1) =
 [] [] []
 [] [] []

(:,:,2) =
 [] [] []
 [] [] []
```

```
--> cell(1,3)

ans =
 [] [] []
```

The same expressions, using the second form.

```
--> cell([2,6])

ans =
 [] [] [] [] [] []
 [] [] [] [] [] []

--> cell([1,3])

ans =
 [] [] []
```

14.4 CELLFUN Appy a Function To Elements of a Cell Array

14.4.1 Usage

The `cellfun` function is used to apply a function handle (or anonymous function) to each element of a cell array and to collect the outputs into an array. The general syntax for its use is

```
y = cellfun(fun, x)
```

where `x` is an N-dimensional array. In this case, each element of the output `y\_i` is defined as `fun(x{i})`. You can also supply multiple arguments to `cellfun`, provided all of the arguments are the same size

```
y = cellfun(fun, x, z, ...)
```

in which case each output `y\_i` is defined as `fun(x{i},z{i},...)`. Note that unlike `arrayfun`, the `cellfun` function will allow for different types (if there are overloaded versions of the function `fun`) for each element.

If the function returns multiple outputs, then `arrayfun` can be called with multiple outputs, in which case each output goes to a separate array output

```
[y1,y2,...] = cellfun(fun, x, z, ...)
```

The assumption is that the output types for each call to `fun` is the same across the inputs.

Finally, some hints can be provided to `cellfun` using the syntax

```
[y1,y2,...] = cellfun(fun, x, z, ..., 'param', value, 'param', value)
```

where `param` and `value` take on the following possible values:

- `'UniformOutput'` - if the `value` is `true` then each output of `fun` must be a scalar, and the outputs are concatenated into an array the same size as the input arrays. If the `value` is `false` then the outputs are encapsulated into a cell array, with each entry in the cell array containing the call to `fun(x\_i,z\_i,...)`.

- `'ErrorHandler'` - in this case `value` is a function handle that gets called when `fun` throws an error. If `'ErrorHandler'` is not specified, then `arrayfun` allows the error to propogate (i.e., and exception is thrown).

14.5 CIRCSHIFT Circularly Shift an Array

14.5.1 USAGE

Applies a circular shift along each dimension of a given array. The syntax for its use is

```
y = circshift(x,shiftvec)
```

where `x` is an n-dimensional array, and `shiftvec` is a vector of integers, each of which specify how much to shift `x` along the corresponding dimension.

14.5.2 Example

The following examples show some uses of `circshift` on N-dimensional arrays.

```
--> x = int32(rand(4,5)*10)

x =
  4  8  3  2  9
  0  8  0  5  3
  9  1  5  8  2
  4  5 10  3  7

--> circshift(x,[1,0])

ans =
  4  5 10  3  7
  4  8  3  2  9
  0  8  0  5  3
  9  1  5  8  2

--> circshift(x,[0,-1])

ans =
  8  3  2  9  4
  8  0  5  3  0
  1  5  8  2  9
  5 10  3  7  4

--> circshift(x,[2,2])

ans =
  8  2  9  1  5
  3  7  4  5 10
  2  9  4  8  3
  5  3  0  8  0

--> x = int32(rand(4,5,3)*10)

x =

(:,:,1) =
  2  7  7  3 10
  2  2  3  7  0
  4  8  1  4  0
 10  2  7  8  9
```

```
(:,:,2) =
  5  7 10  9  4
  0  3  5  0  4
  4  5  1  3  6
  9  1  5  1  5

(:,:,3) =
  1  5  6  9  2
  8 10  6  5  7
  6  2  1  6  8
  1  9  6  5  3

--> circshift(x,[1,0,0])

ans =

(:,:,1) =
 10  2  7  8  9
  2  7  7  3 10
  2  2  3  7  0
  4  8  1  4  0

(:,:,2) =
  9  1  5  1  5
  5  7 10  9  4
  0  3  5  0  4
  4  5  1  3  6

(:,:,3) =
  1  9  6  5  3
  1  5  6  9  2
  8 10  6  5  7
  6  2  1  6  8

--> circshift(x,[0,-1,0])

ans =

(:,:,1) =
  7  7  3 10  2
  2  3  7  0  2
  8  1  4  0  4
  2  7  8  9 10

(:,:,2) =
  7 10  9  4  5
  3  5  0  4  0
  5  1  3  6  4
  1  5  1  5  9

(:,:,3) =
  5  6  9  2  1
 10  6  5  7  8
```

```
  2  1  6  8  6
  9  6  5  3  1

--> circshift(x,[0,0,-1])

ans =

(:,:,1) =
  5  7 10  9  4
  0  3  5  0  4
  4  5  1  3  6
  9  1  5  1  5

(:,:,2) =
  1  5  6  9  2
  8 10  6  5  7
  6  2  1  6  8
  1  9  6  5  3

(:,:,3) =
  2  7  7  3 10
  2  2  3  7  0
  4  8  1  4  0
 10  2  7  8  9

--> circshift(x,[2,-3,1])

ans =

(:,:,1) =
  6  8  6  2  1
  5  3  1  9  6
  9  2  1  5  6
  5  7  8 10  6

(:,:,2) =
  4  0  4  8  1
  8  9 10  2  7
  3 10  2  7  7
  7  0  2  2  3

(:,:,3) =
  3  6  4  5  1
  1  5  9  1  5
  9  4  5  7 10
  0  4  0  3  5
```

14.6 COND Condition Number of a Matrix

14.6.1 Usage

Calculates the condition number of a matrix. To compute the 2-norm condition number of a matrix (ratio of largest to smallest singular values), use the syntax

```
y = cond(A)
```

where A is a matrix. If you want to compute the condition number in a different norm (e.g., the 1-norm), use the second syntax

```
y = cond(A,p)
```

where `p` is the norm to use when computing the condition number. The following choices of `p` are supported

- `p = 1` returns the 1-norm, or the max column sum of A
- `p = 2` returns the 2-norm (largest singular value of A)
- `p = inf` returns the infinity norm, or the max row sum of A
- `p = 'fro'` returns the Frobenius-norm (vector Euclidean norm, or RMS value)

14.6.2 Function Internals

The condition number is defined as

$$\frac{\|A\|_p}{\|A^{-1}\|_p}$$

This equation is precisely how the condition number is computed for the case `p ~= 2`. For the `p=2` case, the condition number can be computed much more efficiently using the ratio of the largest and smallest singular values.

14.6.3 Example

The condition number of this matrix is large

```
--> A = [1,1;0,1e-15]

A =
    1.0000    1.0000
         0    0.0000

--> cond(A)

ans =
 2.0000e+15

--> cond(A,1)

ans =
 2000000000000002
```

You can also (for the case `p=1` use `rcond` to calculate an estimate of the condition number

```
--> 1/rcond(A)

ans =
 2.0000e+15
```

14.7 DET Determinant of a Matrix

14.7.1 Usage

Calculates the determinant of a matrix. Note that for all but very small problems, the determinant is not particularly useful. The condition number `cond` gives a more reasonable estimate as to the suitability of a matrix for inversion than comparing `det(A)` to zero. In any case, the syntax for its use is

```
y = det(A)
```

where A is a square matrix.

14.7.2 Function Internals

The determinant is calculated via the `LU` decomposition. Note that the determinant of a product of matrices is the product of the determinants. Then, we have that

$$LU = PA$$

where `L` is lower triangular with 1s on the main diagonal, `U` is upper triangular, and `P` is a row-permutation matrix. Taking the determinant of both sides yields

$$|LU| = |L||U| = |U| = |PA| = |P||A|$$

where we have used the fact that the determinant of `L` is 1. The determinant of `P` (which is a row exchange matrix) is either 1 or -1.

14.7.3 Example

Here we assemble a random matrix and compute its determinant

```
--> A = rand(5);
--> det(A)

ans =
   -0.0489
```

Then, we exchange two rows of `A` to demonstrate how the determinant changes sign (but the magnitude is the same)

```
--> B = A([2,1,3,4,5],:);
--> det(B)

ans =
    0.0489
```

14.8 DIAG Diagonal Matrix Construction/Extraction

14.8.1 Usage

The `diag` function is used to either construct a diagonal matrix from a vector, or return the diagonal elements of a matrix as a vector. The general syntax for its use is

```
y = diag(x,n)
```

If `x` is a matrix, then `y` returns the `n`-th diagonal. If `n` is omitted, it is assumed to be zero. Conversely, if `x` is a vector, then `y` is a matrix with `x` set to the `n`-th diagonal.

14.8.2 Examples

Here is an example of `diag` being used to extract a diagonal from a matrix.

```
--> A = int32(10*rand(4,5))

A =
  5  8  8  3  6
  4  8  4  3  7
  9  5  8  4  2
  1  0 10  0  4

--> diag(A)

ans =
 5
 8
 8
 0

--> diag(A,1)

ans =
 8
 4
 4
 4
```

Here is an example of the second form of `diag`, being used to construct a diagonal matrix.

```
--> x = int32(10*rand(1,3))

x =
 6 3 9

--> diag(x)

ans =
 6 0 0
 0 3 0
 0 0 9

--> diag(x,-1)

ans =
 0 0 0 0
 6 0 0 0
 0 3 0 0
 0 0 9 0
```

14.9 EXPM Matrix Exponential

14.9.1 Usage

Calculates `e\^A` for a square, full rank matrix `A`. The syntax for its use is

```
y = expm(A)
```

Internally, `expm` is mapped to a simple `e\^A` expression (which in turn uses the eigenvalue expansion of `A` to compute the exponential).

14.9.2 Example

An example of `expm`

```
--> A = [1 1 0; 0 0 2; 0 0 -1]

A =
  1  1  0
  0  0  2
  0  0 -1

--> expm(A)

ans =
    2.7183    1.7183    1.0862
         0    1.0000    1.2642
         0         0    0.3679
```

14.10 EYE Identity Matrix

14.10.1 USAGE

Creates an identity matrix of the specified size. The syntax for its use is

```
y = eye(n)
```

where `n` is the size of the identity matrix. The type of the output matrix is `float`.

14.10.2 Example

The following example demonstrates the identity matrix.

```
--> eye(3)

ans =
 1 0 0
 0 1 0
 0 0 1
```

14.11 FIND Find Non-zero Elements of An Array

14.11.1 Usage

Returns a vector that contains the indicies of all non-zero elements in an array. The usage is

```
y = find(x)
```

The indices returned are generalized column indices, meaning that if the array `x` is of size `[d1,d2,...,dn]`, and the element `x(i1,i2,...,in)` is nonzero, then `y` will contain the integer

$$i_1 + (i_2 - 1)d_1 + (i_3 - 1)d_1 d_2 + \ldots$$

The second syntax for the `find` command is

```
[r,c] = find(x)
```

which returns the row and column index of the nonzero entries of `x`. The third syntax for the `find` command also returns the values

```
[r,c,v] = find(x).
```

Note that if the argument is a row vector, then the returned vectors are also row vectors. This form is particularly useful for converting sparse matrices into IJV form.

The `find` command also supports some additional arguments. Each of the above forms can be combined with an integer indicating how many results to return:

```
y = find(x,k)
```

where `k` is the maximum number of results to return. This form will return the first `k` results. You can also specify an optional flag indicating whether to take the first or last `k` values:

```
y = find(x,k,'first')
y = find(x,k,'last')
```

in the case of the `'last'` argument, the last `k` values are returned.

14.11.2 Example

Some simple examples of its usage, and some common uses of `find` in FreeMat programs.

```
--> a = [1,2,5,2,4];
--> find(a==2)

ans =
 2 4
```

Here is an example of using find to replace elements of `A` that are `0` with the number `5`.

```
--> A = [1,0,3;0,2,1;3,0,0]

A =
 1 0 3
 0 2 1
 3 0 0

--> n = find(A==0)

n =
 2
 4
 6
 9

--> A(n) = 5

A =
 1 5 3
 5 2 1
 3 5 5
```

Incidentally, a better way to achieve the same concept is:

```
--> A = [1,0,3;0,2,1;3,0,0]

A =
 1 0 3
 0 2 1
 3 0 0

--> A(A==0) = 5

A =
 1 5 3
 5 2 1
 3 5 5
```

Now, we can also return the indices as row and column indices using the two argument form of `find`:

```
--> A = [1,0,3;0,2,1;3,0,0]

A =
 1 0 3
 0 2 1
 3 0 0

--> [r,c] = find(A)
r =
 1
 3
 2
 1
 2

c =
 1
 1
 2
 3
 3
```

Or the three argument form of `find`, which returns the value also:

```
--> [r,c,v] = find(A)
r =
 1
 3
 2
 1
 2

c =
 1
 1
 2
 3
 3

v =
```

```
 1
 3
 2
 3
 1
```

14.12 FLIPDIM Reverse a Matrix Along a Given Dimension

14.12.1 USAGE

Reverses an array along the given dimension. The syntax for its use is

```
   y = flipdim(x,n)
```

where `x` is matrix, and `n` is the dimension to reverse.

14.12.2 Example

The following examples show some uses of `flipdim` on N-dimensional arrays.

```
--> x = int32(rand(4,5,3)*10)

x =

(:,:,1) =
  5  2  4  2  8
  7  6  6  6  7
  7  0  1  1  0
  3  2  1  9  9

(:,:,2) =
 10  6  3  3  1
  1  2  5  7 10
  9  7  5  1  4
  3 10  4  4  3

(:,:,3) =
  3  6  5  8  9
  9  8  5  3  0
  1  7  9  4  8
  4  6  4  9  5

--> flipdim(x,1)

ans =

(:,:,1) =
  3  2  1  9  9
  7  0  1  1  0
  7  6  6  6  7
  5  2  4  2  8

(:,:,2) =
  3 10  4  4  3
  9  7  5  1  4
```

```
  1  2  5  7 10
 10  6  3  3  1

(:,:,3) =
  4  6  4  9  5
  1  7  9  4  8
  9  8  5  3  0
  3  6  5  8  9

--> flipdim(x,2)

ans =

(:,:,1) =
  8  2  4  2  5
  7  6  6  6  7
  0  1  1  0  7
  9  9  1  2  3

(:,:,2) =
  1  3  3  6 10
 10  7  5  2  1
  4  1  5  7  9
  3  4  4 10  3

(:,:,3) =
  9  8  5  6  3
  0  3  5  8  9
  8  4  9  7  1
  5  9  4  6  4

--> flipdim(x,3)

ans =

(:,:,1) =
  3  6  5  8  9
  9  8  5  3  0
  1  7  9  4  8
  4  6  4  9  5

(:,:,2) =
 10  6  3  3  1
  1  2  5  7 10
  9  7  5  1  4
  3 10  4  4  3

(:,:,3) =
  5  2  4  2  8
  7  6  6  6  7
  7  0  1  1  0
  3  2  1  9  9
```

14.13 FLIPLR Reverse the Columns of a Matrix

14.13.1 USAGE

Reverses the columns of a matrix. The syntax for its use is

```
y = fliplr(x)
```

where `x` is matrix. If `x` is an N-dimensional array then the second dimension is reversed.

14.13.2 Example

The following example shows `fliplr` applied to a 2D matrix.

```
--> x = int32(rand(4)*10)

x =
  6  4  7  4
  8  5  4  1
  5  8  7  9
  1 10  9  9

--> fliplr(x)

ans =
  4  7  4  6
  1  4  5  8
  9  7  8  5
  9  9 10  1
```

For a 3D array, note how the columns in each slice are flipped.

```
--> x = int32(rand(4,4,3)*10)

x =

(:,:,1) =
  4  8  1  8
  1  5  5  2
  2 10  5  8
  4  8  2  1

(:,:,2) =
  0  3  4  1
  6  6 10  8
  4  3  3  6
  2  9  7  3

(:,:,3) =
  6  5  1  1
  6  8 10  3
  4  3  7  9
  9  4  4  3

--> fliplr(x)

ans =
```

```
(:,:,1) =
  8  1  8  4
  2  5  5  1
  8  5 10  2
  1  2  8  4

(:,:,2) =
  1  4  3  0
  8 10  6  6
  6  3  3  4
  3  7  9  2

(:,:,3) =
  1  1  5  6
  3 10  8  6
  9  7  3  4
  3  4  4  9
```

14.14 FLIPUD Reverse the Columns of a Matrix

14.14.1 USAGE

Reverses the rows of a matrix. The syntax for its use is

```
y = flipud(x)
```

where `x` is matrix. If `x` is an N-dimensional array then the first dimension is reversed.

14.14.2 Example

The following example shows `flipud` applied to a 2D matrix.

```
--> x = int32(rand(4)*10)

x =
 9 4 5 3
 8 9 7 4
 4 8 6 3
 6 7 0 9

--> flipud(x)

ans =
 6 7 0 9
 4 8 6 3
 8 9 7 4
 9 4 5 3
```

For a 3D array, note how the rows in each slice are flipped.

```
--> x = int32(rand(4,4,3)*10)

x =

(:,:,1) =
```

```
  7  4  3  3
  0 10 10  6
  2  8  1  8
  1  1  9  8

(:,:,2) =
  4  4  3  2
  4  4  7  1
  4  9  9  8
  5  5  1  6

(:,:,3) =
  9  7  7  5
  8  9  5  6
  5 10  6  8
  4  2  8  3

--> flipud(x)

ans =

(:,:,1) =
  1  1  9  8
  2  8  1  8
  0 10 10  6
  7  4  3  3

(:,:,2) =
  5  5  1  6
  4  9  9  8
  4  4  7  1
  4  4  3  2

(:,:,3) =
  4  2  8  3
  5 10  6  8
  8  9  5  6
  9  7  7  5
```

14.15 IPERMUTE Array Inverse Permutation Function

14.15.1 Usage

The `ipermute` function rearranges the contents of an array according to the inverse of the specified permutation vector. The syntax for its use is

```
y = ipermute(x,p)
```

where `p` is a permutation vector - i.e., a vector containing the integers `1...ndims(x)` each occuring exactly once. The resulting array `y` contains the same data as the array `x`, but ordered according to the inverse of the given permutation. This function and the `permute` function are inverses of each other.

14.15.2 Example

First we create a large multi-dimensional array, then permute it and then inverse permute it, to retrieve the original array:

```
--> A = randn(13,5,7,2);
--> size(A)

ans =
 13  5  7  2

--> B = permute(A,[3,4,2,1]);
--> size(B)

ans =
  7  2  5 13

--> C = ipermute(B,[3,4,2,1]);
--> size(C)

ans =
 13  5  7  2

--> any(A~=C)

ans =

(:,:,1,1) =
 0 0 0 0 0

(:,:,2,1) =
 0 0 0 0 0

(:,:,3,1) =
 0 0 0 0 0

(:,:,4,1) =
 0 0 0 0 0

(:,:,5,1) =
 0 0 0 0 0

(:,:,6,1) =
 0 0 0 0 0

(:,:,7,1) =
 0 0 0 0 0

(:,:,1,2) =
 0 0 0 0 0

(:,:,2,2) =
 0 0 0 0 0

(:,:,3,2) =
```

```
 0 0 0 0 0

(:,:,4,2) =
 0 0 0 0 0

(:,:,5,2) =
 0 0 0 0 0

(:,:,6,2) =
 0 0 0 0 0

(:,:,7,2) =
 0 0 0 0 0
```

14.16 ISFLOAT Test for Floating Point Array

14.16.1 Usage

The syntax for `isfloat` is

```
x = isfloat(y)
```

and it returns a logical 1 if the argument is a floating point array (i.e., a `single` or `double`), and a logical 0 otherwise.

14.17 ISINTEGER Test for Integer Array

14.17.1 Usage

The syntax for `isinteger` is

```
x = isinteger(y)
```

and it returns a logical 1 if the argument is an integer. The decision of whether the argument is an integer or not is made based on the class of `y`, not on its value.

14.18 LINSPACE Linearly Spaced Vector

14.18.1 Usage

Generates a row vector with the specified number of elements, with entries uniformly spaced between two specified endpoints. The syntax for its use is either

```
y = linspace(a,b,count)
```

or, for a default `count = 100`,

```
y = linspace(a,b);
```

14.18.2 Examples

Here is a simple example of using `linspace`

```
--> x = linspace(0,1,5)

x =
         0    0.2500    0.5000    0.7500    1.0000
```

14.19 LOGSPACE Logarithmically Spaced Vector

14.19.1 Usage

Generates a row vector with the specified number number of elements, with entries logarithmically spaced between two specified endpoints. The syntax for its use is either

```
y = logspace(a,b,count)
```

or, for a default `count = 50`,

```
y = logspace(a,b)
```

A third special use is when

```
y = logspace(a,pi)
```

where it generates points between `10\^a` and `pi`

Contributed by Paulo Xavier Candeias under GPL.

14.19.2 Example

Here is an example of the use of `logspace`

```
--> logspace(1,2,3)

ans =
   10.0000   31.6228  100.0000
```

14.20 MESHGRID Generate Grid Mesh For Plots

14.20.1 Usage

The `meshgrid` function generates arrays that can be used for the generation of surface plots. The syntax is one of

```
[X,Y] = meshgrid(x)
[X,Y] = meshgrid(x,y)
[X,Y,Z] = meshgrid(x,y,z)
```

where `x,y,z` are vectors, and `X,Y,Z` are matrices. In the first case `[X,Y] = meshgrid(x)`, the rows of `X` and the columns of `Y` contain copies of the vector `x`. In the second case `[X,Y] = meshgrid(x,y)`, the rows of `X` contain copies of `x`, and the columns of `Y` contain copies of `y`. In the third case, each input is copied along the row, column or slice direction of the corresponding output variable.

14.20.2 Example

In the first example:

```
--> [X,Y] = meshgrid(-2:.4:2)
X =
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
```

```
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000
   -2.0000   -1.6000   -1.2000   -0.8000   -0.4000    0.0000    0.4000    0.8000    1.2000    1.6000

Y =
   -2.0000   -2.0000   -2.0000   -2.0000   -2.0000   -2.0000   -2.0000   -2.0000   -2.0000   -2.0000
   -1.6000   -1.6000   -1.6000   -1.6000   -1.6000   -1.6000   -1.6000   -1.6000   -1.6000   -1.6000
   -1.2000   -1.2000   -1.2000   -1.2000   -1.2000   -1.2000   -1.2000   -1.2000   -1.2000   -1.2000
   -0.8000   -0.8000   -0.8000   -0.8000   -0.8000   -0.8000   -0.8000   -0.8000   -0.8000   -0.8000
   -0.4000   -0.4000   -0.4000   -0.4000   -0.4000   -0.4000   -0.4000   -0.4000   -0.4000   -0.4000
    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000
    0.4000    0.4000    0.4000    0.4000    0.4000    0.4000    0.4000    0.4000    0.4000    0.4000
    0.8000    0.8000    0.8000    0.8000    0.8000    0.8000    0.8000    0.8000    0.8000    0.8000
    1.2000    1.2000    1.2000    1.2000    1.2000    1.2000    1.2000    1.2000    1.2000    1.2000
    1.6000    1.6000    1.6000    1.6000    1.6000    1.6000    1.6000    1.6000    1.6000    1.6000
    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000
```

Next, we use different vectors for `X` and for `Y`:

```
--> [X,Y] = meshgrid([1,2,3,4],[6,7,8])
X =
 1 2 3 4
 1 2 3 4
 1 2 3 4

Y =
 6 6 6 6
 7 7 7 7
 8 8 8 8
```

14.21 NAN Not-a-Number Constant

14.21.1 Usage

Returns a value that represents "not-a-number" for both 32 and 64-bit floating point values. This constant is meant to represent the result of arithmetic operations whose output cannot be meaningfully defined (like zero divided by zero). There are several forms for the `NaN` function. The first form returns a double precision `NaN`.

```
y = nan
```

The next form takes a class name that can be either `'double'`

```
y = nan('double')
```

or `'single'`:

```
y = nan('single')
```

With a single parameter it generates a square matrix of `nan`s.

```
y = nan(n)
```

Alternatively, you can specify the dimensions of the array via

```
y = nan(m,n,p,...)
```

or

```
y = nan([m,n,p,...])
```

Finally, you can add a classname of either `'single'` or `'double'`.

14.21.2 Example

The following examples demonstrate a few calculations with the not-a-number constant.

```
--> nan*0

ans =
 NaN

--> nan-nan

ans =
 NaN
```

Note that `NaN`s are preserved under type conversion to floating point types (i.e., `float`, `double`, `complex` and `dcomplex` types), but not integer types.

```
--> uint32(nan)

ans =
 0

--> complex(nan)

ans =
 NaN
```

14.22 NDGRID Generate N-Dimensional Grid

14.22.1 Usage

Generates N-dimensional grids, each of which is constant in all but one dimension. The syntax for its use is either

```
[y1, y2, ..., ym] = ndgrid(x1, x2, ..., xn)
```

where `m <= n` or

```
[y1, y2, ..., ym] = ndgrid(x1)
```

which is equivalent to the first form, with `x1=x2=...=xn`. Each output `yi` is an `n`-dimensional array, with values such that

$$y_i(d_1, \ldots, d_{i-1}, d_i, d_{i+1}, \ldots, d_m) = x_i(d_i)$$

`ndgrid` is useful for evaluating multivariate functionals over a range of arguments. It is a generalization of `meshgrid`, except that `meshgrid` transposes the dimensions corresponding to the first two arguments to better fit graphical applications.

14.22.2 Example

Here is a simple `ndgrid` example

```
--> [a,b] = ndgrid(1:2,3:5)
a =
 1 1 1
 2 2 2

b =
```

```
 3 4 5
 3 4 5

--> [a,b,c] = ndgrid(1:2,3:5,0:1)
a =

(:,:,1) =
 1 1 1
 2 2 2

(:,:,2) =
 1 1 1
 2 2 2

b =

(:,:,1) =
 3 4 5
 3 4 5

(:,:,2) =
 3 4 5
 3 4 5

c =

(:,:,1) =
 0 0 0
 0 0 0

(:,:,2) =
 1 1 1
 1 1 1
```

Here we use the second form

```
--> [a,b,c] = ndgrid(1:3)
a =

(:,:,1) =
 1 1 1
 2 2 2
 3 3 3

(:,:,2) =
 1 1 1
 2 2 2
 3 3 3

(:,:,3) =
 1 1 1
 2 2 2
 3 3 3

b =
```

```
(:,:,1) =
 1 2 3
 1 2 3
 1 2 3

(:,:,2) =
 1 2 3
 1 2 3
 1 2 3

(:,:,3) =
 1 2 3
 1 2 3
 1 2 3

c =

(:,:,1) =
 1 1 1
 1 1 1
 1 1 1

(:,:,2) =
 2 2 2
 2 2 2
 2 2 2

(:,:,3) =
 3 3 3
 3 3 3
 3 3 3
```

14.23 NONZEROS Retrieve Nonzero Matrix Entries

14.23.1 USAGE

Returns a dense column vector containing the nonzero elements of the argument matrix. The syntax for its use is

```
y = nonzeros(x)
```

where `x` is the argument array. The argument matrix may be sparse as well as dense.

14.23.2 Example

Here is an example of using `nonzeros` on a sparse matrix.

```
--> a = rand(8); a(a>0.2) = 0;
--> A = sparse(a)

A =
 1 1 0.0596135
 7 1 0.0283717
 8 1 0.0337801
```

```
 5 2 0.0700267
 1 4 0.0881058
 4 4 0.00699947
 5 4 0.0494723
 8 5 0.0420057
 4 6 0.153486
 7 6 0.0654851
 1 7 0.174397
 4 7 0.0684673
 2 8 0.13853
--> nonzeros(A)

ans =
    0.0596
    0.0284
    0.0338
    0.0700
    0.0881
    0.0070
    0.0495
    0.0420
    0.1535
    0.0655
    0.1744
    0.0685
    0.1385
```

14.24 NORM Norm Calculation

14.24.1 Usage

Calculates the norm of a matrix. There are two ways to use the `norm` function. The general syntax is

```
y = norm(A,p)
```

where `A` is the matrix to analyze, and `p` is the type norm to compute. The following choices of `p` are supported

- `p = 1` returns the 1-norm, or the max column sum of A
- `p = 2` returns the 2-norm (largest singular value of A)
- `p = inf` returns the infinity norm, or the max row sum of A
- `p = 'fro'` returns the Frobenius-norm (vector Euclidean norm, or RMS value)

For a vector, the regular norm calculations are performed:

- `1 <= p < inf` returns `sum(abs(A).\^p)\^(1/p)`
- `p` unspecified returns `norm(A,2)`
- `p = inf` returns max(abs(A))
- `p = -inf` returns min(abs(A))

14.24.2 Examples

Here are the various norms calculated for a sample matrix

```
--> A = float(rand(3,4))

A =
    0.8462    0.9465    0.6874    0.8668
    0.1218    0.9206    0.5877    0.5837
    0.7081    0.6608    0.2035    0.5083

--> norm(A,1)

ans =
    2.5280

--> norm(A,2)

ans =
    2.2997

--> norm(A,inf)

ans =
    3.3470

--> norm(A,'fro')

ans =
    2.3712
```

Next, we calculate some vector norms.

```
--> A = float(rand(4,1))

A =
    0.3458
    0.1427
    0.3998
    0.7194

--> norm(A,1)

ans =
    1.6078

--> norm(A,2)

ans =
    0.9041

--> norm(A,7)

ans =
    0.7217
```

```
--> norm(A,inf)

ans =
    0.7194

--> norm(A,-inf)

ans =
    0.1427
```

14.25 NUM2STR Convert Numbers To Strings

14.25.1 Usage

Converts an array into its string representation. The general syntax for this function is

```
s = num2str(X)
```

where `s` is a string (or string matrix) and `X` is an array. By default, the `num2str` function uses 4 digits of precision and an exponent if required. If you want more digits of precision, you can specify the precition via the form

```
s = num2str(X, precision)
```

where `precision` is the number of digits to include in the string representation. For more control over the format of the output, you can also specify a format specifier (see `printf` for more details).

```
s = num2str(X, format)
```

where `format` is the specifier string.

14.26 ONES Array of Ones

14.26.1 Usage

Creates an array of ones of the specified size. Two seperate syntaxes are possible. The first syntax specifies the array dimensions as a sequence of scalar dimensions:

```
y = ones(d1,d2,...,dn).
```

The resulting array has the given dimensions, and is filled with all ones. The type of `y` is `float`, a 32-bit floating point array. To get arrays of other types, use the typecast functions (e.g., `uint8`, `int8`, etc.).

The second syntax specifies the array dimensions as a vector, where each element in the vector specifies a dimension length:

```
y = ones([d1,d2,...,dn]).
```

This syntax is more convenient for calling `ones` using a variable for the argument. In both cases, specifying only one dimension results in a square matrix output.

14.26.2 Example

The following examples demonstrate generation of some arrays of ones using the first form.

```
--> ones(2,3,2)

ans =
```

```
(:,:,1) =
 1 1 1
 1 1 1

(:,:,2) =
 1 1 1
 1 1 1

--> ones(1,3)

ans =
 1 1 1
```

The same expressions, using the second form.

```
--> ones([2,6])

ans =
 1 1 1 1 1 1
 1 1 1 1 1 1

--> ones([1,3])

ans =
 1 1 1
```

Finally, an example of using the type casting function `uint16` to generate an array of 16-bit unsigned integers with a value of 1.

```
--> uint16(ones(3))

ans =
 1 1 1
 1 1 1
 1 1 1
```

14.27 PERMUTE Array Permutation Function

14.27.1 Usage

The `permute` function rearranges the contents of an array according to the specified permutation vector. The syntax for its use is

```
y = permute(x,p)
```

where `p` is a permutation vector - i.e., a vector containing the integers `1...ndims(x)` each occuring exactly once. The resulting array `y` contains the same data as the array `x`, but ordered according to the permutation. This function is a generalization of the matrix transpose operation.

14.27.2 Example

Here we use `permute` to transpose a simple matrix (note that permute also works for sparse matrices):

```
--> A = [1,2;4,5]

A =
```

```
 1 2
 4 5

--> permute(A,[2,1])

ans =
 1 4
 2 5

--> A'

ans =
 1 4
 2 5
```

Now we permute a larger n-dimensional array:

```
--> A = randn(13,5,7,2);
--> size(A)

ans =
 13  5  7  2

--> B = permute(A,[3,4,2,1]);
--> size(B)

ans =
  7  2  5 13
```

14.28 PINV Moore-Penrose Pseudoinverse

14.28.1 Usage

Calculates the Moore-Penrose pseudoinverse of a matrix. The general syntax for its use is

```
y = pinv(A,tol)
```

or for a default specification of the tolerance `tol`,

```
y = pinv(A)
```

For any `m x n` matrix `A`, the Moore-Penrose pseudoinverse is the unique `n x m` matrix `B` that satisfies the following four conditions

- `A B A = A`
- `B A B = B`
- `(A B)' = A B`
- `(B A)' = B A`

Also, it is true that `B y` is the minimum norm, least squares solution to `A x = y`. The Moore-Penrose pseudoinverse is computed from the singular value decomposition of `A`, with singular values smaller than `tol` being treated as zeros. If `tol` is not specified then it is chosen as

```
tol = max(size(A)) * norm(A) * teps(A).
```

14.28.2 Function Internals

The calculation of the MP pseudo-inverse is almost trivial once the svd of the matrix is available. First, for a real, diagonal matrix with positive entries, the pseudo-inverse is simply

$$\left(\Sigma^{+}\right)_{ii} = \begin{cases} 1/\sigma_{ii} & \sigma_{ii} > 0 \\ 0 & \text{else} \end{cases}$$

One can quickly verify that this choice of matrix satisfies the four properties of the pseudoinverse. Then, the pseudoinverse of a general matrix `A = U S V'` is defined as

$$A^{+} = VS^{+}U'$$

and again, using the facts that `U' U = I` and `V V' = I`, one can quickly verify that this choice of pseudoinverse satisfies the four defining properties of the MP pseudoinverse. Note that in practice, the diagonal pseudoinverse `S\^{+}` is computed with a threshold (the `tol` argument to `pinv`) so that singular values smaller than `tol` are treated like zeros.

14.28.3 Examples

Consider a simple `1 x 2` matrix example, and note the various Moore-Penrose conditions:

```
--> A = float(rand(1,2))

A =
    0.4840    0.0187

--> B = pinv(A)

B =
    2.0630
    0.0796

--> A*B*A

ans =
    0.4840    0.0187

--> B*A*B

ans =
    2.0630
    0.0796

--> A*B

ans =
    1.0000

--> B*A

ans =
    0.9985    0.0385
    0.0385    0.0015
```

To demonstrate that `pinv` returns the least squares solution, consider the following very simple case

```
--> A = float([1;1;1;1])

A =
 1
 1
 1
 1
```

The least squares solution to `A x = b` is just `x = mean(b)`, and computing the `pinv` of `A` demonstrates this

```
--> pinv(A)

ans =
    0.2500    0.2500    0.2500    0.2500
```

Similarly, we can demonstrate the minimum norm solution with the following simple case

```
--> A = float([1,1])

A =
 1 1
```

The solutions of `A x = 5` are those `x\_1` and `x\_2` such that `x\_1 + x\_2 = 5`. The norm of `x` is `x\_1\^ + x\_2\^2`, which is `x\_1\^2 + (5-x\_1)\^2`, which is minimized for `x\_1 = x\_2 = 2.5`:

```
--> pinv(A) * 5.0

ans =
    2.5000
    2.5000
```

14.29 RANK Calculate the Rank of a Matrix

14.29.1 Usage

Returns the rank of a matrix. There are two ways to use the `rank` function is

```
y = rank(A,tol)
```

where `tol` is the tolerance to use when computing the rank. The second form is

```
y = rank(A)
```

in which case the tolerance `tol` is chosen as

```
tol = max(size(A))*max(s)*eps,
```

where `s` is the vector of singular values of `A`. The rank is computed using the singular value decomposition `svd`.

14.29.2 Examples

Some examples of matrix rank calculations

```
--> rank([1,3,2;4,5,6])

ans =
 2
```

```
--> rank([1,2,3;2,4,6])

ans =
 1
```

Here we construct an ill-conditioned matrix, and show the use of the `tol` argument.

```
--> A = [1,0;0,eps/2]

A =
    1.0000         0
         0    0.0000

--> rank(A)

ans =
 1

--> rank(A,eps/8)

ans =
 2
```

14.30 RCOND Reciprocal Condition Number Estimate

14.30.1 Usage

The `rcond` function is a FreeMat wrapper around LAPACKs function `XGECON`, which estimates the 1-norm condition number (reciprocal). For the details of the algorithm see the LAPACK documentation. The syntax for its use is

```
   x = rcond(A)
```

where `A` is a matrix.

14.30.2 Example

Here is the reciprocal condition number for a random square matrix

```
--> A = rand(30);
--> rcond(A)

ans =
 4.4279e-04
```

And here we calculate the same value using the definition of (reciprocal) condition number

```
--> 1/(norm(A,1)*norm(inv(A),1))

ans =
 4.3595e-04
```

Note that the values are very similar. LAPACKs `rcond` function is far more efficient than the explicit calculation (which is also used by the `cond` function.

14.31 REPMAT Array Replication Function

14.31.1 Usage

The `repmat` function replicates an array the specified number of times. The source and destination arrays may be multidimensional. There are three distinct syntaxes for the `repmap` function. The first form:

```
y = repmat(x,n)
```

replicates the array `x` on an `n-times-n` tiling, to create a matrix `y` that has `n` times as many rows and columns as `x`. The output `y` will match `x` in all remaining dimensions. The second form is

```
y = repmat(x,m,n)
```

And creates a tiling of `x` with `m` copies of `x` in the row direction, and `n` copies of `x` in the column direction. The final form is the most general

```
y = repmat(x,[m n p...])
```

where the supplied vector indicates the replication factor in each dimension.

14.31.2 Example

Here is an example of using the `repmat` function to replicate a row 5 times. Note that the same effect can be accomplished (although somewhat less efficiently) by a multiplication.

```
--> x = [1 2 3 4]

x =
 1 2 3 4

--> y = repmat(x,[5,1])

y =
 1 2 3 4
 1 2 3 4
 1 2 3 4
 1 2 3 4
 1 2 3 4
```

The `repmat` function can also be used to create a matrix of scalars or to provide replication in arbitrary dimensions. Here we use it to replicate a 2D matrix into a 3D volume.

```
--> x = [1 2;3 4]

x =
 1 2
 3 4

--> y = repmat(x,[1,1,3])

y =

(:,:,1) =
 1 2
 3 4

(:,:,2) =
```

```
 1 2
 3 4

(:,:,3) =
 1 2
 3 4
```

14.32 RESHAPE Reshape An Array

14.32.1 Usage

Reshapes an array from one size to another. Two seperate syntaxes are possible. The first syntax specifies the array dimensions as a sequence of scalar dimensions:

```
y = reshape(x,d1,d2,...,dn).
```

The resulting array has the given dimensions, and is filled with the contents of `x`. The type of `y` is the same as `x`. The second syntax specifies the array dimensions as a vector, where each element in the vector specifies a dimension length:

```
y = reshape(x,[d1,d2,...,dn]).
```

This syntax is more convenient for calling `reshape` using a variable for the argument. The `reshape` function requires that the length of `x` equal the product of the `di` values. Note that arrays are stored in column format, which means that elements in `x` are transferred to the new array `y` starting with the first column first element, then proceeding to the last element of the first column, then the first element of the second column, etc.

14.32.2 Example

Here are several examples of the use of `reshape` applied to various arrays. The first example reshapes a row vector into a matrix.

```
--> a = uint8(1:6)

a =
 1 2 3 4 5 6

--> reshape(a,2,3)

ans =
 1 3 5
 2 4 6
```

The second example reshapes a longer row vector into a volume with two planes.

```
--> a = uint8(1:12)

a =
  1  2  3  4  5  6  7  8  9 10 11 12

--> reshape(a,[2,3,2])

ans =

(:,:,1) =
```

```
  1  3  5
  2  4  6

(:,:,2) =
  7  9 11
  8 10 12
```

The third example reshapes a matrix into another matrix.

```
--> a = [1,6,7;3,4,2]

a =
 1 6 7
 3 4 2

--> reshape(a,3,2)

ans =
 1 4
 3 7
 6 2
```

14.33 RREF Reduced Row Echelon Form of a Matrix

14.33.1 Usage

Calculates the reduced row echelon form of a matrix using Gauss Jordan elimination with partial pivoting. The generic syntax for `rref` is

```
R = rref(A)
```

A default tolerance of `max(size(A))*eps*norm(A,inf)` is used to detect negligible column elements. The second form of `rref` returns a vector `k` as well as `R`

```
[R,k] = rref(A)
```

where `k` is a vector that correponds to the columns of `A` used as pivot columns. If you want to control the tolerance used to identify negligible elements, you can use the form

```
[R,k] = rref(A, tolerance)
```

This implementation of `rref` is based on the one from the matcompat lib for octave. It is copyright Paul Kienzle, and distributed under the GNU GPL.

14.34 SHIFTDIM Shift Array Dimensions Function

14.34.1 Usage

The `shiftdim` function is used to shift the dimensions of an array. The general syntax for the `shiftdim` function is

```
y = shiftdim(x,n)
```

where `x` is a multidimensional array, and `n` is an integer. If `n` is a positive integer, then `shiftdim` circularly shifts the dimensions of `x` to the left, wrapping the dimensions around as necessary. If `n` is a negative integer, then `shiftdim` shifts the dimensions of `x` to the right, introducing singleton dimensions as necessary. In its second form:

```
  [y,n] = shiftdim(x)
```

the `shiftdim` function will shift away (to the left) the leading singleton dimensions of `x` until the leading dimension is not a singleton dimension (recall that a singleton dimension `p` is one for which `size(x,p) == 1`).

14.34.2 Example

Here are some simple examples of using `shiftdim` to remove the singleton dimensions of an array, and then restore them:

```
--> x = uint8(10*randn(1,1,1,3,2));
--> [y,n] = shiftdim(x);
--> n

ans =
 3

--> size(y)

ans =
 3 2

--> c = shiftdim(y,-n);
--> size(c)

ans =
 1 1 1 3 2

--> any(c~=x)

ans =

(:,:,1,1,1) =
 0

(:,:,1,1,2) =
 0
```

Note that these operations (where shifting involves only singleton dimensions) do not actually cause data to be resorted, only the size of the arrays change. This is not true for the following example, which triggers a call to `permute`:

```
--> z = shiftdim(x,4);
```

Note that `z` is now the transpose of `x`

```
--> squeeze(x)

ans =
 11  1
  0  0
  0  8

--> squeeze(z)

ans =
 11  0  0
  1  0  8
```

14.35 SORT Sort

14.35.1 Usage

Sorts an n-dimensional array along the specified dimensional. The first form sorts the array along the first non-singular dimension.

```
B = sort(A)
```

Alternately, the dimension along which to sort can be explicitly specified

```
B = sort(A,dim)
```

FreeMat does not support vector arguments for `dim` - if you need `A` to be sorted along multiple dimensions (i.e., row first, then columns), make multiple calls to `sort`. Also, the direction of the sort can be specified using the `mode` argument

```
B = sort(A,dim,mode)
```

where `mode = 'ascend'` means to sort the data in ascending order (the default), and `mode = 'descend'` means to sort the data into descending order.

When two outputs are requested from `sort`, the indexes are also returned. Thus, for

```
[B,IX] = sort(A)
[B,IX] = sort(A,dim)
[B,IX] = sort(A,dim,mode)
```

an array `IX` of the same size as `A`, where `IX` records the indices of `A` (along the sorting dimension) corresponding to the output array `B`.

Two additional issues worth noting. First, a cell array can be sorted if each cell contains a `string`, in which case the strings are sorted by lexical order. The second issue is that FreeMat uses the same method as MATLAB to sort complex numbers. In particular, a complex number `a` is less than another complex number `b` if `abs(a) < abs(b)`. If the magnitudes are the same then we test the angle of `a`, i.e. `angle(a) < angle(b)`, where `angle(a)` is the phase of `a` between `-pi,pi`.

14.35.2 Example

Here are some examples of sorting on numerical arrays.

```
--> A = int32(10*rand(4,3))

A =
 8 2 8
 0 5 5
 2 5 7
 3 7 1

--> [B,IX] = sort(A)
B =
 0 2 1
 2 5 5
 3 5 7
 8 7 8

IX =
 2 1 4
 3 2 2
 4 3 3
```

```
 1 4 1

--> [B,IX] = sort(A,2)
B =
 2 8 8
 0 5 5
 2 5 7
 1 3 7

IX =
 2 1 3
 1 2 3
 1 2 3
 3 1 2

--> [B,IX] = sort(A,1,'descend')
B =
 8 7 8
 3 5 7
 2 5 5
 0 2 1

IX =
 1 4 1
 4 2 3
 3 3 2
 2 1 4
```

Here we sort a cell array of strings.

```
--> a = {'hello','abba','goodbye','jockey','cake'}

a =
 [hello] [abba] [goodbye] [jockey] [cake]

--> b = sort(a)

b =
 [abba] [cake] [goodbye] [hello] [jockey]
```

14.36 SQUEEZE Remove Singleton Dimensions of an Array

14.36.1 Usage

This function removes the singleton dimensions of an array. The syntax for its use is

```
y = squeeze(x)
```

where `x` is a multidimensional array. Generally speaking, if `x` is of size `d1 x 1 x d2 x ...`, then `squeeze(x)` is of size `d1 x d2 x ...`, i.e., each dimension of `x` that was singular (size 1) is squeezed out.

14.36.2 Example

Here is a many dimensioned, ungainly array, both before and after squeezing;

```
--> x = zeros(1,4,3,1,1,2);
--> size(x)

ans =
 1 4 3 1 1 2

--> y = squeeze(x);
--> size(y)

ans =
 4 3 2
```

14.37 SUBSREF Array Dereferencing

14.37.1 Usage

This function can be used to index into basic array types (or structures). It provides a functional interface to execute complex indexing expressions such as `a.b(3){5}` at run time (i.e. while executing a script or a function) without resorting to using `eval`. Note that this function should be overloaded for use with user defined classes, and that it cannot be overloaeded for base types. The basic syntax of the function is:

```
b = subsref(a,s)
```

where `s` is a structure array with two fields. The first field is

- `type` is a string containing either `'()'` or `'{}'` or `'.'` depending on the form of the call.
- `subs` is a cell array or string containing the the subscript information.

When multiple indexing experssions are combined together such as `b = a(5).foo{:}`, the `s` array should contain the following entries

```
s(1).type = '()'  s(1).subs = {5}
s(2).type = '.'   s(2).subs = 'foo'
s(3).type = '{}'  s(3).subs = ':'
```

14.38 TRACE Sum Diagonal Elements of an Array

14.38.1 Usage

Returns the sum of the diagonal elements of a square matrix. The general syntax for its use is

```
y = trace(x)
```

where x is a square matrix.

14.39 TRANSPOSE Matrix Transpose

14.39.1 Usage

Performs a (nonconjugate) transpose of a matrix. The syntax for its use is

```
y = transpose(x)
```

and is a synonym for `y = x.'`.

14.39.2 Example

Here is an example of the transpose of a complex matrix. Note that the entries are not conjugated.

```
--> A = [1+i,2+i;3-2*i,4+2*i]

A =
   1.0000 +  1.0000i   2.0000 +  1.0000i
   3.0000 -  2.0000i   4.0000 +  2.0000i

--> transpose(A)

ans =
   1.0000 +  1.0000i   3.0000 -  2.0000i
   2.0000 +  1.0000i   4.0000 +  2.0000i
```

14.40 TRIL Lower Triangular Matrix Function

14.40.1 Usage

Returns the lower triangular matrix of a square matrix. The general syntax for its use is

```
y = tril(x)
```

where —x— is a square matrix. This returns the lower triangular matrix (i.e.: all cells on or above the diagonal are set to 0). You can also specify a different diagonal using the alternate form

```
y = tril(x,n)
```

where n is the diagonal offset. In this mode, the diagonal specified is not set to zero in the returned matrix (e.g.: tril(x) and tril(x,-1)) will return the same value.

14.41 TRIU Upper Triangular Matrix Function

14.41.1 Usage

Returns the upper triangular matrix of a square matrix. The general syntax for its use is

```
y = triu(x)
```

where x is a square matrix. This returns the upper triangular matrix (i.e.: all elements on or below the diagonal are set to 0). You can also specify a different diagonal using the alternate form

```
y = triu(x,n)
```

where n is the diagonal offset. In this mode, the diagonal specified is not set to zero in the returned matrix (e.g.: tril(x) and tril(x,1)) will return the same value.

14.42 UNIQUE Unique

14.42.1 Usage

Returns a vector containing the unique elements of an array. The first form is simply

```
y = unique(x)
```

where `x` is either a numerical array or a cell-array of strings. The result is sorted in increasing order. You can also retrieve two sets of index vectors

```
[y, m, n] = unique(x)
```

such that `y = x(m)` and `x = y(n)`. If the argument `x` is a matrix, you can also indicate that FreeMat should look for unique rows in the matrix via

```
y = unique(x,'rows')
```

and

```
[y, m, n] = unique(x,'rows')
```

14.42.2 Example

Here is an example in row mode

```
--> A = randi(1,3*ones(15,3))

A =
 2 3 2
 2 1 1
 2 2 3
 2 1 3
 2 2 3
 2 1 2
 1 2 2
 1 1 1
 3 1 3
 2 2 2
 1 3 3
 1 2 3
 3 1 1
 3 3 1
 2 3 3

--> unique(A,'rows')

ans =
 1 1 1
 1 2 2
 1 2 3
 1 3 3
 2 1 1
 2 1 2
 2 1 3
 2 2 2
 2 2 3
 2 3 2
 2 3 3
 3 1 1
 3 1 3
 3 3 1

--> [b,m,n] = unique(A,'rows');
--> b

ans =
```

```
 1 1 1
 1 2 2
 1 2 3
 1 3 3
 2 1 1
 2 1 2
 2 1 3
 2 2 2
 2 2 3
 2 3 2
 2 3 3
 3 1 1
 3 1 3
 3 3 1

--> A(m,:)

ans =
 1 1 1
 1 2 2
 1 2 3
 1 3 3
 2 1 1
 2 1 2
 2 1 3
 2 2 2
 2 2 3
 2 3 2
 2 3 3
 3 1 1
 3 1 3
 3 3 1

--> b(n,:)

ans =
 2 3 2
 2 1 1
 2 2 3
 2 1 3
 2 2 3
 2 1 2
 1 2 2
 1 1 1
 3 1 3
 2 2 2
 1 3 3
 1 2 3
 3 1 1
 3 3 1
 2 3 3
```

Here is an example in vector mode

```
--> A = randi(1,5*ones(10,1))
```

```
A =
 5
 5
 5
 3
 5
 3
 4
 1
 3
 2

--> unique(A)

ans =
 1
 2
 3
 4
 5

--> [b,m,n] = unique(A,'rows');
--> b

ans =
 1
 2
 3
 4
 5

--> A(m)

ans =
 1
 2
 3
 4
 5

--> b(n)

ans =
 5
 5
 5
 3
 5
 3
 4
 1
 3
 2
```

For cell arrays of strings.

```
--> A = {'hi','bye','good','tell','hi','bye'}

A =
 [hi] [bye] [good] [tell] [hi] [bye]

--> unique(A)

ans =
 [bye] [good] [hi] [tell]
```

14.43 XNRM2 BLAS Norm Calculation

14.43.1 Usage

Calculates the 2-norm of a vector. The syntax for its use is

```
y = xnrm2(A)
```

where `A` is the n-dimensional array to analyze. This form uses the underlying BLAS implementation to compute the 2-norm.

14.44 ZEROS Array of Zeros

14.44.1 Usage

Creates an array of zeros of the specified size. Two seperate syntaxes are possible. The first syntax specifies the array dimensions as a sequence of scalar dimensions:

```
y = zeros(d1,d2,...,dn).
```

The resulting array has the given dimensions, and is filled with all zeros. The type of `y` is `double`, a 64-bit floating point array. To get arrays of other types, use the typecast functions (e.g., `uint8`, `int8`, etc.). An alternative syntax is to use the following notation:

```
y = zeros(d1,d2,...,dn,classname)
```

where `classname` is one of 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', 'float', 'logical'.

The second syntax specifies the array dimensions as a vector, where each element in the vector specifies a dimension length:

```
y = zeros([d1,d2,...,dn]),
```

or

```
y = zeros([d1,d2,...,dn],classname).
```

This syntax is more convenient for calling `zeros` using a variable for the argument. In both cases, specifying only one dimension results in a square matrix output.

14.44.2 Example

The following examples demonstrate generation of some zero arrays using the first form.

```
--> zeros(2,3,2)

ans =

(:,:,1) =
 0 0 0
 0 0 0

(:,:,2) =
 0 0 0
 0 0 0

--> zeros(1,3)

ans =
 0 0 0
```

The same expressions, using the second form.

```
--> zeros([2,6])

ans =
 0 0 0 0 0 0
 0 0 0 0 0 0

--> zeros([1,3])

ans =
 0 0 0
```

Finally, an example of using the type casting function `uint16` to generate an array of 16-bit unsigned integers with zero values.

```
--> uint16(zeros(3))

ans =
 0 0 0
 0 0 0
 0 0 0
```

Here we use the second syntax where the class of the output is specified explicitly

```
--> zeros(3,'int16')

ans =
 0 0 0
 0 0 0
 0 0 0
```

Chapter 15

Random Number Generation

15.1 RAND Uniform Random Number Generator

15.1.1 Usage

Creates an array of pseudo-random numbers of the specified size. The numbers are uniformly distributed on `[0,1)`. Two seperate syntaxes are possible. The first syntax specifies the array dimensions as a sequence of scalar dimensions:

```
y = rand(d1,d2,...,dn).
```

The resulting array has the given dimensions, and is filled with random numbers. The type of `y` is `double`, a 64-bit floating point array. To get arrays of other types, use the typecast functions.

The second syntax specifies the array dimensions as a vector, where each element in the vector specifies a dimension length:

```
y = rand([d1,d2,...,dn]).
```

This syntax is more convenient for calling `rand` using a variable for the argument.

Finally, `rand` supports two additional forms that allow you to manipulate the state of the random number generator. The first retrieves the state

```
y = rand('state')
```

which is a 625 length integer vector. The second form sets the state

```
rand('state',y)
```

or alternately, you can reset the random number generator with

```
rand('state',0)
```

15.1.2 Example

The following example demonstrates an example of using the first form of the `rand` function.

```
--> rand(2,2,2)

ans =

(:,:,1) =
    0.8539    0.1733
    0.0415    0.1300
```

```
(:,:,2) =
    0.7163    0.5752
    0.5953    0.3728
```

The second example demonstrates the second form of the `rand` function.

```
--> rand([2,2,2])

ans =

(:,:,1) =
    0.4992    0.2797
    0.6513    0.3209

(:,:,2) =
    0.6244    0.7774
    0.0934    0.1820
```

The third example computes the mean and variance of a large number of uniform random numbers. Recall that the mean should be `1/2`, and the variance should be `1/12 ~ 0.083`.

```
--> x = rand(1,10000);
--> mean(x)

ans =
    0.4952

--> var(x)

ans =
    0.0845
```

Now, we use the state manipulation functions of `rand` to exactly reproduce a random sequence. Note that unlike using `seed`, we can exactly control where the random number generator starts by saving the state.

```
--> rand('state',0)    % restores us to startup conditions
--> a = rand(1,3)      % random sequence 1

a =
    0.3759    0.0183    0.9134

--> b = rand('state'); % capture the state vector
--> c = rand(1,3)      % random sequence 2

c =
    0.3580    0.7604    0.8077

--> rand('state',b);   % restart the random generator so...
--> c = rand(1,3)      % we get random sequence 2 again

c =
    0.3580    0.7604    0.8077
```

15.2 RANDBETA Beta Deviate Random Number Generator

15.2.1 Usage

Creates an array of beta random deviates based on the supplied two parameters. The general syntax for `randbeta` is

```
y = randbeta(alpha, beta)
```

where `alpha` and `beta` are the two parameters of the random deviate. There are three forms for calling `randbeta`. The first uses two vectors `alpha` and `beta` of the same size, in which case the output `y` is the same size as both inputs, and each deviate uses the corresponding values of `alpha` and `beta` from the arguments. In the other forms, either `alpha` or `beta` are scalars.

15.2.2 Function Internals

The probability density function (PDF) of a beta random variable is

$$f(x) = x^(a-1) * (1-x)^(b-1)/B(a,b)$$

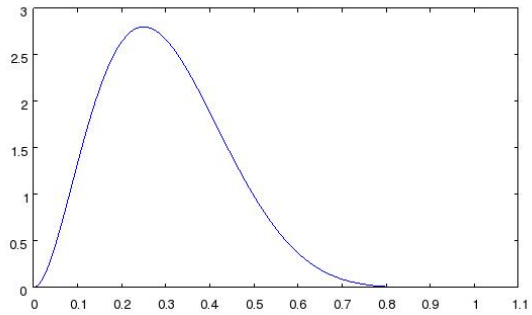
for `x` between 0 and 1. The function `B(a,b)` is defined so that the integral of `f(x)` is 1.

15.2.3 Example

Here is a plot of the PDF of a beta random variable with `a=3`, `b=7`.

```
--> a = 3; b = 7;
--> x = (0:100)/100; t = x.^(a-1).*(1-x).^(b-1);
--> t = t/(sum(t)*.01);
--> plot(x,t);
```

which is plotted as



If we generate a few random deviates with these values, we see they are distributed around the peak of roughly `0.25`.

```
--> randbeta(3*ones(1,5),7*ones(1,5))

ans =
    0.4343    0.4220    0.3992    0.2727    0.2475
```

15.3 RANDBIN Generate Binomial Random Variables

15.3.1 Usage

Generates random variables with a binomial distribution. The general syntax for its use is

```
y = randbin(N,p)
```

where `N` is a vector representing the number of Bernoulli trials, and `p` is the success probability associated with each trial.

15.3.2 Function Internals

A Binomial random variable describes the number of successful outcomes from `N` Bernoulli trials, with the probability of success in each trial being `p`. The probability distribution is

$$P(n) = \frac{N!}{n!(N-n)!} p^n (1-p)^{N-n}$$

15.3.3 Example

Here we generate `10` binomial random variables, corresponding to `N=100` trials, each with probability `p=0.1`, using both `randbin` and then again using `rand` (to simulate the trials):

```
--> randbin(100,.1*ones(1,10))

ans =
  6  7  6  7 13  7  7 10 13 15

--> sum(rand(100,10)<0.1)

ans =
 11  9  8  9 15 16 11 17  4  7
```

15.4 RANDCHI Generate Chi-Square Random Variable

15.4.1 Usage

Generates a vector of chi-square random variables with the given number of degrees of freedom. The general syntax for its use is

```
y = randchi(n)
```

where `n` is an array containing the degrees of freedom for each generated random variable.

15.4.2 Function Internals

A chi-square random variable is essentially distributed as the squared Euclidean norm of a vector of standard Gaussian random variables. The number of degrees of freedom is generally the number of elements in the vector. In general, the PDF of a chi-square random variable is

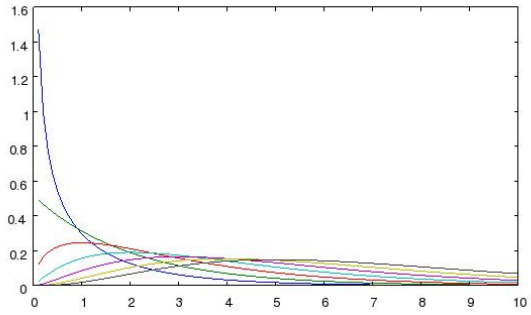
$$f(x) = \frac{x^{r/2-1} e^{-x/2}}{\Gamma(r/2) 2^{r/2}}$$

15.4.3 Example

First, a plot of the PDF for a family of chi-square random variables

```
--> f = zeros(7,100);
--> x = (1:100)/10;
--> for n=1:7;t=x.^(n/2-1).*exp(-x/2);f(n,:)=10*t/sum(t);end
--> plot(x,f');
```

The PDF is below:



Here is an example of using `randchi` and `randn` to compute some chi-square random variables with four degrees of freedom.

```
--> randchi(4*ones(1,6))

ans =
    2.6122    6.2362    0.8717    1.4935    6.0370    5.2771

--> sum(randn(4,6).^2)

ans =
    0.0399    4.6296    0.8697    0.5796    1.5490    5.8538
```

15.5 RANDEXP Generate Exponential Random Variable

15.5.1 Usage

Generates a vector of exponential random variables with the specified parameter. The general syntax for its use is

```
y = randexp(lambda)
```

where `lambda` is a vector containing the parameters for the generated random variables.

15.5.2 Function Internals

The exponential random variable is usually associated with the waiting time between events in a Poisson random process. The PDF of an exponential random variable is:

$$f(x) = \lambda e^{-\lambda x}$$

15.5.3 Example

Here is an example of using the `randexp` function to generate some exponentially distributed random variables

```
--> randexp(ones(1,6))

ans =
    0.7969    0.2401    0.5891    1.5129    0.9998    2.7738
```

15.6 RANDF Generate F-Distributed Random Variable

15.6.1 Usage

Generates random variables with an F-distribution. The general syntax for its use is

```
y = randf(n,m)
```

where `n` and `m` are vectors of the number of degrees of freedom in the numerator and denominator of the chi-square random variables whose ratio defines the statistic.

15.6.2 Function Internals

The statistic `F\_{n,m}` is defined as the ratio of two chi-square random variables:

$$F_{n,m} = \frac{\chi_n^2/n}{\chi_m^2/m}$$

The PDF is given by

$$f_{n,m} = \frac{m^{m/2} n^{n/2} x^{n/2-1}}{(m+nx)^{(n+m)/2} B(n/2, m/2)},$$

where `B(a,b)` is the beta function.

15.6.3 Example

Here we use `randf` to generate some F-distributed random variables, and then again using the `randchi` function:

```
--> randf(5*ones(1,9),7)

ans =
    0.5241    0.8414    0.4859    1.1266    0.4792    2.3743    2.9095    0.5825    0.4244

--> randchi(5*ones(1,9))./randchi(7*ones(1,9))

ans =
    0.3737    0.2363    1.5733    0.7003    1.1385    0.6337    0.4597    0.2691    0.5190
```

15.7 RANDGAMMA Generate Gamma-Distributed Random Variable

15.7.1 Usage

Generates random variables with a gamma distribution. The general syntax for its use is

```
y = randgamma(a,r),
```

where `a` and `r` are vectors describing the parameters of the gamma distribution. Roughly speaking, if `a` is the mean time between changes of a Poisson random process, and we wait for the `r` change, the resulting wait time is Gamma distributed with parameters `a` and `r`.

15.7.2 Function Internals

The Gamma distribution arises in Poisson random processes. It represents the waiting time to the occurance of the `r`-th event in a process with mean time `a` between events. The probability distribution of a Gamma random variable is

$$P(x) = \frac{a^r x^{r-1} e^{-ax}}{\Gamma(r)}.$$

Note also that for integer values of `r` that a Gamma random variable is effectively the sum of `r` exponential random variables with parameter `a`.

15.7.3 Example

Here we use the `randgamma` function to generate Gamma-distributed random variables, and then generate them again using the `randexp` function.

```
--> randgamma(1,15*ones(1,9))

ans =
   10.0227   12.4783   18.0388   21.7056   14.1249   15.9260   22.0177   15.9170   24.3781

--> sum(randexp(ones(15,9)))

ans =
   14.5031   12.8908   10.5201   16.9976    9.8463   12.7479   13.6879   21.7005   11.4172
```

15.8 RANDI Uniformly Distributed Integer

15.8.1 Usage

Generates an array of uniformly distributed integers between the two supplied limits. The general syntax for `randi` is

```
y = randi(low,high)
```

where `low` and `high` are arrays of integers. Scalars can be used for one of the arguments. The output `y` is a uniformly distributed pseudo-random number between `low` and `high` (inclusive).

15.8.2 Example

Here is an example of a set of random integers between zero and 5:

```
--> randi(zeros(1,6),5*ones(1,6))

ans =
 5 5 0 4 4 2
```

15.9 RANDMULTI Generate Multinomial-distributed Random Variables

15.9.1 Usage

This function generates samples from a multinomial distribution given the probability of each outcome. The general syntax for its use is

```
y = randmulti(N,pvec)
```

where `N` is the number of experiments to perform, and `pvec` is the vector of probabilities describing the distribution of outcomes.

15.9.2 Function Internals

A multinomial distribution describes the number of times each of `m` possible outcomes occurs out of `N` trials, where each outcome has a probability `p\_i`. More generally, suppose that the probability of a Bernoulli random variable `X\_i` is `p\_i`, and that

$$\sum_{i=1}^{m} p_i = 1.$$

Then the probability that `X\_i` occurs `x\_i` times is

$$P_N(x_1, x_2, \ldots, x_n) = \frac{N!}{x_1! \cdots x_n!} p_1^{x_1} \cdots p_n^{x_n}.$$

15.9.3 Example

Suppose an experiment has three possible outcomes, say heads, tails and edge, with probabilities `0.4999`, `0.4999` and `0.0002`, respectively. Then if we perform ten thousand coin flips we get

```
--> randmulti(10000,[0.4999,0.4999,0.0002])

ans =
 5051    0 4948
```

15.10 RANDN Gaussian (Normal) Random Number Generator

15.10.1 Usage

Creates an array of pseudo-random numbers of the specified size. The numbers are normally distributed with zero mean and a unit standard deviation (i.e., `mu = 0, sigma = 1`). Two seperate syntaxes are possible. The first syntax specifies the array dimensions as a sequence of scalar dimensions:

```
y = randn(d1,d2,...,dn).
```

The resulting array has the given dimensions, and is filled with random numbers. The type of `y` is `double`, a 64-bit floating point array. To get arrays of other types, use the typecast functions.

The second syntax specifies the array dimensions as a vector, where each element in the vector specifies a dimension length:

```
y = randn([d1,d2,...,dn]).
```

This syntax is more convenient for calling `randn` using a variable for the argument.

Finally, `randn` supports two additional forms that allow you to manipulate the state of the random number generator. The first retrieves the state

```
y = randn('state')
```

which is a 625 length integer vector. The second form sets the state

```
randn('state',y)
```

or alternately, you can reset the random number generator with

```
randn('state',0)
```

15.10.2 Function Internals

Recall that the probability density function (PDF) of a normal random variable is

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{-(x-\mu)^2}{2\sigma^2}}.$$

The Gaussian random numbers are generated from pairs of uniform random numbers using a transformation technique.

15.10.3 Example

The following example demonstrates an example of using the first form of the `randn` function.

```
--> randn(2,2,2)

ans =

(:,:,1) =
   -1.3838    0.9091
   -1.1738    0.1705

(:,:,2) =
   -0.0336    0.4572
    0.7566   -1.1720
```

The second example demonstrates the second form of the `randn` function.

```
--> randn([2,2,2])

ans =

(:,:,1) =
    1.2183   -0.5558
    0.1605    0.1819

(:,:,2) =
    0.5727   -0.5929
   -0.3895   -0.2424
```

In the next example, we create a large array of 10000 normally distributed pseudo-random numbers. We then shift the mean to 10, and the variance to 5. We then numerically calculate the mean and variance using `mean` and `var`, respectively.

```
--> x = 10+sqrt(5)*randn(1,10000);
--> mean(x)

ans =
   10.0370

--> var(x)

ans =
    4.9402
```

Now, we use the state manipulation functions of `randn` to exactly reproduce a random sequence. Note that unlike using `seed`, we can exactly control where the random number generator starts by saving the state.

```
--> randn('state',0)    % restores us to startup conditions
--> a = randn(1,3)      % random sequence 1

a =
   -0.0362   -0.1404    0.6934

--> b = randn('state'); % capture the state vector
--> c = randn(1,3)      % random sequence 2
```

```
c =
    0.5998    0.7086   -0.9394

--> randn('state',b);   % restart the random generator so...
--> c = randn(1,3)      % we get random sequence 2 again

c =
    0.5998    0.7086   -0.9394
```

15.11 RANDNBIN Generate Negative Binomial Random Variables

15.11.1 Usage

Generates random variables with a negative binomial distribution. The general syntax for its use is

```
y = randnbin(r,p)
```

where `r` is a vector of integers representing the number of successes, and `p` is the probability of success.

15.11.2 Function Internals

A negative binomial random variable describes the number of failures `x` that occur in `x+r` bernoulli trials, with a success on the `x+r` trial. The pdf is given by

$$P_{r,p}(x) = \binom{x+r-1}{r-1} p^r (1-p)^x.$$

15.11.3 Example

Here we generate some negative binomial random variables:

```
--> randnbin(3*ones(1,4),.01)

ans =
 437 215 199 187

--> randnbin(6*ones(1,4),.01)

ans =
  471 1233  768  338
```

15.12 RANDNCHI Generate Noncentral Chi-Square Random Variable

15.12.1 Usage

Generates a vector of non-central chi-square random variables with the given number of degrees of freedom and the given non-centrality parameters. The general syntax for its use is

```
y = randnchi(n,mu)
```

where `n` is an array containing the degrees of freedom for each generated random variable (with each element of `n` ¿= 1), and `mu` is the non-centrality shift (must be positive).

15.12.2 Function Internals

A non-central chi-square random variable is the sum of a chisquare deviate with `n-1` degrees of freedom plus the square of a normal deviate with mean `mu` and standard deviation 1.

15.12.3 Examples

Here is an example of a non-central chi-square random variable:

```
--> randnchi(5*ones(1,9),0.3)

ans =
   12.8187    1.5030    1.9084    3.6028    1.1185    4.1872    4.5202    3.4539    0.4578
```

15.13 RANDNF Generate Noncentral F-Distribution Random Variable

15.13.1 Usage

Generates a vector of non-central F-distributed random variables with the specified parameters. The general syntax for its use is

```
y = randnf(n,m,c)
```

where `n` is the number of degrees of freedom in the numerator, and `m` is the number of degrees of freedom in the denominator. The vector `c` determines the non-centrality shift of the numerator.

15.13.2 Function Internals

A non-central F-distributed random variable is the ratio of a non-central chi-square random variable and a central chi-square random variable, i.e.,

$$F_{n,m,c} = \frac{\chi^2_{n,c}/n}{\chi^2_m/m}.$$

15.13.3 Example

Here we use the `randf` to generate some non-central F-distributed random variables:

```
--> randnf(5*ones(1,9),7,1.34)

ans =
    0.5880    1.6093    0.4639    0.7857    2.5543    0.5044    3.3383    1.4102    1.1489
```

15.14 RANDP Generate Poisson Random Variable

15.14.1 Usage

Generates a vector Poisson random variables with the given parameters. The general syntax for its use is

```
y = randp(nu),
```

where `nu` is an array containing the rate parameters for the generated random variables.

15.14.2 Function Internals

A Poisson random variable is generally defined by taking the limit of a binomial distribution as the sample size becomes large, with the expected number of successes being fixed (so that the probability of success decreases as `1/N`). The Poisson distribution is given by

$$P_\nu(n) = \frac{\nu^n e^{-nu}}{n!}.$$

15.14.3 Example

Here is an exmaple of using `randp` to generate some Poisson random variables, and also using `randbin` to do the same using `N=1000` trials to approximate the Poisson result.

```
--> randp(33*ones(1,10))

ans =
 39 39 27 27 35 31 29 28 33 25

--> randbin(1000*ones(1,10),33/1000*ones(1,10))

ans =
 31 17 42 19 34 36 34 41 30 30
```

15.15 RANDPERM Random permutation

15.15.1 USAGE

```
   y = randperm(n)
```

`y` is a random permutation of integers from 1 to `n`. `randperm` calls `rand` and changes its state.

15.15.2 Example

```
--> y = randperm(10)

y =
  2  5 10  8  1  6  3  7  9  4
```

15.16 SEED Seed the Random Number Generator

15.16.1 Usage

Seeds the random number generator using the given integer seeds. Changing the seed allows you to choose which pseudo-random sequence is generated. The seed takes two `uint32` values:

```
  seed(s,t)
```

where `s` and `t` are the seed values. Note that due to limitations in `ranlib`, the values of `s,t` must be between `0 <= s,t <= 2\^30`.

15.16.2 Example

Here's an example of how the seed value can be used to reproduce a specific random number sequence.

```
--> seed(32,41);
--> rand(1,5)

ans =
    0.8589    0.3727    0.5551    0.9557    0.7367

--> seed(32,41);
--> rand(1,5)

ans =
    0.8589    0.3727    0.5551    0.9557    0.7367
```

Chapter 16

Input/Ouput Functions

16.1 CSVREAD Read Comma Separated Value (CSV) File

16.1.1 Usage

The `csvread` function reads a text file containing comma separated values (CSV), and returns the resulting numeric matrix (2D). The function supports multiple syntaxes. The first syntax for `csvread` is

```
x = csvread('filename')
```

which attempts to read the entire CSV file into array `x`. The file can contain only numeric values. Each entry in the file should be separated from other entries by a comma. However, FreeMat will attempt to make sense of the entries if the comma is missing (e.g., a space separated file will also parse correctly). For complex values, you must be careful with the spaces). The second form of `csvread` allows you to specify the first row and column (zero-based index)

```
x = csvread('filename',firstrow,firstcol)
```

The last form allows you to specify the range to read also. This form is

```
x = csvread('filename',firstrow,firstcol,readrange)
```

where `readrange` is either a 4-vector of the form `[R1,C1,R2,C2]`, where `R1,C1` is the first row and column to use, and `R2,C2` is the last row and column to use. You can also specify the `readrange` as a spreadsheet range `B12..C34`, in which case the index for the range is 1-based (as in a typical spreadsheet), so that `A1` is the first cell in the upper left corner. Note also that `csvread` is somewhat limited.

16.1.2 Example

Here is an example of a CSV file that we wish to read in

```
    sample_data.csv
10, 12, 13, 00, 45, 16
09, 11, 52, 93, 05, 06
01, 03, 04, 04, 90, -3
14, 17, 13, 67, 30, 43
21, 33, 14, 44, 01, 00
```

We start by reading the entire file

```
--> csvread('sample_data.csv')

ans =
 10 12 13  0 45 16
```

```
  9 11 52 93  5  6
  1  3  4  4 90 -3
 14 17 13 67 30 43
 21 33 14 44  1  0
```

Next, we read everything starting with the second row, and third column

```
--> csvread('sample_data.csv',1,2)

ans =
 52 93  5  6
  4  4 90 -3
 13 67 30 43
 14 44  1  0
```

Finally, we specify that we only want the `3 x 3` submatrix starting with the second row, and third column

```
--> csvread('sample_data.csv',1,2,[1,2,3,4])

ans =
 52 93  5
  4  4 90
 13 67 30
```

16.2 CSVWRITE Write Comma Separated Value (CSV) File

16.2.1 Usage

The `csvwrite` function writes a given matrix to a text file using comma separated value (CSV) notation. Note that you can create CSV files with arbitrary sized matrices, but that `csvread` has limits on line length. If you need to reliably read and write large matrices, use `rawwrite` and `rawread` respectively. The syntax for `csvwrite` is

```
csvwrite('filename',x)
```

where `x` is a numeric array. The contents of `x` are written to `filename` as comma-separated values. You can also specify a row and column offset to `csvwrite` to force `csvwrite` to write the matrix `x` starting at the specified location in the file. This syntax of the function is

```
csvwrite('filename',x,startrow,startcol)
```

where `startrow` and `startcol` are the offsets in zero-based indexing.

16.2.2 Example

Here we create a simple matrix, and write it to a CSV file

```
--> x = [1,2,3;5,6,7]

x =
 1 2 3
 5 6 7

--> csvwrite('csvwrite.csv',x)
--> csvread('csvwrite.csv')

ans =
 1 2 3
 5 6 7
```

Next, we do the same with an offset.

```
--> csvwrite('csvwrite.csv',x,1,2)
--> csvread('csvwrite.csv')

ans =
 0 0 0 0
 0 1 2 3
 0 5 6 7
```

Note the extra zeros.

16.3 DISP Display a Variable or Expression

16.3.1 Usage

Displays the result of a set of expressions. The `disp` function takes a variable number of arguments, each of which is an expression to output:

```
disp(expr1,expr2,...,exprn)
```

This is functionally equivalent to evaluating each of the expressions without a semicolon after each.

16.3.2 Example

Here are some simple examples of using `disp`.

```
--> a = 32;
--> b = 1:4;
--> disp(a,b,pi)
 32

 1 2 3 4

    3.1416
```

16.4 DLMREAD Read ASCII-delimited File

16.4.1 Usage

Loads a matrix from an ASCII-formatted text file with a delimiter between the entries. This function is similar to the `load -ascii` command, except that it can handle complex data, and it allows you to specify the delimiter. Also, you can read only a subset of the data from the file. The general syntax for the `dlmread` function is

```
y = dlmread(filename)
```

where `filename` is a string containing the name of the file to read. In this form, FreeMat will guess at the type of the delimiter in the file. The guess is made by examining the input for common delimiter characters, which are `,;:` or a whitespace (e.g., tab). The text in the file is preprocessed to replace these characters with whitespace and the file is then read in using a whitespace for the delimiter.

If you know the delimiter in the file, you can specify it using this form of the function:

```
y = dlmread(filename, delimiter)
```

where `delimiter` is a string containing the delimiter. If `delimiter` is the empty string, then the delimiter is guessed from the file.

You can also read only a portion of the file by specifying a start row and start column:

```
y = dlmread(filename, delimiter, startrow, startcol)
```

where `startrow` and `startcol` are zero-based. You can also specify the data to read using a range argument:

```
y = dlmread(filename, delimiter, range)
```

where `range` is either a vector `[startrow,startcol,stoprow,stopcol]` or is specified in spreadsheet notation as `B4..ZA5`.

Note that complex numbers can be present in the file if they are encoded without whitespaces inside the number, and use either `i` or `j` as the indicator. Note also that when the delimiter is given, each incidence of the delimiter counts as a separator. Multiple separators generate zeros in the matrix.

16.5 FCLOSE File Close Function

16.5.1 Usage

Closes a file handle, or all open file handles. The general syntax for its use is either

```
fclose(handle)
```

or

```
fclose('all')
```

In the first case a specific file is closed, In the second, all open files are closed. Note that until a file is closed the file buffers are not flushed. Returns a '0' if the close was successful and a '-1' if the close failed for some reason.

16.5.2 Example

A simple example of a file being opened with `fopen` and then closed with `fclose`.

```
--> fp = fopen('test.dat','wb','ieee-le')

fp =
 3

--> fclose(fp)
```

16.6 FEOF End Of File Function

16.6.1 Usage

Check to see if we are at the end of the file. The usage is

```
b = feof(handle)
```

The `handle` argument must be a valid and active file handle. The return is true (logical 1) if the current position is at the end of the file, and false (logical 0) otherwise. Note that simply reading to the end of a file will not cause `feof` to return `true`. You must read past the end of the file (which will cause an error anyway). See the example for more details.

16.6.2 Example

Here, we read to the end of the file to demonstrate how `feof` works. At first pass, we force a read of the contents of the file by specifying `inf` for the dimension of the array to read. We then test the end of file, and somewhat counter-intuitively, the answer is `false`. We then attempt to read past the end of the file, which causes an error. An `feof` test now returns the expected value of `true`.

```
--> fp = fopen('test.dat','rb');
--> x = fread(fp,[512,inf],'float');
--> feof(fp)

ans =
 1

--> x = fread(fp,[1,1],'float');
--> feof(fp)

ans =
 1
```

16.7 FFLUSH Force File Flush

16.7.1 Usage

Flushes any pending output to a given file. The general use of this function is

```
fflush(handle)
```

where `handle` is an active file handle (as returned by `fopen`).

16.8 FGETLINE Read a String from a File

16.8.1 Usage

Reads a string from a file. The general syntax for its use is

```
s = fgetline(handle)
```

This function reads characters from the file `handle` into a `string` array `s` until it encounters the end of the file or a newline. The newline, if any, is retained in the output string. If the file is at its end, (i.e., that `feof` would return true on this handle), `fgetline` returns an empty string.

16.8.2 Example

First we write a couple of strings to a test file.

```
--> fp = fopen('testtext','w');
--> fprintf(fp,'String 1\n');
--> fprintf(fp,'String 2\n');
--> fclose(fp);
```

Next, we read then back.

```
--> fp = fopen('testtext','r')

fp =
 4
```

```
--> fgetline(fp)

ans =
String 1

--> fgetline(fp)

ans =
String 2

--> fclose(fp);
```

16.9 FOPEN File Open Function

16.9.1 Usage

Opens a file and returns a handle which can be used for subsequent file manipulations. The general syntax for its use is

```
fp = fopen(fname,mode,byteorder)
```

Here `fname` is a string containing the name of the file to be opened. `mode` is the mode string for the file open command. The first character of the mode string is one of the following:

- `'r'` Open file for reading. The file pointer is placed at the beginning of the file. The file can be read from, but not written to.
- `'r+'` Open for reading and writing. The file pointer is placed at the beginning of the file. The file can be read from and written to, but must exist at the outset.
- `'w'` Open file for writing. If the file already exists, it is truncated to zero length. Otherwise, a new file is created. The file pointer is placed at the beginning of the file.
- `'w+'` Open for reading and writing. The file is created if it does not exist, otherwise it is truncated to zero length. The file pointer placed at the beginning of the file.
- `'a'` Open for appending (writing at end of file). The file is created if it does not exist. The file pointer is placed at the end of the file.
- `'a+'` Open for reading and appending (writing at end of file). The file is created if it does not exist. The file pointer is placed at the end of the file.

Starting with FreeMat 4, all files are treated as binary files by default. To invoke the operating systems 'CR/LF ¡-¿ CR' translation (on Win32) add a 't' to the mode string, as in 'rt+'.

Also, you can supply a second argument to `fopen` to retrieve error messages if the `fopen` fails.

```
[fp,messages] = fopen(fname,mode,byteorder)
```

Finally, FreeMat has the ability to read and write files of any byte-sex (endian). The third (optional) input indicates the byte-endianness of the file. If it is omitted, the native endian-ness of the machine running FreeMat is used. Otherwise, the third argument should be one of the following strings:

- `'le','ieee-le','little-endian','littleEndian','little','l','ieee-le.l64','s'`
- `'be','ieee-be','big-endian','bigEndian','big','b','ieee-be.l64','a'`

If the file cannot be opened, or the file mode is illegal, then an error occurs. Otherwise, a file handle is returned (which is an integer). This file handle can then be used with `fread`, `fwrite`, or `fclose` for file access.

Note that three handles are assigned at initialization time:

- Handle 0 - is assigned to standard input
- Handle 1 - is assigned to standard output
- Handle 2 - is assigned to standard error

These handles cannot be closed, so that user created file handles start at `3`.

16.9.2 Examples

Here are some examples of how to use `fopen`. First, we create a new file, which we want to be little-endian, regardless of the type of the machine. We also use the `fwrite` function to write some floating point data to the file.

```
--> fp = fopen('test.dat','w','ieee-le')

fp =
 4

--> fwrite(fp,float([1.2,4.3,2.1]))

ans =
 12

--> fclose(fp)
```

Next, we open the file and read the data back

```
--> fp = fopen('test.dat','r','ieee-le')

fp =
 4

--> fread(fp,[1,3],'float')

ans =
    1.2000    4.3000    2.1000

--> fclose(fp)
```

Now, we re-open the file in append mode and add two additional `float`s to the file.

```
--> fp = fopen('test.dat','a+','le')

fp =
 4

--> fwrite(fp,float([pi,e]))

ans =
 8

--> fclose(fp)
```

Finally, we read all 5 `float` values from the file

```
--> fp = fopen('test.dat','r','ieee-le')

fp =
 4

--> fread(fp,[1,5],'float')

ans =
    1.2000    4.3000    2.1000    3.1416    2.7183

--> fclose(fp)
```

16.10 FORMAT Control the Format of Matrix Display

16.10.1 Usage

FreeMat supports several modes for displaying matrices (either through the `disp` function or simply by entering expressions on the command line. There are several options for the format command. The default mode is equivalent to

```
format short
```

which generally displays matrices with 4 decimals, and scales matrices if the entries have magnitudes larger than roughly `1e2` or smaller than `1e-2`. For more information you can use

```
format long
```

which displays roughly 7 decimals for `float` and `complex` arrays, and 14 decimals for `double` and `dcomplex`. You can also use

```
format short e
```

to get exponential format with 4 decimals. Matrices are not scaled for exponential formats. Similarly, you can use

```
format long e
```

which displays the same decimals as `format long`, but in exponential format. You can also use the `format` command to retrieve the current format:

```
s = format
```

where `s` is a string describing the current format.

16.10.2 Example

We start with the short format, and two matrices, one of double precision, and the other of single precision.

```
--> format short
--> a = randn(4)

a =
   -0.3756    0.0920    0.9516    1.8527
    0.5078   -0.2088   -0.3120   -0.2380
    0.5578    0.7695    0.0226    2.9326
   -0.4420   -0.4871   -0.7582   -0.5059
```

```
--> b = float(randn(4))

b =
    0.2010    0.3416    0.1562   -0.5460
    1.2842   -0.3808   -1.2720   -0.3398
   -0.7660   -0.6251    2.4811    0.7956
   -0.1727    0.8577    1.5701   -1.5048
```

Note that in the short format, these two matrices are displayed with the same format. In `long` format, however, they display differently

```
--> format long
--> a

ans =
  -0.37559630424227   0.09196341864118   0.95155934364300   1.85265231634028
   0.50776589164635  -0.20877480315311  -0.31198760445638  -0.23799081322695
   0.55783547335483   0.76954243414671   0.02264031516947   2.93263318869123
  -0.44202929771190  -0.48708606879623  -0.75822963661106  -0.50590405332950

--> b

ans =
   0.2010476   0.3415550   0.1561587  -0.5460028
   1.2841575  -0.3808453  -1.2719837  -0.3397521
  -0.7659672  -0.6251388   2.4811494   0.7956446
  -0.1726678   0.8576548   1.5701485  -1.5048176
```

Note also that we we scale the contents of the matrices, FreeMat rescales the entries with a scale premultiplier.

```
--> format short
--> a*1e4

ans =

   1.0e+04 *
   -0.3756    0.0920    0.9516    1.8527
    0.5078   -0.2088   -0.3120   -0.2380
    0.5578    0.7695    0.0226    2.9326
   -0.4420   -0.4871   -0.7582   -0.5059

--> a*1e-4

ans =

   1.0e-04 *
   -0.3756    0.0920    0.9516    1.8527
    0.5078   -0.2088   -0.3120   -0.2380
    0.5578    0.7695    0.0226    2.9326
   -0.4420   -0.4871   -0.7582   -0.5059

--> b*1e4

ans =
```

```
   1.0e+04 *
    0.2010    0.3416    0.1562   -0.5460
    1.2842   -0.3808   -1.2720   -0.3398
   -0.7660   -0.6251    2.4811    0.7956
   -0.1727    0.8577    1.5701   -1.5048

--> b*1e-4

ans =

   1.0e-04 *
    0.2010    0.3416    0.1562   -0.5460
    1.2842   -0.3808   -1.2720   -0.3398
   -0.7660   -0.6251    2.4811    0.7956
   -0.1727    0.8577    1.5701   -1.5048
```

Next, we use the exponential formats:

```
--> format short e
--> a*1e4

ans =
 -3.7560e+03  9.1963e+02  9.5156e+03  1.8527e+04
  5.0777e+03 -2.0877e+03 -3.1199e+03 -2.3799e+03
  5.5784e+03  7.6954e+03  2.2640e+02  2.9326e+04
 -4.4203e+03 -4.8709e+03 -7.5823e+03 -5.0590e+03

--> a*1e-4

ans =
 -3.7560e-05  9.1963e-06  9.5156e-05  1.8527e-04
  5.0777e-05 -2.0877e-05 -3.1199e-05 -2.3799e-05
  5.5784e-05  7.6954e-05  2.2640e-06  2.9326e-04
 -4.4203e-05 -4.8709e-05 -7.5823e-05 -5.0590e-05

--> b*1e4

ans =
  2.0105e+03  3.4156e+03  1.5616e+03 -5.4600e+03
  1.2842e+04 -3.8085e+03 -1.2720e+04 -3.3975e+03
 -7.6597e+03 -6.2514e+03  2.4811e+04  7.9564e+03
 -1.7267e+03  8.5765e+03  1.5701e+04 -1.5048e+04

--> b*1e-4

ans =
  2.0105e-05  3.4155e-05  1.5616e-05 -5.4600e-05
  1.2842e-04 -3.8085e-05 -1.2720e-04 -3.3975e-05
 -7.6597e-05 -6.2514e-05  2.4811e-04  7.9564e-05
 -1.7267e-05  8.5765e-05  1.5701e-04 -1.5048e-04
```

Finally, if we assign the `format` function to a variable, we can retrieve the current format:

```
--> format short
--> t = format
```

```
t =
short
```

16.11 FPRINTF Formated File Output Function (C-Style)

16.11.1 Usage

Prints values to a file. The general syntax for its use is

```
fprintf(fp,format,a1,a2,...).
```

or,

```
fprintf(format,a1,a2,...).
```

Here `format` is the format string, which is a string that controls the format of the output. The values of the variables `ai` are substituted into the output as required. It is an error if there are not enough variables to satisfy the format string. Note that this `fprintf` command is not vectorized! Each variable must be a scalar. The value `fp` is the file handle. If `fp` is omitted, file handle `1` is assumed, and the behavior of `fprintf` is effectively equivalent to `printf`. For more details on the format string, see `printf`.

16.11.2 Examples

A number of examples are present in the Examples section of the `printf` command.

16.12 FREAD File Read Function

16.12.1 Usage

Reads a block of binary data from the given file handle into a variable of a given shape and precision. The general use of the function is

```
A = fread(handle,size,precision)
```

The `handle` argument must be a valid value returned by the fopen function, and accessable for reading. The `size` argument determines the number of values read from the file. The `size` argument is simply a vector indicating the size of the array `A`. The `size` argument can also contain a single `inf` dimension, indicating that FreeMat should calculate the size of the array along that dimension so as to read as much data as possible from the file (see the examples listed below for more details). The data is stored as columns in the file, not rows.

Alternately, you can specify two return values to the `fread` function, in which case the second value contains the number of elements read

```
[A,count] = fread(...)
```

where `count` is the number of elements in `A`.

The third argument determines the type of the data. Legal values for this argument are listed below:

- 'uint8','uchar','unsigned char' for an unsigned, 8-bit integer.
- 'int8','char','integer*1' for a signed, 8-bit integer.
- 'uint16','unsigned short' for an unsigned, 16-bit integer.
- 'int16','short','integer*2' for a signed, 16-bit integer.
- 'uint32','unsigned int' for an unsigned, 32-bit integer.
- 'int32','int','integer*4' for a signed, 32-bit integer.

- 'single','float32','float','real*4' for a 32-bit floating point.
- 'double','float64','real*8' for a 64-bit floating point.

Starting with FreeMat 4, the format for the third argument has changed. If you specify only a type, such as `'float'`, the data is read in as single precision, but the output type is always `'double'`. This behavior is consistent with Matlab. If you want the output type to match the input type (as was previous behavior in FreeMat), you must preface the precision string with a `'*'`. Thus, the precision string `'*float'` implies that data is read in as single precision, and the output is also single precision.

The third option is to specify the input and output types explicitly. You can do this by specifiying a precision string of the form `'type1 => type2'`, where `'type1'` is the input type and `'type2'` is the output type. For example, if the input type is `'double'` and the output type is to be a `'float'`, then a type spec of `'double => float'` should be used.

16.12.2 Example

First, we create an array of `512 x 512` Gaussian-distributed `float` random variables, and then writing them to a file called `test.dat`.

```
--> A = float(randn(512));
--> fp = fopen('test.dat','w');
--> fwrite(fp,A);
--> fclose(fp);
```

Read as many floats as possible into a row vector

```
--> fp = fopen('test.dat','r');
--> x = fread(fp,[1,inf],'float');
--> fclose(fp);
--> who x
  Variable Name       Type   Flags             Size
              x    double                   [1x262144]
```

Note that `x` is a `double` array. This behavior is new to FreeMat 4. Read the same floats into a 2-D float array.

```
--> fp = fopen('test.dat','r');
--> x = fread(fp,[512,inf],'float');
--> fclose(fp);
--> who x
  Variable Name       Type   Flags             Size
              x    double                   [512x512]
```

To read them as a single precision float array, we can use the following form:

```
--> fp = fopen('test.dat','r');
--> x = fread(fp,[512,inf],'*float');
--> fclose(fp);
--> who x
  Variable Name       Type   Flags             Size
              x    single                   [512x512]
```

16.13 FSCANF Formatted File Input Function (C-Style)

16.13.1 Usage

Reads values from a file. The general syntax for its use is

```
[a,count] = fscanf(handle,format,[size])
```

Here `format` is the format string, which is a string that controls the format of the input, `size` specifies the amount of data to be read. Values that are parsed from the `text` are stored in a. Note that fscanf is vectorized - the format string is reused as long as there are entries in the `text` string. See `printf` for a description of the format. Note that if the file is at the end-of-file, the fscanf will return

16.14 FSEEK Seek File To A Given Position

16.14.1 Usage

Moves the file pointer associated with the given file handle to the specified offset (in bytes). The usage is

```
fseek(handle,offset,style)
```

The `handle` argument must be a value and active file handle. The `offset` parameter indicates the desired seek offset (how much the file pointer is moved in bytes). The `style` parameter determines how the offset is treated. Three values for the `style` parameter are understood:

- string `'bof'` or the value -1, which indicate the seek is relative to the beginning of the file. This is equivalent to `SEEK\_SET` in ANSI C.
- string `'cof'` or the value 0, which indicates the seek is relative to the current position of the file. This is equivalent to `SEEK\_CUR` in ANSI C.
- string `'eof'` or the value 1, which indicates the seek is relative to the end of the file. This is equivalent to `SEEK\_END` in ANSI C.

The offset can be positive or negative.

16.14.2 Example

The first example reads a file and then "rewinds" the file pointer by seeking to the beginning. The next example seeks forward by 2048 bytes from the files current position, and then reads a line of 512 floats.

```
--> % First we create the file
--> fp = fopen('test.dat','wb');
--> fwrite(fp,float(rand(4096,1)));
--> fclose(fp);
--> % Now we open it
--> fp = fopen('test.dat','rb');
--> % Read the whole thing
--> x = fread(fp,[1,inf],'float');
--> % Rewind to the beginning
--> fseek(fp,0,'bof');
--> % Read part of the file
--> y = fread(fp,[1,1024],'float');
--> who x y
  Variable Name       Type   Flags             Size
              x    double                  [1x4096]
              y    double                  [1x1024]
--> % Seek 2048 bytes into the file
--> fseek(fp,2048,'cof');
--> % Read 512 floats from the file
--> x = fread(fp,[512,1],'float');
--> % Close the file
--> fclose(fp);
```

16.15 FTELL File Position Function

16.15.1 Usage

Returns the current file position for a valid file handle. The general use of this function is

```
n = ftell(handle)
```

The `handle` argument must be a valid and active file handle. The return is the offset into the file relative to the start of the file (in bytes).

16.15.2 Example

Here is an example of using `ftell` to determine the current file position. We read 512 4-byte floats, which results in the file pointer being at position 512*4 = 2048.

```
--> fp = fopen('test.dat','wb');
--> fwrite(fp,randn(512,1));
--> fclose(fp);
--> fp = fopen('test.dat','rb');
--> x = fread(fp,[512,1],'float');
--> ftell(fp)

ans =
 2048
```

16.16 FWRITE File Write Function

16.16.1 Usage

Writes an array to a given file handle as a block of binary (raw) data. The general use of the function is

```
n = fwrite(handle,A)
```

The `handle` argument must be a valid value returned by the fopen function, and accessable for writing. The array `A` is written to the file a column at a time. The form of the output data depends on (and is inferred from) the precision of the array `A`. If the write fails (because we ran out of disk space, etc.) then an error is returned. The output `n` indicates the number of elements successfully written.

Note that unlike MATLAB, FreeMat 4 does not default to `uint8` for writing arrays to files. Alternately, the type of the data to be written to the file can be specified with the syntax

```
n = fwrite(handle,A,type)
```

where `type` is one of the following legal values:

- 'uint8','uchar','unsigned char' for an unsigned, 8-bit integer.
- 'int8','char','integer*1' for a signed, 8-bit integer.
- 'uint16','unsigned short' for an unsigned, 16-bit integer.
- 'int16','short','integer*2' for a signed, 16-bit integer.
- 'uint32','unsigned int' for an unsigned, 32-bit integer.
- 'int32','int','integer*4' for a signed, 32-bit integer.
- 'single','float32','float','real*4' for a 32-bit floating point.
- 'double','float64','real*8' for a 64-bit floating point.

16.16.2 Example

Heres an example of writing an array of `512 x 512` Gaussian-distributed `float` random variables, and then writing them to a file called `test.dat`.

```
--> A = float(randn(512));
--> fp = fopen('test.dat','w');
--> fwrite(fp,A,'single');
--> fclose(fp);
```

16.17 GETLINE Get a Line of Input from User

16.17.1 Usage

Reads a line (as a string) from the user. This function has two syntaxes. The first is

```
a = getline(prompt)
```

where `prompt` is a prompt supplied to the user for the query. The second syntax omits the `prompt` argument:

```
a = getline
```

Note that this function requires command line input, i.e., it will only operate correctly for programs or scripts written to run inside the FreeMat GUI environment or from the X11 terminal. If you build a stand-alone application and expect it to operate cross-platform, do not use this function (unless you include the FreeMat console in the final application).

16.18 GETPRINTLIMIT Get Limit For Printing Of Arrays

16.18.1 Usage

Returns the limit on how many elements of an array are printed using either the `disp` function or using expressions on the command line without a semi-colon. The default is set to one thousand elements. You can increase or decrease this limit by calling `setprintlimit`. This function is provided primarily so that you can temporarily change the output truncation and then restore it to the previous value (see the examples).

```
n=getprintlimit
```

where `n` is the current limit in use.

16.18.2 Example

Here is an example of using `getprintlimit` along with `setprintlimit` to temporarily change the output behavior of FreeMat.

```
--> A = randn(100,1);
--> n = getprintlimit

n =
 1000

--> setprintlimit(5);
--> A

ans =
   -0.6933
   -0.9500
```

```
    0.0824
   -1.1740
   -0.3467
Print limit has been reached.  Use setprintlimit function to enable longer printouts
--> setprintlimit(n)
```

16.19 HTMLREAD Read an HTML Document into FreeMat

16.19.1 Usage

Given a filename, reads an HTML document, (attempts to) parse it, and returns the result as a FreeMat data structure. The syntax for its use is:

```
p = htmlread(filename)
```

where `filename` is a `string`. The resulting object `p` is a data structure containing the information in the document. Note that this function works by internally converting the HTML document into something closer to XHTML, and then using the XML parser to parse it. In some cases, the converted HTML cannot be properly parsed. In such cases, a third party tool such as "tidy" will probably do a better job.

16.20 IMREAD Read Image File To Matrix

16.20.1 Usage

Reads the image data from the given file into a matrix. Note that FreeMat's support for `imread` is not complete. Only some of the formats specified in the MATLAB API are implemented. The syntax for its use is

```
[A,map,alpha] = imread(filename)
```

where `filename` is the name of the file to read from. The returned arrays `A` contain the image data, `map` contains the colormap information (for indexed images), and `alpha` contains the alphamap (transparency). The returned values will depend on the type of the original image. Generally you can read images in the `jpg,png,xpm,ppm` and some other formats.

16.21 IMWRITE Write Matrix to Image File

16.21.1 Usage

Write the image data from the matrix into a given file. Note that FreeMat's support for `imwrite` is not complete. You can write images in the `jpg,png,xpm,ppm` and some other formats. The syntax for its use is

```
  imwrite(A, filename)
  imwrite(A, map, filename)
  imwrite(A, map, filename, 'Alpha', alpha)

or Octave-style syntax:
  imwrite(filename, A)
  imwrite(filename, A, map)
  imwrite(filename, A, map, alpha)
```

where `filename` is the name of the file to write to. The input array `A` contains the image data (2D for gray or indexed, and 3D for color). If `A` is an integer array (int8, uint8, int16, uint16, int32, uint32), the values of its elements should be within 0-255. If `A` is a floating-point array (float or double), the value of its elements should be in the range [0,1]. `map` contains the colormap information (for indexed images), and `alpha` the alphamap (transparency).

16.21.2 Example

Here is a simple example of `imread/imwrite`. First, we generate a grayscale image and save it to an image file.

```
--> a =  uint8(255*rand(64));
--> figure(1), image(a), colormap(gray)
--> title('image to save')
--> imwrite(a, 'test.bmp')
```

Then, we read image file and show it:

```
--> b = imread('test.bmp');
--> figure(2), image(b), colormap(gray)
--> title('loaded image')
```

16.22 INPUT Get Input From User

16.22.1 Usage

The `input` function is used to obtain input from the user. There are two syntaxes for its use. The first is

```
r = input('prompt')
```

in which case, the prompt is presented, and the user is allowed to enter an expression. The expression is evaluated in the current workspace or context (so it can use any defined variables or functions), and returned for assignment to the variable (`r` in this case). In the second form of the `input` function, the syntax is

```
r = input('prompt','s')
```

in which case the text entered by the user is copied verbatim to the output.

16.23 LOAD Load Variables From A File

16.23.1 Usage

Loads a set of variables from a file in a machine independent format. The `load` function takes one argument:

```
load filename,
```

or alternately,

```
load('filename')
```

This command is the companion to `save`. It loads the contents of the file generated by `save` back into the current context. Global and persistent variables are also loaded and flagged appropriately. By default, FreeMat assumes that files that end in a `.mat` or `.MAT` extension are MATLAB-formatted files. Also, FreeMat assumes that files that end in `.txt` or `.TXT` are ASCII files. For other filenames, FreeMat first tries to open the file as a FreeMat binary format file (as created by the `save` function). If the file fails to open as a FreeMat binary file, then FreeMat attempts to read it as an ASCII file.

You can force FreeMat to assume a particular format for the file by using alternate forms of the `load` command. In particular,

```
load -ascii filename
```

will load the data in file `filename` as an ASCII file (space delimited numeric text) loaded into a single variable in the current workspace with the name `filename` (without the extension).

For MATLAB-formatted data files, you can use

```
load -mat filename
```

which forces FreeMat to assume that `filename` is a MAT-file, regardless of the extension on the filename.

You can also specify which variables to load from a file (not from an ASCII file - only single 2-D variables can be successfully saved and retrieved from ASCII files) using the additional syntaxes of the `load` command. In particular, you can specify a set of variables to load by name

```
load filename Var_1 Var_2 Var_3 ...
```

where `Var\_n` is the name of a variable to load from the file. Alternately, you can use the regular expression syntax

```
load filename -regexp expr_1 expr_2 expr_3 ...
```

where `expr\_n` is a regular expression (roughly as expected by `regexp`). Note that a simpler regular expression mechanism is used for this syntax than the full mechanism used by the `regexp` command.

Finally, you can use `load` to create a variable containing the contents of the file, instead of automatically inserting the variables into the curent workspace. For this form of `load` you must use the function syntax, and capture the output:

```
V = load('arg1','arg2',...)
```

which returns a structure `V` with one field for each variable retrieved from the file. For ASCII files, `V` is a double precision matrix.

16.23.2 Example

Here is a simple example of `save`/`load`. First, we save some variables to a file.

```
--> D = {1,5,'hello'};
--> s = 'test string';
--> x = randn(512,1);
--> z = zeros(512);
--> who
  Variable Name       Type   Flags             Size
             D       cell                    [1x3]
             s       char                   [1x11]
             x     double                 [512x1]
             z     double                 [512x512]
--> save loadsave.dat
```

Next, we clear the variables, and then load them back from the file.

```
--> clear D s x z
--> who
  Variable Name       Type   Flags             Size
           ans     double                   [0x0]
--> load loadsave.dat
--> who
  Variable Name       Type   Flags             Size
             D       cell                    [1x3]
           ans     double                   [0x0]
             s       char                   [1x11]
             x     double                 [512x1]
             z     double                 [512x512]
```

16.24 PAUSE Pause Script Execution

16.24.1 Usage

The `pause` function can be used to pause execution of FreeMat scripts. There are several syntaxes for its use. The first form is

```
pause
```

This form of the `pause` function pauses FreeMat until you press any key. The second form of the `pause` function takes an argument

```
pause(p)
```

where `p` is the number of seconds to pause FreeMat for. The pause argument should be accurate to a millisecond on all supported platforms. Alternately, you can control all `pause` statements using:

```
pause on
```

which enables pauses and

```
pause off
```

which disables all `pause` statements, both with and without arguments.

16.25 PRINTF Formated Output Function (C-Style)

16.25.1 Usage

Prints values to the output. The general syntax for its use is

```
printf(format,a1,a2,...)
```

Here `format` is the format string, which is a string that controls the format of the output. The values of the variables `a\_i` are substituted into the output as required. It is an error if there are not enough variables to satisfy the format string. Note that this `printf` command is not vectorized! Each variable must be a scalar.

It is important to point out that the `printf` function does not add a newline (or carriage return) to the output by default. That can lead to some confusing behavior if you do not know what to expect. For example, the command `printf('Hello')` does not appear to produce any output. In fact, it does produce the text, but it then gets overwritten by the prompt. To see the text, you need `printf('Hello\\n')`. This seems odd, but allows you to assemble a line using multiple `printf` commands, including the `'\\n'` when you are done with the line. You can also use the `'\r'` character as an explicit carriage return (with no line feed). This allows you to write to the same line many times (to show a progress string, for example).

16.25.2 Format of the format string

The format string is a character string, beginning and ending in its initial shift state, if any. The format string is composed of zero or more directives: ordinary characters (not unchanged to the output stream; and conversion specifications, each of which results in fetching zero or more subsequent arguments. Each conversion specification is introduced by the character conversion specifier. In between there may be (in this order) zero or more flags, an optional minimum field width, and an optional precision.

The arguments must correspond properly (after type promotion) with the conversion specifier, and are used in the order given.

16.25.3 The flag characters

The character % is followed by zero or more of the following flags:

- \# The value should be converted to an "alternate form". For o conversions, the first character of the output string is made zero (by prefixing a 0 if it was not zero already). For x and X conversions, a nonzero result has the string '0x' (or '0X' for X conversions) prepended to it. For a, A, e, E, f, F, g, and G conversions, the result will always contain a decimal point, even if no digits follow it (normally, a decimal point appears in the results of those conversions only if a digit follows). For g and G conversions, trailing zeros are not removed from the result as they would otherwise be. For other conversions, the result is undefined.
- 0 The value should be zero padded. For d, i, o, u, x, X, a, A, e, E, f, F, g, and G conversions, the converted value is padded on the left with zeros rather than blanks. If the 0 and - flags both appear, the 0 flag is ignored. If a precision is given with a numeric conversion (d, i, o, u, x, and X), the 0 flag is ignored. For other conversions, the behavior is undefined.
- - The converted value is to be left adjusted on the field boundary. (The default is right justification.) Except for n conversions, the converted value is padded on the right with blanks, rather than on the left with blanks or zeros. A - overrides a 0 if both are given.
- ' ' (a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
- + A sign (+ or -) always be placed before a number produced by a signed conversion. By default a sign is used only for negative numbers. A + overrides a space if both are used.

16.25.4 The field width

An optional decimal digit string (with nonzero first digit) specifying a minimum field width. If the converted value has fewer characters than the field width, it will be padded with spaces on the left (or right, if the left-adjustment flag has been given). A negative field width is taken as a '-' flag followed by a positive field width. In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is expanded to contain the conversion result.

16.25.5 The precision

An optional precision, in the form of a period ('.') followed by an optional decimal digit string. If the precision is given as just '.', or the precision is negative, the precision is taken to be zero. This gives the minimum number of digits to appear for d, i, o, u, x, and X conversions, the number of digits to appear after the radix character for a, A, e, E, f, and F conversions, the maximum number of significant digits for g and G conversions, or the maximum number of characters to be printed from a string for s conversions.

16.25.6 The conversion specifier

A character that specifies the type of conversion to be applied. The conversion specifiers and their meanings are:

- d,i The int argument is converted to signed decimal notation. The precision, if any, gives the minimum number of digits that must appear; if the converted value requires fewer digits, it is padded on the left with zeros. The default precision is 1. When 0 is printed with an explicit precision 0, the output is empty.
- o,u,x,X The unsigned int argument is converted to unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal (x and X) notation. The letters abcdef are used for x conversions; the letters ABCDEF are used for X conversions. The precision, if any, gives the minimum number of digits that must appear; if the converted value requires fewer digits, it is padded on the left with zeros. The default precision is 1. When 0 is printed with an explicit precision 0, the output is empty.

- `e,E` The double argument is rounded and converted in the style `[-]d.ddde dd` where there is one digit before the decimal-point character and the number of digits after it is equal to the precision; if the precision is missing, it is taken as `6`; if the precision is zero, no decimal-point character appears. An `E` conversion uses the letter `E` (rather than `e`) to introduce the exponent. The exponent always contains at least two digits; if the value is zero, the exponent is `00`.
- `f,F` The double argument is rounded and converted to decimal notation in the style `[-]ddd.ddd`, where the number of digits after the decimal-point character is equal to the precision specification. If the precision is missing, it is taken as `6`; if the precision is explicitly zero, no decimal-point character appears. If a decimal point appears, at least one digit appears before it.
- `g,G` The double argument is converted in style `f` or `e` (or `F` or `E` for `G` conversions). The precision specifies the number of significant digits. If the precision is missing, `6` digits are given; if the precision is zero, it is treated as `1`. Style e is used if the exponent from its conversion is less than `-4` or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result; a decimal point appears only if it is followed by at least one digit.
- `c` The int argument is converted to an unsigned char, and the resulting character is written.
- `s` The string argument is printed.
- `%` A `'%'` is written. No argument is converted. The complete conversion specification is `'%%'`.

16.25.7 Example

Here are some examples of the use of `printf` with various arguments. First we print out an integer and double value.

```
--> printf('intvalue is %d, floatvalue is %f\n',3,1.53);
intvalue is 3, floatvalue is 1.530000
```

Next, we print out a string value.

```
--> printf('string value is %s\n','hello');
string value is hello
```

Now, we print out an integer using 12 digits, zeros up front.

```
--> printf('integer padded is %012d\n',32);
integer padded is 000000000032
```

Print out a double precision value with a sign, a total of 18 characters (zero prepended if necessary), a decimal point, and 12 digit precision.

```
--> printf('float value is %+018.12f\n',pi);
float value is +0003.141592653590
```

16.26 RAWREAD Read N-dimensional Array From File

16.26.1 Usage

The syntax for `rawread` is

```
function x = rawread(fname,size,precision,byteorder)
```

where `fname` is the name of the file to read from, and `size` is an n-dimensional vector that stores the size of the array in each dimension. The argument `precision` is the type of the data to read in:

- 'uint8','uchar','unsigned char' for unsigned, 8-bit integers

- 'int8','char','integer*1' for signed, 8-bit integers
- 'uint16','unsigned short' for unsigned, 16-bit integers
- 'int16','short','integer*2' for signed, 16-bit integers
- 'uint32','unsigned int' for unsigned, 32-bit integers
- 'int32','int','integer*4' for signed, 32-bit integers
- 'uint64','unsigned int' for unsigned, 64-bit integers
- 'int64','int','integer*8' for signed, 64-bit integers
- 'single','float32','float','real*4' for 32-bit floating point
- 'double','float64','real*8' for 64-bit floating point
- 'complex','complex*8' for 64-bit complex floating point (32 bits for the real and imaginary part).
- 'dcomplex','complex*16' for 128-bit complex floating point (64 bits for the real and imaginary part).

As a special feature, one of the size elements can be 'inf', in which case, the largest possible array is read in. If `byteorder` is left unspecified, the file is assumed to be of the same byte-order as the machine `FreeMat` is running on. If you wish to force a particular byte order, specify the `byteorder` argument as

- `'le','ieee-le','little-endian','littleEndian','little'`
- `'be','ieee-be','big-endian','bigEndian','big'`

16.27 RAWWRITE Write N-dimensional Array From File

16.27.1 Usage

The syntax for `rawwrite` is

```
function rawwrite(fname,x,byteorder)
```

where `fname` is the name of the file to write to, and the (numeric) array `x` is writen to the file in its native type (e.g. if `x` is of type `int16`, then it will be written to the file as 16-bit signed integers. If `byteorder` is left unspecified, the file is assumed to be of the same byte-order as the machine `FreeMat` is running on. If you wish to force a particular byte order, specify the `byteorder` argument as

- `'le','ieee-le','little-endian','littleEndian','little'`
- `'be','ieee-be','big-endian','bigEndian','big'`

16.28 SAVE Save Variables To A File

16.28.1 Usage

Saves a set of variables to a file in a machine independent format. There are two formats for the function call. The first is the explicit form, in which a list of variables are provided to write to the file:

```
save filename a1 a2 ...
```

In the second form,

```
save filename
```

all variables in the current context are written to the file. The format of the file is a simple binary encoding (raw) of the data with enough information to restore the variables with the `load` command. The endianness of the machine is encoded in the file, and the resulting file should be portable between machines of similar types (in particular, machines that support IEEE floating point representation).

You can also specify both the filename as a string, in which case you also have to specify the names of the variables to save. In particular

```
save('filename','a1','a2')
```

will save variables `a1` and `a2` to the file.

Starting with version 2.0, FreeMat can also read and write MAT files (the file format used by MATLAB) thanks to substantial work by Thomas Beutlich. Support for MAT files in version 2.1 has improved over previous versions. In particular, classes should be saved properly, as well as a broader range of sparse matrices. Compression is supported for both reading and writing to MAT files. MAT file support is still in the alpha stages, so please be cautious with using it to store critical data. The file format is triggered by the extension. To save files with a MAT format, simply use a filename with a ".mat" ending.

The `save` function also supports ASCII output. This is a very limited form of the save command - it can only save numeric arrays that are 2-dimensional. This form of the `save` command is triggered using

```
save -ascii filename var1 var 2
```

although where `-ascii` appears on the command line is arbitrary (provided it comes after the `save` command, of course). Be default, the `save` command uses an 8-digit exponential format notation to save the values to the file. You can specify that you want 16-digits using the

```
save -ascii -double filename var1 var2
```

form of the command. Also, by default, `save` uses spaces as the delimiters between the entries in the matrix. If you want tabs instead, you can use

```
save -ascii -tabs filename var1 var2
```

(you can also use both the `-tabs` and `-double` flags simultaneously).

Finally, you can specify that `save` should only save variables that match a particular regular expression. Any of the above forms can be combined with the `-regexp` flag:

```
save filename -regexp pattern1 pattern2
```

in which case variables that match any of the patterns will be saved.

16.28.2 Example

Here is a simple example of `save`/`load`. First, we save some variables to a file.

```
--> D = {1,5,'hello'};
--> s = 'test string';
--> x = randn(512,1);
--> z = zeros(512);
--> who
  Variable Name       Type   Flags             Size
              D       cell                    [1x3]
              s       char                    [1x11]
              x     double                    [512x1]
              z     double                    [512x512]
--> save loadsave.dat
```

Next, we clear the variables, and then load them back from the file.

```
--> clear D s x z
--> who
  Variable Name       Type   Flags             Size
           ans    double                    [0x0]
--> load loadsave.dat
--> who
  Variable Name       Type   Flags             Size
             D      cell                     [1x3]
           ans    double                     [0x0]
             s      char                     [1x11]
             x    double                     [512x1]
             z    double                     [512x512]
```

16.29 SETPRINTLIMIT Set Limit For Printing Of Arrays

16.29.1 Usage

Changes the limit on how many elements of an array are printed using either the `disp` function or using expressions on the command line without a semi-colon. The default is set to one thousand elements. You can increase or decrease this limit by calling

```
setprintlimit(n)
```

where `n` is the new limit to use.

16.29.2 Example

Setting a smaller print limit avoids pages of output when you forget the semicolon on an expression.

```
--> A = randn(512);
--> setprintlimit(10)
--> A

ans =

 Columns 1 to 12

   -0.2514   -0.1353   -1.3148    1.7915   -0.4740   -1.6836   -0.2605    0.1477   -0.1555    0.8534
Print limit has been reached.  Use setprintlimit function to enable longer printouts
--> setprintlimit(1000)
```

16.30 SPRINTF Formated String Output Function (C-Style)

16.30.1 Usage

Prints values to a string. The general syntax for its use is

```
y = sprintf(format,a1,a2,...).
```

Here `format` is the format string, which is a string that controls the format of the output. The values of the variables `a\_i` are substituted into the output as required. It is an error if there are not enough variables to satisfy the format string. Note that this `sprintf` command is not vectorized! Each variable must be a scalar. The returned value `y` contains the string that would normally have been printed. For more details on the format string, see `printf`.

16.30.2 Examples

Here is an example of a loop that generates a sequence of files based on a template name, and stores them in a cell array.

```
--> l = {}; for i = 1:5; s = sprintf('file_%d.dat',i); l(i) = {s}; end;
--> l

ans =
 [file_1.dat] [file_2.dat] [file_3.dat] [file_4.dat] [file_5.dat]
```

16.31 SSCANF Formated String Input Function (C-Style)

16.31.1 Usage

Reads values from a string. The general syntax for its use is

```
[a, count, errmsg, nextind] = sscanf(text,format,[size])
```

Here `format` is the format string, which is a string that controls the format of the input, `size` specifies the amount of data to be read. Values that are parsed from the `text` are stored in a. Note that sscanf is vectorized - the format string is reused as long as there are entries in the `text` string. See `printf` for a description of the format.

16.32 STR2NUM Convert a String to a Number

16.32.1 Usage

Converts a string to a number. The general syntax for its use is

```
x = str2num(string)
```

Here `string` is the data string, which contains the data to be converted into a number. The output is in double precision, and must be typecasted to the appropriate type based on what you need. Note that by definition, `str2num` is entirely equivalent to `eval(['[' string ']'],[])` with all of the associated problems where `string` contains text that causes side effects.

16.33 TYPE Type Contents of File or Function

16.33.1 Usage

Displays the contents of a file or a function to the screen or console. The syntax for its use is

```
type filename
type('filename')
```

or

```
type function
type('function')
```

in which case the function named `'function.m'` will be displayed.

16.33.2 Example

Here we use `type` to display the contents of itself

```
--> type('type')
%!
%@Module TYPE Type Contents of File or Function
%@@Section IO
%@@Usage
%Displays the contents of a file or a function to the screen
%or console.  The syntax for its use is
%@[
%   type filename
%   type('filename')
%@]
%or
%@[
%   type function
%   type('function')
%@]
%in which case the function named @|'function.m'| will be displayed.
%@@Example
%Here we use @|type| to display the contents of itself
%@<
%type('type')
%@>
%!

function type(filename)
fp = fopen(filename,'r');
if (fp == -1)
  f = which(filename);
  if (isempty(f)), return; end
  filename = f;
  fp = fopen(filename,'r');
end
if (fp == -1), return; end
while (~feof(fp))
  printf('%s',fgetline(fp));
end
fclose(fp);
```

16.34 URLWRITE Retrieve a URL into a File

16.34.1 Usage

Given a URL and a timeout, attempts to retrieve the URL and write the contents to a file. The syntax is

```
f = urlwrite(url,filename,timeout)
```

The `timeout` is in milliseconds. Note that the URL must be a complete spec (i.e., including the name of the resource you wish to retrieve). So for example, you cannot use `http://www.google.com` as a URL, but must instead use `http://www.google.com/index.html`.

16.35 WAVPLAY

16.35.1 Usage

Plays a linear PCM set of samples through the audio system. This function is only available if the `portaudio` library was available when FreeMat was built. The syntax for the command is one of:

```
wavplay(y)
wavplay(y,sampling_rate)
wavplay(...,mode)
```

where `y` is a matrix of audio samples. If `y` has two columns, then the audio playback is in stereo. The `y` input can be of types `float, double, int32, int16, int8, uint8`. For `float` and `double` types, the sample values in `y` must be between `-1` and `1`. The `sampling\_rate` specifies the rate at which the data is recorded. If not specified, the `sampling\_rate` defaults to `11025Hz`. Finally, you can specify a playback mode of `'sync'` which is synchronous playback or a playback mode of `'async'` which is asynchronous playback. For `'sync'` playback, the wavplay function returns when the playback is complete. For `'async'` playback, the function returns immediately (unless a former playback is still issuing).

16.36 WAVREAD Read a WAV Audio File

16.36.1 Usage

The `wavread` function (attempts) to read the contents of a linear PCM audio WAV file. This function could definitely use improvements - it is based on a very simplistic notion of a WAV file. The simplest form for its use is

```
y = wavread(filename)
```

where `filename` is the name of the WAV file to read. If no extension is provided, FreeMat will add a '.wav' extension. This loads the data from the WAV file into `y`, and returns it in `double` precision, normalized format. If you want additional information on, for example, the WAV sampling rate or bit depth, you can request it via

```
[y, SamplingRate, BitDepth] = wavread(filename)
```

where `SamplingRate` and `BitDepth` are the sampling rate (in Hz) and the bit depth of the original data in the WAV file. If you only want to load part of the WAV file, you can use

```
[...] = wavread(filename, N)
```

where `N` indicates the number of samples to read from the file. Alternately, you can indicate a range of samples to load via

```
[...] = wavread(filename, [N1 N2])
```

which returns only the indicated samples from each channel in the file. By default, the output format is `double` precision. You can cntrol the format of the output by indicating

```
[...] = wavread(filename, format)
```

where `format` is either `'double'` for double precision output, or `'native'` for native precision output (meaning whatever bitdepth that was present in the original file). Finally, you can use the `'size'` flag

```
y_siz = wavread(filename,'size')
```

which returns a vector `[samples channels]` indicating the size of the data present in the WAV file.

16.37 WAVRECORD

16.37.1 Usage

Records linear PCM sound from the audio system. This function is only available if the `portaudio` library was available when FreeMat was built. The syntax for this command is one of:

```
y = wavrecord(samples,rate)
y = wavrecord(...,channels)
y = wavrecord(...,'datatype')
```

where `samples` is the number of samples to record, and `rate` is the sampling rate. If not specified, the `rate` defaults to `11025Hz`. If you want to record in stero, specify `channels = 2`. Finally, you can specify the type of the recorded data (defaults to `FM\_DOUBLE`). Valid choices are `float, double, int32, int16, int8, uint8`.

16.38 WAVWRITE Write a WAV Audio File

16.38.1 Usage

The `wavwrite` funtion writes an audio signal to a linear PCM WAV file. The simplest form for its use is

```
wavwrite(y,filename)
```

which writes the data stored in `y` to a WAV file with the name `filename`. By default, the output data is assumed to be sampled at a rate of 8 KHz, and is output using 16 bit integer format. Each column of `y` is written as a separate channel. The data are clipped to the range `[-1,1]` prior to writing them out. If you want the data to be written with a different sampling frequency, you can use the following form of the `wavwrite` command:

```
wavwrite(y,SampleRate,filename)
```

where `SampleRate` is in Hz. Finally, you can specify the number of bits to use in the output form of the file using the form

```
wavwrite(y,SampleRate,NBits,filename)
```

where `NBits` is the number of bits to use. Legal values include `8,16,24,32`. For less than 32 bit output format, the data is truncated to the range `[-1,1]`, and an integer output format is used (type 1 PCM in WAV-speak). For 32 bit output format, the data is written in type 3 PCM as floating point data.

16.39 XMLREAD Read an XML Document into FreeMat

16.39.1 Usage

Given a filename, reads an XML document, parses it, and returns the result as a FreeMat data structure. The syntax for its use is:

```
p = xmlread(filename)
```

where `filename` is a `string`. The resulting object `p` is a data structure containing the information in the document. Note that the returned object `p` is not the same object as the one returned by MATLAB's `xmlread`, although the information content is the same. The output is largely compatible with the output of the parseXML example in the `xmlread` documentation of the MATLAB API.

Chapter 17

String Functions

17.1 BLANKS Create a blank string

17.1.1 Usage

```
str = blanks(n)
```

Create a string `str` containing `n` blank charaters.

17.1.2 Example

A simple example:

```
--> sprintf(['x0123456789y\n','x',blanks(10),'y\n'])

ans =
x0123456789y
x          y
```

17.2 CELLSTR Convert character array to cell array of strings

17.2.1 Usage

The `cellstr` converts a character array matrix into a a cell array of individual strings. Each string in the matrix is placed in a different cell, and extra spaces are removed. The syntax for the command is

```
y = cellstr(x)
```

where `x` is an `N x M` array of characters as a string.

17.2.2 Example

Here is an example of how to use `cellstr`

```
--> a = ['quick';'brown';'fox  ';'is   ']

a =
quick
brown
fox
is
--> cellstr(a)
```

```
ans =
 [quick]
 [brown]
 [fox]
 [is]
```

17.3 DEBLANK Remove trailing blanks from a string

17.3.1 Usage

The `deblank` function removes spaces at the end of a string when used with the syntax

```
y = deblank(x)
```

where `x` is a string, in which case, all of the extra spaces in `x` are stripped from the end of the string. Alternately, you can call `deblank` with a cell array of strings

```
y = deblank(c)
```

in which case each string in the cell array is deblanked.

17.3.2 Example

A simple example

```
--> deblank('hello   ')

ans =
hello
```

and a more complex example with a cell array of strings

```
--> deblank({'hello  ','there ','  is  ','  sign  '})

ans =
 [hello] [there] [  is] [  sign]
```

17.4 ISALPHA Test for Alpha Characters in a String

17.4.1 Usage

The `isalpha` functions returns a logical array that is 1 for characters in the argument string that are letters, and is a logical 0 for characters in the argument that are not letters. The syntax for its use is

```
x = isalpha(s)
```

where `s` is a `string`. Note that this function is not locale sensitive, and returns a logical 1 for letters in the classic ASCII sense (a through z, and A through Z).

17.4.2 Example

A simple example of `isalpha`:

```
--> isalpha('numb3r5')

ans =
 1 1 1 1 0 1 0
```

17.5 ISDIGIT Test for Digit Characters in a String

17.5.1 Usage

The `isdigit` functions returns a logical array that is 1 for characters in the argument string that are digits, and is a logical 0 for characters in the argument that are not digits. The syntax for its use is

```
x = isdigit(s)
```

where `s` is a `string`.

17.5.2 Example

A simple example of `isdigit`:

```
--> isdigit('numb3r5')

ans =
 0 0 0 0 1 0 1
```

17.6 ISSPACE Test for Space Characters in a String

17.6.1 Usage

The `isspace` functions returns a logical array that is 1 for characters in the argument string that are spaces, and is a logical 0 for characters in the argument that are not spaces. The syntax for its use is

```
x = isspace(s)
```

where `s` is a `string`. A blank character is considered a space, newline, tab, carriage return, formfeed, and vertical tab.

17.6.2 Example

A simple example of `isspace`:

```
--> isspace('  hello there world ')

ans =
 1 1 0 0 0 0 0 1 0 0 0 0 0 1 0 0 0 0 0 1
```

17.7 LOWER Convert strings to lower case

17.7.1 Usage

The `lower` function converts a string to lower case with the syntax

```
y = lower(x)
```

where `x` is a string, in which case all of the upper case characters in `x` (defined as the range `'A'-'Z'`) are converted to lower case. Alternately, you can call `lower` with a cell array of strings

```
y = lower(c)
```

in which case each string in the cell array is converted to lower case.

17.7.2 Example

A simple example:

```
--> lower('this Is Strange CAPitalizaTion')

ans =
this is strange capitalization
```

and a more complex example with a cell array of strings

```
--> lower({'This','Is','Strange','CAPitalizaTion'})

ans =
 [this] [is] [strange] [capitalization]
```

17.8 REGEXP Regular Expression Matching Function

17.8.1 Usage

Matches regular expressions in the provided string. This function is complicated, and compatibility with MATLABs syntax is not perfect. The syntax for its use is

```
regexp('str','expr')
```

which returns a row vector containing the starting index of each substring of `str` that matches the regular expression described by `expr`. The second form of `regexp` returns six outputs in the following order:

```
[start stop tokenExtents match tokens names] = regexp('str','expr')
```

where the meaning of each of the outputs is defined below.

- `start` is a row vector containing the starting index of each substring that matches the regular expression.
- `stop` is a row vector containing the ending index of each substring that matches the regular expression.
- `tokenExtents` is a cell array containing the starting and ending indices of each substring that matches the `tokens` in the regular expression. A token is a captured part of the regular expression. If the `'once'` mode is used, then this output is a `double` array.
- `match` is a cell array containing the text for each substring that matches the regular expression. In `'once'` mode, this is a string.
- `tokens` is a cell array of cell arrays of strings that correspond to the tokens in the regular expression. In `'once'` mode, this is a cell array of strings.
- `named` is a structure array containing the named tokens captured in a regular expression. Each named token is assigned a field in the resulting structure array, and each element of the array corresponds to a different match.

If you want only some of the the outputs, you can use the following variant of `regexp`:

```
[o1 o2 ...] = regexp('str','expr', 'p1', 'p2', ...)
```

where `p1` etc. are the names of the outputs (and the order we want the outputs in). As a final variant, you can supply some mode flags to `regexp`

```
[o1 o2 ...] = regexp('str','expr', p1, p2, ..., 'mode1', 'mode2')
```

where acceptable `mode` flags are:

- 'once' - only the first match is returned.
- 'matchcase' - letter case must match (selected by default for regexp)
- 'ignorecase' - letter case is ignored (selected by default for regexpi)
- 'dotall' - the '.' operator matches any character (default)
- 'dotexceptnewline' - the '.' operator does not match the newline character
- 'stringanchors' - the \^ and $ operators match at the beginning and end (respectively) of a string.
- 'lineanchors' - the \^ and $ operators match at the beginning and end (respectively) of a line.
- 'literalspacing' - the space characters and comment characters \# are matched as literals, just like any other ordinary character (default).
- 'freespacing' - all spaces and comments are ignored in the regular expression. You must use ' ' and '#' to match spaces and comment characters, respectively.

Note the following behavior differences between MATLABs regexp and FreeMats:

- If you have an old version of pcre installed, then named tokens must use the older <?P<name> syntax, instead of the new <?<name> syntax.
- The pcre library is pickier about named tokens and their appearance in expressions. So, for example, the regexp from the MATLAB manual '(?<first>\\w+)\\s+(?<last>\\w+)(?¡last¿ w+), s+(?¡first¿ w+)'— does not work correctly (as of this writing) because the same named tokens appear multiple times. The workaround is to assign different names to each token, and then collapse the results later.

17.8.2 Example

Some examples of using the regexp function

```
--> [start,stop,tokenExtents,match,tokens,named] = regexp('quick down town zoo','(.)own')
start =
  7 12

stop =
 10 15

tokenExtents =
 [1x2 double array] [1x2 double array]

match =
 [down] [town]

tokens =
 [1x1 cell array] [1x1 cell array]

named =
  []
```

17.9 REGEXPREP Regular Expression Replacement Function

17.9.1 Usage

Replaces regular expressions in the provided string. The syntax for its use is

```
outstring = regexprep(instring,pattern,replacement,modes)
```

Here `instring` is the string to be operated on. And `pattern` is a regular expression of the type accepted by `regexp`. For each match, the contents of the matched string are replaced with the replacement text. Tokens in the regular expression can be used in the replacement text using `$N` where `N` is the number of the token to use. You can also specify the same `mode` flags that are used by `regexp`.

17.10 STRCMP String Compare Function

17.10.1 USAGE

Compares two strings for equality. The general syntax for its use is

```
p = strcmp(x,y)
```

where `x` and `y` are two strings. Returns `true` if `x` and `y` are the same size, and are equal (as strings). Otherwise, it returns `false`. In the second form, `strcmp` can be applied to a cell array of strings. The syntax for this form is

```
p = strcmp(cellstra,cellstrb)
```

where `cellstra` and `cellstrb` are cell arrays of a strings to compare. Also, you can also supply a character matrix as an argument to `strcmp`, in which case it will be converted via `cellstr` (so that trailing spaces are removed), before being compared.

17.10.2 Example

The following piece of code compares two strings:

```
--> x1 = 'astring';
--> x2 = 'bstring';
--> x3 = 'astring';
--> strcmp(x1,x2)

ans =
 0

--> strcmp(x1,x3)

ans =
 1
```

Here we use a cell array strings

```
--> x = {'astring','bstring',43,'astring'}

x =
 [astring] [bstring] [43] [astring]

--> p = strcmp(x,'astring')

p =
 1 0 0 1
```

Here we compare two cell arrays of strings

```
--> strcmp({'this','is','a','pickle'},{'what','is','to','pickle'})

ans =
 0 1 0 1
```

Finally, the case where one of the arguments is a matrix string

```
--> strcmp({'this','is','a','pickle'},['peter ';'piper ';'hated ';'pickle'])

ans =
 0 0 0 0
```

17.11 STRCMPI String Compare Case Insensitive Function

17.11.1 Usage

Compares two strings for equality ignoring case. The general syntax for its use is

```
p = strcmpi(x,y)
```

where `x` and `y` are two strings, or cell arrays of strings. See `strcmp` for more help.

17.12 STRFIND Find Substring in a String

17.12.1 Usage

Searches through a string for a pattern, and returns the starting positions of the pattern in an array. There are two forms for the `strfind` function. The first is for single strings

```
ndx = strfind(string, pattern)
```

the resulting array `ndx` contains the starting indices in `string` for the pattern `pattern`. The second form takes a cell array of strings

```
ndx = strfind(cells, pattern)
```

and applies the search operation to each string in the cell array.

17.12.2 Example

Here we apply `strfind` to a simple string

```
--> a = 'how now brown cow?'

a =
how now brown cow?
--> b = strfind(a,'ow')

b =
  2  6 11 16
```

Here we search over multiple strings contained in a cell array.

```
--> a = {'how now brown cow','quick brown fox','coffee anyone?'}

a =
 [how now brown cow] [quick brown fox] [coffee anyone?]

--> b = strfind(a,'ow')

b =
 [1x4 double array] [9] []
```

17.13 STRNCMP String Compare Function To Length N

17.13.1 USAGE

Compares two strings for equality, but only looks at the first N characters from each string. The general syntax for its use is

```
  p = strncmp(x,y,n)
```

where `x` and `y` are two strings. Returns `true` if `x` and `y` are each at least `n` characters long, and if the first `n` characters from each string are the same. Otherwise, it returns `false`. In the second form, `strncmp` can be applied to a cell array of strings. The syntax for this form is

```
  p = strncmp(cellstra,cellstrb,n)
```

where `cellstra` and `cellstrb` are cell arrays of a strings to compare. Also, you can also supply a character matrix as an argument to `strcmp`, in which case it will be converted via `cellstr` (so that trailing spaces are removed), before being compared.

17.13.2 Example

The following piece of code compares two strings:

```
--> x1 = 'astring';
--> x2 = 'bstring';
--> x3 = 'astring';
--> strncmp(x1,x2,4)

ans =
 0

--> strncmp(x1,x3,4)

ans =
 1
```

Here we use a cell array strings

```
--> x = {'ast','bst',43,'astr'}

x =
 [ast] [bst] [43] [astr]

--> p = strncmp(x,'ast',3)

p =
 1 0 0 1
```

Here we compare two cell arrays of strings

```
--> strncmp({'this','is','a','pickle'},{'think','is','to','pickle'},3)

ans =
 1 0 0 1
```

Finally, the case where one of the arguments is a matrix string

```
--> strncmp({'this','is','a','pickle'},['peter ';'piper ';'hated ';'pickle'],4);
```

17.14 STRREP String Replace Function

17.14.1 Usage

Replace every occurance of one string with another. The general syntax for its use is

```
p = strrep(source,find,replace)
```

Every instance of the string `find` in the string `source` is replaced with the string `replace`. Any of `source`, `find` and `replace` can be a cell array of strings, in which case each entry has the replace operation applied.

17.14.2 Example

Here are some examples of the use of `strrep`. First the case where are the arguments are simple strings

```
--> strrep('Matlab is great','Matlab','FreeMat')

ans =
FreeMat is great
```

And here we have the replace operation for a number of strings:

```
--> strrep({'time is money';'A stitch in time';'No time for games'},'time','money')

ans =
 [money is money]
 [A stitch in money]
 [No money for games]
```

17.15 STRSTR String Search Function

17.15.1 Usage

Searches for the first occurance of one string inside another. The general syntax for its use is

```
p = strstr(x,y)
```

where `x` and `y` are two strings. The returned integer `p` indicates the index into the string `x` where the substring `y` occurs. If no instance of `y` is found, then `p` is set to zero.

17.15.2 Example

Some examples of `strstr` in action

```
--> strstr('hello','lo')

ans =
 4

--> strstr('quick brown fox','own')

ans =
 9

--> strstr('free stuff','lunch')

ans =
 0
```

17.16 STRTRIM Trim Spaces from a String

17.16.1 Usage

Removes the white-spaces at the beginning and end of a string (or a cell array of strings). See `isspace` for a definition of a white-space. There are two forms for the `strtrim` function. The first is for single strings

```
y = strtrim(strng)
```

where `strng` is a string. The second form operates on a cell array of strings

```
y = strtrim(cellstr)
```

and trims each string in the cell array.

17.16.2 Example

Here we apply `strtrim` to a simple string

```
--> strtrim('  lot of blank spaces    ');
```

and here we apply it to a cell array

```
--> strtrim({'  space','enough ',' for ',''})

ans =
 [space] [enough] [for] []
```

17.17 UPPER Convert strings to upper case

17.17.1 Usage

The `upper` function converts a string to upper case with the syntax

```
y = upper(x)
```

where `x` is a string, in which case all of the lower case characters in `x` (defined as the range `'a'-'z'`) are converted to upper case. Alternately, you can call `upper` with a cell array of strings

```
y = upper(c)
```

in which case each string in the cell array is converted to upper case.

17.17.2 Example

A simple example:

```
--> upper('this Is Strange CAPitalizaTion')

ans =
THIS IS STRANGE CAPITALIZATION
```

and a more complex example with a cell array of strings

```
--> upper({'This','Is','Strange','CAPitalizaTion'})

ans =
 [THIS] [IS] [STRANGE] [CAPITALIZATION]
```

Chapter 18

Transforms/Decompositions

18.1 EIG Eigendecomposition of a Matrix

18.1.1 Usage

Computes the eigendecomposition of a square matrix. The `eig` function has several forms. The first returns only the eigenvalues of the matrix:

```
s = eig(A)
```

The second form returns both the eigenvectors and eigenvalues as two matrices (the eigenvalues are stored in a diagonal matrix):

```
[V,D] = eig(A)
```

where `D` is the diagonal matrix of eigenvalues, and `V` is the matrix of eigenvectors.

Eigenvalues and eigenvectors for asymmetric matrices `A` normally are computed with balancing applied. Balancing is a scaling step that normaly improves the quality of the eigenvalues and eigenvectors. In some instances (see the Function Internals section for more details) it is necessary to disable balancing. For these cases, two additional forms of `eig` are available:

```
s = eig(A,'nobalance'),
```

which computes the eigenvalues of `A` only, and does not balance the matrix prior to computation. Similarly,

```
[V,D] = eig(A,'nobalance')
```

recovers both the eigenvectors and eigenvalues of `A` without balancing. Note that the 'nobalance' option has no affect on symmetric matrices.

FreeMat also provides the ability to calculate generalized eigenvalues and eigenvectors. Similarly to the regular case, there are two forms for `eig` when computing generalized eigenvector (see the Function Internals section for a description of what a generalized eigenvector is). The first returns only the generalized eigenvalues of the matrix pair `A,B`

```
s = eig(A,B)
```

The second form also computes the generalized eigenvectors, and is accessible via

```
[V,D] = eig(A,B)
```

18.1.2 Function Internals

Recall that `v` is an eigenvector of `A` with associated eigenvalue `d` if

$$Av = dv.$$

This decomposition can be written in matrix form as

$$AV = VD$$

where

$$V = [v_1, v_2, \ldots, v_n], D = \mathrm{diag}(d_1, d_2, \ldots, d_n).$$

The `eig` function uses the `LAPACK` class of functions `GEEVX` to compute the eigenvalue decomposition for non-symmetric (or non-Hermitian) matrices `A`. For symmetric matrices, `SSYEV` and `DSYEV` are used for `float` and `double` matrices (respectively). For Hermitian matrices, `CHEEV` and `ZHEEV` are used for `complex` and `dcomplex` matrices.

For some matrices, the process of balancing (in which the rows and columns of the matrix are pre-scaled to facilitate the search for eigenvalues) is detrimental to the quality of the final solution. This is particularly true if the matrix contains some elements on the order of round off error. See the Example section for an example.

A generalized eigenvector of the matrix pair `A,B` is simply a vector `v` with associated eigenvalue `d` such that

$$Av = dBv,$$

where `B` is a square matrix of the same size as `A`. This decomposition can be written in matrix form as

$$AV = BVD$$

where

$$V = [v_1, v_2, \ldots, v_n], D = \mathrm{diag}(d_1, d_2, \ldots, d_n).$$

For general matrices `A` and `B`, the `GGEV` class of routines are used to compute the generalized eigendecomposition. If howevever, `A` and `B` are both symmetric (or Hermitian, as appropriate), Then FreeMat first attempts to use `SSYGV` and `DSYGV` for `float` and `double` arguments and `CHEGV` and `ZHEGV` for `complex` and `dcomplex` arguments (respectively). These routines requires that `B` also be positive definite, and if it fails to be, FreeMat will revert to the routines used for general arguments.

18.1.3 Example

Some examples of eigenvalue decompositions. First, for a diagonal matrix, the eigenvalues are the diagonal elements of the matrix.

```
--> A = diag([1.02f,3.04f,1.53f])

A =
    1.0200         0         0
         0    3.0400         0
         0         0    1.5300

--> eig(A)

ans =
    1.0200
    1.5300
    3.0400
```

Next, we compute the eigenvalues of an upper triangular matrix, where the eigenvalues are again the diagonal elements.

```
--> A = [1.0f,3.0f,4.0f;0,2.0f,6.7f;0.0f,0.0f,1.0f]

A =
    1.0000    3.0000    4.0000
         0    2.0000    6.7000
         0         0    1.0000

--> eig(A)

ans =
 1
 2
 1
```

Next, we compute the complete eigenvalue decomposition of a random matrix, and then demonstrate the accuracy of the solution

```
--> A = float(randn(2))

A =
    0.3747   -1.5129
   -0.6283   -1.1096

--> [V,D] = eig(A)
V =
    0.9526    0.6096
   -0.3042    0.7927

D =
    0.8578         0
         0   -1.5928

--> A*V - V*D

ans =

   1.0e-08 *
   -5.9605         0
   -2.9802         0
```

Now, we consider a matrix that requires the nobalance option to compute the eigenvalues and eigenvectors properly. Here is an example from MATLAB's manual.

```
--> B = [3,-2,-.9,2*eps;-2,4,1,-eps;-eps/4,eps/2,-1,0;-.5,-.5,.1,1]

B =
    3.0000   -2.0000   -0.9000    0.0000
   -2.0000    4.0000    1.0000   -0.0000
   -0.0000    0.0000   -1.0000         0
   -0.5000   -0.5000    0.1000    1.0000

--> [VB,DB] = eig(B)
VB =
    0.6153   -0.4176   -0.0000   -0.1495
   -0.7881   -0.3261   -0.0000    0.1316
   -0.0000   -0.0000    0.0000   -0.9570
```

```
    0.0189    0.8481    1.0000   -0.2110

DB =
    5.5616         0         0         0
         0    1.4384         0         0
         0         0    1.0000         0
         0         0         0   -1.0000

--> B*VB - VB*DB

ans =
         0         0    0.0000   -0.0000
         0    0.0000   -0.0000    0.0000
   -0.0000   -0.0000   -0.0000   -0.0000
    0.0000    0.0000    0.0000   -0.5088

--> [VN,DN] = eig(B,'nobalance')
VN =
    0.6153   -0.4176   -0.0000   -0.1528
   -0.7881   -0.3261         0    0.1345
   -0.0000   -0.0000   -0.0000   -0.9781
    0.0189    0.8481   -1.0000    0.0443

DN =
    5.5616         0         0         0
         0    1.4384         0         0
         0         0    1.0000         0
         0         0         0   -1.0000

--> B*VN - VN*DN

ans =

   1.0e-15 *
   -1.7764   -0.1110   -0.5587   -0.1665
    3.5527    1.0547    0.3364   -0.1943
    0.0172    0.0015    0.0066         0
    0.1527   -0.2220    0.2220    0.0833
```

18.2 FFT (Inverse) Fast Fourier Transform Function

18.2.1 Usage

Computes the Discrete Fourier Transform (DFT) of a vector using the Fast Fourier Transform technique. The general syntax for its use is

```
y = fft(x,n,d)
```

where `x` is an `n`-dimensional array of numerical type. Integer types are promoted to the `double` type prior to calculation of the DFT. The argument `n` is the length of the FFT, and `d` is the dimension along which to take the DFT. If —n— is larger than the length of `x` along dimension `d`, then `x` is zero-padded (by appending zeros) prior to calculation of the DFT. If `n` is smaller than the length of `x` along the given dimension, then `x` is truncated (by removing elements at the end) to length `n`.

If `d` is omitted, then the DFT is taken along the first non-singleton dimension of `x`. If `n` is omitted, then the DFT length is chosen to match of the length of `x` along dimension `d`.

Note that FFT support on Linux builds requires availability of the FFTW libraries at compile time. On Windows and Mac OS X, single and double precision FFTs are available by default.

18.2.2 Function Internals

The output is computed via

$$y(m_1,\ldots,m_{d-1},l,m_{d+1},\ldots,m_p) = \sum_{k=1}^{n} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)e^{-\frac{2\pi(k-1)l}{n}}.$$

For the inverse DFT, the calculation is similar, and the arguments have the same meanings as the DFT:

$$y(m_1,\ldots,m_{d-1},l,m_{d+1},\ldots,m_p) = \frac{1}{n}\sum_{k=1}^{n} x(m_1,\ldots,m_{d-1},k,m_{d+1},\ldots,m_p)e^{\frac{2\pi(k-1)l}{n}}.$$

The FFT is computed using the FFTPack library, available from netlib at `http://www.netlib.org`. Generally speaking, the computational cost for a FFT is (in worst case) `O(n\^2)`. However, if `n` is composite, and can be factored as

$$n = \prod_{k=1}^{p} m_k,$$

then the DFT can be computed in

$$O(n\sum_{k=1}^{p} m_k)$$

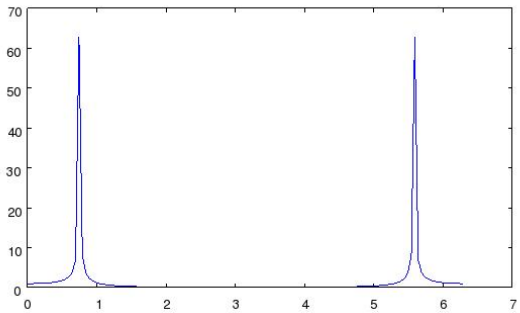
operations. If `n` is a power of 2, then the FFT can be calculated in `O(n log\_2 n)`. The calculations for the inverse FFT are identical.

18.2.3 Example

The following piece of code plots the FFT for a sinusoidal signal:

```
--> t = linspace(0,2*pi,128);
--> x = cos(15*t);
--> y = fft(x);
--> plot(t,abs(y));
```

The resulting plot is:



The FFT can also be taken along different dimensions, and with padding and/or truncation. The following example demonstrates the Fourier Transform being computed along each column, and then along each row.

```
--> A = [2,5;3,6]

A =
 2 5
```

```
 3 6

--> real(fft(A,[],1))

ans =
  5 11
 -1 -1

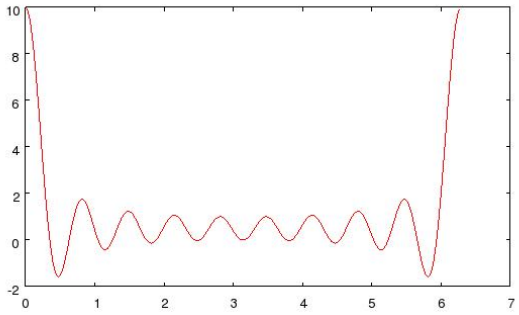
--> real(fft(A,[],2))

ans =
  7 -3
  9 -3
```

Fourier transforms can also be padded using the `n` argument. This pads the signal with zeros prior to taking the Fourier transform. Zero padding in the time domain results in frequency interpolation. The following example demonstrates the FFT of a pulse (consisting of 10 ones) with (red line) and without (green circles) padding.

```
--> delta(1:10) = 1;
--> plot((0:255)/256*pi*2,real(fft(delta,256)),'r-');
--> hold on
--> plot((0:9)/10*pi*2,real(fft(delta)),'go');
```

The resulting plot is:



18.3 FFTN N-Dimensional Forward FFT

18.3.1 Usage

Computes the DFT of an N-dimensional numerical array along all dimensions. The general syntax for its use is

```
y = fftn(x)
```

which computes the same-size FFTs for each dimension of `x`. Alternately, you can specify the size vector

```
y = fftn(x,dims)
```

where `dims` is a vector of sizes. The array `x` is zero padded or truncated as necessary in each dimension so that the output is of size `dims`. The `fftn` function is implemented by a sequence of calls to `fft`.

18.4 FFTSHIFT Shift FFT Output

18.4.1 Usage

The `fftshift` function shifts the DC component (zero-frequency) of the output from an FFT to the center of the array. For vectors this means swapping the two halves of the vector. For matrices, the first and third quadrants are swapped. So on for N-dimensional arrays. The syntax for its use is

```
y = fftshift(x).
```

Alternately, you can specify that only one dimension be shifted

```
y = fftshift(x,dim).
```

18.5 HILBERT Hilbert Transform

18.5.1 Usage

The `hilbert` function computes the hilbert transform of the argument vector or matrix. The FreeMat `hilbert` function is compatible with the one from the MATLAB API. This means that the output of the `hilbert` function is the sum of the original function and an imaginary signal containing the Hilbert transform of it. There are two syntaxes for the hilbert function. The first is

```
y = hilbert(x)
```

where `x` is real vector or matrix. If `x` is a matrix, then he Hilbert transform is computed along the columns of `x`. The second syntax provides a dimension along which to take the transform.

```
y = hilbert(x,n)
```

where `n` is the dimension along which to apply the transformation.

18.6 IFFTN N-Dimensional Inverse FFT

18.6.1 Usage

Computes the inverse DFT of an N-dimensional numerical array along all dimensions. The general syntax for its use is

```
y = ifftn(x)
```

which computes the same-size inverse FFTs for each dimension of `x`. Alternately, you can specify the size vector

```
y = ifftn(x,dims)
```

where `dims` is a vector of sizes. The array `x` is zero padded or truncated as necessary in each dimension so that the output is of size `dims`. The `ifftn` function is implemented by a sequence of calls to `ifft`.

18.7 IFFTSHIFT Inverse Shift FFT Output

18.7.1 Usage

The `ifftshift` function shifts the DC component (zero-frequency) of the output from the center of the array back to the first position and iseffectively the inverse of `fftshift`. For vectors this means swapping the two halves of the vector. For matrices, the first and third quadrants are swapped. So on for N-dimensional arrays. The syntax for its use is

```
y = ifftshift(x).
```

Alternately, you can specify that only one dimension be shifted

```
y = ifftshift(x,dim).
```

18.8 INV Invert Matrix

18.8.1 Usage

Inverts the argument matrix, provided it is square and invertible. The syntax for its use is

```
y = inv(x)
```

Internally, the `inv` function uses the matrix divide operators. For sparse matrices, a sparse matrix solver is used.

18.8.2 Example

Here we invert some simple matrices

```
--> a = randi(zeros(3),5*ones(3))

a =
 5 3 3
 4 1 3
 5 2 5

--> b = inv(a)

b =
    0.0909    0.8182   -0.5455
    0.4545   -0.9091    0.2727
   -0.2727   -0.4545    0.6364

--> a*b

ans =
    1.0000    0.0000   -0.0000
    0.0000    1.0000         0
    0.0000    0.0000    1.0000

--> b*a

ans =
    1.0000    0.0000         0
    0.0000    1.0000         0
    0.0000   -0.0000    1.0000
```

18.9 LU LU Decomposition for Matrices

18.9.1 Usage

Computes the LU decomposition for a matrix. The form of the command depends on the type of the argument. For full (non-sparse) matrices, the primary form for `lu` is

```
[L,U,P] = lu(A),
```

where `L` is lower triangular, `U` is upper triangular, and `P` is a permutation matrix such that `L*U = P*A`. The second form is

```
[V,U] = lu(A),
```

where V is P'*L (a row-permuted lower triangular matrix), and U is upper triangular. For sparse, square matrices, the LU decomposition has the following form:

```
[L,U,P,Q,R] = lu(A),
```

where A is a sparse matrix of either double or dcomplex type. The matrices are such that L*U=P*R*A*Q, where L is a lower triangular matrix, U is upper triangular, P and Q are permutation vectors and R is a diagonal matrix of row scaling factors. The decomposition is computed using UMFPACK for sparse matrices, and LAPACK for dense matrices.

18.9.2 Example

First, we compute the LU decomposition of a dense matrix.

```
--> a = float([1,2,3;4,5,8;10,12,3])

a =
  1  2  3
  4  5  8
 10 12  3

--> [l,u,p] = lu(a)
l =
    1.0000         0         0
    0.1000    1.0000         0
    0.4000    0.2500    1.0000

u =
   10.0000   12.0000    3.0000
         0    0.8000    2.7000
         0         0    6.1250

p =
 0 0 1
 1 0 0
 0 1 0

--> l*u

ans =
 10 12  3
  1  2  3
  4  5  8

--> p*a

ans =
 10 12  3
  1  2  3
  4  5  8
```

Now we repeat the exercise with a sparse matrix, and demonstrate the use of the permutation vectors.

```
--> a = sparse([1,0,0,4;3,2,0,0;0,0,0,1;4,3,2,4])

a =
```

```
 1 1 1
 2 1 3
 4 1 4
 2 2 2
 4 2 3
 4 3 2
 1 4 4
 3 4 1
 4 4 4
--> [l,u,p,q,r] = lu(a)
l =
 1 1 1
 2 2 1
 3 3 1
 4 4 1
u =
 1 1 0.153846
 1 2 0.230769
 2 2 0.4
 1 3 0.307692
 2 3 0.6
 3 3 0.2
 1 4 0.307692
 3 4 0.8
 4 4 1
p =
 4
 2
 1
 3

q =
 3
 2
 1
 4

r =
 1 1 0.2
 2 2 0.2
 3 3 1
 4 4 0.0769231
--> full(l*a)

ans =
 1 0 0 4
 3 2 0 0
 0 0 0 1
 4 3 2 4

--> b = r*a

b =
 1 1 0.2
```

```
 2 1 0.6
 3 1 0
 4 1 0.307692
 1 2 0
 2 2 0.4
 3 2 0
 4 2 0.230769
 1 3 0
 2 3 0
 3 3 0
 4 3 0.153846
 1 4 0.8
 2 4 0
 3 4 1
 4 4 0.307692
--> full(b(p,q))

ans =
    0.1538    0.2308    0.3077    0.3077
         0    0.4000    0.6000         0
         0         0    0.2000    0.8000
         0         0         0    1.0000
```

18.10 QR QR Decomposition of a Matrix

18.10.1 Usage

Computes the QR factorization of a matrix. The `qr` function has multiple forms, with and without pivoting. The non-pivot version has two forms, a compact version and a full-blown decomposition version. The compact version of the decomposition of a matrix of size `M x N` is

```
[q,r] = qr(a,0)
```

where `q` is a matrix of size `M x L` and `r` is a matrix of size `L x N` and `L = min(N,M)`, and `q*r = a`. The QR decomposition is such that the columns of `Q` are orthonormal, and `R` is upper triangular. The decomposition is computed using the LAPACK routine `xgeqrf`, where `x` is the precision of the matrix. FreeMat supports decompositions of `single` and `double` types.

The second form of the non-pivot decomposition omits the second `0` argument:

```
[q,r] = qr(a)
```

This second form differs from the previous form only for matrices with more rows than columns (`M > N`). For these matrices, the full decomposition is of a matrix `Q` of size `M x M` and a matrix `R` of size `M x N`. The full decomposition is computed using the same LAPACK routines as the compact decomposition, but on an augmented matrix `[a 0]`, where enough columns are added to form a square matrix.

Generally, the QR decomposition will not return a matrix `R` with diagonal elements in any specific order. The remaining two forms of the `qr` command utilize permutations of the columns of `a` so that the diagonal elements of `r` are in decreasing magnitude. To trigger this form of the decomposition, a third argument is required, which records the permutation applied to the argument `a`. The compact version is

```
[q,r,e] = qr(a,0)
```

where `e` is an integer vector that describes the permutation of the columns of `a` necessary to reorder the diagonal elements of `r`. This result is computed using the LAPACK routines `(s,d)geqp3`. In the non-compact version of the QR decomposition with pivoting,

```
[q,r,e] = qr(a)
```

the returned matrix `e` is a permutation matrix, such that `q*r*e' = a`.

18.11 SVD Singular Value Decomposition of a Matrix

18.11.1 Usage

Computes the singular value decomposition (SVD) of a matrix. The `svd` function has three forms. The first returns only the singular values of the matrix:

```
s = svd(A)
```

The second form returns both the singular values in a diagonal matrix `S`, as well as the left and right eigenvectors.

```
[U,S,V] = svd(A)
```

The third form returns a more compact decomposition, with the left and right singular vectors corresponding to zero singular values being eliminated. The syntax is

```
[U,S,V] = svd(A,0)
```

18.11.2 Function Internals

Recall that `sigma\_i` is a singular value of an `M x N` matrix `A` if there exists two vectors `u\_i, v\_i` where `u\_i` is of length `M`, and `v\_i` is of length `u\_i` and

$$Av_i = \sigma_i u_i$$

and generally

$$A = \sum_{i=1}^{K} \sigma_i u_i * v_i',$$

where `K` is the rank of `A`. In matrix form, the left singular vectors `u\_i` are stored in the matrix `U` as

$$U = [u_1, \ldots, u_m], V = [v_1, \ldots, v_n]$$

The matrix `S` is then of size `M x N` with the singular values along the diagonal. The SVD is computed using the `LAPACK` class of functions `GESVD` (Note that this has changed. Previous versions of FreeMat used `GESDD`, which yields a valid, but slightly different choice of the decomposition. Starting in version 4, it was changed to `GESVD` to improve compatibility.

18.11.3 Examples

Here is an example of a partial and complete singular value decomposition.

```
--> A = float(randn(2,3))

A =
    0.1962   -1.7828   -1.0621
   -0.6022   -0.6335    0.5810

--> [U,S,V] = svd(A)
U =
   -0.9929   -0.1189
   -0.1189    0.9929

S =
    2.0957         0         0
         0    1.0268         0
```

```
V =
   -0.0588   -0.6051    0.7940
    0.8806   -0.4061   -0.2443
    0.4702    0.6848    0.5567

--> U*S*V'

ans =
    0.1962   -1.7828   -1.0621
   -0.6022   -0.6335    0.5810

--> svd(A)

ans =
    2.0957
    1.0268
```

Chapter 19

Signal Processing Functions

19.1 CONV Convolution Function

19.1.1 Usage

The `conv` function performs a one-dimensional convolution of two vector arguments. The syntax for its use is

```
z = conv(x,y)
```

where `x` and `y` are vectors. The output is of length `nx + ny -1`. The `conv` function calls `conv2` to do the calculation. See its help for more details.

19.2 CONV2 Matrix Convolution

19.2.1 Usage

The `conv2` function performs a two-dimensional convolution of matrix arguments. The syntax for its use is

```
Z = conv2(X,Y)
```

which performs the full 2-D convolution of `X` and `Y`. If the input matrices are of size `[xm,xn]` and `[ym,yn]` respectively, then the output is of size `[xm+ym-1,xn+yn-1]`. Another form is

```
Z = conv2(hcol,hrow,X)
```

where `hcol` and `hrow` are vectors. In this form, `conv2` first convolves `Y` along the columns with `hcol`, and then convolves `Y` along the rows with `hrow`. This is equivalent to `conv2(hcol(:)*hrow(:)',Y)`.

You can also provide an optional `shape` argument to `conv2` via either

```
Z = conv2(X,Y,'shape')
Z = conv2(hcol,hrow,X,'shape')
```

where `shape` is one of the following strings

- `'full'` - compute the full convolution result - this is the default if no `shape` argument is provided.
- `'same'` - returns the central part of the result that is the same size as `X`.
- `'valid'` - returns the portion of the convolution that is computed without the zero-padded edges. In this situation, `Z` has size `[xm-ym+1,xn-yn+1]` when `xm>=ym` and `xn>=yn`. Otherwise `conv2` returns an empty matrix.

19.2.2 Function Internals

The convolution is computed explicitly using the definition:

$$Z(m,n) = \sum_k \sum_j X(k,j)Y(m-k,n-j)$$

If the full output is requested, then `m` ranges over `0 <= m < xm+ym-1` and `n` ranges over `0 <= n < xn+yn-1`.
For the case where `shape` is `'same'`, the output ranges over `(ym-1)/2 <= m < xm + (ym-1)/2` and `(yn-1)/2 <= n < xn + (`

Chapter 20

Numerical Methods

20.1 CUMTRAPZ Trapezoidal Rule Cumulative Integration

20.1.1 Usage

The cumtrapz routine has the following syntax @[[z] = cumtrapz(x,y) @] where —x— is a dependent vector and —y— an m-by-n matrix equal in at least one dimension to x. (e.g.:x = time samples, y = f(t))

Alternatively, you can enter

```
[z] = cumtrapz(y)
```

for a unit integration of —y—.

If —y— is a matrix, m must be equal to length(x) (e.g.: y must have the same number of rows as x has elements). In this case, integrals are taken for each row, returned in a resulting vector z of dimension (1,n)

20.2 ODE45 Numerical Solution of ODEs

20.2.1 Usage

function [t,y] = ode45(f,tspan,y0,options,varargin) function SOL = ode45(f,tspan,y0,options,varargin)

ode45 is a solver for ordinary differential equations and initial value problems. To solve the ODE

```
y'(t) =  f(t,y)
y(0)  =  y0
```

over the interval tspan=[t0 t1], you can use ode45. For example, to solve the ode

y' = y y(0) = 1

whose exact solution is y(t)=exp(t), over the interval t0=0, t1=3, do

```
-->       [t,y]=ode45(@(t,y) y,[0 3],1)
t =

 Columns 1 to 12

         0    0.0030    0.0180    0.0930    0.3930    0.6930    0.9930    1.2930    1.5930    1.8930

 Columns 13 to 14

    2.7930    3.0000

y =
    1.0000
```

```
    1.0030
    1.0182
    1.0975
    1.4814
    1.9997
    2.6993
    3.6437
    4.9185
    6.6392
    8.9620
   12.0975
   16.3299
   20.0854
```

If you want a dense output (i.e., an output that also contains an interpolating spline), use instead

```
-->       SOL=ode45(@(t,y) y,[0 3],1)

SOL =
    x: 1x14 double array
    y: 1x14 double array
    xe:
    ye:
    ie:
    solver: generic_ode_solver
    interpolant: 1x1 functionpointer array
    idata: 1x1 struct array
```

You can view the result using

```
      plot(0:0.01:3,deval(SOL,0:0.01:3))
```

You will notice that this function is available for "every" value of t, while
plot(t,y,'o-')
is only available at a few points.

The optional argument 'options' is a structure. It may contain any of the following fields:

'AbsTol' - Absolute tolerance, default is 1e-6. 'RelTol' - Relative tolerance, default is 1e-3. 'MaxStep' - Maximum step size, default is (tspan(2)-tspan(1))/10 'InitialStep' - Initial step size, default is maxstep/100 'Stepper' - To override the default Fehlberg integrator 'Events' - To provide an event function 'Projection' - To provide a projection function

The varargin is ignored by this function, but is passed to all your callbacks, i.e., f, the event function and the projection function.

==Event Function==

The event function can be used to detect situations where the integrator should stop, possibly because the right-hand-side has changed, because of a collision, etc...

An event function should look like

function [val,isterminal,direction]=event(t,y,...)

The return values are:

val - the value of the event function. isterminal - whether or not this event should cause termination of the integrator. direction - 1=upcrossings only matter, -1=downcrossings only, 0=both.

== Projection function ==

For geometric integration, you can provide a projection function which will be called after each time step. The projection function has the following signature:

function yn=project(t,yn,...);

If the output yn is very different from the input yn, the quality of interpolation may decrease.

20.3 TRAPZ Trapezoidal Rule Integration

20.3.1 Usage

The trapz routine has the following syntax @[z = trapz(x,y) @] where —x— is a dependent vector and —y— an m-by-n matrix equal in at least one dimension to x. (e.g.:—x— = time samples, y = f(t))

Alternatively, you can enter

```
z = trapz(y)
```

for a unit integration of y.

If y is a matrix, m must be equal to length(x) (e.g.: y must have the same number of rows as x has elements). In this case, integrals are taken for each row, returned in a resulting vector z of dimension (1,n)

Chapter 21

Operating System Functions

21.1 CD Change Working Directory Function

21.1.1 Usage

Changes the current working directory to the one specified as the argument. The general syntax for its use is

```
cd('dirname')
```

but this can also be expressed as

```
cd 'dirname'
```

or

```
cd dirname
```

Examples of all three usages are given below. Generally speaking, `dirname` is any string that would be accepted by the underlying OS as a valid directory name. For example, on most systems, `'.'` refers to the current directory, and `'..'` refers to the parent directory. Also, depending on the OS, it may be necessary to "escape" the directory seperators. In particular, if directories are seperated with the backwards-slash character `'\\'`, then the path specification must use double-slashes `'\\\\'`. Note: to get file-name completion to work at this time, you must use one of the first two forms of the command.

21.1.2 Example

The `pwd` command returns the current directory location. First, we use the simplest form of the `cd` command, in which the directory name argument is given unquoted.

```
--> pwd

ans =
/home/sbasu/Devel/FreeMat/help/tmp
--> cd ..
--> pwd

ans =
/home/sbasu/Devel/FreeMat/help
```

Next, we use the "traditional" form of the function call, using both the parenthesis and a variable to store the quoted string.

```
--> a = pwd;
--> cd(a)
--> pwd

ans =
/home/sbasu/Devel/FreeMat/help/tmp
```

21.2 COPYFILE Copy Files

21.2.1 Usage

Copies a file or files from one location to another. There are several syntaxes for this function that are acceptable:

```
copyfile(file_in,file_out)
```

copies the file from `file\_in` to `file\_out`. Also, the second argument can be a directory name:

```
copyfile(file_in,directory_out)
```

in which case `file\_in` is copied into the directory specified by `directory\_out`. You can also use `copyfile` to copy entire directories as in

```
copyfile(dir_in,dir_out)
```

in which case the directory contents are copied to the destination directory (which is created if necessary). Finally, the first argument to `copyfile` can contain wildcards

```
copyfile(pattern,directory_out)
```

in which case all files that match the given pattern are copied to the output directory. Note that to remain compatible with the MATLAB API, this function will delete/replace destination files that already exist, unless they are marked as read-only. If you want to force the copy to succeed, you can append a `'f'` argument to the `copyfile` function:

```
copyfile(arg1,arg2,'f')
```

or equivalently

```
copyfile arg1 arg2 f
```

21.3 DELETE Delete a File

21.3.1 Usage

Deletes a file. The general syntax for its use is

```
delete('filename')
```

or alternately

```
delete filename
```

which removes the file described by `filename` which must be relative to the current path.

21.4 DIR List Files Function

21.4.1 Usage

In some versions of FreeMat (pre 3.1), the `dir` function was aliased to the `ls` function. Starting with version `3.1`, the `dir` function has been rewritten to provide compatibility with MATLAB. The general syntax for its use is

```
dir
```

in which case, a listing of the files in the current directory are output to the console. Alternately, you can specify a target via

```
dir('name')
```

or using the string syntax

```
dir name
```

If you want to capture the output of the `dir` command, you can assign the output to an array

```
result = dir('name')
```

(or you can omit `'name'` to get a directory listing of the current directory. The resulting array `result` is a structure array containing the fields:

- `name` the filename as a string
- `date` the modification date and time stamp as a string
- `bytes` the size of the file in bytes as a `uint64`
- `isdir` a logical that is `1` if the file corresponds to a directory.

Note that `'name'` can also contain wildcards (e.g., `dir *.m` to get a listing of all FreeMat scripts in the current directory.

21.5 DIRSEP Director Seperator

21.5.1 Usage

Returns the directory seperator character for the current platform. The general syntax for its use is

```
y = dirsep
```

This function can be used to build up paths (or see `fullfile` for another way to do this.

21.6 FILEATTRIB Get and Set File or Directory Attributes

21.6.1 Usage

Retrieves information about a file or directory. The first version uses the syntax

```
y = fileattrib(filename)
```

where `filename` is the name of a file or directory. The returned structure contains several entries, corresponding to the attributes of the file. Here is a list of the entries, and their meaning:

- `Name` - the full pathname for the file
- `archive` - not used, set to `0`

- `system` - not used, set to `0`
- `hidden` - set to `1` for a hidden file, and `0` else.
- `directory` - set to `1` for a directory, and `0` for a file.
- `UserRead` - set to `1` if the user has read permission, `0` otherwise.
- `UserWrite` - set to `1` if the user has write permission, `0` otherwise.
- `UserExecute` - set to `1` if the user has execute permission, `0` otherwise.
- `GroupRead` - set to `1` if the group has read permission, `0` otherwise.
- `GroupWrite` - set to `1` if the group has write permission, `0` otherwise.
- `GroupExecute` - set to `1` if the group has execute permission, `0` otherwise.
- `OtherRead` - set to `1` if the world has read permission, `0` otherwise.
- `OtherWrite` - set to `1` if the world has write permission, `0` otherwise.
- `OtherExecute` - set to `1` if the world has execute permission, `0` otherwise.

You can also provide a wildcard filename to get the attributes for a set of files e.g.,

```
y = fileattrib('foo*')
```

You can also use `fileattrib` to change the attributes of a file and/or directories. To change attributes, use one of the following syntaxes

```
y = fileattrib(filename,attributelist)
y = fileattrib(filename,attributelist,userlist)
y = fileattrib(filename,attributelist,userlist,'s')
```

where `attributelist` is a string that consists of a list of attributes, each preceeded by a `+` to enable the attribute, and `-` to disable the attribute. The valid list of attributes that can be changed are

- `'w'` - change write permissions
- `'r'` - change read permissions
- `'x'` - change execute permissions

for example, `'-w +r'` would indicate removal of write permissions and addition of read permissions. The `userlist` is a string that lists the realm of the permission changes. If it is not specified, it defaults to `'u'`.

- `'u'` - user or owner permissions
- `'g'` - group permissions
- `'o'` - other permissions ("world" in normal Unix terminology)
- `'a'` - equivalent to 'ugo'.

Finally, if you specify a `'s'` for the last argument, the attribute change is applied recursively, so that setting the attributes for a directory will apply to all the entries within the directory.

21.7 FILEPARTS Extract Filename Parts

21.7.1 Usage

The `fileparts` takes a filename, and returns the path, filename, extension, and (for MATLAB-compatibility) an empty version number of the file. The syntax for its use is

```
[path,name,extension,version] = fileparts(filename)
```

where `filename` is a string containing the description of the file, and `path` is the `path` to the file,

21.8 FULLFILE Build a Full Filename From Pieces

21.8.1 Usage

The `fullfile` routine constructs a full filename from a set of pieces, namely, directory names and a filename. The syntax is:

```
x = fullfile(dir1,dir2,...,dirn,filename)
```

where each of the arguments are strings. The `fullfile` function is equivalent to `[dir1 dirsep dir2 dirsep ... dirn dirs`

21.8.2 Example

```
--> fullfile('path','to','my','file.m')

ans =
path/to/my/file.m
```

21.9 GETENV Get the Value of an Environment Variable

21.9.1 Usage

The `getenv` function returns the value for an environment variable from the underlying OS. The syntax for the `getenv` function is

```
y = getenv(environment_variable)
```

where `environment\_variable` is the name of the environment variable to return. The return is a string.

21.9.2 Example

Here is an example of using the `getenv` function to get the value for the `HOME` variable

```
--> getenv('HOME')

ans =
/home/sbasu
```

21.10 GETPATH Get Current Search Path

21.10.1 Usage

Returns a `string` containing the current FreeMat search path. The general syntax for its use is

```
y = getpath
```

The delimiter between the paths depends on the system being used. For Win32, the delimiter is a semicolon. For all other systems, the delimiter is a colon.

21.10.2 Example

The `getpath` function is straightforward.

```
--> getpath

ans =
/usr/local/FreeMat/MFiles:/localhome/basu/MFiles
```

21.11 LS List Files Function

21.11.1 Usage

Lists the files in a directory or directories. The general syntax for its use is

```
ls('dirname1','dirname2',...,'dirnameN')
```

but this can also be expressed as

```
ls 'dirname1' 'dirname2' ... 'dirnameN'
```

or

```
ls dirname1 dirname2 ... dirnameN
```

For compatibility with some environments, the function `dir` can also be used instead of `ls`. Generally speaking, `dirname` is any string that would be accepted by the underlying OS as a valid directory name. For example, on most systems, `'.'` refers to the current directory, and `'..'` refers to the parent directory. Also, depending on the OS, it may be necessary to "escape" the directory seperators. In particular, if directories are seperated with the backwards-slash character `'\\'`, then the path specification must use double-slashes `'\\\\'`. Two points worth mentioning about the `ls` function:

- To get file-name completion to work at this time, you must use one of the first two forms of the command.
- If you want to capture the output of the `ls` command, use the `system` function instead.

21.11.2 Example

First, we use the simplest form of the `ls` command, in which the directory name argument is given unquoted.

```
--> ls m*.m
```

Next, we use the "traditional" form of the function call, using both the parenthesis and the quoted string.

```
--> ls('m*.m')
```

In the third version, we use only the quoted string argument without parenthesis.

```
--> ls 'm*.m'
```

21.12 MKDIR Make Directory

21.12.1 Usage

Creates a directory. The general syntax for its use is

```
mkdir('dirname')
```

which creates the directory `dirname` if it does not exist. The argument `dirname` can be either a relative path or an absolute path. For compatibility with MATLAB, the following syntax is also allowed

```
mkdir('parentdir','dirname')
```

which attempts to create a directory `dirname` in the directory given by `parentdir`. However, this simply calls `mkdir([parentdir dirsep dirname])`, and if this is not the required behavior, please file an enhancement request to have it changed. Note that `mkdir` returns a logical `1` if the call succeeded, and a logical `0` if not.

21.13 PWD Print Working Directory Function

21.13.1 Usage

Returns a `string` describing the current working directory. The general syntax for its use is

```
y = pwd
```

21.13.2 Example

The `pwd` function is fairly straightforward.

```
--> pwd

ans =
/home/sbasu/Devel/FreeMat/help/tmp
```

21.14 RMDIR Remove Directory

21.14.1 Usage

Deletes a directory. The general syntax for its use is

```
rmdir('dirname')
```

which removes the directory `dirname` if it is empty. If you want to delete the directory and all subdirectories and files in it, use the syntax

```
rmdir('dirname','s')
```

21.15 SETPATH Set Current Search Path

21.15.1 Usage

Changes the current FreeMat search path. The general syntax for its use is

```
setpath(y)
```

where `y` is a `string` containing a delimited list of directories to be searched for M files and libraries. The delimiter between the paths depends on the system being used. For Win32, the delimiter is a semicolon. For all other systems, the delimiter is a colon.

@Example The `setpath` function is straightforward.

```
--> getpath

ans =
/usr/local/FreeMat/MFiles:/localhome/basu/MFiles
--> setpath('/usr/local/FreeMat/MFiles:/localhome/basu/MFiles')
--> getpath

ans =
/usr/local/FreeMat/MFiles:/localhome/basu/MFiles
```

21.16 SYSTEM Call an External Program

21.16.1 Usage

The `system` function allows you to call an external program from within FreeMat, and capture the output. The syntax of the `system` function is

```
y = system(cmd)
```

where `cmd` is the command to execute. The return array `y` is of type `cell-array`, where each entry in the array corresponds to a line from the output.

21.16.2 Example

Here is an example of calling the `ls` function (the list files function under Un*x-like operating system).

```
--> y = system('ls a*.m')

y =
 [addtest2.m] [addtest3.m] [addtest.m]

--> y{1}

ans =
addtest2.m
```

Chapter 22

Optimization and Curve Fitting

22.1 FITFUN Fit a Function

22.1.1 Usage

Fits `n` (non-linear) functions of `m` variables using least squares and the Levenberg-Marquardt algorithm. The general syntax for its usage is

```
[xopt,yopt] = fitfun(fcn,xinit,y,weights,tol,params...)
```

Where `fcn` is the name of the function to be fit, `xinit` is the initial guess for the solution (required), `y` is the right hand side, i.e., the vector `y` such that:

$$xopt = \arg\min_x \|\mathrm{diag}(weights) * (f(x) - y)\|_2^2,$$

the output `yopt` is the function `fcn` evaluated at `xopt`. The vector `weights` must be the same size as `y`, and contains the relative weight to assign to an error in each output value. Generally, the ith weight should reflect your confidence in the ith measurement. The parameter `tol` is the tolerance used for convergence. The function `fcn` must return a vector of the same size as `y`, and `params` are passed to `fcn` after the argument `x`, i.e.,

$$y = fcn(x, param1, param2, ...).$$

Note that both `x` and `y` (and the output of the function) must all be real variables. Complex variables are not handled yet.

22.2 GAUSFIT Gaussian Curve Fit

22.2.1 Usage

The `gausfit` routine has the following syntax

```
[mu,sigma,dc,gain,yhat] = gausfit(t,y,w,mug,sigmag,dcg,gaing).
```

where the required inputs are

- `t` - the values of the independant variable (e.g., time samples)
- `y` - the values of the dependant variable (e.g., f(t))

The following inputs are all optional, and default values are available for each of them.

- `w` - the weights to use in the fitting (set to ones if omitted)
- `mug` - initial estimate of the mean

- `sigmag` - initial estimate of the sigma (standard deviation)
- `dcg` - initial estimate of the DC value
- `gaing` - initial estimate of the gain

The fit is of the form `yhat=gain*exp((t-mu).\^2/(2*sigma\^2))+dc`. The outputs are

- `mu` - the mean of the fit
- `sigma` - the sigma of the fit
- `dc` - the dc term of the fit
- `gain` - the gain of the gaussian fit
- `yhat` - the output samples (the Gaussian fits)

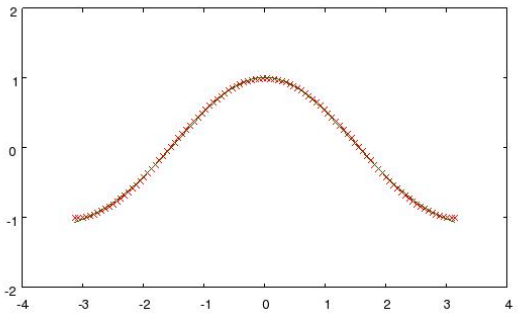
Because the fit is nonlinear, a good initial guess is critical to convergence of the solution. Thus, you can supply initial guesses for each of the parameters using the `mug`, `sigmag`, `dcg`, `gaing` arguments. Any arguments not supplied are estimated using a simple algorithm. In particular, the DC value is estimated by taking the minimum value from the vector `y`. The gain is estimated from the range of `y`. The mean and standard deviation are estimated using the first and second order moments of `y`. This function uses `fitfun`.

22.2.2 Example

Suppose we want to fit a cycle of a cosine using a Gaussian shape.

```
--> t = linspace(-pi,pi);
--> y = cos(t);
--> [mu,sigma,dc,gain,yhat] = gausfit(t,y);
--> plot(t,y,'rx',t,yhat,'g-');
```

Which results in the following plot



22.3 INTERP2 2-D Interpolation

22.3.1 Usage

Given a set of monotonically increasing `x` coordinates and a corresponding set of `y` values, performs simple linear interpolation to a new set of `x` coordinates. The general syntax for its usage is

```
zi = interp2(z,xi,yi)
```

where `xi` and `yi` are vectors of the same length. The output vector `zi` is the same size as the input vector `xi`. For each element of `xi`, the values in `zi` are linearly interpolated by default. Interpolation method can be selected as:

```
zi = interp2(z,xi,yi,method)
```

Default interpolation method is `'linear'`. Other methods are `'nearest'`, and `'cubic'`. For values in `xi, yi` that are outside the size of `z`, the default value returned is NaN. To change this behavior, you can specify the extrapolation value:

```
zi = interp2(z,xi,yi,method,extrapval)
```

The `z` and `xi,yi` vectors must be real, although complex types are allowed for `z`.

22.4 INTERPLIN1 Linear 1-D Interpolation

22.4.1 Usage

Given a set of monotonically increasing `x` coordinates and a corresponding set of `y` values, performs simple linear interpolation to a new set of `x` coordinates. The general syntax for its usage is

```
yi = interplin1(x1,y1,xi)
```

where `x1` and `y1` are vectors of the same length, and the entries in `x1` are monotoniccally increasing. The output vector `yi` is the same size as the input vector `xi`. For each element of `xi`, the values in `y1` are linearly interpolated. For values in `xi` that are outside the range of `x1` the default value returned is `nan`. To change this behavior, you can specify the extrapolation flag:

```
yi = interplin1(x1,y1,xi,extrapflag)
```

Valid options for `extrapflag` are:

- `'nan'` - extrapolated values are tagged with `nan`s
- `'zero'` - extrapolated values are set to zero
- `'endpoint'` - extrapolated values are set to the endpoint values
- `'extrap'` - linear extrapolation is performed

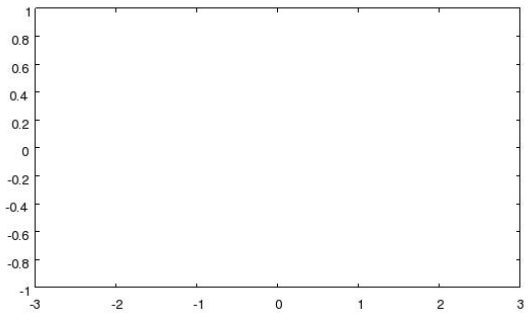
The `x1` and `xi` vectors must be real, although complex types are allowed for `y1`.

22.4.2 Example

Here is an example of simple linear interpolation with the different extrapolation modes. We start with a fairly coarse sampling of a cosine.

```
--> x = linspace(-pi*7/8,pi*7/8,15);
--> y = cos(x);
--> plot(x,y,'ro');
```

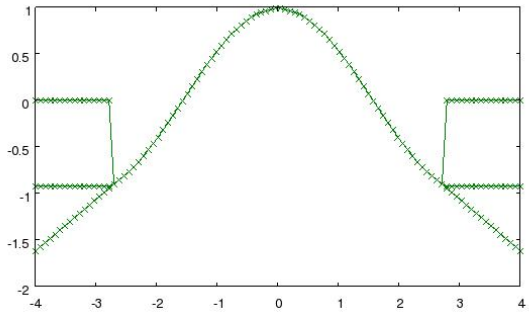
which is shown here



Next, we generate a finer sampling over a slightly broader range (in this case `[-pi,pi]`). First, we demonstrate the `'nan'` extrapolation method

```
--> xi = linspace(-4,4,100);
--> yi_nan = interplin1(x,y,xi,'nan');
--> yi_zero = interplin1(x,y,xi,'zero');
--> yi_endpoint = interplin1(x,y,xi,'endpoint');
--> yi_extrap = interplin1(x,y,xi,'extrap');
--> plot(x,y,'ro',xi,yi_nan,'g-x',xi,yi_zero,'g-x',xi,yi_endpoint,'g-x',xi,yi_extrap,'g-x');
```

which is shown here



22.5 POLY Convert Roots To Polynomial Coefficients

22.5.1 Usage

This function calculates the polynomial coefficients for given roots

```
p = poly(r)
```

when `r` is a vector, is a vector whose elements are the coefficients of the polynomial whose roots are the elements of `r`. Alternately, you can provide a matrix

```
p = poly(A)
```

when `A` is an `N x N` square matrix, is a row vector with `N+1` elements which are the coefficients of the characteristic polynomial, `det(lambda*eye(size(A))-A)`.

Contributed by Paulo Xavier Candeias under GPL.

22.5.2 Example

Here are some examples of the use of `poly`

```
--> A = [1,2,3;4,5,6;7,8,0]

A =
 1 2 3
 4 5 6
 7 8 0

--> p = poly(A)

p =
    1.0000   -6.0000  -72.0000  -27.0000

--> r = roots(p)

r =
```

```
   12.1229
   -5.7345
   -0.3884
```

22.6 POLYDER Polynomial Coefficient Differentiation

22.6.1 Usage

The `polyder` function returns the polynomial coefficients resulting from differentiation of polynomial `p`. The syntax for its use is either

```
 pder = polyder(p)
```

for the derivitave of polynomial p, or

```
 convp1p2der = polyder(p1,p2)
```

for the derivitave of polynomial conv(p1,p2), or still

```
 [nder,dder] = polyder(n,d)
```

for the derivative of polynomial `n/d` (`nder` is the numerator and `dder` is the denominator). In all cases the polynomial coefficients are assumed to be in decreasing degree. Contributed by Paulo Xavier Candeias under GPL

22.6.2 Example

Here are some examples of the use of `polyder`

```
--> polyder([2,3,4])

ans =
 4 3

--> polyder([2,3,4],7)

```

22.7 POLYFIT Fit Polynomial To Data

22.7.1 Usage

The `polyfit` routine has the following syntax

```
  p = polyfit(x,y,n)
```

where `x` and `y` are vectors of the same size, and `n` is the degree of the approximating polynomial. The resulting vector `p` forms the coefficients of the optimal polynomial (in descending degree) that fit `y` with `x`.

22.7.2 Function Internals

The `polyfit` routine finds the approximating polynomial

$$p(x) = p_1 x^n + p_2 x^{n-1} + \cdots + p_n x + p_{n+1}$$

such that

$$\sum_i (p(x_i) - y_i)^2$$

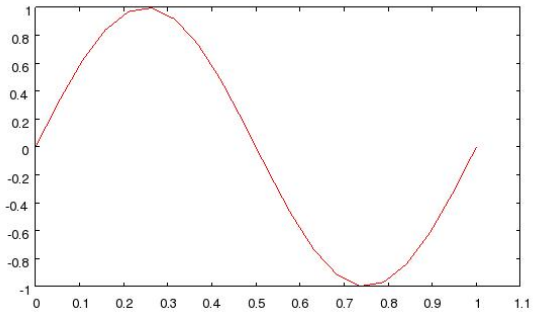
is minimized. It does so by forming the Vandermonde matrix and solving the resulting set of equations using the backslash operator. Note that the Vandermonde matrix can become poorly conditioned with large `n` quite rapidly.

22.7.3 Example

A classic example from Edwards and Penny, consider the problem of approximating a sinusoid with a polynomial. We start with a vector of points evenly spaced on the unit interval, along with a vector of the sine of these points.

```
--> x = linspace(0,1,20);
--> y = sin(2*pi*x);
--> plot(x,y,'r-')
```

The resulting plot is shown here



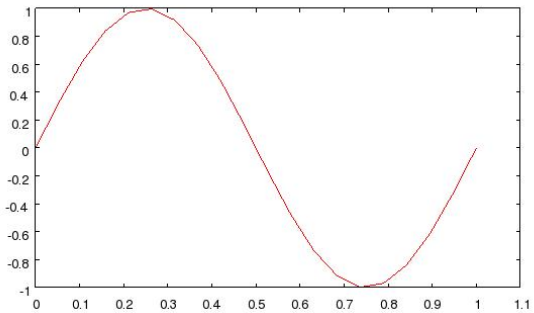
Next, we fit a third degree polynomial to the sine, and use `polyval` to plot it

```
--> p = polyfit(x,y,3)

p =
   21.9170  -32.8756   11.1897   -0.1156

--> f = polyval(p,x);
--> plot(x,y,'r-',x,f,'ko');
```

The resulting plot is shown here



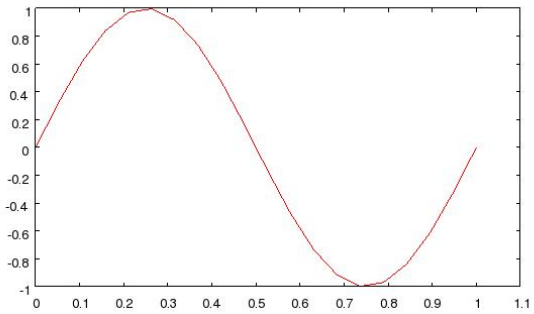
Increasing the order improves the fit, as

```
--> p = polyfit(x,y,11)

p =
   12.4644  -68.5541  130.0555  -71.0940  -38.2814  -14.1222   85.1018   -0.5642  -41.2861   -0.0029

--> f = polyval(p,x);
--> plot(x,y,'r-',x,f,'ko');
```

The resulting plot is shown here



22.8 POLYINT Polynomial Coefficient Integration

22.8.1 Usage

The polyint function returns the polynomial coefficients resulting from integration of polynomial p. The syntax for its use is either

```
 pint = polyint(p,k)
```

or, for a default `k = 0`,

```
 pint = polyint(p);
```

where `p` is a vector of polynomial coefficients assumed to be in decreasing degree and `k` is the integration constant. Contributed by Paulo Xavier Candeias under GPL

22.8.2 Example

Here is are some examples of the use of `polyint`.

```
--> polyint([2,3,4])

ans =
    0.6667    1.5000    4.0000         0
```

And

```
--> polyint([2,3,4],5)

ans =
    0.6667    1.5000    4.0000    5.0000
```

22.9 POLYVAL Evaluate Polynomial Fit at Selected Points

22.9.1 Usage

The `polyval` routine has the following syntax

```
y = polyval(p,x)
```

where `p` is a vector of polynomial coefficients, in decreasing degree (as generated by `polyfit`, for example). If `x` is a matrix, the polynomial is evaluated in the matrix sense (in which case `x` must be square).

22.9.2 Function Internals

The polynomial is evaluated using a recursion method. If the polynomial is

$$p(x) = p_1 x^n + p_2 x^{n-1} + \cdots + p_n x + p_{n+1}$$

then the calculation is performed as

$$p(x) = ((p_1)x + p_2)x + p_3$$

22.9.3 Example

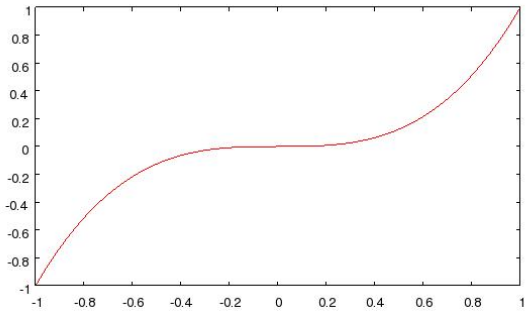
Here is a plot of `x\^3` generated using polyval

```
--> p = [1 0 0 0]

p =
 1 0 0 0

--> x = linspace(-1,1);
--> y = polyval(p,x);
--> plot(x,y,'r-')
```

Here is the resulting plot



22.10 ROOTS Find Roots of Polynomial

22.10.1 Usage

The `roots` routine will return a column vector containing the roots of a polynomial. The general syntax is

```
z = roots(p)
```

where `p` is a vector containing the coefficients of the polynomial ordered in descending powers.

22.10.2 Function Internals

Given a vector

$$[p_1, p_2, \ldots p_n]$$

which describes a polynomial

$$p_1 x^{n-1} + p_2 x^{n-2} + \cdots + p_n$$

we construct the companion matrix (which has a characteristic polynomial matching the polynomial described by `p`), and then find the eigenvalues of it (which are the roots of its characteristic polynomial), and which are also the roots of the polynomial of interest. This technique for finding the roots is described in the help page for `roots` on the Mathworks website.

22.10.3 Example

Here is an example of finding the roots to the polynomial

$$x^3 - 6x^2 - 72x - 27$$

```
--> roots([1 -6 -72 -27])

ans =
   12.1229
   -5.7345
   -0.3884
```

Chapter 23

Handle-Based Graphics

23.1 AXES Create Handle Axes

23.1.1 Usage

This function has three different syntaxes. The first takes no arguments,

```
h = axes
```

and creates a new set of axes that are parented to the current figure (see `gcf`). The newly created axes are made the current axes (see `gca`) and are added to the end of the list of children for the current figure. The second form takes a set of property names and values

```
h = axes(propertyname,value,propertyname,value,...)
```

Creates a new set of axes, and then sets the specified properties to the given value. This is a shortcut for calling `set(h,propertyname,value)` for each pair. The third form takes a handle as an argument

```
axes(handle)
```

and makes `handle` the current axes, placing it at the head of the list of children for the current figure.

23.2 AXIS Setup Axis Behavior

23.2.1 Usage

Control the axis behavior. There are several versions of the axis command based on what you would like the axis command to do. The first versions set scalings for the current plot. The general syntax for its use is

```
axis([xmin xmax ymin ymax zmin zmax cmin cmax])
```

which sets the limits in the X, Y, Z and color axes. You can also set only the X, Y and Z axes:

```
axis([xmin xmax ymin ymax zmin zmax])
```

or only the X and Y axes:

```
axis([xmin xmax ymin ymax])
```

To retrieve the current axis limits, use the syntax

```
x = axis
```

where `x` is a 4-vector for 2D plots, and a 6-vector for 3D plots.

There are a number of axis options supported by FreeMat. The first version sets the axis limits to be automatically selected by FreeMat for each dimension. This state is the default one for new axes created by FreeMat.

```
axis auto
```

The next option sets all of the axis limits to `manual` mode. This state turns off automatic scaling of the axis based on the children of the current axis object.

```
axis manual
```

The next option sets the axis limits to fit tightly around the data.

```
axis tight
```

The next option adjusts the axis limits and plotbox aspect ratio so that the axis fills the position rectangle.

```
axis fill
```

The next option puts the axis in matrix mode. This mode is equivalent to the standard mode, but with the vertical axis reversed. Thus, the origin of the coordinate system is at the top left corner of the plot. This mode makes plots of matrix elements look normal (i.e., an identity matrix goes from upper left to lower right).

```
axis ij
```

The next option puts the axis in normal mode, with the origin at the lower left corner.

```
axis xy
```

The next option sets the axis parameters (specifically the data aspect ratio) so that equal ticks on each axis represent equal length. In this mode, spheres look spherical insteal of ellipsoidal.

```
axis equal
```

The next option is the same as `axis equal`, but sets the plot box to fit tightly around the data (so no background shows through). It is the best option to use when displaying images.

```
axis image
```

The next option makes the axis box square.

```
axis square
```

The next option restores many of the normal characteristics of the axis. In particular, it undoes the effects of `square` `image` and `equal` modes.

```
axis normal
```

The next mode freezes axis properties so that 3D objects can be rotated properly.

```
axis vis3d
```

The next mode turns off all labels, tick marks and background.

```
axis on
```

The next mode turns on all labels, tick marks and background.

```
axis off
```

The next mode is similar to `axis off`, but also repacks the figure as tightly as possible. The result is a plot box that takes up the entire `outerposition` vector.

```
axis maximal
```

The `axis` command can also be applied to a particular axis (as opposed to the current axis as returned by `gca`) handle

```
axis(M,...)
```

23.3 AXISPROPERTIES Axis Object Properties

23.3.1 Usage

Below is a summary of the properties for the axis.

- `activepositionproperty` - `four vector` - Not used.
- `alim` - `two vector` - Controls the mapping of transparency. The vector `[a\_1,a\_2]@` defines the scale for transparency. Plots then map `a\_1` to a completely opaque value, and `a\_2` to a completely transparent value. This mapping is applied to the alpha data of the plot data.
- `alimmode` - `{'auto','manual'}` - For `auto` mode, we map the alpha ranges of all objects in the plot to a full scale. For `manual` mode, we use the `alim` vector.
- `ambientlightcolor` - `colorspec` - Not used.
- `box` - `On/Off` - Not used.
- `cameraposition` - `three vector` - Set the position for the camera in axis space.
- `camerapositionmode` - `{'auto','manual'}` - For `manual` mode, the camera position is picked up from the `cameraposition` vector. For `auto` mode, the camera position is set to be centered on the `x` and `y` axis limits, and beyond the `z` maximum limit.
- `cameratarget` - `three vector` - Defines the point in axis space that the camera is targetted at.
- `cameratargetmode` - `{'auto','manual'}` - For `manual` mode the camera target is picked up from the `cameratarget` vector. For `auto` mode, the camera target is chosen to be the center of the three axes.
- `cameraupvector` - `three vector` - Defines the upwards vector for the camera (what is ultimately mapped to the vertical axis of the plot or screen). This vector must not be parallel to the vector that is defined by the optical axis (i.e., the one connecting the target to the camera position).
- `cameraupvectormode` - `{'auto','manual'}` - For `manual` mode, the camera up vector is picked up from the `cameraupvector`. The `auto` mode chooses the up vector to point along the positive `y` axis.
- `cameraviewangle` - `scalar` - Not used.
- `cameraviewanglemode` - `{'auto','manual'}` - Not used.
- `children` - `vector of handles` - A vector containing handles to children of the current axis. Be careful as to how you manipulate this vector. FreeMat uses a reference counting mechanism for graphics objects, so if you remove a handle from the `children` property of an axis, and you have not added it to the `children` property of another object, it will be deleted.
- `clim` - `two vector` - The color range vector. This vector contains two values that dictate how children of this axis get mapped to the colormap. Values between the two endpoints of this vector are mapped to the extremes of the colormap.
- `climmode` - `{'auto','manual'}` - For `auto` mode, the color limits are chosen to span the colordata for all of the children objects. For `manual` mode, the color mapping is based on `clim`.
- `clipping` - `{'on','off'}` - Not used.
- `color` - `colorspec` - The color used to draw the background box for the axes. Defaults to white.
- `colororder` - `color vector` - A vector of color specs (in RGB) that are cycled between when drawing line plots into this axis. The default is order blue,green,red,cyan,magenta,yellow,black.
- `datalimits` - `six vector` - A vector that contains the x, y and z limits of the data for children of the current axis. Changes to this property are ignored - it is calculated by FreeMat based on the datasets.

- `dataaspectratio` - `three vector` - A vector that describes the aspect ratio of the data. You can think of this as the relative scaling of units for each axis. For example, if one unit along the x axis is twice as long as one unit along the y axis, you would specify a data aspect ratio of `[2,1,1]`.
- `dataaspectratiomode` - `{'auto','manual'}` - When the data aspect ratio is set to `manual`, the data is scaled by the data aspect ratio before being plotted. When the data aspect ratio mode is `auto` a complex set of rules are applied to determine how the data should be scaled. If `dataaspectratio` mode is `auto` and `plotboxaspectratio` is `auto`, then the default data aspect ratio is set to `[1,1,1]` and the default plot box aspect ratio is chosen proportional to `[xrange,yrange,zrange]`, where `xrange` is the span of data along the `x` axis, and similarly for `yrange` and `zrange`. If `plotboxaspectratio` is set to `[px,py,pz]`, then the `dataaspectratio` is set to `[xrange/px,yrange/py,zrange/pz]`. If one of the axes has been specified manually, then the data will be scaled to fit the axes as well as possible.
- `fontangle` - `{'normal','italic','oblique'}` - The angle of the fonts used for text labels (e.g., tick labels).
- `fontsize` - `scalar` - The size of fonts used for text labels (tick labels).
- `fontunits` - Not used.
- `fontweight` - `{'normal','bold','light','demi'}` - The weight of the font used for tick labels.
- `gridlinestyle` - `{'-','--',':','-.','none'}` - The line style to use for drawing the grid lines. Defaults to `':'`.
- `handlevisibility` - Not used.
- `hittest` - Not used.
- `interruptible` - Not used.
- `layer` - Not used.
- `linestyleorder` - `linestyle vector` - A vector of linestyles that are cycled through when plotted line series.
- `linewidth` - `scalar` - The width of line used to draw grid lines, axis lines, and other lines.
- `minorgridlinestyle` - `{'-','--',':','-.','none'}` - The line style used for drawing grid lines through minor ticks.
- `nextplot` - `{'add','replace','replacechildren'}` - Controls how the next plot interacts with the axis. If it is set to `'add'` the next plot will be added to the current axis. If it is set to `'replace'` the new plot replaces all of the previous children.
- `outerposition` - `four vector` - Specifies the coordinates of the outermost box that contains the axis relative to the containing figure. This vector is in normalized coordinates and corresponds to the `x, y, width, height` coordinates of the box.
- `parent` - `handle` - The handle for the containing object (a figure).
- `plotboxaspectratio` - `three vector` - Controls the aspect ratio of the plot box. See the entry under `dataaspectratio` for details on how FreeMat uses this vector in combination with the axis limits and the `plotboxaspectratio` to determine how to scale the data.
- `plotboxaspectratiomode` - `{'auto','manual'}` - The plot box aspect ratio mode interacts with the `dataaspectratiomode` and the axis limits.
- `position` - `fourvector` - The normalized coordinates of the plot box space. Should be inside the rectable defined by `outerposition`.

- `positionmode` - `{'auto','manual'}` - the position mode is normally `'auto'` which means that FreeMat computes the position vector to fit the plot inside the `outerposition` vector. If you set the `position` vector manually (using a `set` command), this `mode` flag becomes `'manual'` and remains that way until reset to @—'auto'.
- `projection` - Not used.
- `selected` - Not used.
- `selectionhighlight` - Not used.
- `tag` - A string that can be set to tag the axes with a name.
- `textheight` - `scalar` - This value is set by FreeMat to the height of the current font in pixels.
- `tickdir` - `{'in','out'}` - The direction of ticks. Defaults to `'in'` for 2D plots, and `'out'` for 3D plots if `tickdirmode` is `auto`.
- `tickdirmode` - `{'auto','manual'}` - When set to `'auto'` the `tickdir` defaults to `'in'` for 2D plots, and `'out'` for 3D plots.
- `ticklength` - `two vector` - The first element is the length of the tick in 2D plots, and the second is the length of the tick in the 3D plots. The lengths are described as fractions of the longer dimension (width or height).
- `tightinset` - Not used.
- `title` - `handle` - The handle of the label used to represent the title of the plot.
- `type` - `string` - Takes the value of `'axes'` for objects of the axes type.
- `units` - Not used.
- `userdata` - `array` - An arbitrary array you can set to anything you want.
- `visible` - `{'on','off'}` - If set to `'on'` the axes are drawn as normal. If set to `'off'`, only the children of the axes are drawn. The plot box, axis lines, and tick labels are not drawn.
- `xaxislocation` - `{'top','bottom'}` - Controls placement of the x axis.
- `yaxislocation` - `{'left','right'}` - Controls placement of the y axis.
- `xcolor` - `colorspec` - The color of the x elements including the the x axis line, ticks, grid lines and tick labels
- `ycolor` - `colorspec` - The color of the y elements including the the y axis line, ticks, grid lines and tick labels.
- `zcolor` - `colorspec` - The color of the z elements including the the z axis line, ticks, grid lines and tick labels.
- `xdir` - `{'normal','reverse'}` - For `normal`, axes are drawn as you would expect (e.g, in default 2D mode, the x axis has values increasing from left to right. For `reverse`, the x axis has values increasing from right to left.
- `ydir` - `{'normal','reverse'}` - For `normal`, axes are drawn as you would expect (e.g, in default 2D mode, the y axis has values increasing from bottom to top. For `reverse`, the y axis has values increasing from top to bottom.
- `zdir` - `{'normal','reverse'}` - For `normal`, axes are drawn as you would expect. In default 3D mode, the z axis has values increasing in some direction (usually up). For `reverse` the z axis increases in the opposite direction.

- `xgrid` - `{'on','off'}` - Set to `on` to draw grid lines from ticks on the x axis.
- `ygrid` - `{'on','off'}` - Set to `on` to draw grid lines from ticks on the y axis.
- `zgrid` - `{'on','off'}` - Set to `on` to draw grid lines from ticks on the z axis.
- `xlabel` - `handle` - The handle of the text label attached to the x axis. The position of that label and the rotation angle is computed automatically by FreeMat.
- `ylabel` - `handle` - The handle of the text label attached to the y axis. The position of that label and the rotation angle is computed automatically by FreeMat.
- `zlabel` - `handle` - The handle of the text label attached to the z axis. The position of that label and the rotation angle is computed automatically by FreeMat.
- `xlim` - `two vector` - Contains the limits of the data along the x axis. These are set automatically for `xlimmode`. When manually set it allows you to zoom into the data. The first element of this vector should be the smallest x value you want mapped to the axis, and the second element should be the largest.
- `ylim` - `two vector` - Contains the limits of the data along the y axis. These are set automatically for `ylimmode`. When manually set it allows you to zoom into the data. The first element of this vector should be the smallest y value you want mapped to the axis, and the second element should be the largest.
- `zlim` - `two vector` - Contains the limits of the data along the z axis. These are set automatically for `zlimmode`. When manually set it allows you to zoom into the data. The first element of this vector should be the smallest z value you want mapped to the axis, and the second element should be the largest.
- `xlimmode` - `{'auto','manual'}` - Determines if `xlim` is determined automatically or if it is determined manually. When determined automatically, it is chosen to span the data range (at least).
- `ylimmode` - `{'auto','manual'}` - Determines if `ylim` is determined automatically or if it is determined manually. When determined automatically, it is chosen to span the data range (at least).
- `zlimmode` - `{'auto','manual'}` - Determines if `zlim` is determined automatically or if it is determined manually. When determined automatically, it is chosen to span the data range (at least).
- `xminorgrid` - `{'on','off'}` - Set to `on` to draw grid lines from minor ticks on the x axis.
- `yminorgrid` - `{'on','off'}` - Set to `on` to draw grid lines from minor ticks on the y axis.
- `zminorgrid` - `{'on','off'}` - Set to `on` to draw grid lines from minor ticks on the z axis.
- `xscale` - `{'linear','log'}` - Determines if the data on the x axis is linear or logarithmically scaled.
- `yscale` - `{'linear','log'}` - Determines if the data on the y axis is linear or logarithmically scaled.
- `zscale` - `{'linear','log'}` - Determines if the data on the z axis is linear or logarithmically scaled.
- `xtick` - `vector` - A vector of x coordinates where ticks are placed on the x axis. Setting this vector allows you complete control over the placement of ticks on the axis.
- `ytick` - `vector` - A vector of y coordinates where ticks are placed on the y axis. Setting this vector allows you complete control over the placement of ticks on the axis.
- `ztick` - `vector` - A vector of z coordinates where ticks are placed on the z axis. Setting this vector allows you complete control over the placement of ticks on the axis.

- `xticklabel` - `string vector` - A string vector, of the form `'string`string—string'— that contains labels to assign to the labels on the axis. If this vector is shorter than `xtick`, then FreeMat will cycle through the elements of this vector to fill out the labels.
- `yticklabel` - `string vector` - A string vector, of the form `'string`string—string'— that contains labels to assign to the labels on the axis. If this vector is shorter than `ytick`, then FreeMat will cycle through the elements of this vector to fill out the labels.
- `zticklabel` - `string vector` - A string vector, of the form `'string`string—string'— that contains labels to assign to the labels on the axis. If this vector is shorter than `ztick`, then FreeMat will cycle through the elements of this vector to fill out the labels.
- `xtickmode` - `{'auto','manual'}` - Set to `'auto'` if you want FreeMat to calculate the tick locations. Setting `'xtick'` will cause this property to switch to `'manual'`.
- `ytickmode` - `{'auto','manual'}` - Set to `'auto'` if you want FreeMat to calculate the tick locations. Setting `'ytick'` will cause this property to switch to `'manual'`.
- `ztickmode` - `{'auto','manual'}` - Set to `'auto'` if you want FreeMat to calculate the tick locations. Setting `'ztick'` will cause this property to switch to `'manual'`.
- `xticklabelmode` - `{'auto','manual'}` - Set to `'auto'` if you want FreeMat to set the tick labels. This will be based on the vector `xtick`.
- `yticklabelmode` - `{'auto','manual'}` - Set to `'auto'` if you want FreeMat to set the tick labels. This will be based on the vector `ytick`.
- `zticklabelmode` - `{'auto','manual'}` - Set to `'auto'` if you want FreeMat to set the tick labels. This will be based on the vector `ztick`.

23.4 CLA Clear Current Axis

23.4.1 Usage

Clears the current axes. The syntax for its use is

```
cla
```

23.5 CLABEL Add Labels To Contour Plot

23.5.1 Usage

The `clabel` function adds labels to a contour plot Generate contour labels for a contour plot. The syntax for its use is either:

```
handles = clabel(contourhandle,property,value,property,value,...)
```

which labels all of the contours in the plot, or

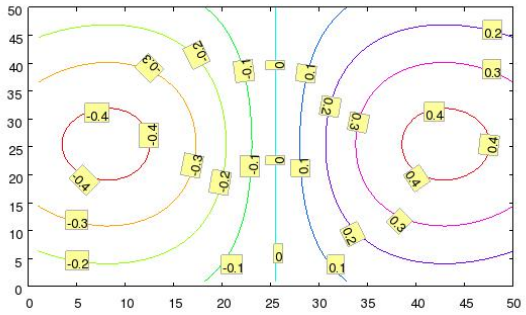
```
handles = clabel(contourhandle,vals,property,value,property,value,...)
```

which only labels those contours indicated by the vector `vals`. The `contourhandle` must be the handle to a contour plot object. The remaining property/value pairs are passed to the `text` function to control the parameters of the generated text labels. See the `text properties` for the details on what can be used in those labels.

23.5.2 Example

```
--> [x,y] = meshgrid(linspace(-1,1,50));
--> z = x.*exp(-(x.^2+y.^2));
--> h = contour(z);
--> clabel(h,'backgroundcolor',[1,1,.6],'edgecolor',[.7,.7,.7]);
```

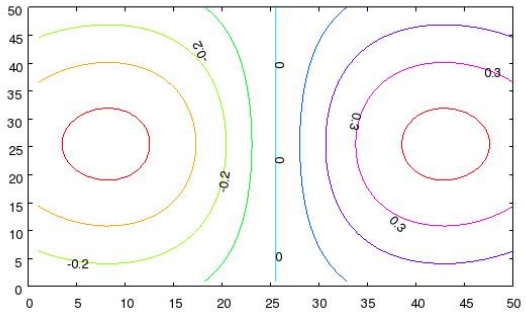
which results in



Alternately, we can just label a subset of the contours

```
--> h = contour(z);
--> clabel(h,[-.2,0,.3]);
```

which results in



23.6 CLF Clear Figure

23.6.1 Usage

This function clears the contents of the current figure. The syntax for its use is

```
clf
```

23.7 CLIM Adjust Color limits of plot

23.7.1 Usage

There are several ways to use `clim` to adjust the color limits of a plot. The various syntaxes are

```
clim
clim([lo,hi])
clim('auto')
clim('manual')
clim('mode')
clim(handle,...)
```

The first form (without arguments), returns a 2-vector containing the current limits. The second form sets the limits on the plot to `[lo,hi]`. The third and fourth form set the mode for the limit to `auto` and `manual` respectively. In `auto` mode, FreeMat chooses the range for the axis automatically. The `clim('mode')` form returns the current mode for the axis (either `'auto'` or `'manual'`).

Switching to `manual` mode does not change the limits, it simply allows you to modify them (and disables the automatic adjustment of the limits as more objects are added to the plot). Also, if you specify a set of limits explicitly, the mode is set to `manual`

Finally, you can specify the handle of an axis to manipulate instead of using the current one.

23.7.2 Example

Here is an example of using `clim` to change the effective window and level onto an image. First, the image with default limits

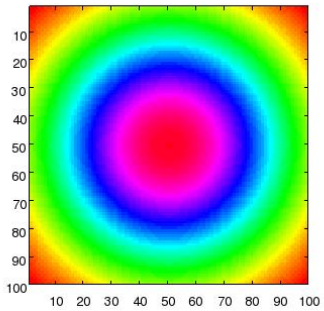
```
--> x = repmat(linspace(-1,1),[100,1]); y = x';
--> z = exp(-x.^2-y.^2);
--> image(z);
--> min(z(:))

ans =
    0.1353

--> max(z(:))

ans =
    0.9998
```

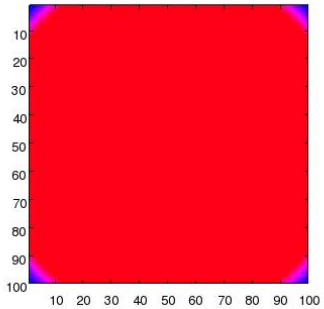
which results in



Next, we change the colorscale of the image using the `clim` function

```
--> image(z);
--> clim([0,0.2]);
```

which results in



23.8 CLOSE Close Figure Window

23.8.1 Usage

Closes a figure window, either the currently active window, a window with a specific handle, or all figure windows. The general syntax for its use is

```
close(handle)
```

in which case the figure window with the speicified `handle` is closed. Alternately, issuing the command with no argument

```
close
```

is equivalent to closing the currently active figure window. Finally the command

```
close('all')
```

closes all figure windows currently open.

23.9 COLORBAR Add Colorbar to Current Plot

23.9.1 Usage

There are a number of syntaxes for the `colorbar` command. The first takes no arguments, and adds a vertical colorbar to the right of the current axes.

```
colorbar
```

You can also pass properties to the newly created axes object using the second syntax for colorbar

```
colorbar(properties...)
```

23.10 COLORMAP Image Colormap Function

23.10.1 Usage

Changes the colormap for the current figure. The generic syntax for its use is

```
colormap(map)
```

where `map` is a an array organized as `3 \times N`), which defines the RGB (Red Green Blue) coordinates for each color in the colormap. You can also use the function with no arguments to recover the current colormap

```
map = colormap
```

23.10.2 Function Internals

Assuming that the contents of the colormap function argument `c` are labeled as:

$$c = \begin{bmatrix} r_1 & g_1 & b_1 \\ r_1 & g_2 & b_2 \\ r_1 & g_3 & b_3 \\ \vdots & \vdots & \vdots \end{bmatrix}$$

then these columns for the RGB coordinates of pixel in the mapped image. Assume that the image occupies the range $[a, b]$. Then the RGB color of each pixel depends on the value x via the following integer

$$k = 1 + \lfloor 256 \frac{x - a}{b - a} \rfloor,$$

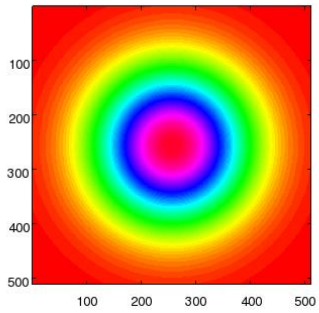
so that a pixel corresponding to image value x will receive RGB color $[r_k, g_k, b_k]$. Colormaps are generally used to pseudo color images to enhance visibility of features, etc.

23.10.3 Examples

We start by creating a smoothly varying image of a 2D Gaussian pulse.

```
--> x = linspace(-1,1,512)'*ones(1,512);
--> y = x';
--> Z = exp(-(x.^2+y.^2)/0.3);
--> image(Z);
```

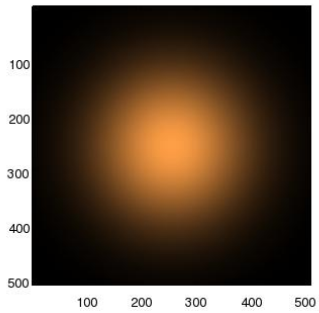
which we display with the default (grayscale) colormap here.



Next we switch to the `copper` colormap, and redisplay the image.

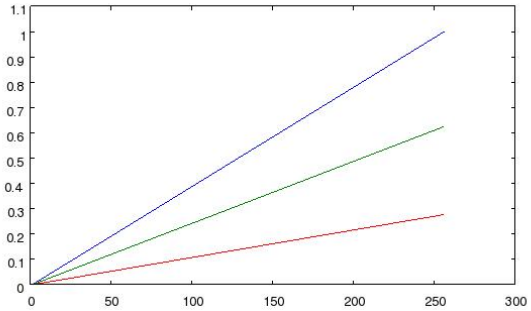
```
--> colormap(copper);
--> image(Z);
```

which results in the following image.



If we capture the output of the `copper` command and plot it, we obtain the following result:

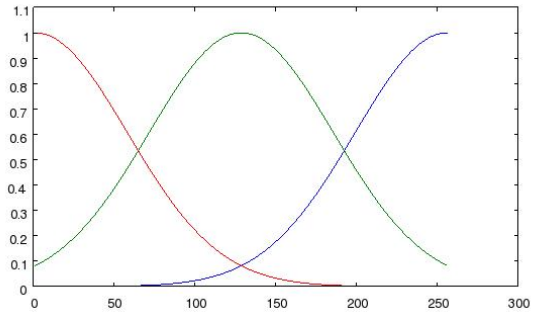
```
--> a = copper;
--> plot(a);
```



Note that in the output that each of the color components are linear functions of the index, with the ratio between the red, blue and green components remaining constant as a function of index. The result is

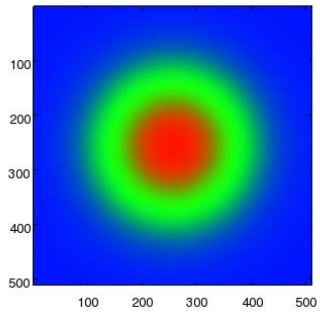
an intensity map with a copper tint. We can similarly construct a colormap of our own by defining the three components seperately. For example, suppose we take three gaussian curves, one for each color, centered on different parts of the index space:

```
--> t = linspace(0,1,256);
--> A = [exp(-(t-1.0).^2/0.1);exp(-(t-0.5).^2/0.1);exp(-t.^2/0.1)]';
--> plot(A);
```



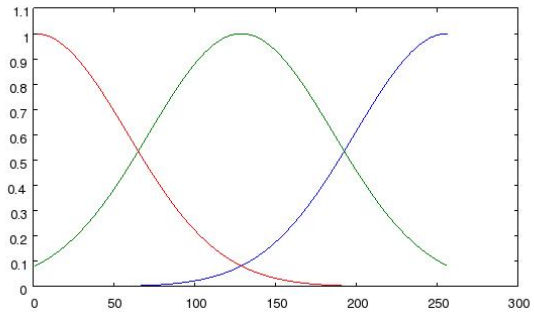
The resulting image has dark bands in it near the color transitions.

```
--> image(Z);
--> colormap(A);
```



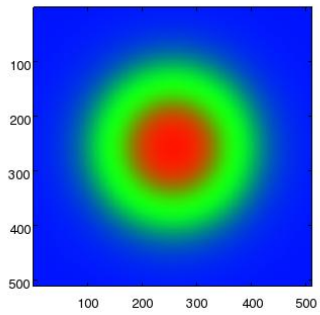
These dark bands are a result of the nonuniform color intensity, which we can correct for by renormalizing each color to have the same norm.

```
--> w = sqrt(sum(A'.^2));
--> sA = diag(1./w)*A;
--> plot(A);
```



The resulting image has no more dark bands.

```
--> image(Z);
--> colormap(A);
```



23.11 COLORSPEC Color Property Description

23.11.1 Usage

There are a number of ways of specifying a color value for a color-based property. Examples include line colors, marker colors, and the like. One option is to specify color as an RGB triplet

```
set(h,'color',[r,g,b])
```

where `r,g,b` are between @[0,1]@. Alternately, you can use color names to specify a color.

- `'none'` - No color.
- `'y','yellow'` - The color @[1,1,0]@ in RGB space.
- `'m','magenta'` - The color @[1,0,1]@ in RGB space.
- `'c','cyan'` - The color @[0,1,1]@ in RGB space.
- `'r','red'` - The color @[1,0,0]@ in RGB space.
- `'g','green'` - The color @[0,1,0]@ in RGB space.
- `'b','blue'` - The color @[0,0,1]@ in RGB space.
- `'w','white'` - The color @[1,1,1]@ in RGB space.
- `'k','black'` - The color @[0,0,0]@ in RGB space.

23.12 CONTOUR Contour Plot Function

23.12.1 Usage

This command generates contour plots. There are several syntaxes for the command. The simplest is

```
contour(Z)
```

which generates a contour plot of the data in matrix `Z`, and will automatically select the contour levels. The `x,y` coordinates of the contour default to `1:n` and `1:m`, where `n` is the number of columns and `m` is the number of rows in the `Z` matrix. Alternately, you can specify a scalar `n`

```
contour(Z,n)
```

which indicates that you want `n` contour levels. For more control, you can provide a vector `v` containing the levels to contour. If you want to generate a contour for a particular level, you must pass a vector `[t,t]` where `t` is the level you want to contour. If you have data that lies on a particular `X,Y` grid, you can pass either vectors `x,y` or matrices `X,Y` to the contour function via

```
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
```

Each form of `contour` can optionally take a line spec to indicate the color and linestyle of the contours to draw:

```
contour(...,linespec)
```

or any of the other forms of `contour`. Furthermore, you can supply an axis to target the `contour` plot to (so that it does not get added to the current axis, which is the default):

```
contour(axis_handle,...)
```

Finally, the `contour` command returns a handle to the newly returned contour plot.

```
handle = contour(...)
```

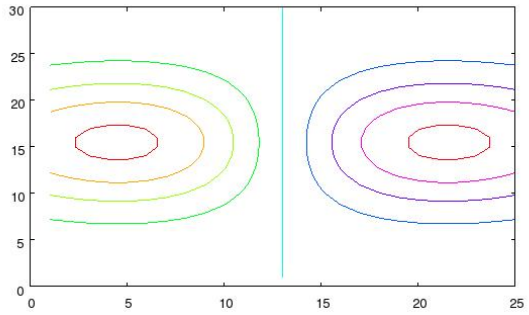
To place labels on the contour plot, use the `clabel` function.

23.12.2 Example

Here is a simple example of a contour plot with the default `x,y` coordinates:

```
--> [x,y] = meshgrid(linspace(-1,1,25),linspace(-2,2,30));
--> z = x.*exp(-x.^2-y.^2);
--> contour(z)
```

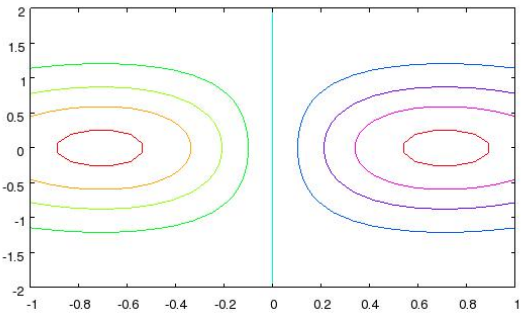
which results in the following plot



Here, we specify the `x` and `y` coordinates explictly

```
--> contour(x,y,z)
```

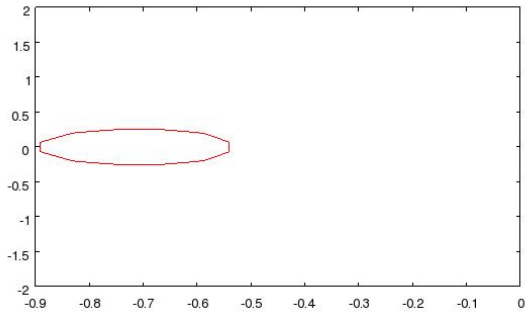
note that the axis limits have changed appropriately



By default, contours are created at values selected by FreeMat. To provide our own set of contour values (asymmetrically about zero in this case), we supply them as

```
--> contour(x,y,z,[-.4,0.,3])
```

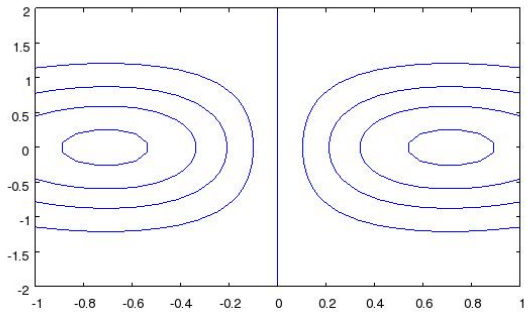
which is here



Also be default, `contour` uses the current color map and `clim` limits to determine the coloring of the contours. Here, we override the color spec so that we have all black contour

```
--> contour(x,y,z,'b-')
```

which is here



23.13 CONTOUR3 3D Contour Plot Function

23.13.1 Usage

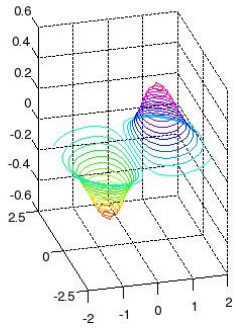
This command generates contour plots where the lines are plotted in 3D. The syntax for its use is identical to the `contour` function. Please see its help for details.

23.13.2 Example

Here is a simple example of a 3D contour plot.

```
--> [x,y] = meshgrid([-2:.25:2]);
--> z=x.*exp(-x.^2-y.^2);
--> contour3(x,y,z,30);
--> axis square;
--> view(-15,25)
```

The resulting plot



23.14 COPPER Copper Colormap

23.14.1 Usage

Returns a copper colormap. The syntax for its use is

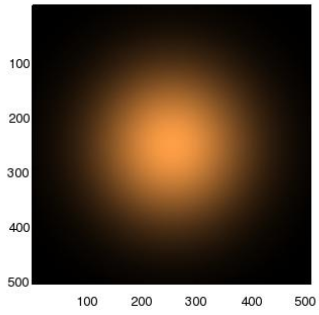
```
y = copper
```

23.14.2 Example

Here is an example of an image displayed with the `copper` colormap

```
--> x = linspace(-1,1,512)'*ones(1,512);
--> y = x';
--> Z = exp(-(x.^2+y.^2)/0.3);
--> image(Z);
--> colormap(copper);
```

which results in the following image



23.15 COPY Copy Figure Window

23.15.1 Usage

Copies the currently active figure window to the clipboard. The syntax for its use is:

```
copy
```

The resulting figure is copied as a bitmap to the clipboard, and can then be pasted into any suitable application.

23.16 COUNTOUR Contour Object Properties

23.16.1 Usage

Below is a summary of the properties for a line series.

- `contourmatrix` - `array` - the matrix containing contour data for the plot. This is a `2 x N` matrix containing x and y coordinates for points on the contours. In addition, each contour line starts with a column containing the number of points and the contour value.
- `displayname` - `string` - The name of this line series as it appears in a legend.
- `floating` - `{'on','off'}` - set to on to have floating (3D) contours
- `levellist` - `vector` - a vector of Z-values for the contours
- `levellistmode` - `{'auto','manual'}` - set to auto for automatic selection of Z-values of the contours.
- `linecolor` - color of the contour lines.
- `linestyle` - `{'-','--',':','-.','none'}` - the line style to draw the contour in.
- `linewidth` - `scalar` - the width of the lines
- `parent` - `handle` - The axis that contains this object
- `tag` - `string` - A string that can be used to tag the object.
- `type` - `string` - Returns the string `'contour'`.
- `userdata` - `array` - Available to store any variable you want in the handle object.
- `visible` - `{'on','off'}` - Controls visibility of the the line.
- `xdata` - `matrix` - Contains the x coordinates of the surface on which the zdata is defined. This can either be a monotonic vector of the same number of columns as `zdata`, or a 2D matrix that is the same size as `zdata`.
- `xdatamode` - `{'auto','manual'}` - When set to `'auto'` FreeMat will autogenerate the x coordinates for the contours. These values will be `1,..,N` where `N` is the number of columns of `zdata`.
- `ydata` - `matrix` - Contains the y coordinates of the surface on which the zdata is defined. This can either be a monotonic vector of the same number of rows as `zdata` or a 2D matrix that is the same size as `zdata`.
- `ydatamode` - `{'auto','manual'}` - When set to `'auto'` FreeMat will autogenerate the y coordinates for the contour data.
- `zdata` - `matrix` - The matrix of z values that are to be contoured.

23.17 DATACURSORMODE Interactive Data Cursor

23.17.1 Usage

Toggles the data cursor which allows interactive data exploration.

```
datacursormode('on')
```

23.18 DRAWNOW Flush the Event Queue

23.18.1 Usage

The `drawnow` function can be used to process the events in the event queue of the FreeMat application. The syntax for its use is

```
drawnow
```

Now that FreeMat is threaded, you do not generally need to call this function, but it is provided for compatibility.

23.19 FIGLOWER Lower a Figure Window

23.19.1 Usage

Lowers a figure window indicated by the figure number. The syntax for its use is

```
figlower(fignum)
```

where `fignum` is the number of the figure to lower. The figure will be lowerd to the bottom of the GUI stack (meaning that it we be behind other windows). Note that this function does not cause `fignum` to become the current figure, you must use the `figure` command for that. Similarly, if `fignum` is the current figure, it will remain the current figure (even though the figure is now behind others).

23.20 FIGRAISE Raise a Figure Window

23.20.1 Usage

Raises a figure window indicated by the figure number. The syntax for its use is

```
figraise(fignum)
```

where `fignum` is the number of the figure to raise. The figure will be raised to the top of the GUI stack (meaning that it we be visible). Note that this function does not cause `fignum` to become the current figure, you must use the `figure` command for that.

23.21 FIGURE Figure Window Select and Create Function

23.21.1 Usage

Changes the active figure window to the specified figure number. The general syntax for its use is

```
figure(number)
```

where `number` is the figure number to use. If the figure window corresponding to `number` does not already exist, a new window with this number is created. If it does exist then it is brought to the forefront and made active. You can use `gcf` to obtain the number of the current figure.

Note that the figure number is also the handle for the figure. While for most graphical objects (e.g., axes, lines, images), the handles are large integers, for figures, the handle is the same as the figure number. This means that the figure number can be passed to `set` and `get` to modify the properties of the current figure, (e.g., the colormap). So, for figure `3`, for example, you can use `get(3,'colormap')` to retrieve the colormap for the current figure.

23.22 FIGUREPROPERTIES Figure Object Properties

23.22.1 Usage

Below is a summary of the properties for the axis.

- `alphamap` - `vector` - Contains the alpha (transparency) map for the figure. If this is set to a scalar, then all values are mapped to the same transparency. It defaults to `1`, which is all values being fully opaque. If you set this to a vector, the values of graphics objects will be mapped to different transparency values, based on the setting of their `alphadatamapping` property.
- `color` - `colorspec` - The background color of the figure (defaults to a gray `[0.6,0.6,0.6]`). During printing, this color is set to white, and then is restored.
- `colormap` - `color vector` - an `N x 3` matrix of RGB values that specifies the colormap for the figure. Defaults to an `HSV` map.
- `children` - `handle vector` - the handles for objects that are children of this figure. These should be axis objects.
- `currentaxes` - `handle` - the handle for the current axes. Also returned by `gca`.
- `doublebuffer` - Not used.
- `parent` - Not used.
- `position` - Not used.
- `type` - `string` - returns the string `'figure'`.
- `userdata` - `array` - arbitrary array you can use to store data associated with the figure.
- `nextplot` - `{'add','replace','replacechildren'}` - If set to `'add'` then additional axes are added to the list of children for the current figure. If set to `'replace'`, then a new axis replaces all of the existing children.
- `figsize` - `two vector` - the size of the figure window in pixels (width x height).
- `renderer` - `{'painters','opengl'}` - When set to `'painters'` drawing is based on the Qt drawing methods (which can handle flat shading of surfaces with transparency). If you set the renderer to `'opengl'` then OpenGL is used for rendering. Support for OpenGL is currently in the alpha stage, and FreeMat does not enable it automatically. You can set the renderer mode to `'opengl'` manually to experiment. Also, OpenGL figures cannot be printed yet.

23.23 GCA Get Current Axis

23.23.1 Usage

Returns the handle for the current axis. The syntax for its use is

```
handle = gca
```

where `handle` is the handle of the active axis. All object creation functions will be children of this axis.

23.24 GCF Get Current Figure

23.24.1 Usage

Returns the figure number for the current figure (which is also its handle, and can be used to set properties of the current figure using `set`). The syntax for its use is

```
figure_number = gcf
```

where `figure\_number` is the number of the active figure (also the handle of the figure).

Note that figures have handles, just like axes, images, plots, etc. However the handles for figures match the figure number (while handles for other graphics objects tend to be large, somewhat arbitrary integers). So, to retrieve the colormap of the current figure, you could use `get(gcf,'colormap')`, or to obtain the colormap for figure 3, use `get(3,'colormap')`.

23.25 GET Get Object Property

23.25.1 Usage

This function allows you to retrieve the value associated with a property. The syntax for its use is

```
value = get(handle,property)
```

where `property` is a string containing the name of the property, and `value` is the value for that property. The type of the variable `value` depends on the property being set. See the help for the properties to see what values you can set.

23.26 GLSHOW Show a GL Assembly in a GL Window

23.26.1 Usage

Shows a GL Assembly in a GL Window. The syntax for its use is

```
glshow(name,scale)
```

which shows the `glassembly` named `name` in a new GL window, with the scale set to `scale`. Roughly speaking `scale` should represent the radial size of the object that you want to see in the window.

23.27 GRAY Gray Colormap

23.27.1 Usage

Returns a gray colormap. The syntax for its use is

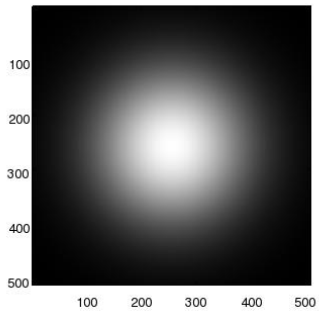
```
y = gray
```

23.27.2 Example

Here is an example of an image displayed with the `gray` colormap

```
--> x = linspace(-1,1,512)'*ones(1,512);
--> y = x';
--> Z = exp(-(x.^2+y.^2)/0.3);
--> image(Z);
--> colormap(gray);
```

which results in the following image



23.28 GRID Plot Grid Toggle Function

23.28.1 Usage

Toggles the drawing of grid lines on the currently active plot. The general syntax for its use is

```
grid(state)
```

where `state` is either

```
grid('on')
```

to activate the grid lines, or

```
grid('off')
```

to deactivate the grid lines. If you specify no argument then `grid` toggles the state of the grid:

```
grid
```

You can also specify a particular axis to the grid command

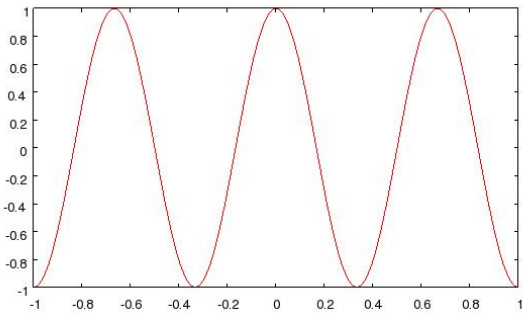
```
grid(handle,...)
```

where `handle` is the handle for a particular axis.

23.28.2 Example

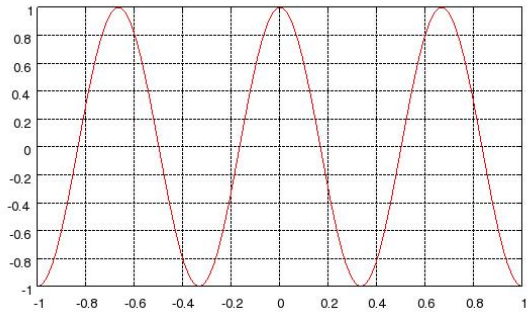
Here is a simple plot without grid lines.

```
--> x = linspace(-1,1);
--> y = cos(3*pi*x);
--> plot(x,y,'r-');
```



Next, we activate the grid lines.

```
--> plot(x,y,'r-');
--> grid on
```



23.29 HCONTOUR Create a contour object

23.29.1 Usage

Creates a contour object and parents it to the current axis. The syntax for its use is

```
handle = hcontour(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current axis.

23.30 HIMAGE Create a image object

23.30.1 Usage

Creates a image object and parents it to the current axis. The syntax for its use is

```
handle = himage(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current axis.

23.31 HIST Histogram Function

23.31.1 Usage

```
n=hist (y)
n=hist (y,x)
n=hist (y,x,norm)
```

Produce histogram counts or plots.

With one vector input argument, plot a histogram of the values with 10 bins. The range of the histogram bins is determined by the range of the data.

Given a second scalar argument, use that as the number of bins.

Given a second vector argument, use that as the centers of the bins, with the width of the bins determined from the adjacent values in the vector.

If third argument is provided, the histogram is normalised such that the sum of the bars is equal to `norm`.

Extreme values are lumped in the first and last bins.

23.32 HLINE Create a line object

23.32.1 Usage

Creates a line object and parents it to the current axis. The syntax for its use is

```
handle = hline(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current axis.

23.33 HOLD Plot Hold Toggle Function

23.33.1 Usage

Toggles the hold state on the currently active plot. The general syntax for its use is

```
hold(state)
```

where `state` is either

```
hold('on')
```

to turn hold on, or

```
hold('off')
```

to turn hold off. If you specify no argument then `hold` toggles the state of the hold:

```
hold
```

You can also specify a particular axis to the hold command

```
hold(handle,...)
```

where `handle` is the handle for a particular axis.

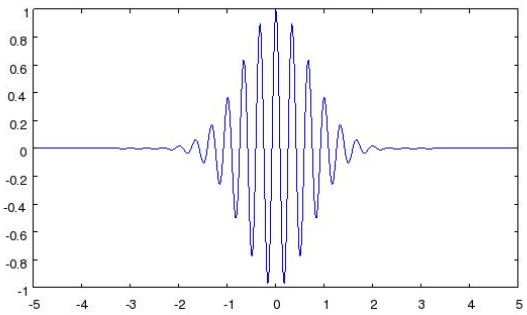
23.33.2 Function Internals

The `hold` function allows one to construct a plot sequence incrementally, instead of issuing all of the plots simultaneously using the `plot` command.

23.33.3 Example

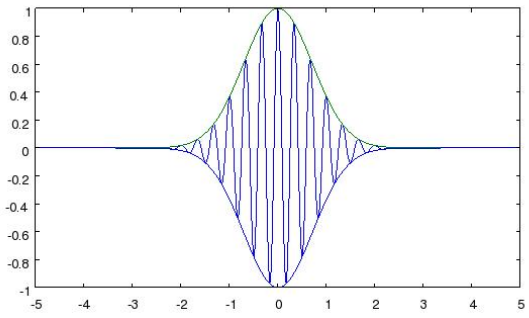
Here is an example of using both the `hold` command and the multiple-argument `plot` command to construct a plot composed of three sets of data. The first is a plot of a modulated Gaussian.

```
--> x = linspace(-5,5,500);
--> t = exp(-x.^2);
--> y = t.*cos(2*pi*x*3);
--> plot(x,y);
```



We now turn the hold state to `'on'`, and add another plot sequence, this time composed of the top and bottom envelopes of the modulated Gaussian. We add the two envelopes simultaneously using a single `plot` command. The fact that `hold` is `'on'` means that these two envelopes are added to (instead of replace) the current contents of the plot.

```
--> plot(x,y);
--> hold on
--> plot(x,t,'g-',x,-t,'b-')
```



23.34 HPATCH Create a patch object

23.34.1 Usage

Creates a patch object and parents it to the current axis. The syntax for its use is

```
handle = hpatch(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current axis.

23.35 HPOINT Get Point From Window

23.35.1 Usage

This function waits for the user to click on the current figure window, and then returns the coordinates of that click. The generic syntax for its use is

```
[x,y] = hpoint
```

23.36 HRAWPLOT Generate a Raw Plot File

23.36.1 Usage

This function takes a sequence of commands, and generates a raw plot (to a file) that renders the commands. It is a useful tool for creating high quality fully customized PDF plots from within FreeMat scripts that are portable. The syntax for its use

```
hrawplot(filename,commands)
```

where `filename` is the name of the file to plot to, and `commands` is a cell array of strings. Each entry in the cell array contains a string with a command text. The commands describe a simple mini-language for describing plots. The complete dictionary of commands is given

- `LINE x1 y1 x2 y2` – draw a line

- `FONT name size` – select a font of the given name and size
- `TEXT x1 y1 string` – draw the given text string at the given location
- `STYLE style` – select line style ('solid' or 'dotted')
- `PAGE` – force a new page
- `SIZE x1 y1` – Set the page mapping
- `BOX x1 y1 x2 y2` – draw a filled box covering the given coordinates
- `HTEXTBOX x1 y1 x2 y2 string` – Draw a horizontal box with the given string centered in it
- `VTEXTBOX x1 y1 x2 y2 string` – Draw a vertical box with the given string centered in it (rotated 90 degrees)
- `BRUSH string` – Set the brush color ('red','blue', etc)
- `PEN string` – Set the pen color

23.37 HSURFACE Create a surface object

23.37.1 Usage

Creates a surface object and parents it to the current axis. The syntax for its use is

```
handle = hsurface(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current axis.

23.38 HTEXT Create a text object

23.38.1 Usage

Creates a text object and parents it to the current axis. The syntax for its use is

```
handle = htext(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current axis.

23.39 HTEXTBITMAP Get Text Rendered as a Bitmap

23.39.1 Usage

This function takes a fontname, a size, and a text string and returns a bitmap containing the text. The generic syntax for its use is

```
bitmap = htextbitmap(fontname,size,text)
```

where the output bitmap contains the text rendered into a matrix.

23.40 IMAGE Image Display Function

23.40.1 Usage

The `image` command has the following general syntax

```
handle = image(x,y,C,properties...)
```

where `x` is a two vector containing the `x` coordinates of the first and last pixels along a column, and `y` is a two vector containing the `y` coordinates of the first and last pixels along a row. The matrix `C` constitutes the image data. It must either be a scalar matrix, in which case the image is colormapped using the `colormap` for the current figure. If the matrix is `M x N x 3`, then `C` is intepreted as RGB data, and the image is not colormapped. The `properties` argument is a set of `property/value` pairs that affect the final image. You can also omit the `x` and `y`,

```
handle = image(C, properties...)
```

in which case they default to `x = [1,size(C,2)]` and `y = [1,size(C,1)]`. Finally, you can use the `image` function with only formal arguments

```
handle = image(properties...)
```

To support legacy FreeMat code, you can also use the following form of `image`

```
image(C, zoomfactor)
```

which is equivalent to `image(C)` with the axes removed so that the image takes up the full figure window, and the size of the figure window adjusted to achieve the desired zoom factor using the `zoom` command.

23.40.2 Example

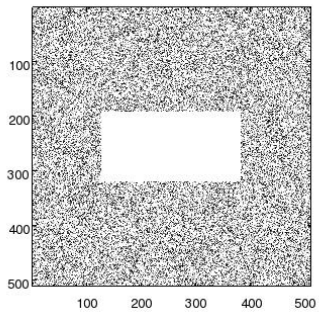
In this example, we create an image that is `512 x 512` pixels square, and set the background to a noise pattern. We set the central `128 x 256` pixels to be white.

```
--> x = rand(512);
--> x((-64:63)+256,(-128:127)+256) = 1.0;
--> figure

ans =
 1

--> image(x)
--> colormap(gray)
```

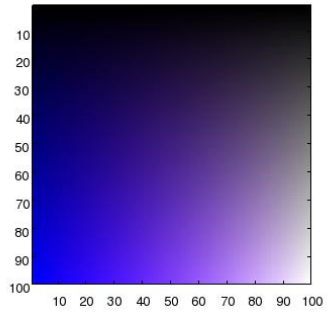
The resulting image looks like:



Here is an example of an RGB image

```
--> t = linspace(0,1);
--> red = t'*t;
--> green = t'*(t.^2);
--> blue = t'*(0*t+1);
--> A(:,:,1) = red;
--> A(:,:,2) = green;
--> A(:,:,3) = blue;
--> image(A);
```

The resulting image looks like:



23.41 IMAGEPROPERTIES Image Object Properties

23.41.1 Usage

Below is a summary of the properties for the axis.

- `alphadata` - `vector` - This is a vector that should contain as many elements as the image data itself `cdata`, or a single scalar. For a single scalar, all values of the image take on the same transparency. Otherwise, the transparency of each pixel is determined by the corresponding value from the `alphadata` vector.

- `alphadatamapping` - `{'scaled','direct','none'}` - For `none` mode (the default), no transparency is applied to the data. For `direct` mode, the vector `alphadata` contains values between @[0,M-1]— where `M` is the length of the alpha map stored in the figure. For `scaled` mode, the `alim` vector for the figure is used to linearly rescale the alpha data prior to lookup in the alpha map.

- `cdata` - `array` - This is either a `M x N` array or an `M x N x 3` array. If the data is `M x N` the image is a scalar image (indexed mode), where the color associated with each image pixel is computed using the colormap and the `cdatamapping` mode. If the data is `M x N x 3` the image is assumed to be in RGB mode, and the colorpanes are taken directly from `cdata` (the colormap is ignored). Note that in this case, the data values must be between @[0,1]— for each color channel and each pixel.

- `cdatamapping` - `{'scaled','direct'}` - For `scaled` (the default), the pixel values are scaled using the `clim` vector for the figure prior to looking up in the colormap. For `direct` mode, the pixel values must be in the range `[0,N-1` where `N` is the number of colors in the colormap if the data is integer type. For floating point data types, values must be in the range `[1,N]`.

- `children` - Not used.

- `parent` - `handle` - The axis containing the image.

- `tag` - `string` - You can set this to any string you want.

- `type` - `string` - Set to the string `'image'`.

- xdata - two vector - contains the x coordinates of the first and last column (respectively). Defaults to [1,C] where C is the number of columns in the image.
- ydata - two vector - contains the y coordinates of the first and last row (respectively). Defaults to [1,R] where R is the number of rows in the image.
- userdata - array - Available to store any variable you want in the handle object.
- visible - {'on','off'} - Controls whether the image is visible or not.

23.42 IMAGESC Image Display Function

23.42.1 Usage

The imagesc command has the following general syntax

```
handle = imagesc(x,y,C,clim)
```

where x is a two vector containing the x coordinates of the first and last pixels along a column, and y is a two vector containing the y coordinates of the first and last pixels along a row. The matrix C constitutes the image data. It must either be a scalar matrix, in which case the image is colormapped using the colormap for the current figure. If the matrix is M x N x 3, then C is intepreted as RGB data, and the image is not colormapped. The clim argument is a pairs [low high] that specifies scaling. You can also omit the x and y,

```
handle = imagesc(C, clim)
```

in which case they default to x = [1,size(C,2)] and y = [1,size(C,1)]. Finally, you can use the image function with only formal arguments

```
handle = imagesc(properties...)
```

23.42.2 Example

In this example, we create an image that is 512 x 512 pixels square, and set the background to a noise pattern. We set the central 128 x 256 pixels to be white.

```
--> x = rand(512);
--> x((-64:63)+256,(-128:127)+256) = 1.0;
--> figure

ans =
 1

--> imagesc(x,[0 .5])
--> colormap(gray)
```

23.43 IS2DVIEW Test Axes For 2D View

23.43.1 Usage

This function returns true if the current axes are in a 2-D view, and false otherwise. The generic syntax for its use is

```
y = is2dview(x)
```

where x is the handle of an axes object.

23.44 ISHOLD Test Hold Status

23.44.1 Usage

Returns the state of the `hold` flag on the currently active plot. The general syntax for its use is

```
ishold
```

and it returns a logical 1 if `hold` is `on`, and a logical 0 otherwise.

23.45 LEGEND Add Legent to Plot

23.45.1 Usage

This command adds a legend to the current plot. Currently, the following forms of the `legend` command are supported. The first form creates a legend with the given labels for the data series:

```
legend('label1','label2',...)
```

where `'label1'` is the text label associated with data plot 1 and so on. You can also use the `legend` command to control the appearance of the legend in the current plot. To remove the legend from the current plot, use

```
legend('off')
```

To hide the legend for the current plot (but do not remove it)

```
legend('hide')
```

And to show the legend that has been hidden, use

```
legend('show')
```

You can also toggle the display of the box surrounding the legend. Use

```
legend('boxoff')
```

or

```
legend('boxon')
```

to turn the legend box off or on, respectively. To toggle the visible state of the current legend, use

```
legend('toggle')
```

Specifying no arguments at all (apart from an optional location argument as specified below) results in the legend being rebuilt. This form is useful for picking up font changes or relocating the legend.

```
legend
```

By default, the `legend` command places the new legend in the upper right corner of the current plot. To change this behavior, use the `'location'` specifier (must be the last two options to the command)

```
legend(...,'location',option)
```

where `option` takes on the following possible values

- `north`,`N` - top center of plot
- `south`,`S` - bottom center of plot
- `east`,`E` - middle right of plot

- `west`,`W` - middle left of plot
- `northeast`,`NE` - top right of plot (default behavior)
- `northwest`,`NW` - top left of plot
- `southeast`,`SE` - bottom right of plot
- `southwest`,`SW` - bottom left of plot

This implementation of `legend` is incomplete relative to the MATLAB API. The functionality will be improved in future versions of FreeMat.

23.46 LINE Line Display Function

23.46.1 Usage

The `line` command has the following general syntax

```
handle = line(x,y,z,properties...)
```

where...

23.47 LINEPROPERTIES Line Series Object Properties

23.47.1 Usage

Below is a summary of the properties for a line series.

- `color` - `colorspec` - The color that is used to draw the line.
- `children` - Not used.
- `displayname` - The name of this line series as it appears in a legend.
- `linestyle` - `{'-','--',':','-.','none'}` - The style of the line.
- `linewidth` - `scalar` - The width of the line.
- `marker` - `{'+','o','*','.','x','square','s','diamond','d','\^','v','>','<'}` - The marker for data points on the line. Some of these are redundant, as `'square'` `'s'` are synonyms, and `'diamond'` and `'d'` are also synonyms.
- `markeredgecolor` - `colorspec` - The color used to draw the marker. For some of the markers (circle, square, etc.) there are two colors used to draw the marker. This property controls the edge color (which for unfilled markers) is the primary color of the marker.
- `markerfacecolor` - `colorspec` - The color used to fill the marker. For some of the markers (circle, square, etc.) there are two colors used to fill the marker.
- `markersize` - `scalar` - Control the size of the marker. Defaults to 6, which is effectively the radius (in pixels) of the markers.
- `parent` - `handle` - The axis that contains this object.
- `tag` - `string` - A string that can be used to tag the object.
- `type` - `string` - Returns the string `'line'`.
- `visible` - `{'on','off'}` - Controls visibility of the the line.

- `xdata` - `vector` - Vector of x coordinates of points on the line. Must be the same size as the `ydata` and `zdata` vectors.
- `ydata` - `vector` - Vector of y coordinates of points on the line. Must be the same size as the `xdata` and `zdata` vectors.
- `zdata` - `vector` - Vector of z coordinates of points on the line. Must be the same size as the `xdata` and `ydata` vectors.
- `xdatamode` - `{'auto','manual'}` - When set to `'auto'` FreeMat will autogenerate the x coordinates for the points on the line. These values will be `1,..,N` where `N` is the number of points in the line.
- `userdata` - `array` - Available to store any variable you want in the handle object.

23.48 LOGLOG Log-Log Plot Function

23.48.1 Usage

This command has the exact same syntax as the `plot` command:

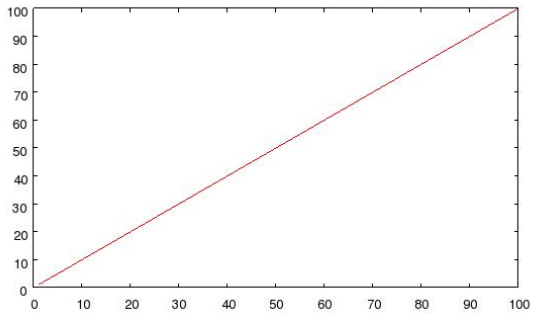
```
loglog(<data 1>,{linespec 1},<data 2>,{linespec 2}...,properties...)
```

in fact, it is a simple wrapper around `plot` that sets the x and y axis to have a logarithmic scale.

23.48.2 Example

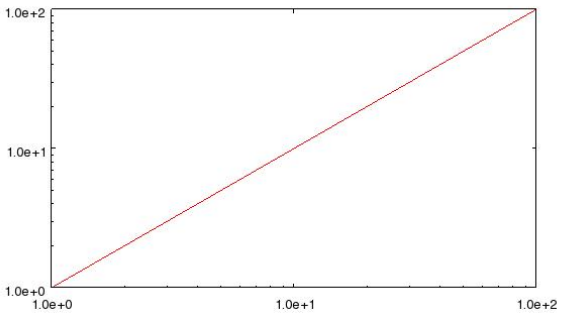
Here is an example of a doubly exponential signal plotted first on a linear plot:

```
--> x = linspace(1,100);
--> y = x;
--> plot(x,y,'r-');
```



and now on a log-log plot

```
--> loglog(x,y,'r-');
```



23.49 NEWPLOT Get Handle For Next Plot

23.49.1 Usage

Returns the handle for the next plot operation. The general syntax for its use is

```
h = newplot
```

This routine checks the `nextplot` properties of the current figure and axes to see if they are set to `replace` or not. If the figures `nextplot` property is set to replace, the current figure is cleared. If the axes `nextplot` property is set to `replace` then the axes are cleared for the next operation.

23.50 PATCH Patch Graphics Function

23.50.1 Usage

This routine is used to create a patch object that can be plotting 2D and 3D surfaces. A patch is a polygon defined by the xyz coordinates of its vertices and optionally by the color at the vertices. There are several forms for the `patch` function:

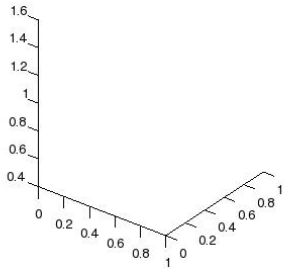
```
h = patch(X,Y,C,properties...)
h = patch(X,Y,Z,C,properties...)
h = patch(properties...)
h = patch(V)
```

Where `X`, `Y` and `Z` are matrices or vectors of `x`, `y` or `z` coordinates and `C` is a matrix or vector of color values (the colormap for the current fig is applied).

23.50.2 Example

Here we generate a surface specifying all four components.

```
--> x = [ 0 1 0 1]';
--> y = [ 0 0 1 1]';
--> c = [ 1 1 1 ];
--> patch(x,y,c)
--> axis equal
--> view(3)
```



23.51 PCOLOR Pseudocolor Plot

23.51.1 Usage

This routine is used to create a pseudocolor plot of the data. A pseudocolor plot is a essentially a surface plot seen from above. There are two forms for the `pcolor` command:

```
pcolor(C)
```

which uses a rectangular grid. Alternately, you can specify `X,Y` matrices or vectors.

```
pcolor(X,Y,C)
```

23.52 PLOT Plot Function

23.52.1 Usage

This is the basic plot command for FreeMat. The general syntax for its use is

```
plot(<data 1>,{linespec 1},<data 2>,{linespec 2}...,properties...)
```

where the `<data>` arguments can have various forms, and the `linespec` arguments are optional. We start with the `<data>` term, which can take on one of multiple forms:

- Vector Matrix Case – In this case the argument data is a pair of variables. A set of `x` coordinates in a numeric vector, and a set of `y` coordinates in the columns of the second, numeric matrix. `x` must have as many elements as `y` has columns (unless `y` is a vector, in which case only the number of elements must match). Each column of `y` is plotted sequentially against the common vector `x`.
- Unpaired Matrix Case – In this case the argument data is a single numeric matrix `y` that constitutes the `y`-values of the plot. An `x` vector is synthesized as `x = 1:length(y)`, and each column of `y` is plotted sequentially against this common `x` axis.
- Complex Matrix Case – Here the argument data is a complex matrix, in which case, the real part of each column is plotted against the imaginary part of each column. All columns receive the same line styles.

Multiple data arguments in a single plot command are treated as a *sequence*, meaning that all of the plots are overlapped on the same set of axes. The `linespec` is a string used to change the characteristics of the line. In general, the `linespec` is composed of three optional parts, the `colorspec`, the `symbolspec` and the `linestylespec` in any order. Each of these specifications is a single character that determines the corresponding characteristic. First, the `colorspec`:

- `'b'` - Color Blue
- `'g'` - Color Green
- `'r'` - Color Red
- `'c'` - Color Cyan
- `'m'` - Color Magenta
- `'y'` - Color Yellow
- `'k'` - Color Black

The `symbolspec` specifies the (optional) symbol to be drawn at each data point:

- `'.'` - Dot symbol
- `'o'` - Circle symbol
- `'x'` - Times symbol
- `'+'` - Plus symbol
- `'*'` - Asterisk symbol

- 's' - Square symbol
- 'd' - Diamond symbol
- 'v' - Downward-pointing triangle symbol
- '\^' - Upward-pointing triangle symbol
- '<' - Left-pointing triangle symbol
- '>' - Right-pointing triangle symbol

The linestylespec specifies the (optional) line style to use for each data series:

- '-' - Solid line style
- ':' - Dotted line style
- '-.' - Dot-Dash-Dot-Dash line style
- '--' - Dashed line style

For sequences of plots, the linespec is recycled with color order determined by the properties of the current axes. You can also use the properties argument to specify handle properties that will be inherited by all of the plots generated during this event. Finally, you can also specify the handle for the axes that are the target of the plot operation.

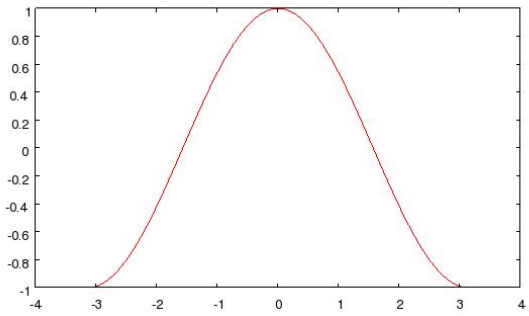
```
handle = plot(handle,...)
```

23.52.2 Example

The most common use of the plot command probably involves the vector-matrix paired case. Here, we generate a simple cosine, and plot it using a red line, with no symbols (i.e., a linespec of 'r-').

```
--> x = linspace(-pi,pi);
--> y = cos(x);
--> plot(x,y,'r-');
```

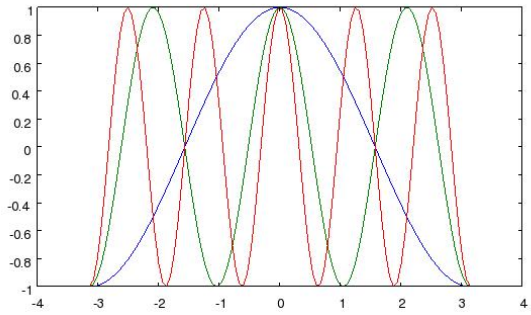
which results in the following plot.



Next, we plot multiple sinusoids (at different frequencies). First, we construct a matrix, in which each column corresponds to a different sinusoid, and then plot them all at once.

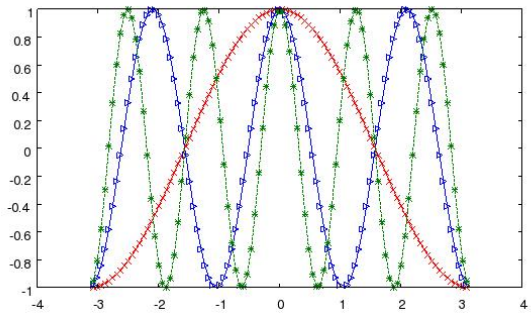
```
--> x = linspace(-pi,pi);
--> y = [cos(x(:)),cos(3*x(:)),cos(5*x(:))];
--> plot(x,y);
```

In this case, we do not specify a `linespec`, so that we cycle through the colors automatically (in the order listed in the previous section).



This time, we produce the same plot, but as we want to assign individual `linespecs` to each line, we use a sequence of arguments in a single plot command, which has the effect of plotting all of the data sets on a common axis, but which allows us to control the `linespec` of each plot. In the following example, the first line (harmonic) has red, solid lines with times symbols marking the data points, the second line (third harmonic) has blue, solid lines with right-pointing triangle symbols, and the third line (fifth harmonic) has green, dotted lines with asterisk symbols.

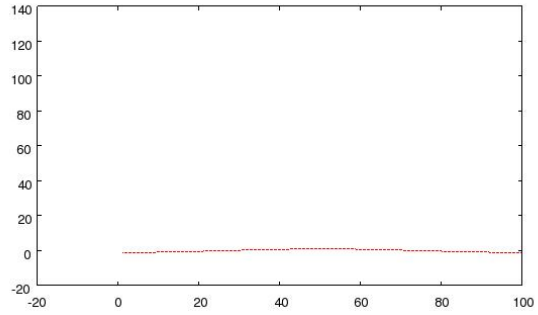
```
--> plot(x,y(:,1),'rx-',x,y(:,2),'b>-',x,y(:,3),'g*:');
```



The second most frequently used case is the unpaired matrix case. Here, we need to provide only one data component, which will be automatically plotted against a vector of natural number of the appropriate length. Here, we use a plot sequence to change the style of each line to be dotted, dot-dashed, and dashed.

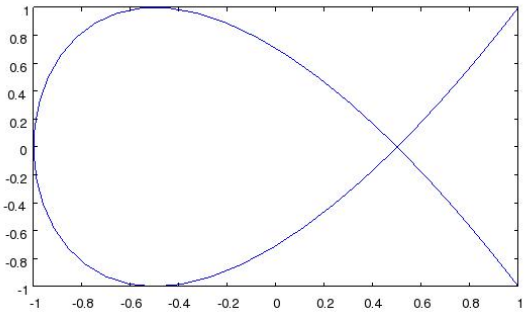
```
--> plot(y(:,1),'r:',y(:,2),'b;',y(:,3),'g|');
```

Note in the resulting plot that the `x`-axis no longer runs from `[-pi,pi]`, but instead runs from `[1,100]`.



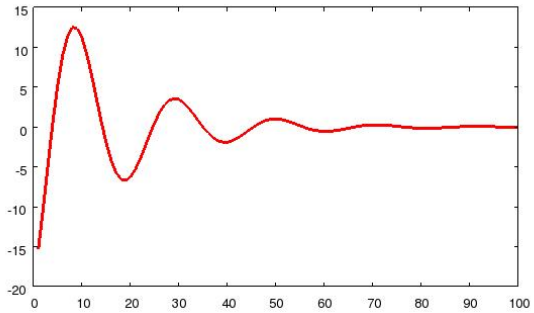
The final case is for complex matrices. For complex arguments, the real part is plotted against the imaginary part. Hence, we can generate a 2-dimensional plot from a vector as follows.

```
--> y = cos(2*x) + i * cos(3*x);
--> plot(y);
```



Here is an example of using the handle properties to influence the behavior of the generated lines.

```
--> t = linspace(-3,3);
--> plot(cos(5*t).*exp(-t),'r-','linewidth',3);
```



23.53 PLOT3 Plot 3D Function

23.53.1 Usage

This is the 3D plot command. The general syntax for its use is

```
plot3(X,Y,Z,{linespec 1},X,Y,Z,{linespec 2},...,properties...)
```

where `X` `Y` and `Z` are the coordinates of the points on the 3D line. Note that in general, all three should be vectors. If some or all of the quantities are matrices, then FreeMat will attempt to expand the vector arguments to the same size, and then generate multiple plots, one for each column of the matrices. The linespec is optional, see `plot` for details. You can specify `properties` for the generated line plots. You can also specify a handle as an axes to target

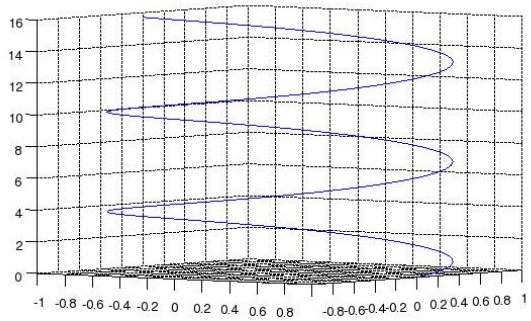
```
plot3(handle,...)
```

23.53.2 Example

Here is a simple example of a 3D helix.

```
--> t = linspace(0,5*pi,200);
--> x = cos(t); y = sin(t); z = t;
--> plot3(x,y,z);
--> view(3);
```

Shown here



23.54 POINT Get Axis Position From Mouse Click

23.54.1 Usage

Returns information about the currently displayed image based on a use supplied mouse-click. The general syntax for its use is

```
t = point
```

The returned vector `y` has two elements:

$$t = [x, y]$$

where `x,y` are the coordinates in the current axes of the click. This function has changed since FreeMat 1.10. If the click is not inside the active area of any set of axes, a pair of NaNs are returned.

23.55 PRINT Print a Figure To A File

23.55.1 Usage

This function "prints" the currently active fig to a file. The generic syntax for its use is

```
print(filename)
```

or, alternately,

```
print filename
```

where `filename` is the (string) filename of the destined file. The current fig is then saved to the output file using a format that is determined by the extension of the filename. The exact output formats may vary on different platforms, but generally speaking, the following extensions should be supported cross-platform:

- `jpg`, `jpeg` – JPEG file
- `pdf` – Portable Document Format file
- `png` – Portable Net Graphics file
- `svg` – Scalable Vector Graphics file

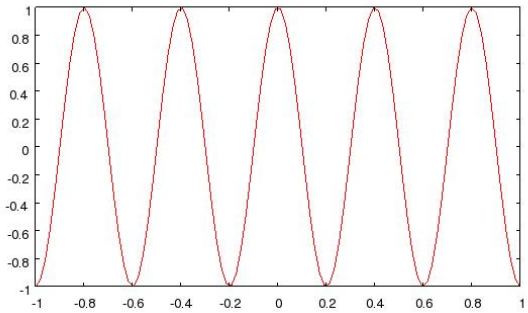
Postscript (PS, EPS) is supported on non-Mac-OSX Unix only. Note that only the fig is printed, not the window displaying the fig. If you want something like that (essentially a window-capture) use a seperate utility or your operating system's built in screen capture ability.

23.55.2 Example

Here is a simple example of how the figures in this manual are generated.

```
--> x = linspace(-1,1);
--> y = cos(5*pi*x);
--> plot(x,y,'r-');
--> print('printfig1.jpg')
--> print('printfig1.png')
```

which creates two plots `printfig1.png`, which is a Portable Net Graphics file, and `printfig1.jpg` which is a JPEG file.



23.56 PVALID Validate Property Name

23.56.1 Usage

This function checks to see if the given string is a valid property name for an object of the given type. The syntax for its use is

```
b = pvalid(type,propertyname)
```

where `string` is a string that contains the name of a valid graphics object type, and `propertyname` is a string that contains the name of the property to test for.

23.56.2 Example

Here we test for some properties on an `axes` object.

```
--> pvalid('axes','type')

ans =
 1

--> pvalid('axes','children')

ans =
 1

--> pvalid('axes','foobar')

ans =
 0
```

23.57 SEMILOGX Semilog X Axis Plot Function

23.57.1 Usage

This command has the exact same syntax as the `plot` command:

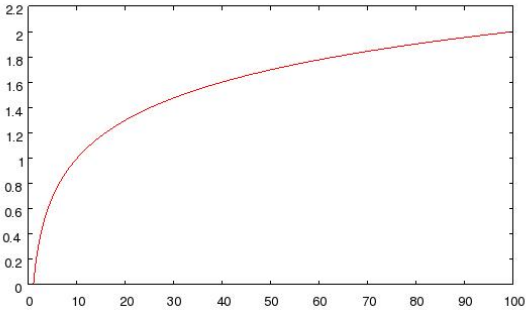
```
semilogx(<data 1>,{linespec 1},<data 2>,{linespec 2}...,properties...)
```

in fact, it is a simple wrapper around `plot` that sets the x axis to have a logarithmic scale.

23.57.2 Example

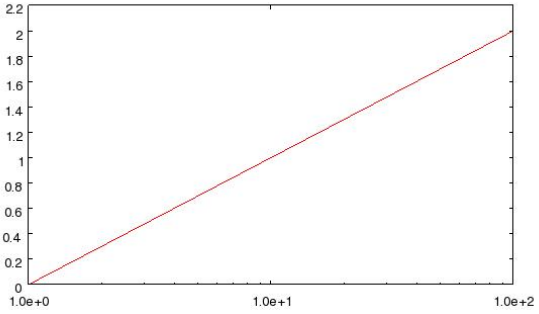
Here is an example of an exponential signal plotted first on a linear plot:

```
--> y = linspace(0,2);
--> x = (10).^y;
--> plot(x,y,'r-');
```



and now with a logarithmic x axis

```
--> semilogx(x,y,'r-');
```



23.58 SEMILOGY Semilog Y Axis Plot Function

23.58.1 Usage

This command has the exact same syntax as the `plot` command:

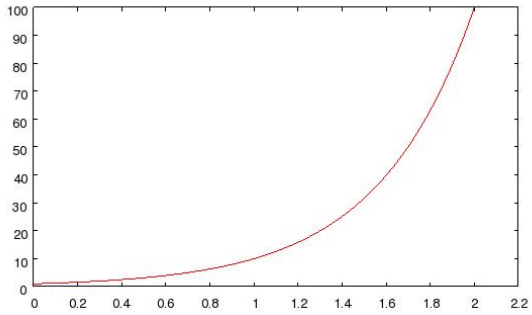
```
semilogy(<data 1>,{linespec 1},<data 2>,{linespec 2}...,properties...)
```

in fact, it is a simple wrapper around `plot` that sets the y axis to have a logarithmic scale.

23.58.2 Example

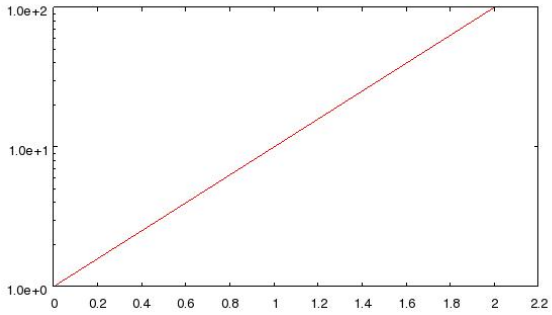
Here is an example of an exponential signal plotted first on a linear plot:

```
--> x = linspace(0,2);
--> y = 10.0.^x;
--> plot(x,y,'r-');
```



and now with a logarithmic y axis

```
--> semilogy(x,y,'r-');
```



23.59 SET Set Object Property

23.59.1 Usage

This function allows you to change the value associated with a property. The syntax for its use is

```
set(handle,property,value,property,value,...)
```

where `property` is a string containing the name of the property, and `value` is the value for that property. The type of the variable `value` depends on the property being set. See the help for the properties to see what values you can set.

23.60 SIZEFIG Set Size of Figure

23.60.1 Usage

The `sizefig` function changes the size of the currently selected fig window. The general syntax for its use is

```
sizefig(width,height)
```

where `width` and `height` are the dimensions of the fig window.

23.61 SUBPLOT Subplot Function

23.61.1 Usage

This function divides the current figure into a 2-dimensional grid, each of which can contain a plot of some kind. The function has a number of syntaxes. The first version

```
subplot(row,col,num)
```

which either activates subplot number `num`, or sets up a subplot grid of size `row x col`, and then activates `num`. You can also set up subplots that cover multiple grid elements

```
subplot(row,col,[vec])
```

where `vec` is a set of indexes covered by the new subplot. Finally, as a shortcut, you can specify a string with three components

```
subplot('mnp')
```

or using the alternate notation

```
subplot mnp
```

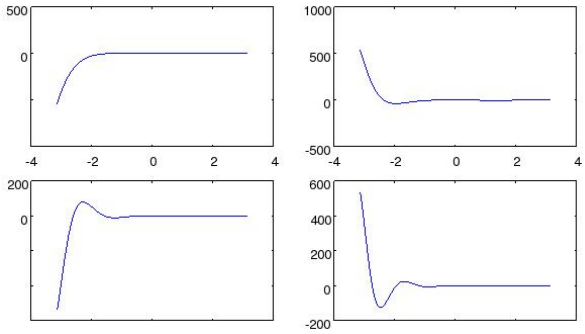
where `m` is the number of rows, `n` is the number of columns and `p` is the index. You can also specify the location of the subplot explicitly using the syntax

```
subplot('position',[left bottom width height])
```

23.61.2 Example

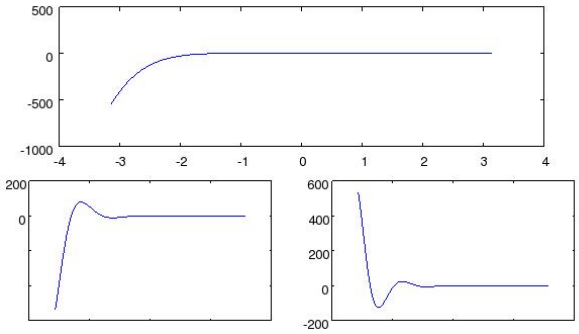
Here is the use of `subplot` to set up a `2 x 2` grid of plots

```
--> t = linspace(-pi,pi);
--> subplot(2,2,1)
--> plot(t,cos(t).*exp(-2*t));
--> subplot(2,2,2);
--> plot(t,cos(t*2).*exp(-2*t));
--> subplot(2,2,3);
--> plot(t,cos(t*3).*exp(-2*t));
--> subplot(2,2,4);
--> plot(t,cos(t*4).*exp(-2*t));
```



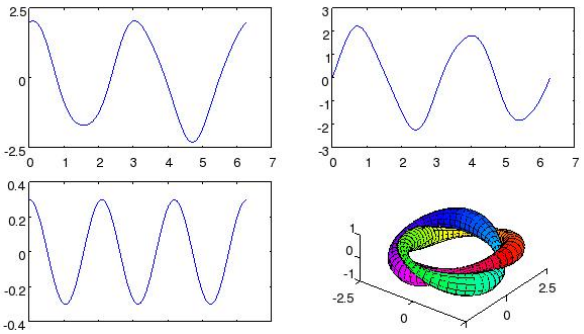
Here we use the second form of `subplot` to generate one subplot that is twice as large.

```
--> t = linspace(-pi,pi);
--> subplot(2,2,[1,2])
--> plot(t,cos(t).*exp(-2*t));
--> subplot(2,2,3);
--> plot(t,cos(t*3).*exp(-2*t));
--> subplot(2,2,4);
--> plot(t,cos(t*4).*exp(-2*t));
```



Note that the subplots can contain any handle graphics objects, not only simple plots.

```
--> t=0:(2*pi/100):(2*pi);
--> x=cos(t*2).*(2+sin(t*3)*.3);
--> y=sin(t*2).*(2+sin(t*3)*.3);
--> z=cos(t*3)*.3;
--> subplot(2,2,1)
--> plot(t,x);
--> subplot(2,2,2);
--> plot(t,y);
--> subplot(2,2,3);
--> plot(t,z);
--> subplot(2,2,4);
--> tubeplot(x,y,z,0.14*sin(t*5)+.29,t,10)
--> axis equal
--> view(3)
```



23.62 SURF Surface Plot Function

23.62.1 Usage

This routine is used to create a surface plot of data. A surface plot is a 3D surface defined by the xyz coordinates of its vertices and optionally by the color at the vertices. The most general syntax for the `surf` function is

```
h = surf(X,Y,Z,C,properties...)
```

Where `X` is a matrix or vector of `x` coordinates, `Y` is a matrix or vector of `y` coordinates, `Z` is a 2D matrix of coordinates, and `C` is a 2D matrix of color values (the colormap for the current fig is applied). In general, `X` and `Y` should be the same size as `Z`, but FreeMat will expand vectors to match the matrix if possible. If you want the color of the surface to be defined by the height of the surface, you can omit `C`

```
h = surf(X,Y,Z,properties...)
```

in which case `C=Z`. You can also eliminate the `X` and `Y` matrices in the specification

```
h = surf(Z,properties)
```

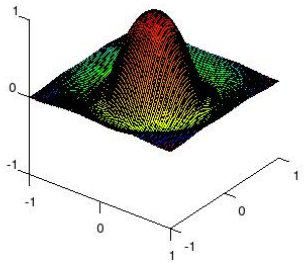
in which case they are set to `1:size(Z,2)` and `1:size(Y,2)` respectively. You can also specify a handle as the target of the `surf` command via

```
h = surf(handle,...)
```

23.62.2 Example

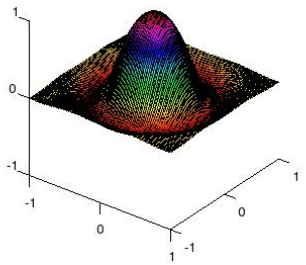
Here we generate a surface specifying all four components.

```
--> x = repmat(linspace(-1,1),[100,1]);
--> y = x';
--> r = x.^2+y.^2;
--> z = exp(-r*3).*cos(5*r);
--> c = r;
--> surf(x,y,z,c)
--> axis equal
--> view(3)
```



If we allow FreeMat to specify the color component, we see that the colorfield is the same as the height

```
--> surf(x,y,z)
--> axis equal
--> view(3)
```



23.63 SURFACEPROPERTIES Surface Object Properties

23.63.1 Usage

Below is a summary of the properties for the axis.

- `alphadata` - `vector` - This is a vector that should contain as many elements as the surface data itself `cdata`, or a single scalar. For a single scalar, all values of the surface take on the same transparency. Otherwise, the transparency of each pixel is determined by the corresponding value from the `alphadata` vector.
- `alphadatamapping` - `{'scaled','direct','none'}` - For `none` mode (the default), no transparency is applied to the data. For `direct` mode, the vector `alphadata` contains values between @[0,M-1]— where `M` is the length of the alpha map stored in the figure. For `scaled` mode, the `alim` vector for the figure is used to linearly rescale the alpha data prior to lookup in the alpha map.
- `ambientstrength` - Not used.
- `backfacelighting` - Not used.
- `cdata` - `array` - This is either a `M x N` array or an `M x N x 3` array. If the data is `M x N` the surface is a scalar surface (indexed mode), where the color associated with each surface pixel is computed using the colormap and the `cdatamapping` mode. If the data is `M x N x 3` the surface is assumed to be in RGB mode, and the colorpanes are taken directly from `cdata` (the colormap is ignored). Note that in this case, the data values must be between @[0,1]— for each color channel and each point on the surface.
- `cdatamapping` - `{'scaled','direct'}` - For `scaled` (the default), the pixel values are scaled using the `clim` vector for the figure prior to looking up in the colormap. For `direct` mode, the pixel values must be in the range `[0,N-1` where `N` is the number of colors in the colormap.
- `children` - Not used.
- `diffusestrength` - Not used.
- `edgealpha` - `{'flat','interp','scalar'}` - Controls how the transparency is mapped for the edges of the surface.
- `edgecolor` - `{'flat','interp','none',colorspec}` - Specifies how the edges are colored. For `'flat'` the edges are flat colored, meaning that the line segments that make up the edges are not shaded. The color for the line is determined by the first edge point it is connected to.
- `edgelighting` - Not used.
- `facealpha` - `{'flat','interp','texturemap',scalar}` - Controls how the transparency of the faces of the surface are controlled. For flat shading, the faces are constant transparency. For interp mode, the faces are smoothly transparently mapped. If set to a scalar, all faces have the same transparency.
- `facecolor` - `{'none','flat','interp',colorspec}` - Controls how the faces are colored. For `'none'` the faces are uncolored, and the surface appears as a mesh without hidden lines removed. For `'flat'` the surface faces have a constant color. For `'interp'` smooth shading is applied to the surface. And if a colorspec is provided, then the faces all have the same color.
- `facelighting` - Not used.
- `linestyle` - `{'-','--',':','-.','none'}` - The style of the line used to draw the edges.
- `linewidth` - `scalar` - The width of the line used to draw the edges.
- `marker` - `{'+','o','*','.','x','square','s','diamond','d','\^','v','>','<'}` - The marker for data points on the line. Some of these are redundant, as `'square' 's'` are synonyms, and `'diamond'` and `'d'` are also synonyms.
- `markeredgecolor` - `colorspec` - The color used to draw the marker. For some of the markers (circle, square, etc.) there are two colors used to draw the marker. This property controls the edge color (which for unfilled markers) is the primary color of the marker.

- markerfacecolor - colorspec - The color used to fill the marker. For some of the markers (circle, square, etc.) there are two colors used to fill the marker.
- markersize - scalar - Control the size of the marker. Defaults to 6, which is effectively the radius (in pixels) of the markers.
- meshstyle - {'both','rows','cols} - This property controls how the mesh is drawn for the surface. For rows and cols modes, only one set of edges is drawn.
- normalmode - Not used.
- parent - handle - The axis containing the surface.
- specularcolorreflectance - Not used.
- specularexponent - Not used.
- specularstrength - Not used.
- tag - string - You can set this to any string you want.
- type - string - Set to the string 'surface'.
- userdata - array - Available to store any variable you want in the handle object.
- vertexnormals - Not used.
- xdata - array - Must be a numeric array of size M x N which contains the x location of each point in the defined surface. Must be the same size as ydata and zdata. Alternately, you can specify an array of size 1 x N in which case FreeMat replicates the vector to fill out an M x N matrix.
- xdatamode - {'auto','manual'} - When set to auto then FreeMat will automatically generate the x coordinates.
- ydata - array - Must be a numeric array of size M x N which contains the y location of each point in the defined surface. Must be the same size as xdata and zdata. Alternately, you can specify an array of size M x 1 in which case FreeMat replicates the vector to fill out an M x N matrix.
- ydatamode - {'auto','manual'} - When set to auto then FreeMat will automatically generate the y coordinates.
- zdata - array - Must be a numeric array of size M x N which contains the y location of each point in the defined surface. Must be the same size as xdata and ydata.
- visible - {'on','off'} - Controls whether the surface is visible or not.

23.64 TEXT Add Text Label to Plot

23.64.1 Usage

Adds a text label to the currently active plot. The general syntax for it is use is either

```
text(x,y,'label')
```

where x and y are both vectors of the same length, in which case the text 'label' is added to the current plot at each of the coordinates x(i),y(i) (using the current axis to map these to screen coordinates). The second form supplies a cell-array of strings as the second argument, and allows you to place many labels simultaneously

```
text(x,y,{'label1','label2',....})
```

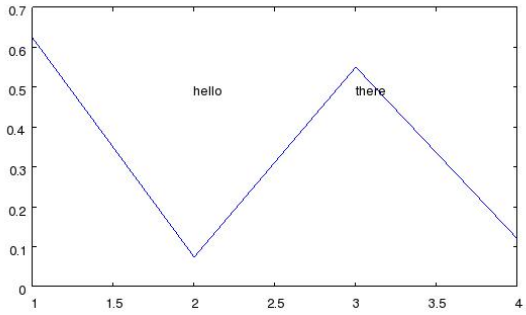
where the number of elements in the cell array must match the size of vectors x and y. You can also specify properties for the labels via

```
handles = text(x,y,{labels},properties...)
```

23.64.2 Example

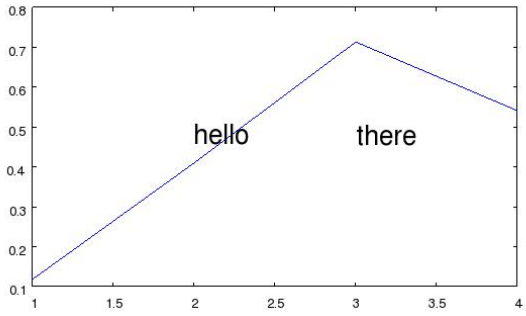
Here is an example of a few labels being added to a random plot:

```
--> plot(rand(1,4))
--> text([2,3],[0.5,0.5],{'hello','there'})
```



Here is the same example, but with larger labels:

```
--> plot(rand(1,4))
--> text([2,3],[0.5,0.5],{'hello','there'},'fontsize',20)
```



23.65 TEXTPROPERTIES Text Object Properties

23.65.1 Usage

Below is a summary of the properties for a text object.

- `boundingbox` - `four vector` - The size of the bounding box containing the text (in pixels). May contain negative values if the text is slanted.
- `children` - Not used.
- `string` - `string` - The text contained in the label.
- `extent` - Not used.
- `horizontalalignment` - `{'left','center','right'}` - Controls the alignment of the text relative to the specified position point.
- `position` - `three vector` - The position of the label in axis coordinates.
- `rotation` - `scalar` - The rotation angle (in degrees) of the label.
- `units` - Not used.

- `verticalalignment` - `{'top','bottom','middle'}` - Controls the alignment fo the text relative to the specified position point in the vertical position.
- `backgroundcolor` - `colorspec` - The color used to fill in the background rectangle for the label. Normally this is `none`.
- `edgecolor` - `colorspec` - The color used to draw the bounding rectangle for the label. Normally this is `none`.
- `linewidth` - `scalar` - The width of the line used to draw the border.
- `linestyle` - `{'-','--',':','-.','none'}` - The style of the line used to draw the border.
- `margin` - `scalar` - The amount of spacing to place around the text as padding when drawing the rectangle.
- `fontangle` - `{'normal','italic','oblique'}` - The angle of the fonts used for the labels.
- `fontsize` - `scalar` - The size of fonts used for the text.
- `fontunits` - Not used.
- `fontweight` - `{'normal','bold','light','demi'}` - The weight of the font used for the label
- `visible` - `{'on','off'}` - Controls visibility of the the line.
- `color` - `colorspec` - The color of the text of the label.
- `children` - Not used.
- `parent` - The handle of the axis that owns this label.
- `tag` - `string` - A string that can be used to tag the object.
- `type` - `string` - Returns the string `'text'`.
- `userdata` - `array` - Available to store any variable you want in the handle object.

23.66 TITLE Plot Title Function

23.66.1 Usage

This command adds a title to the plot. The general syntax for its use is

```
title('label')
```

or in the alternate form

```
title 'label'
```

or simply

```
title label
```

Here `label` is a string variable. You can also specify properties for the label, and a handle to serve as a target for the operation

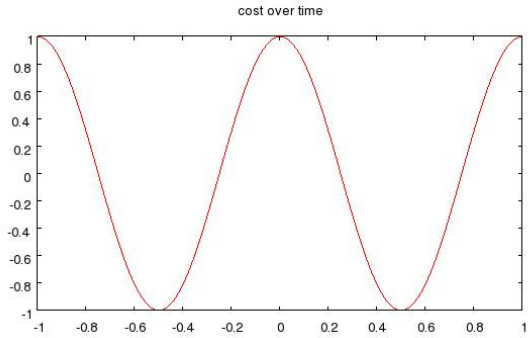
```
title(handle,'label',properties...)
```

23.66.2 Example

Here is an example of a simple plot with a title.

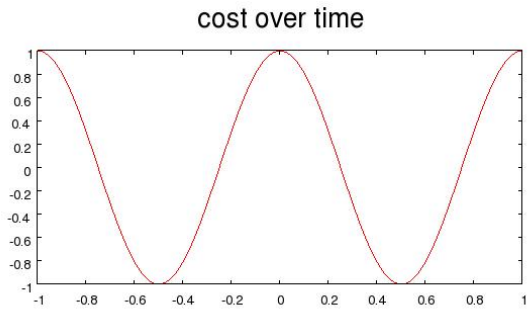
```
--> x = linspace(-1,1);
--> y = cos(2*pi*x);
--> plot(x,y,'r-');
--> title('cost over time');
```

which results in the following plot.



We now increase the size of the font using the properties of the `label`

```
--> title('cost over time','fontsize',20);
```



23.67 TUBEPLOT Creates a Tubeplot

23.67.1 Usage

This `tubeplot` function is from the tubeplot package written by Anders Sandberg. The simplest syntax for the `tubeplot` routine is

```
tubeplot(x,y,z)
```

plots the basic tube with radius 1, where `x,y,z` are vectors that describe the tube. If the radius of the tube is to be varied, use the second form

```
tubeplot(x,y,z,r)
```

which plots the basic tube with variable radius r (either a vector or a scalar value). The third form allows you to specify the coloring using a vector of values:

```
tubeplot(x,y,z,r,v)
```

where the coloring is now dependent on the values in the vector `v`. If you want to create a tube plot with a greater degree of tangential subdivisions (i.e., the tube is more circular, use the form

```
tubeplot(x,y,z,r,v,s)
```

where `s` is the number of tangential subdivisions (default is 6) You can also use `tubeplot` to calculate matrices to feed to `mesh` and `surf`.

```
[X,Y,Z]=tubeplot(x,y,z)
```

returns `N x 3` matrices suitable for mesh or surf.

Note that the tube may pinch at points where the normal and binormal misbehaves. It is suitable for general space curves, not ones that contain straight sections. Normally the tube is calculated using the Frenet frame, making the tube minimally twisted except at inflexion points.

To deal with this problem there is an alternative frame:

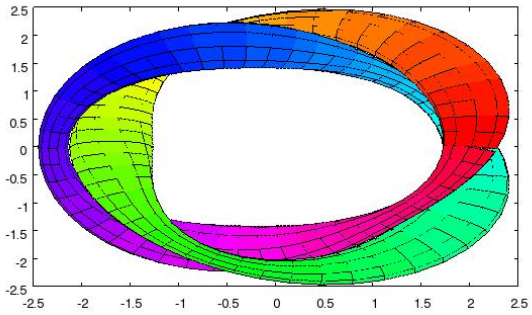
```
tubeplot(x,y,z,r,v,s,vec)
```

calculates the tube by setting the normal to the cross product of the tangent and the vector vec. If it is chosen so that it is always far from the tangent vector the frame will not twist unduly.

23.67.2 Example

Here is an example of a `tubeplot`.

```
--> t=0:(2*pi/100):(2*pi);
--> x=cos(t*2).*(2+sin(t*3)*.3);
--> y=sin(t*2).*(2+sin(t*3)*.3);
--> z=cos(t*3)*.3;
--> tubeplot(x,y,z,0.14*sin(t*5)+.29,t,10);
```



Written by Anders Sandberg, asa@nada.kth.se, 2005 Website says the package is free for anybody to use. www.nada.kth.se/ asa/Ray/Tubeplot/tubeplot.html

23.68 UICONTROL Create a UI Control object

23.68.1 Usage

Creates a UI control object and parents it to the current figure. The syntax for its use is

```
handle = uicontrol(property,value,property,value,...)
```

where `property` and `value` are set. The handle ID for the resulting object is returned. It is automatically added to the children of the current figure.

23.69 UICONTROLPROPERTIES UI Control Properties

23.69.1 Usage

Below is a summary of the properties for user interface controls.

- `backgroundcolor` - `colorspec` - The background color for the widget.
- `busyaction` - Not used.
- `buttondownfcn` - Not used.
- `callback` - `string` - the callback to execute when the GUI control does its action. Clicking a button or moving a scroller will cause the callback to be executed. Also, pressing enter in a text box causes the callback to be executed.
- `cdata` - an `M x N x 3` array that represents an RGB image to use as the truecolor image displayed on push bottons or toggle buttons. The values must be between 0 and 1.
- `children` - Not used.
- `createfcn` - Not used.
- `deletefcn` - Not used;
- `enable` - `{'on','inactive','off'}` - For `on` (the default) the uicontrol behaves normally. For inactive, it is not operational, but looks the same as `on`. For `off`, the control is grayed out.
- `extent` - a read only property that contains the extent of the text for the control.
- `fontangle` - `{'normal','italic','oblique'}` - The angle of the fonts used for text labels (e.g., tick labels).
- `fontsize` - `scalar` - The size of fonts used for text labels (tick labels).
- `fontunits` - Not used.
- `fontname` - `string` - The name of the font to use for the widget.
- `fontweight` - `{'normal','bold','light','demi'}` - The weight of the font used
- `foregroundcolor` - `colorspec` - the foreground color for text.
- `handlevisibility` - Not used.
- `hittest` - Not used.
- `horizontalalignment` - `{'left','center','right}` - determines the justification of text.
- `interruptible` - Not used.
- `keypressfcn` - `functionspec` - a string or function handle that is called when a key is pressed and a uicontrol object has focus.
- `listboxtop` - a scalar (used only by the listbox style of uicontrols) that specifies which string appears at the top of the list box.
- `max` - a scalar that specifies the largest value allowed for the `value` property. The interpretation varies depending on the type of the control
  - `check boxes` - specifies what `value` is set to when the check box is selected.
  - `edit box` - if `max-min>1` then the text box allows for multiple lines of input. Otherwise, it is a single line only.

  - `list box` - if `max-min>1` then multiple item selections are allowed. Otherwise, only single item selections are allowed.
  - `radio buttons` - specifies what `value` is set to when the radio button is selected.
  - `slider` - the maximum value the slider can take.
  - `toggle button` - specifies what `value` is set to when the toggle button is selected.
- `min` - a scalar that specifies the smallest value for the `value` property. The interpretation of it depends on the type of the control
  - `check boxes` - specifies what `value` is set to when the check box is not selected.
  - `edit box` - if `max-min>1` then the text box allows for multiple lines of input. Otherwise, it is a single line only.
  - `list box` - if `max-min>1` then multiple item selections are allowed. Otherwise, only single item selections are allowed.
  - `radio buttons` - specifies what `value` is set to when the radio button is not selected.
  - `slider` - the minimum value the slider can take.
  - `toggle button` - specifies what `value` is set to when the toggle button is not selected.
- `parent` - the handle of the parent object.
- `position` - size and location of the uicontrol as a four vector `[left, bottom, width, height]`. If `width>height` then sliders are horizontal, otherwise the slider is oriented vertically.
- `selected` - `{'on','off'}` - not used.
- `selectionhighlight` - `{'on','off'}` - not used.
- `sliderstep` - a two vector `[min\_step max\_step]` that controls the amount the slider `value` changes when you click the mouse on the control. If you click the arrow for the slider, the value changes by `min\_step`, while if you click the trough, the value changes by `max\_step`. Each value must be in the range `[0,1]`, and is a percentage of the range `max-min`.
- `string` - `string` - the text for the control.
- `style` - @—'pushbutton','toggle','radiobutton','checkbox', 'edit','text','slider','frame','listbox','popupmenu'—.
- `tag` - `string` - user specified label.
- `tooltipstring` - `string` the tooltip for the control.
- `type` - `string` - the text is set to `'uicontrol'`.
- `uicontextmenu` - `handle` the handle of the `uicontextmenu` that shows up when you right-click over the control.
- `units` - not used.
- `userdata` - `array` - any data you want to associate with the control.
- `value` - The meaning of this property depends on the type of the control:
  - check box - set to `max` when checked, and `min` when off.
  - list box - set to a vector of indices corresponding to selected items, with `1` corresponding to the first item in the list.
  - pop up menu - set to the index of the item selected (starting with 1)
  - radio buttons - set to `max` when selected, and set to `min` when not selected.

  - sliders - set to the value of the slider
  - toggle buttons - set to `max` when selected, and set to `min` when not selected.
  - text controls, push buttons - do not use this property.

- `visible` - `{'on','off'}` - controls whether the control is visible or not

23.70 VIEW Set Graphical View

23.70.1 Usage

The `view` function sets the view into the current plot. The simplest form is

```
view(n)
```

where `n=2` sets a standard view (azimuth 0 and elevation 90), and `n=3` sets a standard 3D view (azimuth 37.5 and elevation 30). With two arguments,

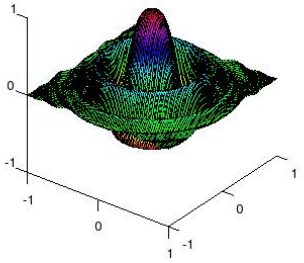
```
view(az,el)
```

you set the viewpoint to azimuth `az` and elevation `el`.

23.70.2 Example

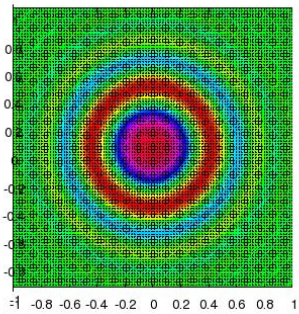
Here is a 3D surface plot shown with a number of viewpoints. First, the default view for a 3D plot.

```
--> x = repmat(linspace(-1,1),[100,1]);
--> y = x';
--> r = x.^2+y.^2;
--> z = exp(-r*3).*cos(5*pi*r);
--> surf(x,y,z);
--> axis equal
--> view(3)
```



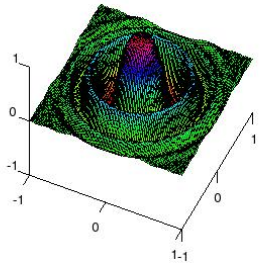
Next, we look at it as a 2D plot

```
--> surf(x,y,z);
--> axis equal
--> view(2)
```



Finally, we generate a different view of the same surface.

```
--> surf(x,y,z);
--> axis equal
--> view(25,50);
```



23.71 WINLEV Image Window-Level Function

23.71.1 Usage

Adjusts the data range used to map the current image to the current colormap. The general syntax for its use is

```
winlev(window,level)
```

where `window` is the new window, and `level` is the new level, or

```
winlev
```

in which case it returns a vector containing the current window and level for the active image.

23.71.2 Function Internals

FreeMat deals with scalar images on the range of `[0,1]`, and must therefor map an arbitrary image `x` to this range before it can be displayed. By default, the `image` command chooses

$$\text{window} = \max x - \min x,$$

and

$$\text{level} = \frac{\text{window}}{2}$$

This ensures that the entire range of image values in `x` are mapped to the screen. With the `winlev` function, you can change the range of values mapped. In general, before display, a pixel `x` is mapped to `[0,1]` via:

$$\max\left(0, \min\left(1, \frac{x - \text{level}}{\text{window}}\right)\right)$$

23.71.3 Examples

The window level function is fairly easy to demonstrate. Consider the following image, which is a Gaussian pulse image that is very narrow:

```
--> t = linspace(-1,1,256);
--> xmat = ones(256,1)*t; ymat = xmat';
--> A = exp(-(xmat.^2 + ymat.^2)*100);
--> image(A);
```

The data range of `A` is `[0,1]`, as we can verify numerically:

```
--> min(A(:))

ans =
 1.3839e-87

--> max(A(:))

ans =
    0.9969
```

To see the tail behavior, we use the `winlev` command to force FreeMat to map a smaller range of `A` to the colormap.

```
--> image(A);
--> winlev(1e-4,0.5e-4)
```

The result is a look at more of the tail behavior of `A`. We can also use the winlev function to find out what the window and level are once set, as in the following example.

```
--> image(A);
--> winlev(1e-4,0.5e-4)
--> winlev

ans =
 1.0000e-04
```

23.72 XLABEL Plot X-axis Label Function

23.72.1 Usage

This command adds a label to the x-axis of the plot. The general syntax for its use is

```
  xlabel('label')
```

or in the alternate form

```
  xlabel 'label'
```

or simply

```
  xlabel label
```

Here `label` is a string variable. You can also specify properties for that label using the syntax

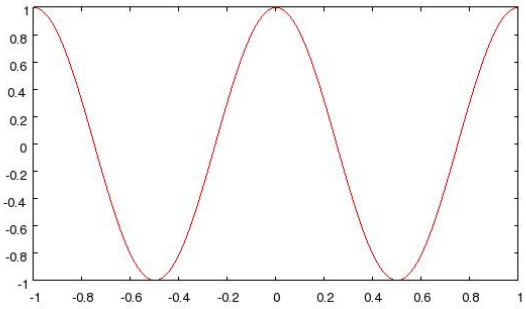
```
  xlabel('label',properties...)
```

23.72.2 Example

Here is an example of a simple plot with a label on the x-axis.

```
--> x = linspace(-1,1);
--> y = cos(2*pi*x);
--> plot(x,y,'r-');
--> xlabel('time');
```

which results in the following plot.



23.73 XLIM Adjust X Axis limits of plot

23.73.1 Usage

There are several ways to use `xlim` to adjust the X axis limits of a plot. The various syntaxes are

```
xlim
xlim([lo,hi])
xlim('auto')
xlim('manual')
xlim('mode')
xlim(handle,...)
```

The first form (without arguments), returns a 2-vector containing the current limits. The second form sets the limits on the plot to `[lo,hi]`. The third and fourth form set the mode for the limit to `auto` and `manual` respectively. In `auto` mode, FreeMat chooses the range for the axis automatically. The `xlim('mode')` form returns the current mode for the axis (either `'auto'` or `'manual'`). Finally, you can specify the handle of an axis to manipulate instead of using the current one.

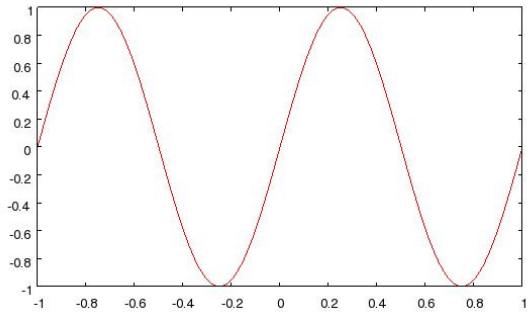
As an additional feature, you can now specify `inf` for a limit, and FreeMat will take that limit from the automatic set. So, for example `xlim([10,inf])` will set the minimum for the x axis, but use the automatic value for the maximum.

23.73.2 Example

```
--> x = linspace(-1,1);
--> y = sin(2*pi*x);
--> plot(x,y,'r-');
--> xlim  % what are the current limits?

ans =
 -1  1
```

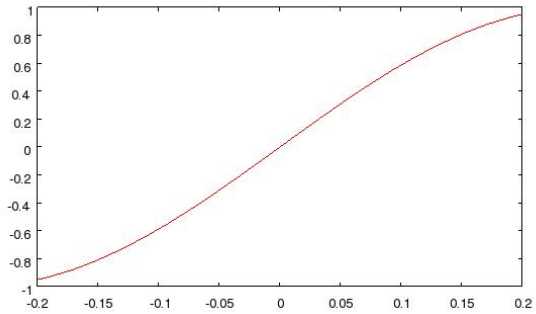
which results in



Next, we zoom in on the plot using the `xlim` function

```
--> plot(x,y,'r-')
--> xlim([-0.2,0.2])
```

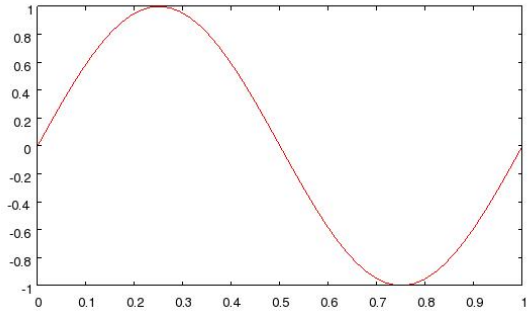
which results in



To demonstrate the infinite limits feature. Consider the following

```
--> plot(x,y,'r-');
--> xlim([0,inf])
```

which results in



23.74 YLABEL Plot Y-axis Label Function

23.74.1 Usage

This command adds a label to the y-axis of the plot. The general syntax for its use is

```
ylabel('label')
```

or in the alternate form

```
ylabel 'label'
```

or simply

```
ylabel label
```

You can also specify properties for that label using the syntax

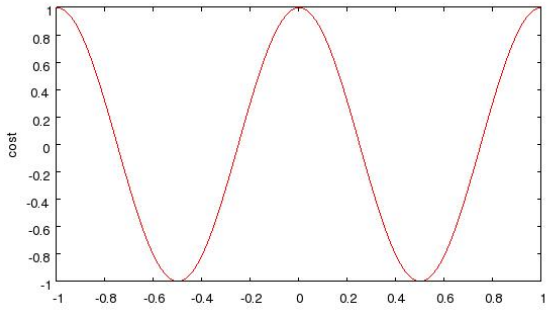
```
ylabel('label',properties...)
```

23.74.2 Example

Here is an example of a simple plot with a label on the y-axis.

```
--> x = linspace(-1,1);
--> y = cos(2*pi*x);
--> plot(x,y,'r-');
--> ylabel('cost');
```

which results in the following plot.



23.75 YLIM Adjust Y Axis limits of plot

23.75.1 Usage

There are several ways to use `ylim` to adjust the Y axis limits of a plot. The various syntaxes are

```
ylim
ylim([lo,hi])
ylim('auto')
ylim('manual')
ylim('mode')
ylim(handle,...)
```

The first form (without arguments), returns a 2-vector containing the current limits. The second form sets the limits on the plot to `[lo,hi]`. The third and fourth form set the mode for the limit to `auto` and `manual` respectively. In `auto` mode, FreeMat chooses the range for the axis automatically. The `ylim('mode')` form returns the current mode for the axis (either `'auto'` or `'manual'`). Finally, you can specify the handle of an axis to manipulate instead of using the current one.

As an additional feature, you can now specify `inf` for a limit, and FreeMat will take that limit from the automatic set. So, for example `ylim([10,inf])` will set the minimum for the y axis, but use the automatic value for the maximum.

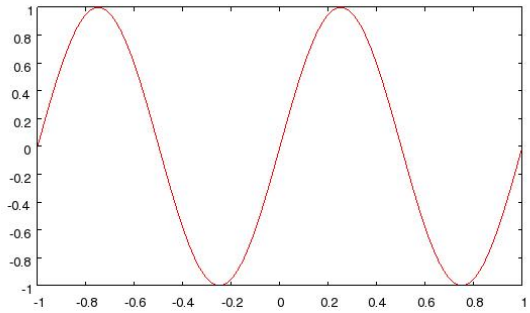
23.75.2 Example

```
--> x = linspace(-1,1);
--> y = sin(2*pi*x);
```

```
--> plot(x,y,'r-');
--> ylim  % what are the current limits?

ans =
   -0.9999    0.9999
```

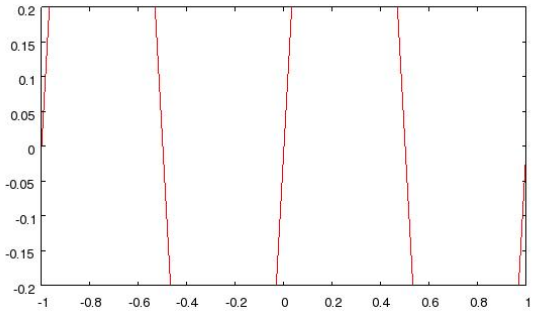
which results in



Next, we zoom in on the plot using the `ylim` function

```
--> plot(x,y,'r-')
--> ylim([-0.2,0.2])
```

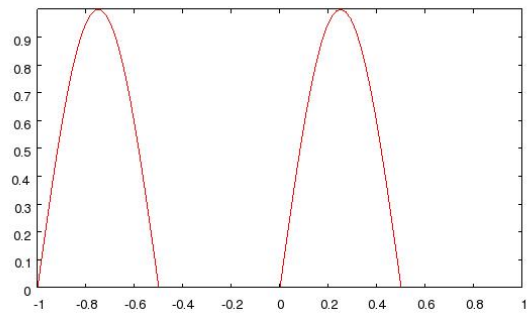
which results in



To demonstrate the infinite limits feature. Consider the following

```
--> plot(x,y,'r-');
--> ylim([0,inf])
```

which results in



23.76 ZLABEL Plot Z-axis Label Function

23.76.1 Usage

This command adds a label to the z-axis of the plot. The general syntax for its use is

```
zlabel('label')
```

or in the alternate form

```
zlabel 'label'
```

or simply

```
zlabel label
```

Here `label` is a string variable. You can also specify properties for that label using the syntax

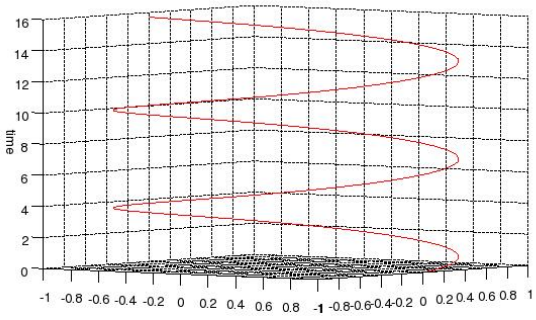
```
zlabel('label',properties...)
```

23.76.2 Example

Here is an example of a simple plot with a label on the `z`-axis.

```
--> t = linspace(0,5*pi);
--> x = cos(t);
--> y = sin(t);
--> z = t;
--> plot3(x,y,z,'r-');
--> view(3);
--> zlabel('time');
```

which results in the following plot.



23.77 ZLIM Adjust Z Axis limits of plot

23.77.1 Usage

There are several ways to use `zlim` to adjust the Z axis limits of a plot. The various syntaxes are

```
zlim
zlim([lo,hi])
zlim('auto')
zlim('manual')
zlim('mode')
zlim(handle,...)
```

The first form (without arguments), returns a 2-vector containing the current limits. The second form sets the limits on the plot to `[lo,hi]`. The third and fourth form set the mode for the limit to `auto` and `manual` respectively. In `auto` mode, FreeMat chooses the range for the axis automatically. The `zlim('mode')` form returns the current mode for the axis (either `'auto'` or `'manual'`). Finally, you can specify the handle of an axis to manipulate instead of using the current one.

23.78 ZOOM Image Zoom Function

23.78.1 Usage

This function changes the zoom factor associated with the currently active image. It is a legacy support function only, and thus is not quite equivalent to the `zoom` function from previous versions of FreeMat. However, it should achieve roughly the same effect. The generic syntax for its use is

```
zoom(x)
```

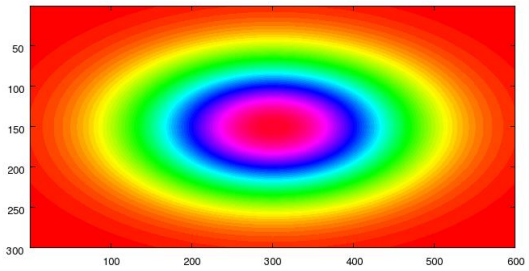
where `x` is the zoom factor to be used. The exact behavior of the zoom factor is as follows:

- `x>0` The image is zoomed by a factor `x` in both directions.
- `x=0` The image on display is zoomed to fit the size of the image window, but the aspect ratio of the image is not changed. (see the Examples section for more details). This is the default zoom level for images displayed with the `image` command.
- `x<0` The image on display is zoomed to fit the size of the image window, with the zoom factor in the row and column directions chosen to fill the entire window. The aspect ratio of the image is not preserved. The exact value of `x` is irrelevant.

23.78.2 Example

To demonstrate the use of the `zoom` function, we create a rectangular image of a Gaussian pulse. We start with a display of the image using the `image` command, and a zoom of 1.

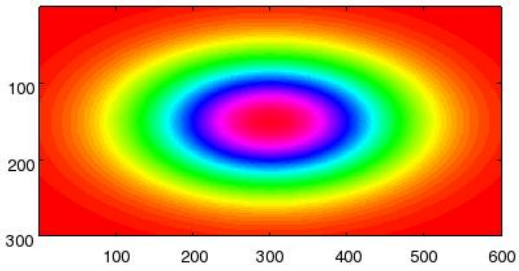
```
--> x = linspace(-1,1,300)'*ones(1,600);
--> y = ones(300,1)*linspace(-1,1,600);
--> Z = exp(-(x.^2+y.^2)/0.3);
--> image(Z);
--> zoom(1.0);
```



At this point, resizing the window accomplishes nothing, as with a zoom factor greater than zero, the size of the image is fixed.

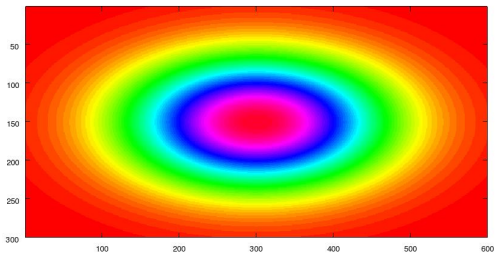
If we change the zoom to another factor larger than 1, we enlarge the image by the specified factor (or shrink it, for zoom factors `0 < x < 1`. Here is the same image zoomed out to 60

```
--> image(Z);
--> zoom(0.6);
```



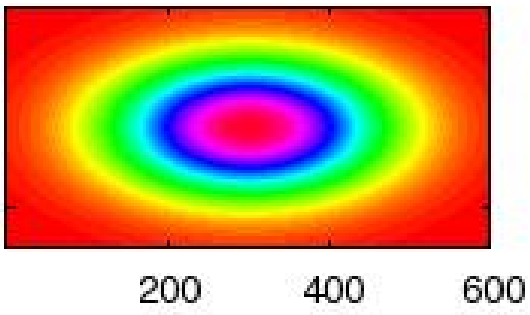
Similarly, we can enlarge it to 130

```
--> image(Z)
--> zoom(1.3);
```



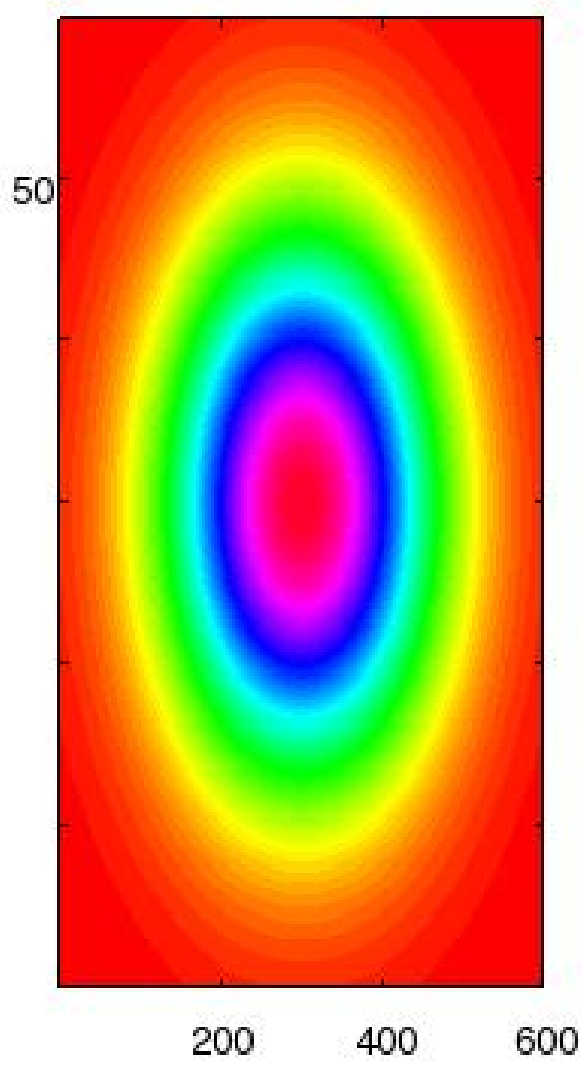
The "free" zoom of `x = 0` results in the image being zoomed to fit the window without changing the aspect ratio. The image is zoomed as much as possible in one direction.

```
--> image(Z);
--> zoom(0);
--> sizefig(200,400);
```



The case of a negative zoom `x < 0` results in the image being scaled arbitrarily. This allows the image aspect ratio to be changed, as in the following example.

```
--> image(Z);
--> zoom(-1);
--> sizefig(200,400);
```



23.79 ZPLANE Zero-pole plot

23.79.1 Usage

This function makes a zero-pole plot of a discrete-time system defined by its zeros and poles. The various syntaxes are

```
zplane(z,p)
```

where `z` and `p` are the zeros and the poles of the system stored as column vectors, or

```
zplane(b,a)
```

where `a` and `b` are the polynomial coefficients of the numerator and denominator stored as line vectors (`roots` is used to find the zeros and poles). The symbol `'o'` represents a zero and the symbol `'x'` represents a pole. The plot includes the unit circle for reference. Contributed by Paulo Xavier Candeias under GPL

Chapter 24

OpenGL Models

24.1 GLASSEMBLY Create a GL Assembly

24.1.1 Usage

Define a GL Assembly. A GL Assembly consists of one or more GL Nodes or GL Assemblies that are placed relative to the coordinate system of the assembly. For example, if we have `glnode` definitions for `'bread'` and `'cheese'`, then a `glassembly` of sandwich would consist of placements of two `'bread'` nodes with a `'cheese'` node in between. Furthermore, a `'lunch'` assembly could consist of a `'sandwich'` a `'chips'` and `'soda'`. Hopefully, you get the idea. The syntax for the `glassembly` command is

```
glassembly(name,part1,transform1,part2,transform2,...)
```

where `part1` is the name of the first part, and could be either a `glnode` or itself be another `glassembly`. Here `transform1` is the `4 x 4 matrix` that transforms the part into the local reference coordinate system.

WARNING!! Currently FreeMat does not detect or gracefully handle self-referential assemblies (i.e, if you try to make a `sandwich` contain a `sandwich`, which you can do by devious methods that I refuse to explain). Do not do this! You have been warned.

24.2 GLCLUMP Create a GL Clump

24.2.1 Usage

Defines an aggregate clump of objects that can be treated as a node. A GL Clump is defined by a vector consisting of the following elements:

```
[r1 g1 b1 n1 p1 p2 p3 ... r2 g2 b2 n2 p1 p2 p3 ... ]
```

i.e., an RGB color spec, followed by a point count `ni`, followed by a length `ni` vector of coordinates that are `x,y,z` triplets. The usage of this function is

```
glclump(name,vector)
```

where `name` is the name of the clump and `vector` is the aforementioned vector of points.

24.3 GLDEFMATERIAL Defines a GL Material

24.3.1 Usage

Define a material. The syntax for its use is

```
gldefmaterial(name,ambient,diffuse,specular,shininess)
```

where `name` is the name of the material, and `ambient` is a `4 x 1` vector containing the ambient component of the material property, and `diffuse` is a `4 x 1` vector and `specular` is a `4 x 1` vector containing the specular component of the material properties and `shininess` is the exponent that governs the shinines of the material.

24.4 GLLINES Create a GL Lineset

24.4.1 Usage

Defines a set of lines that can be treated as a node. A GL Lines is defined by a vector consisting of the following elements:

```
[m1 x1 y1 z1 ... xn yn zn m2 x1 y1 z1 .... ]
```

i.e., a point count followed by that number of triplets. The usage of this function is

```
gllines(name,vector,color)
```

where `name` is the name of the lineset and `vector` is the aforementioned vector of points.

24.5 GLNODE Create a GL Node

24.5.1 Usage

Define a GL Node. A GL Node is an object that can be displayed in a GL Window. It is defined by a triangular mesh of vertices. It must also have a material that defines its appearance (i.e. color, shininess, etc.). The syntax for the `glnode` command is

```
glnode(name,material,pointset)
```

where `material` is the name of a material that has already been defined with `gldefmaterial`, `pointset` is a `3 x N` matrix of points that define the geometry of the object. Note that the points are assumed to be connected in triangular facts, with the points defined counter clock-wise as seen from the outside of the facet. `FreeMat` will compute the normals. The `name` argument must be unique. If you want multiple instances of a given `glnode` in your GLWindow, that is fine, as instances of a `glnode` are created through a `glassembly`.

Chapter 25

Object Oriented Programming

25.1 AND Overloaded Logical And Operator

25.1.1 Usage

This is a method that is invoked to combine two variables using a logical and operator, and is invoked when you call

```
c = and(a,b)
```

or for

```
c = a & b
```

25.2 CAT Concatenation of Arrays

25.2.1 Usage

This function concatenates arrays in a given dimension. The syntax for its use is

```
cat (DIM, A, B)
cat (DIM, A, B, C ...)
```

to return the concatenation along the dimension `DIM` of all arguments. `cat(1, A, B, C)` is the same as `[A; B; C]` or `vertcat(A, B, C)`. `cat(2, A, B, C)` is the same as `[A, B, C]` or `horzcat(A, B, C)`.

25.3 CLASS Class Support Function

25.3.1 Usage

There are several uses for the `class` function. The first version takes a single argument, and returns the class of that variable. The syntax for this form is

```
classname = class(variable)
```

and it returns a string containing the name of the class for `variable`. The second form of the class function is used to construct an object of a specific type based on a structure which contains data elements for the class. The syntax for this version is

```
classvar = class(template, classname, parent1, parent2,...)
```

This should be called inside the constructor for the class. The resulting class will be of the type `classname`, and will be derived from `parent1`, `parent2`, etc. The `template` argument should be a structure array that contains the members of the class. See the `constructors` help for some details on how to use the `class` function. Note that if the `template` argument is an empty structure matrix, then the resulting variable has no fields beyond those inherited from the parent classes.

25.4 COLON Overloaded Colon Operator

25.4.1 Usage

This is a method that is invoked in one of two forms, either the two argument version

```
c = colon(a,b)
```

which is also called using the notation

```
c = a:b
```

and the three argument version

```
d = colon(a,b,c)
```

which is also called using the notation

```
d = a:b:c
```

25.5 CONSTRUCTORS Class Constructors

25.5.1 Usage

When designing a constructor for a FreeMat class, you should design the constructor to take a certain form. The following is the code for the sample `mat` object

```
function p = mat(a)
  if (nargin == 0)
    p.c = [];
    p = class(p,'mat');
  elseif isa(a,'mat')
    p = a;
  else
    p.c = a;
    p = class(p,'mat');
  end
```

Generally speaking when it is provided with zero arguments, the constructor returns a default version of the class using a template structure with the right fields populated with default values. If the constructor is given a single argument that matches the class we are trying to construct, the constructor passes through the argument. This form of the constructor is used for type conversion. In particular,

```
p = mat(a)
```

guarantees that `p` is an array of class `mat`. The last form of the constructor builds a class object given the input. The meaning of this form depends on what makes sense for your class. For example, for a polynomial class, you may want to pass in the coefficients of the polynomial.

25.6 CTRANSPOSE Overloaded Conjugate Transpose Operator

25.6.1 Usage

This is a method that is invoked when a variable has the conjugate transpose operator method applied, and is invoked when you call

```
c = ctranspose(a)
```

or

```
/  c = a'
```

25.7 EQ Overloaded Equals Comparison Operator

25.7.1 Usage

This is a method that is invoked to combine two variables using an equals comparison operator, and is invoked when you call

```
c = eq(a,b)
```

or for

```
c = a == b
```

25.8 GE Overloaded Greater-Than-Equals Comparison Operator

25.8.1 Usage

This is a method that is invoked to combine two variables using a greater than or equals comparison operator, and is invoked when you call

```
c = ge(a,b)
```

or for

```
c = a >= b
```

25.9 GT Overloaded Greater Than Comparison Operator

25.9.1 Usage

This is a method that is invoked to combine two variables using a greater than comparison operator, and is invoked when you call

```
c = gt(a,b)
```

or for

```
c = a > b
```

25.10 HORZCAT Overloaded Horizontal Concatenation

25.10.1 Usage

This is a method for a class that is invoked to concatenate two or more variables of the same class type together. Besides being called when you invoke

```
c = horzcat(a,b,c)
```

when `a` is a class, it is also called for

```
c = [a,b,c]
```

when one of these variables is a class. The exact meaning of horizontal concatenation depends on the class you have designed.

25.11 LDIVIDE Overloaded Left Divide Operator

25.11.1 Usage

This is a method that is invoked when two variables are divided and is invoked when you call

```
c = ldivide(a,b)
```

or for

```
c = a .\ b
```

25.12 LE Overloaded Less-Than-Equals Comparison Operator

25.12.1 Usage

This is a method that is invoked to compare two variables using a less than or equals comparison operator, and is invoked when you call

```
c = le(a,b)
```

or for

```
c = a <= b
```

25.13 LT Overloaded Less Than Comparison Operator

25.13.1 Usage

This is a method that is invoked to compare two variables using a less than comparison operator, and is invoked when you call

```
c = lt(a,b)
```

or for

```
c = a < b
```

25.14 MINUS Overloaded Addition Operator

25.14.1 Usage

This is a method that is invoked when two variables are subtracted and is invoked when you call

```
c = minus(a,b)
```

or for

```
c = a - b
```

25.15 MLDIVIDE Overloaded Matrix Left Divide Operator

25.15.1 Usage

This is a method that is invoked when two variables are divided using the matrix (left) divide operator, and is invoked when you call

```
c = mldivide(a,b)
```

or for

```
c = a \ b
```

25.16 MPOWER Overloaded Matrix Power Operator

25.16.1 Usage

This is a method that is invoked when one variable is raised to another variable using the matrix power operator, and is invoked when you call

```
c = mpower(a,b)
```

or

```
c = a^b
```

25.17 MRDIVIDE Overloaded Matrix Right Divide Operator

25.17.1 Usage

This is a method that is invoked when two variables are divided using the matrix divide operator, and is invoked when you call

```
c = mrdivide(a,b)
```

or for

```
c = a / b
```

25.18 MTIMES Overloaded Matrix Multiplication Operator

25.18.1 Usage

This is a method that is invoked when two variables are multiplied using the matrix operator and is invoked when you call

```
c = mtimes(a,b)
```

or for

```
c = a * b
```

25.19 NE Overloaded Not-Equals Comparison Operator

25.19.1 Usage

This is a method that is invoked to combine two variables using a not-equals comparison operator, and is invoked when you call

```
c = ne(a,b)
```

or for

```
c = a != b
```

25.20 NOT Overloaded Logical Not Operator

25.20.1 Usage

This is a method that is invoked when a variable is logically inverted, and is invoked when you call

```
c = not(a)
```

or for

```
c = ~a
```

25.21 OR Overloaded Logical Or Operator

25.21.1 Usage

This is a method that is invoked to combine two variables using a logical or operator, and is invoked when you call

```
c = or(a,b)
```

or for

```
c = a | b
```

25.22 PLUS Overloaded Addition Operator

25.22.1 Usage

This is a method that is invoked when two variables are added and is invoked when you call

```
c = plus(a,b)
```

or for

```
c = a + b
```

25.23 POWER Overloaded Power Operator

25.23.1 Usage

This is a method that is invoked when one variable is raised to another variable using the dot-power operator, and is invoked when you call

```
c = power(a,b)
```

or

```
c = a.^b
```

25.24 RDIVIDE Overloaded Right Divide Operator

25.24.1 Usage

This is a method that is invoked when two variables are divided and is invoked when you call

```
c = rdivide(a,b)
```

or for

```
c = a ./ b
```

25.25 SUBSASGN Overloaded Class Assignment

25.25.1 Usage

This method is called for expressions of the form

```
a(b) = c, a{b} = c, a.b = c
```

and overloading the `subsasgn` method can allow you to define the meaning of these expressions for objects of class `a`. These expressions are mapped to a call of the form

```
a = subsasgn(a,s,b)
```

where `s` is a structure array with two fields. The first field is

- `type` is a string containing either `'()'` or `'{}'` or `'.'` depending on the form of the call.
- `subs` is a cell array or string containing the the subscript information.

When multiple indexing experssions are combined together such as `a(5).foo{:} = b`, the `s` array contains the following entries

```
s(1).type = '()'  s(1).subs = {5}
s(2).type = '.'   s(2).subs = 'foo'
s(3).type = '{}'  s(3).subs = ':'
```

25.26 SUBSINDEX Overloaded Class Indexing

25.26.1 Usage

This method is called for classes in the expressions of the form

```
c = subsindex(a)
```

where `a` is an object, and `c` is an index vector. It is also called for

```
c = b(a)
```

in which case `subsindex(a)` must return a vector containing integers between `0` and `N-1` where `N` is the number of elements in the vector `b`.

25.27 SUBSREF Overloaded Class Indexing

25.27.1 Usage

This method is called for expressions of the form

```
c = a(b), c = a{b}, c = a.b
```

and overloading the `subsref` method allows you to define the meaning of these expressions for objects of class `a`. These expressions are mapped to a call of the form

```
b = subsref(a,s)
```

where `s` is a structure array with two fields. The first field is

- `type` is a string containing either `'()'` or `'{}'` or `'.'` depending on the form of the call.
- `subs` is a cell array or string containing the the subscript information.

When multiple indexing experssions are combined together such as `b = a(5).foo{:}`, the `s` array contains the following entries

```
s(1).type = '()'  s(1).subs = {5}
s(2).type = '.'   s(2).subs = 'foo'
s(3).type = '{}'  s(3).subs = ':'
```

25.28 TIMES Overloaded Multiplication Operator

25.28.1 Usage

This is a method that is invoked when two variables are multiplied and is invoked when you call

```
c = times(a,b)
```

or for

```
c = a .* b
```

25.29 TRANSPOSE Overloaded Transpose Operator

25.29.1 Usage

This is a method that is invoked when a variable has the transpose operator method applied, and is invoked when you call

```
c = transpose(a)
```

or

```
/  c = a.'
```

25.30 UMINUS Overloaded Unary Minus Operator

25.30.1 Usage

This is a method that is invoked when a variable is negated, and is invoked when you call

```
c = uminus(a)
```

or for

```
c = -a
```

25.31 UPLUS Overloaded Unary Plus Operator

25.31.1 Usage

This is a method that is invoked when a variable is preceeded by a "+", and is invoked when you call

```
c = uplus(a)
```

or for

```
c = +a
```

25.32 VERTCAT Overloaded Vertical Concatenation

25.32.1 Usage

This is a method for a class that is invoked to concatenate two or more variables of the same class type together. Besides being called when you invoke

```
c = vertcat(a,b,c)
```

when `a` is a class, it is also called for

```
c = [a;b;c]
```

when one of the variables is a class. The exact meaning of vertical concatenation depends on the class you have designed.

Chapter 26

Bitwise Operations

26.1 BITAND Bitwise Boolean And Operation

26.1.1 Usage

Performs a bitwise binary and operation on the two arguments and returns the result. The syntax for its use is

```
y = bitand(a,b)
```

where `a` and `b` are multi-dimensional unsigned integer arrays. The and operation is performed using 32 bit unsigned intermediates. Note that if a or b is a scalar, then each element of the other array is and'ed with that scalar. Otherwise the two arrays must match in size.

26.1.2 Example

```
--> bitand(uint16([1,16,255]),uint16([3,17,128]))

ans =
   1  16 128

--> bitand(uint16([1,16,255]),uint16(3))

ans =
 1 0 3
```

26.2 BITCMP Bitwise Boolean Complement Operation

26.2.1 Usage

Usage

Performs a bitwise binary complement operation on the argument and returns the result. The syntax for its use is

```
y = bitcmp(a)
```

where a is an unsigned integer arrays. This version of the command uses as many bits as required by the type of a. For example, if a is an uint8 type, then the complement is formed using 8 bits. The second form of bitcmp allows you to specify the number of bits to use,

```
y = bitcmp(a,n)
```

in which case the complement is taken with respect to n bits, where n must be less than the length of the integer type.

26.2.2 Example

```
--> bitcmp(uint16(2^14-2))

ans =
 49153

--> bitcmp(uint16(2^14-2),14)

ans =
 1
```

26.3 BITOR Bitwise Boolean Or Operation

26.3.1 Usage

Performs a bitwise binary or operation on the two arguments and returns the result. The syntax for its use is

```
y = bitor(a,b)
```

where `a` and `b` are multi-dimensional unsigned integer arrays. The and operation is performed using 32 bit unsigned intermediates. Note that if a or b is a scalar, then each element of the other array is or'ed with that scalar. Otherwise the two arrays must match in size.

26.3.2 Example

```
--> bitand(uint16([1,16,255]),uint16([3,17,128]))

ans =
   1  16 128

--> bitand(uint16([1,16,255]),uint16(3))

ans =
 1 0 3
```

26.4 BITXOR Bitwise Boolean Exclusive-Or (XOR) Operation

26.4.1 Usage

Performs a bitwise binary xor operation on the two arguments and returns the result. The syntax for its use is

```
y = bitxor(a,b)
```

where `a` and `b` are multi-dimensional unsigned integer arrays. The and operation is performed using 32 bit unsigned intermediates. Note that if a or b is a scalar, then each element of the other array is xor'ed with that scalar. Otherwise the two arrays must match in size.

26.4.2 Example

```
--> bitand(uint16([1,16,255]),uint16([3,17,128]))

ans =
   1  16 128
```

```
--> bitand(uint16([1,16,255]),uint16(3))

ans =
 1 0 3
```

Chapter 27

FreeMat Threads

27.1 THREADCALL Call Function In A Thread

27.1.1 Usage

The `threadcall` function is a convenience function for executing a function call in a thread. The syntax for its use is

```
[val1,...,valn] = threadcall(threadid,timeout,funcname,arg1,arg2,...)
```

where `threadid` is the ID of the thread (as returned by the `threadnew` function), `funcname` is the name of the function to call, and `argi` are the arguments to the function, and `timeout` is the amount of time (in milliseconds) that the function is allowed to take.

27.1.2 Example

Here is an example of executing a simple function in a different thread.

```
--> id = threadnew

id =
 3

--> d = threadcall(id,1000,'cos',1.02343)

d =
    0.5204

--> threadfree(id)
```

27.2 THREADFREE Free thread resources

27.2.1 Usage

The `threadfree` is a function to free the resources claimed by a thread that has finished. The syntax for its use is

```
threadfree(handle)
```

where `handle` is the handle returned by the call to `threadnew`. The `threadfree` function requires that the thread be completed. Otherwise it will wait for the thread to complete, potentially for an arbitrarily long period of time. To fix this, you can either call `threadfree` only on threads that are known to have completed, or you can call it using the syntax

```
threadfree(handle,timeout)
```

where `timeout` is a time to wait in milliseconds. If the thread fails to complete before the timeout expires, an error occurs.

27.3 THREADID Get Current Thread Handle

27.3.1 Usage

The `threadid` function in FreeMat tells you which thread is executing the context you are in. Normally, this is thread 1, the main thread. However, if you start a new thread using `threadnew`, you will be operating in a new thread, and functions that call `threadid` from the new thread will return their handles.

27.3.2 Example

From the main thread, we have

```
--> threadid

ans =
 2
```

But from a launched auxilliary thread, we have

```
--> t_id = threadnew

t_id =
 3

--> id = threadcall(t_id,1000,'threadid')

id =
 3

--> threadfree(t_id);
```

27.4 THREADKILL Halt execution of a thread

27.4.1 Usage

The `threadkill` function stops (or attempts to stop) execution of the given thread. It works only for functions defined in M-files (i.e., not for built in or imported functions), and it works by setting a flag that causes the thread to stop execution at the next available statement. The syntax for this function is

```
threadkill(handle)
```

where `handle` is the value returned by a `threadnew` call. Note that the `threadkill` function returns immediately. It is still your responsibility to call `threadfree` to free the thread you have halted.

You cannot kill the main thread (thread id `1`).

27.4.2 Example

Here is an example of stopping a runaway thread using `threadkill`. Note that the thread function in this case is an M-file function. We start by setting up a free running counter, where we can access the counter from the global variables.

```
    freecount.m
function freecount
  global count
  if (~exist('count')) count = 0; end  % Initialize the counter
  while (1)
    count = count + 1;                 % Update the counter
  end
```

We now launch this function in a thread, and use `threadkill` to stop it:

```
--> a = threadnew;
--> global count                    % register the global variable count
--> count = 0;
--> threadstart(a,'freecount',0)    % start the thread
--> count                           % it is counting

ans =
 70

--> sleep(1)                        % Wait a bit
--> count                           % it is still counting

ans =
 545650

--> threadkill(a)                   % kill the counter
--> threadwait(a,1000)              % wait for it to finish

ans =
 1

--> count                           % The count will no longer increase

ans =
 545729

--> sleep(1)
--> count

ans =
 545729

--> threadfree(a)
```

27.5 THREADNEW Create a New Thread

27.5.1 Usage

The `threadnew` function creates a new FreeMat thread, and returns a handle to the resulting thread. The `threadnew` function takes no arguments. They general syntax for the `threadnew` function is

```
handle = threadnew
```

Once you have a handle to a thread, you can start the thread on a computation using the `threadstart` function. The threads returned by `threadnew` are in a dormant state (i.e., not running). Once you are finished with the thread you must call `threadfree` to free the resources associated with that thread.

Some additional important information. Thread functions operate in their own context or workspace, which means that data cannot be shared between threads. The exception is `global` variables, which provide a thread-safe way for multiple threads to share data. Accesses to global variables are serialized so that they can be used to share data. Threads and FreeMat are a new feature, so there is room for improvement in the API and behavior. The best way to improve threads is to experiment with them, and send feedback.

27.6 THREADSTART Start a New Thread Computation

27.6.1 Usage

The `threadstart` function starts a new computation on a FreeMat thread, and you must provide a function (no scripts are allowed) to run inside the thread, pass any parameters that the thread function requires, as well as the number of output arguments expected. The general syntax for the `threadstart` function is

```
threadstart(threadid,function,nargout,arg1,arg2,...)
```

where `threadid` is a thread handle (returned by `threadnew`), where `function` is a valid function name (it can be a built-in imported or M-function), `nargout` is the number of output arguments expected from the function, and `arg1` is the first argument that is passed to the function. Because the function runs in its own thread, the return values of the function are not available imediately. Instead, execution of that function will continue in parallel with the current thread. To retrieve the output of the thread function, you must wait for the thread to complete using the `threadwait` function, and then call `threadvalue` to retrieve the result. You can also stop the running thread prematurely by using the `threadkill` function. It is important to call `threadfree` on the handle you get from `threadnew` when you are finished with the thread to ensure that the resoures are properly freed.

It is also perfectly reasonable to use a single thread multiple times, calling `threadstart` and `threadreturn` multiple times on a single thread. The context is preserved between threads. When calling `threadstart` on a pre-existing thread, FreeMat will attempt to wait on the thread. If the wait fails, then an error will occur.

Some additional important information. Thread functions operate in their own context or workspace, which means that data cannot be shared between threads. The exception is `global` variables, which provide a thread-safe way for multiple threads to share data. Accesses to global variables are serialized so that they can be used to share data. Threads and FreeMat are a new feature, so there is room for improvement in the API and behavior. The best way to improve threads is to experiment with them, and send feedback.

27.6.2 Example

Here we do something very simple. We want to obtain a listing of all files on the system, but do not want the results to stop our computation. So we run the `system` call in a thread.

```
--> a = threadnew;                          % Create the thread
--> threadstart(a,'system',1,'ls -lrt /'); % Start the thread
--> b = rand(100)\rand(100,1);              % Solve some equations simultaneously
--> c = threadvalue(a);                     % Retrieve the file list
--> size(c)                                 % It is large!

ans =
  1 25

--> threadfree(a);
```

The possibilities for threads are significant. For example, we can solve equations in parallel, or take Fast Fourier Transforms on multiple threads. On multi-processor machines or multicore CPUs, these threaded calculations will execute in parallel. Neat.

The reason for the `nargout` argument is best illustrated with an example. Suppose we want to compute the Singular Value Decomposition `svd` of a matrix `A` in a thread. The documentation for the `svd` function

tells us that the behavior depends on the number of output arguments we request. For example, if we want a full decomposition, including the left and right singular vectors, and a diagonal singular matrix, we need to use the three-output syntax, instead of the single output syntax (which returns only the singular values in a column vector):

```
--> A = float(rand(4))

A =
    0.4011    0.4747    0.9193    0.8655
    0.8633    0.0123    0.0599    0.5917
    0.4939    0.5458    0.9481    0.4566
    0.9335    0.8614    0.7993    0.6394

--> [u,s,v] = svd(A)    % Compute the full decomposition
u =
   -0.5290    0.2711    0.7178    0.3626
   -0.3004   -0.8911    0.2379   -0.2431
   -0.4868    0.3556   -0.0927   -0.7925
   -0.6269   -0.0778   -0.6478    0.4259

s =
    2.5579         0         0         0
         0    0.7905         0         0
         0         0    0.4392         0
         0         0         0    0.1705

v =
   -0.5071   -0.7054   -0.3579   -0.3422
   -0.4146    0.3096   -0.6032    0.6070
   -0.5735    0.5955    0.1558   -0.5406
   -0.4921   -0.2279    0.6955    0.4713

--> sigmas = svd(A)     % Only want the singular values

sigmas =
    2.5579
    0.7905
    0.4392
    0.1705
```

Normally, FreeMat uses the left hand side of an assignment to calculate the number of outputs for the function. When running a function in a thread, we separate the assignment of the output from the invokation of the function. Hence, we have to provide the number of arguments at the time we invoke the function. For example, to compute a full decomposition in a thread, we specify that we want 3 output arguments:

```
--> a = threadnew;               % Create the thread
--> threadstart(a,'svd',3,A);    % Start a full decomposition
--> [u1,s1,v1] = threadvalue(a); % Retrieve the function values
--> threadfree(a);
```

If we want to compute just the singular values, we start the thread function with only one output argument:

```
--> a = threadnew;
--> threadstart(a,'svd',1,A);
--> sigmas = threadvalue(a);
--> threadfree(a)
```

27.7 THREADVALUE Retrieve the return values from a thread

27.7.1 Usage

The `threadvalue` function retrieves the values returned by the function specified in the `threadnew` call. The syntax for its use is

```
[arg1,arg2,...,argN] = threadvalue(handle)
```

where `handle` is the value returned by a `threadnew` call. Note that there are issues with `nargout`. See the examples section of `threadnew` for details on how to work around this limitation. Because the function you have spawned with `threadnew` may still be executing, `threadvalue` must first `threadwait` for the function to complete before retrieving the output values. This wait may take an arbitrarily long time if the thread function is caught in an infinite loop. Hence, you can also specify a timeout parameter to `threadvalue` as

```
[arg1,arg2,...,argN] = threadvalue(handle,timeout)
```

where the `timeout` is specified in milliseconds. If the wait times out, an error is raised (that can be caught with a `try` and `catch` block.

In either case, if the thread function itself caused an error and ceased execution abruptly, then calling `threadvalue` will cause that function to raise an error, allowing you to retrieve the error that was caused and correct it. See the examples section for more information.

27.7.2 Example

Here we do something very simple. We want to obtain a listing of all files on the system, but do not want the results to stop our computation. So we run the `system` call in a thread.

```
--> a = threadnew;                          % Create the thread
--> threadstart(a,'system',1,'ls -lrt /'); % Start the thread
--> b = rand(100)\rand(100,1);              % Solve some equations simultaneously
--> c = threadvalue(a);                     % Retrieve the file list
--> size(c)                                 % It is large!

ans =
  1 25

--> threadfree(a);
```

In this example, we force the threaded function to cause an exception (by calling the `error` function as the thread function). When we call `threadvalue`, we get an error, instead of the return value of the function

```
--> a = threadnew

a =
 3

--> threadstart(a,'error',0,'Hello world!'); % Will immediately stop due to error
--> c = threadvalue(a)                      % The error comes to us
Error: Thread: Hello world!
--> threadfree(a)
```

Note that the error has the text `Thread:` prepended to the message to help you identify that this was an error in a different thread.

27.8 THREADWAIT Wait on a thread to complete execution

27.8.1 Usage

The `threadwait` function waits for the given thread to complete execution, and stops execution of the current thread (the one calling `threadwait`) until the given thread completes. The syntax for its use is

```
success = threadwait(handle)
```

where `handle` is the value returned by `threadnew` and `success` is a `logical` vaariable that will be `1` if the wait was successful or `0` if the wait times out. By default, the wait is indefinite. It is better to use the following form of the function

```
success = threadwait(handle,timeout)
```

where `timeout` is the amount of time (in milliseconds) for the `threadwait` function to wait before a timeout occurs. If the `threadwait` function succeeds, then the return value is a logical `1`, and if it fails, the return value is a logical `0`. Note that you can call `threadwait` multiple times on a thread, and if the thread is completed, each one will succeed.

27.8.2 Example

Here we lauch the `sleep` function in a thread with a time delay of 10 seconds. This means that the thread function will not complete until 10 seconds have elapsed. When we call `threadwait` on this thread with a short timeout, it fails, but not when the timeout is long enough to capture the end of the function call.

```
--> a = threadnew;
--> threadstart(a,'sleep',0,10);  % start a thread that will sleep for 10
--> threadwait(a,2000)            % 2 second wait is not long enough

ans =
 0

--> threadwait(a,10000)           % 10 second wait is long enough

ans =
 1

--> threadfree(a)
```

Chapter 28

Function Related Functions

28.1 INLINE Construct Inline Function

28.1.1 Usage

Constructs an inline function object. The syntax for its use is either

```
y = inline(expr)
```

which uses the `symvar` function to identify the variables in the expression, or the explicit form

```
y = inline(expr,var1,var2,...,varn)
```

where the variables are explicitly given. Note that inline functions are only partially supported in FreeMat. If you need features of the inline function that are not currently implemented, please file a feature request at the FreeMat website.

28.1.2 Example

Here we construct an inline expression using the autodetection of `symvar`

```
--> a = inline('x^2')

a =
  inline function object
  f(x) = x^2
--> a(3)

ans =
 9

--> a(i)

ans =
  -1.0000 +  0.0000i
```

In this case, we have multiple arguments (again, autodetected)

```
--> a = inline('x+y-cos(x+y)')

a =
  inline function object
  f(x,y) = x+y-cos(x+y)
```

```
--> a(pi,-pi)

ans =
 -1
```

In this form, we specify which arguments we want to use (thereby also specifying the order of the arguments

```
--> a = inline('x+t-sin(x)','x','t')

a =
  inline function object
  f(x,t) = x+t-sin(x)
--> a(0.5,1)

ans =
    1.0206
```

Inline objects can also be used with `feval`

```
--> a = inline('cos(t)')

a =
  inline function object
  f(t) = cos(t)
--> feval(a,pi/2)

ans =
 6.1232e-17
```

28.2 SYMVAR Find Symbolic Variables in an Expression

28.2.1 Usage

Finds the symbolic variables in an expression. The syntax for its use is

```
  syms = symvar(expr)
```

where `expr` is a string containing an expression, such as `'x\^2 + cos(t+alpha)'`. The result is a cell array of strings containing the non-function identifiers in the expression. Because they are usually not used as identifiers in expressions, the strings `'pi','inf','nan','eps','i','j'` are ignored.

28.2.2 Example

Here are some simple examples:

```
--> symvar('x^2+sqrt(x)')  % sqrt is eliminated as a function

ans =
 [x]

--> symvar('pi+3')         % No identifiers here

ans =
  Empty array 0x1
--> symvar('x + t*alpha')  % x, t and alpha
```

```
ans =
 [alpha]
 [t]
 [x]
```

Chapter 29

FreeMat External Interface

29.1 CENUM Lookup Enumerated C Type

29.1.1 Usage

The `cenum` function allows you to use the textual strings of C enumerated types (that have been defined using `ctypedefine`) in your FreeMat scripts isntead of the hardcoded numerical values. The general syntax for its use is

```
enum_int = cenum(enum_type,enum_string)
```

which looks up the integer value of the enumerated type based on the string. You can also supply an integer argument, in which case `cenum` will find the matching string

```
enum_string = cenum(enum_type,enum_int)
```

29.2 CTYPECAST Cast FreeMat Structure to C Structure

29.2.1 Usage

The `ctypecast` function is a convenience function for ensuring that a FreeMat structure fits the definition of a C struct (as defined via `ctypedefine`. It does so by encoding the structure to a byte array using `ctypefreeze` and then recovering it using the `ctypethaw` function. The usage is simply

```
s = ctypecast(s,typename)
```

where `s` is the structure and `typename` is the name of the C structure that describes the desired layout and types for elements of `s`. This function is equivalent to calling `ctypefreeze` and `ctypethaw` in succession on a FreeMat structure.

29.3 CTYPEDEFINE Define C Type

29.3.1 Usage

The `ctypedefine` function allows you to define C types for use with FreeMat. Three variants of C types can be used. You can use structures, enumerations, and aliases (typedefs). All three are defined through a single function `ctypedefine`. The general syntax for its use is

```
ctypedefine(typeclass,typename,...)
```

where `typeclass` is the variant of the type (legal values are `'struct'`, `'alias'`, `'enum'`). The second argument is the name of the C type. The remaining arguments depend on what the class of the typedef is.

To define a C structure, use the `'struct'` type class. The usage in this case is:

```
ctypedefine('struct',typename,field1,type1,field2,type2,...)
```

The argument `typename` must be a valid identifier string. Each of of the `field` arguments is also a valid identifier string that describe in order, the elements of the C structure. The `type` arguments are `typespecs`. They can be of three types:

- Built in types, e.g. `'uint8'` or `'double'` to name a couple of examples.
- C types that have previously been defined with a call to `ctypedefine`, e.g. `'mytype'` where `'mytype'` has already been defined through a call to `ctypedefine`.
- Arrays of either built in types or previously defined C types with the length of the array coded as an integer in square brackets, for example: `'uint8[10]'` or `'double[1000]'`.

To define a C enumeration, use the `'enum'` type class. The usage in this case is: ctypedefine('enum',typename,name1,value1 @] The argument `typename` must be a valid identifier string. Each of the `name` arguments must also be valid identifier strings that describe the possible values that the enumeration can take an, and their corresponding integer values. Note that the names should be unique. The behavior of the various `cenum` functions is undefined if the names are not unique.

To define a C alias (or typedef), use the following form of `ctypedefine`:

```
ctypedefine('alias',typename,aliased_typename)
```

where `aliased\_typename` is the type that is being aliased to.

29.4 CTYPEFREEZE Convert FreeMat Structure to C Type

29.4.1 Usage

The `ctypefreeze` function is used to convert a FreeMat structure into a C struct as defined by a C structure typedef. To use the `cstructfreeze` function, you must first define the type of the C structure using the `ctypedefine` function. The `ctypefreeze` function then serializes a FreeMat structure to a set of bytes, and returns it as an array. The usage for `ctypefreeze` is

```
byte_array = ctypefreeze(mystruct, 'typename')
```

where `mystruct` is the array we want to 'freeze' to a memory array, and `typename` is the name of the C type that we want the resulting byte array to conform to.

29.5 CTYPENEW Create New Instance of C Structure

29.5.1 Usage

The `ctypenew` function is a convenience function for creating a FreeMat structure that corresponds to a C structure. The entire structure is initialized with zeros. This has some negative implications, because if the structure definition uses `cenums`, they may come out as `'unknown'` values if there are no enumerations corresponding to zero. The use of the function is

```
a = ctypenew('typename')
```

which creates a single structure of C structure type `'typename'`. To create an array of structures, we can provide a second argument

```
a = ctypenew('typename',count)
```

where `count` is the number of elements in the structure array.

29.6 CTYPEPRINT Print C Type

29.6.1 Usage

The `ctypeprint` function prints a C type on the console. The usage is

```
ctypeprint(typename)
```

where `typename` is a string containing the name of the C type to print. Depending on the class of the C type (e.g., structure, alias or enumeration) the `ctypeprint` function will dump information about the type definition.

29.7 CTYPEREAD Read a C Structure From File

29.7.1 Usage

The `ctyperead` function is a convenience function for reading a C structure from a file. This is generally a very bad idea, as direct writing of C structures to files is notoriously unportable. Consider yourself warned. The syntax for this function is

```
a = ctyperead(fid,'typename')
```

where `'typename'` is a string containing the name of the C structure as defined using `ctypedefine`, and `fid` is the file handle returned by the `fopen` command. Note that this form will read a single structure from the file. If you want to read multiple structures into an array, use the following form

```
a = ctyperead(fid,'typename',count)
```

Note that the way this function works is by using `ctypesize` to compute the size of the structure, reading that many bytes from the file, and then calling `ctypethaw` on the resulting buffer. A consequence of this behavior is that the byte-endian corrective behavior of FreeMat does not work.

29.8 CTYPESIZE Compute Size of C Struct

29.8.1 Usage

The `ctypesize` function is used to compute the size of a C structure that is defined using the `ctypedefine` function. The usage of `ctypesize` is

```
size = ctypesize('typename')
```

where `typename` is the name of the C structure you want to compute the size of. The returned count is measured in bytes. Note that as indicated in the help for `ctypedefine` that FreeMat does not automatically pad the entries of the structure to match the particulars of your C compiler. Instead, the assumption is that you have adequate padding entries in your structure to align the FreeMat members with the C ones. See `ctypedefine` for more details. You can also specify an optional count parameter if you want to determine how large multiple structures are

```
size = ctypesize('typename',count)
```

29.9 CTYPETHAW Convert C Struct to FreeMat Structure

29.9.1 Usage

The `ctypethaw` function is used to convert a C structure that is encoded in a byte array into a FreeMat structure using a C structure typedef. To use the `ctypethaw` function, you must first define the type of the C structure using the `ctypedefine` function. The usage of `ctypethaw` is

```
mystruct = ctypethaw(byte_array, 'typename')
```

where `byte\_array` is a `uint8` array containing the bytes that encode the C structure, and `typename` is a string that contains the type description as registered with `ctypedefine`. If you want to retrieve multiple structures from a single byte array, you can specify a count as

```
mystruct = ctypethaw(byte_array, 'typename', count)
```

where `count` is an integer containing the number of structures to retrieve. Sometimes it is also useful to retrieve only part of the structure from a byte array, and then (based on the contents of the structure) retrieve more data. In this case, you can retrieve the residual byte array using the optional second output argument of `ctypethaw`:

```
[mystruct,byte_array_remaining] = ctypethaw(byte_array, 'typename',...)
```

29.10 CTYPEWRITE Write a C Typedef To File

29.10.1 Usage

The `ctypewrite` function is a convenience function for writing a C typedef to a file. This is generally a very bad idea, as writing of C typedefs to files is notoriously unportable. Consider yourself warned. The syntax for this function is

```
ctypewrite(fid,a,'typename')
```

where `a` is the FreeMat typedef to write, `'typename'` is a string containing the name of the C typedef to use when writing the typedef to the file (previously defined using `ctypedefine`), and `fid` is the file handle returned by `fopen`.

29.11 IMPORT Foreign Function Import

29.11.1 Usage

The import function allows you to call functions that are compiled into shared libraries, as if they were FreeMat functions. The usage is

```
import(libraryname,symbol,function,return,arguments)
```

The argument `libraryname` is the name of the library (as a string) to import the function from. The second argument `symbol` (also a string), is the name of the symbol to import from the library. The third argument `function` is the the name of the function after its been imported into Freemat. The fourth argument is a string that specifies the return type of the function. It can take on one of the following types:

- 'uint8' for an unsigned, 8-bit integer.
- 'int8' for a signed, 8-bit integer.
- 'uint16' an unsigned, 16-bit integer.
- 'int16' a signed, 16-bit integer.
- 'uint32' for an unsigned, 32-bit integer.
- 'int32' for a signed, 32-bit integer.
- 'single' for a 32-bit floating point.
- 'double' for a 64-bit floating point.
- 'void' for no return type.

The fourth argument is more complicated. It encodes the arguments of the imported function using a special syntax. In general, the argument list is a string consisting of entries of the form:

```
type[optional bounds check] {optional &}name
```

Here is a list of various scenarios (expressed in 'C'), and the corresponding entries, along with snippets of code.

Scalar variable passed by value: Suppose a function is defined in the library as

```
int fooFunction(float t),
```

i.e., it takes a scalar value (or a string) that is passed by value. Then the corresponding argument string would be

```
'float t'
```

For a C-string, which corresponds to a function prototype of

```
int fooFunction(const char *t),
```

the corresponding argument string would be

```
'string t'
```

Other types are as listed above. Note that FreeMat will automatically promote the type of scalar variables to the type expected by the `C` function. For example, if we call a function expecting a `float` with a `double` or `int16` argument, then FreeMat will automatically apply type promotion rules prior to calling the function.

Scalar variable passed by reference: Suppose a function is defined in the library as

```
int fooFunction(float *t),
```

i.e., it takes a scalar value (or a string) that is passed as a pointer. Then the corresponding argument string would be

```
'float &t'
```

If the function `fooFunction` modifies `t`, then the argument passed in FreeMat will also be modified.

Array variable passed by value: In `C`, it is impossible to distinguish an array being passed from a simple pointer being passed. More often than not, another argument indicates the length of the array. FreeMat has the ability to perform bounds-checking on array values. For example, suppose we have a function of the form

```
int sum_onehundred_ints(int *t),
```

where `sum\_onehundred\_ints` assumes that `t` is a length `100` vector. Then the corresponding FreeMat argument is

```
'float32[100] t'.
```

Note that because the argument is marked as not being passed by reference, that if `sub\_onehundred\_ints` modifies the array `t`, this will not affect the FreeMat argument. Note that the bounds-check expression can be any legal scalar expression that evaluates to an integer, and can be a function of the arguments. For example to pass a square $N \times N$ matrix to the following function:

```
float determinantmatrix(int N, float *A),
```

we can use the following argument to `import`:

```
'int32 N, float[N*N] t'.
```

Array variable passed by reference: If the function in `C` modifies an array, and we wish this to be reflected in the FreeMat side, we must pass that argument by reference. Hence, consider the following hypothetical function that squares the elements of an array (functionally equivalent to $x.^2$):

```
void squarearray(int N, float *A)
```

we can use the following argument to `import`:

```
'int32 N, float[N] &A'.
```

Note that to avoid problems with memory allocation, external functions are not allowed to return pointers. As a result, as a general operating mechanism, the FreeMat code must allocate the proper arrays, and then pass them by reference to the external function.

Sending text to the FreeMat console: Starting with FreeMat 4.0, it is possible for external code that is called using the `import` statement to send text to the FreeMat console. To do so, you must define in each library that wants to send text a function with the name `freemat\_io\_handler` that captures its argument (a function pointer), and stores it for use by functions in the library. That function pointer takes a standard C string argument. Here is a snippet of code to demonstrate how this works:

```
/* just to make it readable */
typedef void (*strfunc)(const char*);

/* The name we want to use for the function */
strfunc FreeMatText;

/* this name is case sensitive and must not be mangled (i.e., use extern "C") */
void freemat_io_handler(strfunc printFunc) {
   FreeMatText = printFunc;
}

double SomeImportedFunction(double t) {
   FreeMatText("I am going to double that argument!\n");
   return (t*2);
}
```

In this case, once `SomeImportedFunction` is called from within FreeMat, the text `''I am going to double that argument'` will appear in the FreeMat console.

Your `freemat\_io\_handler` function is automatically called when your library is loaded by FreeMat, which happens with the first `import` statement that references it.

Repeating `import` calls to import the same function name will be ignored, except the first call. In order to refresh the function without restarting FreeMat, you have to first clear all imported libraries via:

```
clear 'libs'
```

29.11.2 Example

Here is a complete example. We have a `C` function that adds two float vectors of the same length, and stores the result in a third array that is modified by the function. First, the `C` code:

```
    addArrays.c
void addArrays(int N, float *a, float *b, float *c) {
  int i;

  for (i=0;i<N;i++)
   c[i] = a[i] + b[i];
}
```

We then compile this into a dynamic library, say, `add.so`. The import command would then be:

```
import('add.so','addArrays','addArrays','void', ...
       'int32 N, float[N] a, float[N] b, float[N] &c');
```

We could then exercise the function exactly as if it had been written in FreeMat. The following only works on systems using the GNU C Compiler:

```
--> if (strcmp(computer,'MAC')) system('gcc -bundle -flat_namespace -undefined suppress -o add.so addAr
--> if (~strcmp(computer,'MAC')) system('gcc -shared -fPIC -o add.so addArrays.c'); end;
--> import('add.so','addArrays','addArrays','void','int32 N, float[N] a, float[N] b, float[N] &c');
--> a = [3,2,3,1];
--> b = [5,6,0,2];
--> c = [0,0,0,0];
--> addArrays(length(a),a,b,c)

ans =
  []
--> c

ans =
 8 8 3 3
```

29.12 LOADLIB Load Library Function

29.12.1 Usage

The `loadlib` function allows a function in an external library to be added to FreeMat dynamically. This interface is generally to be used as last resort, as the form of the function being called is assumed to match the internal implementation. In short, this is not the interface mechanism of choice. For all but very complicated functions, the `import` function is the preferred approach. Thus, only a very brief summary of it is presented here. The syntax for `loadlib` is

```
loadlib(libfile, symbolname, functionname, nargin, nargout)
```

where `libfile` is the complete path to the library to use, `symbolname` is the name of the symbol in the library, `functionname` is the name of the function after it is imported into FreeMat (this is optional, it defaults to the `symbolname`), `nargin` is the number of input arguments (defaults to 0), and `nargout` is the number of output arguments (defaults to 0). If the number of (input or output) arguments is variable then set the corresponding argument to `-1`.

Chapter 30

Visualization Toolkit Common Classes

30.1 vtkAbstractArray

30.1.1 Usage

vtkAbstractArray is an abstract superclass for data array objects. This class defines an API that all subclasses must support. The data type must be assignable and copy-constructible, but no other assumptions about its type are made. Most of the subclasses of this array deal with numeric data either as scalars or tuples of scalars. A program can use the IsNumeric() method to check whether an instance of vtkAbstractArray contains numbers. It is also possible to test for this by attempting to SafeDownCast an array to an instance of vtkDataArray, although this assumes that all numeric arrays will always be descended from vtkDataArray.

¡p¿

Every array has a character-string name. The naming of the array occurs automatically when it is instantiated, but you are free to change this name using the SetName() method. (The array name is used for data manipulation.)

To create an instance of class vtkAbstractArray, simply invoke its constructor as follows

```
obj = vtkAbstractArray
```

30.1.2 Methods

The class vtkAbstractArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractArray = obj.NewInstance ()`
- `vtkAbstractArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate memory for this array. Delete old storage only if necessary. Note that ext is no longer used.
- `obj.Initialize ()` - Release storage and reset array to initial state.
- `int = obj.GetDataType ()` - Return the underlying data type. An integer indicating data type is returned as specified in vtkSetGet.h.

- `int = obj.GetDataTypeSize ()` - Return the size of the underlying data type. For a bit, 0 is returned. For string 0 is returned. Arrays with variable length components return 0.

- `int = obj.GetElementComponentSize ()` - Return the size, in bytes, of the lowest-level element of an array. For vtkDataArray and subclasses this is the size of the data type. For vtkStringArray, this is sizeof(vtkStdString::value_type), which winds up being sizeof(char).

- `obj.SetNumberOfComponents (int )` - Set/Get the dimention (n) of the components. Must be ¿= 1. Make sure that this is set before allocation.

- `int = obj.GetNumberOfComponentsMinValue ()` - Set/Get the dimention (n) of the components. Must be ¿= 1. Make sure that this is set before allocation.

- `int = obj.GetNumberOfComponentsMaxValue ()` - Set/Get the dimention (n) of the components. Must be ¿= 1. Make sure that this is set before allocation.

- `int = obj.GetNumberOfComponents ()` - Set the number of tuples (a component group) in the array. Note that this may allocate space depending on the number of components. Also note that if allocation is performed no copy is performed so existing data will be lost (if data conservation is sought, one may use the Resize method instead).

- `obj.SetNumberOfTuples (vtkIdType number)` - Set the number of tuples (a component group) in the array. Note that this may allocate space depending on the number of components. Also note that if allocation is performed no copy is performed so existing data will be lost (if data conservation is sought, one may use the Resize method instead).

- `vtkIdType = obj.GetNumberOfTuples ()` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.

- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.

- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at ith location in this array. Note that memory allocation is performed as necessary to hold the data.

- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at the end in this array. Note that memory allocation is performed as necessary to hold the data. Returns the location at which the data was inserted.

- `obj.GetTuples (vtkIdList ptIds, vtkAbstractArray output)` - Given a list of point ids, return an array of tuples. You must insure that the output array has been previously allocated with enough space to hold the data.

- `obj.GetTuples (vtkIdType p1, vtkIdType p2, vtkAbstractArray output)` - Get the tuples for the range of points ids specified (i.e., p1-¿p2 inclusive). You must insure that the output array has been previously allocated with enough space to hold the data.

- `obj.DeepCopy (vtkAbstractArray da)` - Deep copy of data. Implementation left to subclasses, which should support as many type conversions as possible given the data type.

  Subclasses should call vtkAbstractArray::DeepCopy() so that the information object (if one exists) is copied from da.

- `obj.InterpolateTuple (vtkIdType i, vtkIdList ptIndices, vtkAbstractArray source, double weights)` - Set the ith tuple in this array as the interpolated tuple value, given the ptIndices in the source array and associated interpolation weights. This method assumes that the two arrays are of the same type and strcuture.
- `obj.InterpolateTuple (vtkIdType i, vtkIdType id1, vtkAbstractArray source1, vtkIdType id2, vtkAbstr`
- `obj.Squeeze ()` - Resize object to just fit data requirement. Reclaims extra memory.
- `int = obj.Resize (vtkIdType numTuples)` - Resize the array while conserving the data. Returns 1 if resizing succeeded and 0 otherwise.
- `obj.Reset ()` - Return the size of the data.
- `vtkIdType = obj.GetSize ()` - What is the maximum id currently in the array.
- `vtkIdType = obj.GetMaxId ()` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the supplied array.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this data array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `obj.SetName (string )` - Set/get array's name
- `string = obj.GetName ()` - Set/get array's name
- `string = obj.GetDataTypeAsString (void )` - Creates an array for dataType where dataType is one of VTK_BIT, VTK_CHAR, VTK_UNSIGNED_CHAR, VTK_SHORT, VTK_UNSIGNED_SHORT, VTK_INT, VTK_UNSIGNED_INT, VTK_LONG, VTK_UNSIGNED_LONG, VTK_DOUBLE, VTK_DOUBLE, VTK_ID_TYPE, VTK_STRING. Note that the data array returned has be deleted by the user.
- `int = obj.IsNumeric ()` - This method is here to make backward compatibility easier. It must return true if and only if an array contains numeric data.
- `vtkArrayIterator = obj.NewIterator ()` - Subclasses must override this method and provide the right kind of templated vtkArrayIteratorTemplate.
- `vtkIdType = obj.GetDataSize ()` - Tell the array explicitly that the data has changed. This is only necessary to call when you modify the array contents without using the array's API (i.e. you retrieve a pointer to the data and modify the array contents). You need to call this so that the fast lookup will know to rebuild itself. Otherwise, the lookup functions will give incorrect results.
- `obj.DataChanged ()` - Tell the array explicitly that the data has changed. This is only necessary to call when you modify the array contents without using the array's API (i.e. you retrieve a pointer to the data and modify the array contents). You need to call this so that the fast lookup will know to rebuild itself. Otherwise, the lookup functions will give incorrect results.
- `obj.ClearLookup ()` - Delete the associated fast lookup data structure on this array, if it exists. The lookup will be rebuilt on the next call to a lookup function.
- `vtkInformation = obj.GetInformation ()` - Get an information object that can be used to annotate the array. This will always return an instance of vtkInformation, if one is not currently associated with the array it will be created.
- `bool = obj.HasInformation ()`

30.2 vtkAbstractTransform

30.2.1 Usage

vtkAbstractTransform is the superclass for all VTK geometric transformations. The VTK transform hierarchy is split into two major branches: warp transformations and homogeneous (including linear) transformations. The latter can be represented in terms of a 4x4 transformation matrix, the former cannot. ¡p¿Transformations can be pipelined through two mechanisms: ¡p¿1) GetInverse() returns the pipelined inverse of a transformation i.e. if you modify the original transform, any transform previously returned by the GetInverse() method will automatically update itself according to the change. ¡p¿2) You can do pipelined concatenation of transformations through the vtkGeneralTransform class, the vtkPerspectiveTransform class, or the vtkTransform class.

To create an instance of class vtkAbstractTransform, simply invoke its constructor as follows

```
obj = vtkAbstractTransform
```

30.2.2 Methods

The class vtkAbstractTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractTransform = obj.NewInstance ()`
- `vtkAbstractTransform = obj.SafeDownCast (vtkObject o)`
- `obj.TransformPoint (float in[3], float out[3])` - Apply the transformation to a coordinate. You can use the same array to store both the input and output point.
- `obj.TransformPoint (double in[3], double out[3])` - Apply the transformation to a double-precision coordinate. You can use the same array to store both the input and output point.
- `double = obj.TransformPoint (double x, double y, double z)` - Apply the transformation to a double-precision coordinate. Use this if you are programming in Python, tcl or Java.
- `double = obj.TransformPoint (double point[3])` - Apply the transformation to a double-precision coordinate. Use this if you are programming in Python, tcl or Java.
- `float = obj.TransformFloatPoint (float x, float y, float z)` - Apply the transformation to an (x,y,z) coordinate. Use this if you are programming in Python, tcl or Java.
- `float = obj.TransformFloatPoint (float point[3])` - Apply the transformation to an (x,y,z) coordinate. Use this if you are programming in Python, tcl or Java.
- `double = obj.TransformDoublePoint (double x, double y, double z)` - Apply the transformation to a double-precision (x,y,z) coordinate. Use this if you are programming in Python, tcl or Java.
- `double = obj.TransformDoublePoint (double point[3])` - Apply the transformation to a double-precision (x,y,z) coordinate. Use this if you are programming in Python, tcl or Java.
- `obj.TransformNormalAtPoint (float point[3], float in[3], float out[3])` - Apply the transformation to a normal at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformNormal() instead.

- `obj.TransformNormalAtPoint (double point[3], double in[3], double out[3])` - Apply the transformation to a normal at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformNormal() instead.
- `double = obj.TransformNormalAtPoint (double point[3], double normal[3])`
- `double = obj.TransformDoubleNormalAtPoint (double point[3], double normal[3])` - Apply the transformation to a double-precision normal at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformDoubleNormal() instead.
- `float = obj.TransformFloatNormalAtPoint (float point[3], float normal[3])` - Apply the transformation to a single-precision normal at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformFloatNormal() instead.
- `obj.TransformVectorAtPoint (float point[3], float in[3], float out[3])` - Apply the transformation to a vector at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformVector() instead.
- `obj.TransformVectorAtPoint (double point[3], double in[3], double out[3])` - Apply the transformation to a vector at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformVector() instead.
- `double = obj.TransformVectorAtPoint (double point[3], double vector[3])`
- `double = obj.TransformDoubleVectorAtPoint (double point[3], double vector[3])` - Apply the transformation to a double-precision vector at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformDoubleVector() instead.
- `float = obj.TransformFloatVectorAtPoint (float point[3], float vector[3])` - Apply the transformation to a single-precision vector at the specified vertex. If the transformation is a vtkLinearTransform, you can use TransformFloatVector() instead.
- `obj.TransformPoints (vtkPoints inPts, vtkPoints outPts)` - Apply the transformation to a series of points, and append the results to outPts.
- `obj.TransformPointsNormalsVectors (vtkPoints inPts, vtkPoints outPts, vtkDataArray inNms, vtkDataAr` - Apply the transformation to a combination of points, normals and vectors.
- `vtkAbstractTransform = obj.GetInverse ()` - Get the inverse of this transform. If you modify this transform, the returned inverse transform will automatically update. If you want the inverse of a vtkTransform, you might want to use GetLinearInverse() instead which will type cast the result from vtkAbstractTransform to vtkLinearTransform.
- `obj.SetInverse (vtkAbstractTransform transform)` - Set a transformation that this transform will be the inverse of. This transform will automatically update to agree with the inverse transform that you set.
- `obj.Inverse ()` - Invert the transformation.
- `obj.DeepCopy (vtkAbstractTransform )` - Copy this transform from another of the same type.
- `obj.Update ()` - Update the transform to account for any changes which have been made. You do not have to call this method yourself, it is called automatically whenever the transform needs an update.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

- `int = obj.CircuitCheck (vtkAbstractTransform transform)` - Check for self-reference. Will return true if concatenating with the specified transform, setting it to be our inverse, or setting it to be our input will create a circular reference. CircuitCheck is automatically called by SetInput(), SetInverse(), and Concatenate(vtkXTransform *). Avoid using this function, it is experimental.

- `long = obj.GetMTime ()` - Override GetMTime necessary because of inverse transforms.

- `obj.UnRegister (vtkObjectBase O)` - Needs a special UnRegister() implementation to avoid circular references.

- `obj.Identity ()` - @deprecated This method is deprecated in the base class. It is still valid to use it on many of the specialized classes.

30.3 vtkAmoebaMinimizer

30.3.1 Usage

vtkAmoebaMinimizer will modify a set of parameters in order to find the minimum of a specified function. The method used is commonly known as the amoeba method, it constructs an n-dimensional simplex in parameter space (i.e. a tetrahedron if the number or parameters is 3) and moves the vertices around parameter space until a local minimum is found. The amoeba method is robust, reasonably efficient, but is not guaranteed to find the global minimum if several local minima exist.

To create an instance of class vtkAmoebaMinimizer, simply invoke its constructor as follows

```
obj = vtkAmoebaMinimizer
```

30.3.2 Methods

The class vtkAmoebaMinimizer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAmoebaMinimizer class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkAmoebaMinimizer = obj.NewInstance ()`

- `vtkAmoebaMinimizer = obj.SafeDownCast (vtkObject o)`

- `obj.SetParameterValue (string name, double value)` - Set the initial value for the specified parameter. Calling this function for any parameter will reset the Iterations and the FunctionEvaluations counts to zero. You must also use SetParameterScale() to specify the step size by which the parameter will be modified during the minimization. It is preferable to specify parameters by name, rather than by number.

- `obj.SetParameterValue (int i, double value)` - Set the initial value for the specified parameter. Calling this function for any parameter will reset the Iterations and the FunctionEvaluations counts to zero. You must also use SetParameterScale() to specify the step size by which the parameter will be modified during the minimization. It is preferable to specify parameters by name, rather than by number.

- `obj.SetParameterScale (string name, double scale)` - Set the scale to use when modifying a parameter, i.e. the initial amount by which the parameter will be modified during the search for the minimum. It is preferable to identify scalars by name rather than by number.

- `double = obj.GetParameterScale (string name)` - Set the scale to use when modifying a parameter, i.e. the initial amount by which the parameter will be modified during the search for the minimum. It is preferable to identify scalars by name rather than by number.

- `obj.SetParameterScale (int i, double scale)` - Set the scale to use when modifying a parameter, i.e. the initial amount by which the parameter will be modified during the search for the minimum. It is preferable to identify scalars by name rather than by number.

- `double = obj.GetParameterScale (int i)` - Set the scale to use when modifying a parameter, i.e. the initial amount by which the parameter will be modified during the search for the minimum. It is preferable to identify scalars by name rather than by number.

- `double = obj.GetParameterValue (string name)` - Get the value of a parameter at the current stage of the minimization. Call this method within the function that you are minimizing in order to get the current parameter values. It is preferable to specify parameters by name rather than by index.

- `double = obj.GetParameterValue (int i)` - Get the value of a parameter at the current stage of the minimization. Call this method within the function that you are minimizing in order to get the current parameter values. It is preferable to specify parameters by name rather than by index.

- `string = obj.GetParameterName (int i)` - For completeness, an unchecked method to get the name for particular parameter (the result will be NULL if no name was set).

- `int = obj.GetNumberOfParameters ()` - Get the number of parameters that have been set.

- `obj.Initialize ()` - Initialize the minimizer. This will reset the number of parameters to zero so that the minimizer can be reused.

- `obj.Minimize ()` - Iterate until the minimum is found to within the specified tolerance, or until the MaxIterations has been reached.

- `int = obj.Iterate ()` - Perform one iteration of minimization. Returns zero if the tolerance stopping criterion has been met.

- `obj.SetFunctionValue (double )` - Get the function value resulting from the minimization.

- `double = obj.GetFunctionValue ()` - Get the function value resulting from the minimization.

- `obj.SetTolerance (double )` - Specify the fractional tolerance to aim for during the minimization.

- `double = obj.GetTolerance ()` - Specify the fractional tolerance to aim for during the minimization.

- `obj.SetMaxIterations (int )` - Specify the maximum number of iterations to try before giving up.

- `int = obj.GetMaxIterations ()` - Specify the maximum number of iterations to try before giving up.

- `int = obj.GetIterations ()` - Return the number of interations that have been performed. This is not necessarily the same as the number of function evaluations.

- `int = obj.GetFunctionEvaluations ()` - Return the number of times that the function has been evaluated.

- `obj.EvaluateFunction ()` - Evaluate the function. This is usually called internally by the minimization code, but it is provided here as a public method.

30.4 vtkAnimationCue

30.4.1 Usage

vtkAnimationCue and vtkAnimationScene provide the framework to support animations in VTK. vtkAnimationCue represents an entity that changes/ animates with time, while vtkAnimationScene represents scene or setup for the animation, which consists on individual cues or other scenes.

A cue has three states: UNINITIALIZED, ACTIVE and INACTIVE. UNINITIALIZED represents an point in time before the start time of the cue. The cue is in ACTIVE state at a point in time between start time and end time for the cue. While, beyond the end time, it is in INACTIVE state. When the cue enters the ACTIVE state, StartAnimationCueEvent is fired. This event may be handled to initialize the entity to be animated. When the cue leaves the ACTIVE state, EndAnimationCueEvent is fired, which can be handled to cleanup after having run the animation. For every request to render during the ACTIVE state, AnimationCueTickEvent is fired, which must be handled to perform the actual animation.

To create an instance of class vtkAnimationCue, simply invoke its constructor as follows

```
obj = vtkAnimationCue
```

30.4.2 Methods

The class vtkAnimationCue has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnimationCue class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnimationCue = obj.NewInstance ()`
- `vtkAnimationCue = obj.SafeDownCast (vtkObject o)`
- `obj.SetTimeMode (int mode)` - Get/Set the time mode. In Normalized mode, the start and end times of the cue are normalized [0,1] with respect to the start and end times of the container scene. In Relative mode the start and end time of the cue are specified in offset seconds relative to the start time of the container scene.
- `int = obj.GetTimeMode ()` - Get/Set the time mode. In Normalized mode, the start and end times of the cue are normalized [0,1] with respect to the start and end times of the container scene. In Relative mode the start and end time of the cue are specified in offset seconds relative to the start time of the container scene.
- `obj.SetTimeModeToRelative ()` - Get/Set the time mode. In Normalized mode, the start and end times of the cue are normalized [0,1] with respect to the start and end times of the container scene. In Relative mode the start and end time of the cue are specified in offset seconds relative to the start time of the container scene.
- `obj.SetTimeModeToNormalized ()` - Get/Set the Start time for this cue. When the current time is ¿= StartTime, the Cue is in ACTIVE state. if Current time i ¡ StartTime, the Cue is in UNINITIALIZED state. Whenever the cue enters the ACTIVE state from an INACTIVE state, it triggers the StartEvent. The Start time is in seconds relative to the start of the container Scene (when in Relative time mode) or is normalized over the span of the container Scene (when in Normalized time mode).
- `obj.SetStartTime (double )` - Get/Set the Start time for this cue. When the current time is ¿= StartTime, the Cue is in ACTIVE state. if Current time i ¡ StartTime, the Cue is in UNINITIALIZED state. Whenever the cue enters the ACTIVE state from an INACTIVE state, it triggers the StartEvent. The Start time is in seconds relative to the start of the container Scene (when in Relative time mode) or is normalized over the span of the container Scene (when in Normalized time mode).

- `double = obj.GetStartTime ()` - Get/Set the Start time for this cue. When the current time is ¿= StartTime, the Cue is in ACTIVE state. if Current time i ¡ StartTime, the Cue is in UNINITIALIZED state. Whenever the cue enters the ACTIVE state from an INACTIVE state, it triggers the StartEvent. The Start time is in seconds relative to the start of the container Scene (when in Relative time mode) or is normalized over the span of the container Scene (when in Normalized time mode).

- `obj.SetEndTime (double )` - Get/Set the End time for this cue. When the current time is ¿ EndTime, the Cue is in INACTIVE state. Whenever the cue leaves an ACTIVE state to enter INACTIVE state, the EndEvent is triggered. The End time is in seconds relative to the start of the container Scene (when in Relative time mode) or is normalized over the span of the container Scene (when in Normalized time mode).

- `double = obj.GetEndTime ()` - Get/Set the End time for this cue. When the current time is ¿ EndTime, the Cue is in INACTIVE state. Whenever the cue leaves an ACTIVE state to enter INACTIVE state, the EndEvent is triggered. The End time is in seconds relative to the start of the container Scene (when in Relative time mode) or is normalized over the span of the container Scene (when in Normalized time mode).

- `obj.Tick (double currenttime, double deltatime, double clocktime)` - Indicates a tick or point in time in the animation. Triggers a Tick event if currenttime ¿= StartTime and currenttime ¡= EndTime. Whenever the state of the cue changes, either StartEvent or EndEvent is triggerred depending upon whether the cue entered Active state or quit active state respectively. The current time is relative to the start of the container Scene (when in Relative time mode) or is normalized over the span of the container Scene (when in Normalized time mode). deltatime is the time since last call to Tick. deltatime also can be in seconds relative to the start of the container Scene or normalized depending upon the cue's Time mode. clocktime is the time from the scene i.e. it does not depend on the time mode for the cue. For the first call to Tick after a call to Initialize(), the deltatime is 0;

- `obj.Initialize ()` - Called when the playing of the scene begins. This will set the Cue to UNINITIALIZED state.

- `obj.Finalize ()` - Called when the scene reaches the end. If the cue state is ACTIVE when this method is called, this will trigger a EndAnimationCueEvent.

- `double = obj.GetAnimationTime ()` - This is valid only in a AnimationCueTickEvent handler. Before firing the event the animation cue sets the AnimationTime to the time of the tick.

- `double = obj.GetDeltaTime ()` - This is valid only in a AnimationCueTickEvent handler. Before firing the event the animation cue sets the DeltaTime to the difference in time between the current tick and the last tick.

- `double = obj.GetClockTime ()` - This is valid only in a AnimationCueTickEvent handler. Before firing the event the animation cue sets the ClockTime to the time of the tick. ClockTime is directly the time from the animation scene neither normalized nor offsetted to the start of the scene.

30.5 vtkAnimationScene

30.5.1 Usage

vtkAnimationCue and vtkAnimationScene provide the framework to support animations in VTK. vtkAnimationCue represents an entity that changes/ animates with time, while vtkAnimationScene represents scene or setup for the animation, which consists of individual cues or other scenes.

A scene can be played in real time mode, or as a seqence of frames 1/frame rate apart in time.

To create an instance of class vtkAnimationScene, simply invoke its constructor as follows

```
obj = vtkAnimationScene
```

30.5.2 Methods

The class vtkAnimationScene has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnimationScene class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnimationScene = obj.NewInstance ()`
- `vtkAnimationScene = obj.SafeDownCast (vtkObject o)`
- `obj.SetPlayMode (int )` - Get/Set the PlayMode for running/playing the animation scene. In the Sequence mode, all the frames are generated one after the other. The time reported to each Tick of the constituent cues (during Play) is incremented by 1/frame rate, irrespective of the current time. In the RealTime mode, time indicates the instance in time.
- `obj.SetModeToSequence ()` - Get/Set the PlayMode for running/playing the animation scene. In the Sequence mode, all the frames are generated one after the other. The time reported to each Tick of the constituent cues (during Play) is incremented by 1/frame rate, irrespective of the current time. In the RealTime mode, time indicates the instance in time.
- `obj.SetModeToRealTime ()` - Get/Set the PlayMode for running/playing the animation scene. In the Sequence mode, all the frames are generated one after the other. The time reported to each Tick of the constituent cues (during Play) is incremented by 1/frame rate, irrespective of the current time. In the RealTime mode, time indicates the instance in time.
- `int = obj.GetPlayMode ()` - Get/Set the PlayMode for running/playing the animation scene. In the Sequence mode, all the frames are generated one after the other. The time reported to each Tick of the constituent cues (during Play) is incremented by 1/frame rate, irrespective of the current time. In the RealTime mode, time indicates the instance in time.
- `obj.SetFrameRate (double )` - Get/Set the frame rate (in frames per second). This parameter affects only in the Sequence mode. The time interval indicated to each cue on every tick is progressed by 1/frame-rate seconds.
- `double = obj.GetFrameRate ()` - Get/Set the frame rate (in frames per second). This parameter affects only in the Sequence mode. The time interval indicated to each cue on every tick is progressed by 1/frame-rate seconds.
- `obj.AddCue (vtkAnimationCue cue)` - Add/Remove an AnimationCue to/from the Scene. It's an error to add a cue twice to the Scene.
- `obj.RemoveCue (vtkAnimationCue cue)` - Add/Remove an AnimationCue to/from the Scene. It's an error to add a cue twice to the Scene.
- `obj.RemoveAllCues ()` - Add/Remove an AnimationCue to/from the Scene. It's an error to add a cue twice to the Scene.
- `int = obj.GetNumberOfCues ()` - Add/Remove an AnimationCue to/from the Scene. It's an error to add a cue twice to the Scene.
- `obj.Play ()` - Starts playing the animation scene. Fires a vtkCommand::StartEvent before play beings and vtkCommand::EndEvent after play ends.
- `obj.Stop ()` - Stops the animation scene that is running.
- `obj.SetLoop (int )` - Enable/Disable animation loop.

- `int = obj.GetLoop ()` - Enable/Disable animation loop.
- `obj.SetAnimationTime (double time)` - Makes the state of the scene same as the given time.
- `double = obj.GetAnimationTime ()` - Makes the state of the scene same as the given time.
- `obj.SetTimeMode (int mode)` - Overridden to allow change to Normalized mode only if none of the constituent cues is in Relative time mode.
- `int = obj.IsInPlay ()`

30.6 vtkArray

30.6.1 Usage

vtkArray is the root of a hierarchy of arrays that can be used to store data with any number of dimensions. It provides an abstract interface for retrieving and setting array attributes that are independent of the type of values stored in the array - such as the number of dimensions, extents along each dimension, and number of values stored in the array.

To get and set array values, the vtkTypedArray template class derives from vtkArray and provides type-specific methods for retrieval and update.

Two concrete derivatives of vtkTypedArray are provided at the moment: vtkDenseArray and vtkSparseArray, which provide dense and sparse storage for arbitrary-dimension data, respectively. Toolkit users can create their own concrete derivatives that implement alternative storage strategies, such as compressed-sparse-row, etc. You could also create an array that provided read-only access to 'virtual' data, such as an array that returned a Fibonacci sequence, etc.

To create an instance of class vtkArray, simply invoke its constructor as follows

```
obj = vtkArray
```

30.6.2 Methods

The class vtkArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArray = obj.NewInstance ()`
- `vtkArray = obj.SafeDownCast (vtkObject o)`
- `bool = obj.IsDense ()` - Returns true iff the underlying array storage is "dense", i.e. that GetSize() and GetNonNullSize() will always return the same value. If not, the array is "sparse".
- `obj.Resize (vtkIdType i)` - Resizes the array to the given extents (number of dimensions and size of each dimension). Note that concrete implementations of vtkArray may place constraints on the the extents that they will store, so you cannot assume that GetExtents() will always return the same value passed to Resize().

  The contents of the array are undefined after calling Resize() - you should initialize its contents accordingly. In particular, dimension-labels will be undefined, dense array values will be undefined, and sparse arrays will be empty.

- `obj.Resize (vtkIdType i, vtkIdType j)` - Resizes the array to the given extents (number of dimensions and size of each dimension). Note that concrete implementations of vtkArray may place constraints on the the extents that they will store, so you cannot assume that GetExtents() will always return the same value passed to Resize().

  The contents of the array are undefined after calling Resize() - you should initialize its contents accordingly. In particular, dimension-labels will be undefined, dense array values will be undefined, and sparse arrays will be empty.

- `obj.Resize (vtkIdType i, vtkIdType j, vtkIdType k)` - Resizes the array to the given extents (number of dimensions and size of each dimension). Note that concrete implementations of vtkArray may place constraints on the the extents that they will store, so you cannot assume that GetExtents() will always return the same value passed to Resize().

  The contents of the array are undefined after calling Resize() - you should initialize its contents accordingly. In particular, dimension-labels will be undefined, dense array values will be undefined, and sparse arrays will be empty.

- `vtkIdType = obj.GetDimensions ()` - Returns the number of dimensions stored in the array. Note that this is the same as calling GetExtents().GetDimensions().

- `vtkIdType = obj.GetSize ()` - Returns the number of values stored in the array. Note that this is the same as calling GetExtents().GetSize(), and represents the maximum number of values that could ever be stored using the current extents. This is equal to the number of values stored in a dense array, but may be larger than the number of values stored in a sparse array.

- `vtkIdType = obj.GetNonNullSize ()` - Returns the number of non-null values stored in the array. Note that this value will equal GetSize() for dense arrays, and will be less-than-or-equal to GetSize() for sparse arrays.

- `obj.SetName (vtkStdString \&name)` - Sets the array name.

- `vtkStdString = obj.GetName ()` - Returns the array name.

- `obj.SetDimensionLabel (vtkIdType i, vtkStdString \&label)` - Sets the label for the i-th array dimension.

- `vtkStdString = obj.GetDimensionLabel (vtkIdType i)` - Returns the label for the i-th array dimension.

- `vtkArray = obj.DeepCopy ()` - Returns a new array that is a deep copy of this array.

30.7 vtkArrayIterator

30.7.1 Usage

vtkArrayIterator is used to iterate over elements in any vtkAbstractArray subclass. The vtkArrayIteratorTemplateMacro is used to centralize the set of types supported by Execute methods. It also avoids duplication of long switch statement case lists. Note that in this macro VTK_TT is defined to be the type of the iterator for the given type of array. One must include the vtkArrayIteratorIncludes.h header file to provide for extending of this macro by addition of new iterators.

Example usage:

```
vtkArrayIter* iter = array->NewIterator();
switch(array->GetDataType())
  {
  vtkArrayIteratorTemplateMacro(myFunc(static\_cast<VTK\_TT*>(iter), arg2));
  }
iter->Delete();
```

To create an instance of class vtkArrayIterator, simply invoke its constructor as follows

```
obj = vtkArrayIterator
```

30.7.2 Methods

The class vtkArrayIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayIterator = obj.NewInstance ()`
- `vtkArrayIterator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkAbstractArray array)` - Set the array this iterator will iterate over. After Initialize() has been called, the iterator is valid so long as the Array has not been modified (except using the iterator itself). If the array is modified, the iterator must be re-intialized.
- `int = obj.GetDataType ()`

30.8 vtkAssemblyNode

30.8.1 Usage

vtkAssemblyNode represents a node in an assembly. It is used by vtkAssemblyPath to create hierarchical assemblies of props. The props can be either 2D or 3D.

An assembly node refers to a vtkProp, and possibly a vtkMatrix4x4. Nodes are used by vtkAssemblyPath to build fully evaluated path (matrices are concatenated through the path) that is used by picking and other operations involving assemblies.

To create an instance of class vtkAssemblyNode, simply invoke its constructor as follows

```
obj = vtkAssemblyNode
```

30.8.2 Methods

The class vtkAssemblyNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssemblyNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssemblyNode = obj.NewInstance ()`
- `vtkAssemblyNode = obj.SafeDownCast (vtkObject o)`
- `obj.SetViewProp (vtkProp prop)` - Set/Get the prop that this assembly node refers to.
- `vtkProp = obj.GetViewProp ()` - Set/Get the prop that this assembly node refers to.

- `obj.SetMatrix (vtkMatrix4x4 matrix)` - Specify a transformation matrix associated with the prop. Note: if the prop is not a type of vtkProp3D, then the transformation matrix is ignored (and expected to be NULL). Also, internal to this object the matrix is copied because the matrix is used for computation by vtkAssemblyPath.
- `vtkMatrix4x4 = obj.GetMatrix ()` - Specify a transformation matrix associated with the prop. Note: if the prop is not a type of vtkProp3D, then the transformation matrix is ignored (and expected to be NULL). Also, internal to this object the matrix is copied because the matrix is used for computation by vtkAssemblyPath.
- `long = obj.GetMTime ()` - Override the standard GetMTime() to check for the modified times of the prop and matrix.
- `obj.SetProp (vtkProp prop)` - @deprecated Replaced by vtkAssemblyNode::SetViewProp() as of VTK 5.0.
- `vtkProp = obj.GetProp ()` - @deprecated Replaced by vtkAssemblyNode::GetViewProp() as of VTK 5.0.

30.9 vtkAssemblyPath

30.9.1 Usage

vtkAssemblyPath represents an ordered list of assembly nodes that represent a fully evaluated assembly path. This class is used primarily for picking. Note that the use of this class is to add one or more assembly nodes to form the path. (An assembly node consists of an instance of vtkProp and vtkMatrix4x4, the matrix may be NULL.) As each node is added, the matrices are concatenated to create a final, evaluated matrix.

To create an instance of class vtkAssemblyPath, simply invoke its constructor as follows

```
obj = vtkAssemblyPath
```

30.9.2 Methods

The class vtkAssemblyPath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssemblyPath class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssemblyPath = obj.NewInstance ()`
- `vtkAssemblyPath = obj.SafeDownCast (vtkObject o)`
- `obj.AddNode (vtkProp p, vtkMatrix4x4 m)` - Convenience method adds a prop and matrix together, creating an assembly node transparently. The matrix pointer m may be NULL. Note: that matrix is the one, if any, associated with the prop.
- `vtkAssemblyNode = obj.GetNextNode ()` - Get the next assembly node in the list. The node returned contains a pointer to a prop and a 4x4 matrix. The matrix is evaluated based on the preceding assembly hierarchy (i.e., the matrix is not necessarily as the same as the one that was added with AddNode() because of the concatenation of matrices in the assembly hierarchy).
- `vtkAssemblyNode = obj.GetFirstNode ()` - Get the first assembly node in the list. See the comments for GetNextNode() regarding the contents of the returned node. (Note: This node corresponds to the vtkProp associated with the vtkRenderer.

- `vtkAssemblyNode = obj.GetLastNode ()` - Get the last assembly node in the list. See the comments for GetNextNode() regarding the contents of the returned node.
- `obj.DeleteLastNode ()` - Delete the last assembly node in the list. This is like a stack pop.
- `obj.ShallowCopy (vtkAssemblyPath path)` - Perform a shallow copy (reference counted) on the incoming path.
- `long = obj.GetMTime ()` - Override the standard GetMTime() to check for the modified times of the nodes in this path.

30.10 vtkAssemblyPaths

30.10.1 Usage

vtkAssemblyPaths represents an assembly hierarchy as a list of vtkAssemblyPath. Each path represents the complete path from the top level assembly (if any) down to the leaf prop.

To create an instance of class vtkAssemblyPaths, simply invoke its constructor as follows

```
obj = vtkAssemblyPaths
```

30.10.2 Methods

The class vtkAssemblyPaths has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAssemblyPaths class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAssemblyPaths = obj.NewInstance ()`
- `vtkAssemblyPaths = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkAssemblyPath p)` - Add a path to the list.
- `obj.RemoveItem (vtkAssemblyPath p)` - Remove a path from the list.
- `int = obj.IsItemPresent (vtkAssemblyPath p)` - Determine whether a particular path is present. Returns its position in the list.
- `vtkAssemblyPath = obj.GetNextItem ()` - Get the next path in the list.
- `long = obj.GetMTime ()` - Override the standard GetMTime() to check for the modified times of the paths.

30.11 vtkBitArray

30.11.1 Usage

vtkBitArray is an array of bits (0/1 data value). The array is packed so that each byte stores eight bits. vtkBitArray provides methods for insertion and retrieval of bits, and will automatically resize itself to hold new data.

To create an instance of class vtkBitArray, simply invoke its constructor as follows

```
obj = vtkBitArray
```

30.11.2 Methods

The class vtkBitArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBitArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBitArray = obj.NewInstance ()`
- `vtkBitArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate memory for this array. Delete old storage only if necessary. Note that ext is no longer used.
- `obj.Initialize ()` - Release storage and reset array to initial state.
- `int = obj.GetDataType ()`
- `int = obj.GetDataTypeSize ()` - Set the number of n-tuples in the array.
- `obj.SetNumberOfTuples (vtkIdType number)` - Set the number of n-tuples in the array.
- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.
- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at ith location in this array. Note that memory allocation is performed as necessary to hold the data.
- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at the end in this array. Note that memory allocation is performed as necessary to hold the data. Returns the location at which the data was inserted.
- `obj.GetTuple (vtkIdType i, double tuple)` - Copy the tuple value into a user-provided array.
- `obj.SetTuple (vtkIdType i, float tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTuple (vtkIdType i, double tuple)` - Set the tuple value at the ith location in the array.
- `obj.InsertTuple (vtkIdType i, float tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTuple (vtkIdType i, double tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `vtkIdType = obj.InsertNextTuple (float tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTuple (double tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `obj.RemoveTuple (vtkIdType id)` - These methods remove tuples from the data array. They shift data and resize array, so the data array is still valid after this operation. Note, this operation is fairly slow.
- `obj.RemoveFirstTuple ()` - These methods remove tuples from the data array. They shift data and resize array, so the data array is still valid after this operation. Note, this operation is fairly slow.

- `obj.RemoveLastTuple ()` - These methods remove tuples from the data array. They shift data and resize array, so the data array is still valid after this operation. Note, this operation is fairly slow.

- `obj.SetComponent (vtkIdType i, int j, double c)` - Set the data component at the ith tuple and jth component location. Note that i is less then NumberOfTuples and j is less then NumberOfComponents. Make sure enough memory has been allocated (use SetNumberOfTuples() and SetNumberOfComponents()).

- `obj.Squeeze ()` - Free any unneeded memory.

- `int = obj.Resize (vtkIdType numTuples)` - Resize the array while conserving the data.

- `int = obj.GetValue (vtkIdType id)` - Get the data at a particular index.

- `obj.SetNumberOfValues (vtkIdType number)` - Fast method based setting of values without memory checks. First use SetNumberOfValues then use SetValue to actually set them. Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.

- `obj.SetValue (vtkIdType id, int value)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.

- `obj.InsertValue (vtkIdType id, int i)` - Insets values and checks to make sure there is enough memory

- `vtkIdType = obj.InsertNextValue (int i)`

- `obj.InsertComponent (vtkIdType i, int j, double c)` - Insert the data component at ith tuple and jth component location. Note that memory allocation is performed as necessary to hold the data.

- `obj.DeepCopy (vtkDataArray da)` - Deep copy of another bit array.

- `obj.DeepCopy (vtkAbstractArray aa)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array. If save 0, the array must have been allocated with new[] not malloc.

- `obj.SetArray (string array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array. If save 0, the array must have been allocated with new[] not malloc.

- `vtkArrayIterator = obj.NewIterator ()` - Returns a new vtkBitArrayIterator instance.

- `vtkIdType = obj.LookupValue (int value)`

- `obj.LookupValue (int value, vtkIdList ids)`

- `obj.DataChanged ()` - Tell the array explicitly that the data has changed. This is only necessary to call when you modify the array contents without using the array's API (i.e. you retrieve a pointer to the data and modify the array contents). You need to call this so that the fast lookup will know to rebuild itself. Otherwise, the lookup functions will give incorrect results.

- `obj.ClearLookup ()` - Delete the associated fast lookup data structure on this array, if it exists. The lookup will be rebuilt on the next call to a lookup function.

30.12 vtkBox

30.12.1 Usage

vtkBox computes the implicit function and/or gradient for a axis-aligned bounding box. (The superclasses transform can be used to modify this orientation.) Each side of the box is orthogonal to all other sides meeting along shared edges and all faces are orthogonal to the x-y-z coordinate axes. (If you wish to orient this box differently, recall that the superclass vtkImplicitFunction supports a transformation matrix.) vtkCube is a concrete implementation of vtkImplicitFunction.

To create an instance of class vtkBox, simply invoke its constructor as follows

```
obj = vtkBox
```

30.12.2 Methods

The class vtkBox has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBox class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBox = obj.NewInstance ()`
- `vtkBox = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double n[3])`
- `obj.SetXMin (double p[3])` - Set / get the bounding box using various methods.
- `obj.SetXMin (double x, double y, double z)` - Set / get the bounding box using various methods.
- `obj.GetXMin (double p[3])` - Set / get the bounding box using various methods.
- `obj.SetXMax (double p[3])`
- `obj.SetXMax (double x, double y, double z)`
- `obj.GetXMax (double p[3])`
- `obj.SetBounds (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)`
- `obj.SetBounds (double bounds[6])`
- `obj.GetBounds (double bounds[6])`
- `obj.AddBounds (double bounds[6])` - A special method that allows union set operation on bounding boxes. Start with a SetBounds(). Subsequent AddBounds() methods are union set operations on the original bounds. Retrieve the final bounds with a GetBounds() method.

30.13 vtkBoxMuellerRandomSequence

30.13.1 Usage

vtkGaussianRandomSequence is a sequence of pseudo random numbers distributed according to the Gaussian/normal distribution (mean=0 and standard deviation=1).

It based is calculation from a uniformly distributed pseudo random sequence. The initial sequence is a vtkMinimalStandardRandomSequence.

To create an instance of class vtkBoxMuellerRandomSequence, simply invoke its constructor as follows

```
obj = vtkBoxMuellerRandomSequence
```

30.13.2 Methods

The class vtkBoxMuellerRandomSequence has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBoxMuellerRandomSequence class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBoxMuellerRandomSequence = obj.NewInstance ()`
- `vtkBoxMuellerRandomSequence = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetValue ()` - Current value.
- `obj.Next ()` - Move to the next number in the random sequence.
- `vtkRandomSequence = obj.GetUniformSequence ()` - Return the uniformly distributed sequence of random numbers.
- `obj.SetUniformSequence (vtkRandomSequence uniformSequence)` - Set the uniformly distributed sequence of random numbers. Default is a .

30.14 vtkByteSwap

30.14.1 Usage

vtkByteSwap is used by other classes to perform machine dependent byte swapping. Byte swapping is often used when reading or writing binary files.

To create an instance of class vtkByteSwap, simply invoke its constructor as follows

```
obj = vtkByteSwap
```

30.14.2 Methods

The class vtkByteSwap has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkByteSwap class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkByteSwap = obj.NewInstance ()`
- `vtkByteSwap = obj.SafeDownCast (vtkObject o)`

30.15 vtkCharArray

30.15.1 Usage

vtkCharArray is an array of values of type char. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkCharArray, simply invoke its constructor as follows

```
obj = vtkCharArray
```

30.15.2 Methods

The class vtkCharArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCharArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCharArray = obj.NewInstance ()`
- `vtkCharArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, string tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, string tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, string tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (string tuple)` - Get the data at a particular index.
- `char = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, char value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, char f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (char f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `string = obj.WritePointer (vtkIdType id, vtkIdType number)` - Get the address of a particular data index. Performs no checks to verify that the memory has been allocated etc.
- `string = obj.GetPointer (vtkIdType id)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.

- `obj.SetArray (string array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (string array, vtkIdType size, int save, int deleteMethod)`

30.16 vtkCollection

30.16.1 Usage

vtkCollection is a general object for creating and manipulating lists of objects. The lists are unsorted and allow duplicate entries. vtkCollection also serves as a base class for lists of specific types of objects.

To create an instance of class vtkCollection, simply invoke its constructor as follows

```
obj = vtkCollection
```

30.16.2 Methods

The class vtkCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollection = obj.NewInstance ()`
- `vtkCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkObject )` - Add an object to the list. Does not prevent duplicate entries.
- `obj.InsertItem (int i, vtkObject )` - Insert item into the list after the i'th item. Does not prevent duplicate entries. If i ¡ 0 the item is placed at the top of the list.
- `obj.ReplaceItem (int i, vtkObject )` - Replace the i'th item in the collection with a
- `obj.RemoveItem (int i)` - Remove the i'th item in the list. Be careful if using this function during traversal of the list using GetNextItemAsObject (or GetNextItem in derived class). The list WILL be shortened if a valid index is given! If this-¿Current is equal to the element being removed, have it point to then next element in the list.
- `obj.RemoveItem (vtkObject )` - Remove an object from the list. Removes the first object found, not all occurrences. If no object found, list is unaffected. See warning in description of RemoveItem(int).
- `obj.RemoveAllItems ()` - Remove all objects from the list.
- `int = obj.IsItemPresent (vtkObject a)` - Search for an object and return location in list. If the return value is 0, the object was not found. If the object was found, the location is the return value-1.
- `int = obj.GetNumberOfItems ()` - Return the number of objects in the list.
- `obj.InitTraversal ()` - Initialize the traversal of the collection. This means the data pointer is set at the beginning of the list.
- `vtkObject = obj.GetNextItemAsObject ()` - Get the next item in the collection. NULL is returned if the collection is exhausted.

- `vtkObject = obj.GetItemAsObject (int i)` - Get the i'th item in the collection. NULL is returned if i is out of range
- `vtkCollectionIterator = obj.NewIterator ()` - Get an iterator to traverse the objects in this collection.
- `obj.Register (vtkObjectBase o)` - Participate in garbage collection.
- `obj.UnRegister (vtkObjectBase o)` - Participate in garbage collection.

30.17 vtkCollectionIterator

30.17.1 Usage

vtkCollectionIterator provides an alternative way to traverse through the objects in a vtkCollection. Unlike the collection's built in interface, this allows multiple iterators to simultaneously traverse the collection. If items are removed from the collection, only the iterators currently pointing to those items are invalidated. Other iterators will still continue to function normally.

To create an instance of class vtkCollectionIterator, simply invoke its constructor as follows

```
obj = vtkCollectionIterator
```

30.17.2 Methods

The class vtkCollectionIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCollectionIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCollectionIterator = obj.NewInstance ()`
- `vtkCollectionIterator = obj.SafeDownCast (vtkObject o)`
- `obj.SetCollection (vtkCollection )` - Set/Get the collection over which to iterate.
- `vtkCollection = obj.GetCollection ()` - Set/Get the collection over which to iterate.
- `obj.InitTraversal ()` - Position the iterator at the first item in the collection.
- `obj.GoToFirstItem ()` - Position the iterator at the first item in the collection.
- `obj.GoToNextItem ()` - Move the iterator to the next item in the collection.
- `int = obj.IsDoneWithTraversal ()` - Test whether the iterator is currently positioned at a valid item. Returns 1 for yes, 0 for no.
- `vtkObject = obj.GetCurrentObject ()` - Get the item at the current iterator position. Valid only when IsDoneWithTraversal() returns 1.
- `vtkObject = obj.GetObject ()` - @deprecated Replaced by vtkCollectionIterator::GetCurrentObject() as of VTK 5.0.

30.18 vtkConditionVariable

30.18.1 Usage

vtkConditionVariable allows the locking of variables which are accessed through different threads. This header file also defines vtkSimpleConditionVariable which is not a subclass of vtkObject.

The win32 implementation is based on notes provided by Douglas C. Schmidt and Irfan Pyarali, Department of Computer Science, Washington University, St. Louis, Missouri. http://www.cs.wustl.edu/ schmidt/win32-cv-1.html

To create an instance of class vtkConditionVariable, simply invoke its constructor as follows

```
obj = vtkConditionVariable
```

30.18.2 Methods

The class vtkConditionVariable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConditionVariable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConditionVariable = obj.NewInstance ()`
- `vtkConditionVariable = obj.SafeDownCast (vtkObject o)`
- `obj.Signal ()` - Wake one thread waiting for the condition to change.
- `obj.Broadcast ()` - Wake all threads waiting for the condition to change.
- `int = obj.Wait (vtkMutexLock mutex)` - Wait for the condition to change. Upon entry, the mutex must be locked and the lock held by the calling thread. Upon exit, the mutex will be locked and held by the calling thread. Between entry and exit, the mutex will be unlocked and may be held by other threads.

  @param mutex The mutex that should be locked on entry and will be locked on exit (but not in between) @retval Normally, this function returns 0. Should a thread be interrupted by a signal, a non-zero value may be returned.

30.19 vtkContourValues

30.19.1 Usage

vtkContourValues is a general class to manage the creation, generation, and retrieval of contour values. This class serves as a helper class for contouring classes, or those classes operating on lists of contour values.

To create an instance of class vtkContourValues, simply invoke its constructor as follows

```
obj = vtkContourValues
```

30.19.2 Methods

The class vtkContourValues has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkContourValues class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkContourValues = obj.NewInstance ()`
- `vtkContourValues = obj.SafeDownCast (vtkObject o)`
- `obj.SetValue (int i, double value)` - Set the ith contour value.
- `double = obj.GetValue (int i)` - Get the ith contour value. The return value will be clamped if the index i is out of range.
- `obj.GetValues (double contourValues)` - Fill a supplied list with contour values. Make sure you've allocated memory of size GetNumberOfContours().
- `obj.SetNumberOfContours (int number)` - Set the number of contours to place into the list. You only really need to use this method to reduce list size. The method SetValue() will automatically increase list size as needed.
- `int = obj.GetNumberOfContours ()` - Return the number of contours in the
- `obj.GenerateValues (int numContours, double range[2])` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.
- `obj.GenerateValues (int numContours, double rangeStart, double rangeEnd)` - Generate numContours equally spaced contour values between specified range. Contour values will include min/max range values.

30.20 vtkCriticalSection

30.20.1 Usage

vtkCriticalSection allows the locking of variables which are accessed through different threads. This header file also defines vtkSimpleCriticalSection which is not a subclass of vtkObject. The API is identical to that of vtkMutexLock, and the behavior is identical as well, except on Windows 9x/NT platforms. The only difference on these platforms is that vtkMutexLock is more flexible, in that it works across processes as well as across threads, but also costs more, in that it evokes a 600-cycle x86 ring transition. The vtkCriticalSection provides a higher-performance equivalent (on Windows) but won't work across processes. Since it is unclear how, in vtk, an object at the vtk level can be shared across processes in the first place, one should use vtkCriticalSection unless one has a very good reason to use vtkMutexLock. If higher-performance equivalents for non-Windows platforms (Irix, SunOS, etc) are discovered, they should replace the implementations in this class

To create an instance of class vtkCriticalSection, simply invoke its constructor as follows

```
obj = vtkCriticalSection
```

30.20.2 Methods

The class vtkCriticalSection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCriticalSection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCriticalSection = obj.NewInstance ()`
- `vtkCriticalSection = obj.SafeDownCast (vtkObject o)`

- `obj.Lock ()` - Lock the vtkCriticalSection
- `obj.Unlock ()` - Unlock the vtkCriticalSection

30.21 vtkCylindricalTransform

30.21.1 Usage

vtkCylindricalTransform will convert (r,theta,z) coordinates to (x,y,z) coordinates and back again. The angles are given in radians. By default, it converts cylindrical coordinates to rectangular, but GetInverse() returns a transform that will do the opposite. The equation that is used is x = r*cos(theta), y = r*sin(theta), z = z.

To create an instance of class vtkCylindricalTransform, simply invoke its constructor as follows

```
obj = vtkCylindricalTransform
```

30.21.2 Methods

The class vtkCylindricalTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCylindricalTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCylindricalTransform = obj.NewInstance ()`
- `vtkCylindricalTransform = obj.SafeDownCast (vtkObject o)`
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

30.22 vtkDataArray

30.22.1 Usage

vtkDataArray is an abstract superclass for data array objects containing numeric data. It extends the API defined in vtkAbstractArray. vtkDataArray is an abstract superclass for data array objects. This class defines an API that all array objects must support. Note that the concrete subclasses of this class represent data in native form (char, int, etc.) and often have specialized more efficient methods for operating on this data (for example, getting pointers to data or getting/inserting data in native form). Subclasses of vtkDataArray are assumed to contain data whose components are meaningful when cast to and from double.

To create an instance of class vtkDataArray, simply invoke its constructor as follows

```
obj = vtkDataArray
```

30.22.2 Methods

The class vtkDataArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkDataArray = obj.NewInstance ()`
- `vtkDataArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsNumeric ()` - Return the size, in bytes, of the lowest-level element of an array. For vtkDataArray and subclasses this is the size of the data type.
- `int = obj.GetElementComponentSize ()` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.
- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.
- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at ith location in this array. Note that memory allocation is performed as necessary to hold the data. This pure virtual function is redeclared here to avoid declaration hidden warnings.
- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at the end in this array. Note that memory allocation is performed as necessary to hold the data. Returns the location at which the data was inserted. This pure virtual function is redeclared here to avoid declaration hidden warnings.
- `obj.GetTuples (vtkIdList ptIds, vtkAbstractArray output)` - Given a list of point ids, return an array of tuples. You must insure that the output array has been previously allocated with enough space to hold the data.
- `obj.GetTuples (vtkIdType p1, vtkIdType p2, vtkAbstractArray output)` - Get the tuples for the range of points ids specified (i.e., p1-¿p2 inclusive). You must insure that the output array has been previously allocated with enough space to hold the data.
- `obj.InterpolateTuple (vtkIdType i, vtkIdList ptIndices, vtkAbstractArray source, double weights)` - Set the ith tuple in this array as the interpolated tuple value, given the ptIndices in the source array and associated interpolation weights. This method assumes that the two arrays are of the same type and strcuture.
- `obj.InterpolateTuple (vtkIdType i, vtkIdType id1, vtkAbstractArray source1, vtkIdType id2, vtkAbstr`
- `obj.GetTuple (vtkIdType i, double tuple)` - Get the data tuple at ith location by filling in a user-provided array, Make sure that your array is large enough to hold the NumberOfComponents amount of data being returned.
- `double = obj.GetTuple1 (vtkIdType i)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.
- `double = obj.GetTuple2 (vtkIdType i)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.
- `double = obj.GetTuple3 (vtkIdType i)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.
- `double = obj.GetTuple4 (vtkIdType i)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `double = obj.GetTuple9 (vtkIdType i)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.SetTuple (vtkIdType i, float tuple)` - Set the data tuple at ith location. Note that range checking or memory allocation is not performed; use this method in conjunction with SetNumberOfTuples() to allocate space.

- `obj.SetTuple (vtkIdType i, double tuple)` - Set the data tuple at ith location. Note that range checking or memory allocation is not performed; use this method in conjunction with SetNumberOfTuples() to allocate space.

- `obj.SetTuple1 (vtkIdType i, double value)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.SetTuple2 (vtkIdType i, double val0, double val1)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.SetTuple3 (vtkIdType i, double val0, double val1, double val2)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.SetTuple4 (vtkIdType i, double val0, double val1, double val2, double val3)` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.SetTuple9 (vtkIdType i, double val0, double val1, double val2, double val3, double val4, double` - These methods are included as convenience for the wrappers. GetTuple() and SetTuple() which return/take arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertTuple (vtkIdType i, float tuple)` - Insert the data tuple at ith location. Note that memory allocation is performed as necessary to hold the data.

- `obj.InsertTuple (vtkIdType i, double tuple)` - Insert the data tuple at ith location. Note that memory allocation is performed as necessary to hold the data.

- `obj.InsertTuple1 (vtkIdType i, double value)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertTuple2 (vtkIdType i, double val0, double val1)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertTuple3 (vtkIdType i, double val0, double val1, double val2)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertTuple4 (vtkIdType i, double val0, double val1, double val2, double val3)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertTuple9 (vtkIdType i, double val0, double val1, double val2, double val3, double val4, dou` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `vtkIdType = obj.InsertNextTuple (float tuple)` - Insert the data tuple at the end of the array and return the location at which the data was inserted. Memory is allocated as necessary to hold the data.

- `vtkIdType = obj.InsertNextTuple (double tuple)` - Insert the data tuple at the end of the array and return the location at which the data was inserted. Memory is allocated as necessary to hold the data.

- `obj.InsertNextTuple1 (double value)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertNextTuple2 (double val0, double val1)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertNextTuple3 (double val0, double val1, double val2)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertNextTuple4 (double val0, double val1, double val2, double val3)` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.InsertNextTuple9 (double val0, double val1, double val2, double val3, double val4, double val5,` - These methods are included as convenience for the wrappers. InsertTuple() which takes arrays can not be used from wrapped languages. These methods can be used instead.

- `obj.RemoveTuple (vtkIdType id)` - These methods remove tuples from the data array. They shift data and resize array, so the data array is still valid after this operation. Note, this operation is fairly slow.

- `obj.RemoveFirstTuple ()` - These methods remove tuples from the data array. They shift data and resize array, so the data array is still valid after this operation. Note, this operation is fairly slow.

- `obj.RemoveLastTuple ()` - These methods remove tuples from the data array. They shift data and resize array, so the data array is still valid after this operation. Note, this operation is fairly slow.

- `double = obj.GetComponent (vtkIdType i, int j)` - Return the data component at the ith tuple and jth component location. Note that i is less than NumberOfTuples and j is less than NumberOfComponents.

- `obj.SetComponent (vtkIdType i, int j, double c)` - Set the data component at the ith tuple and jth component location. Note that i is less than NumberOfTuples and j is less than NumberOfComponents. Make sure enough memory has been allocated (use SetNumberOfTuples() and SetNumberOfComponents()).

- `obj.InsertComponent (vtkIdType i, int j, double c)` - Insert the data component at ith tuple and jth component location. Note that memory allocation is performed as necessary to hold the data.

- `obj.GetData (vtkIdType tupleMin, vtkIdType tupleMax, int compMin, int compMax, vtkDoubleArray data)` - Get the data as a double array in the range (tupleMin,tupleMax) and (compMin, compMax). The resulting double array consists of all data in the tuple range specified and only the component range specified. This process typically requires casting the data from native form into doubleing point values. This method is provided as a convenience for data exchange, and is not very fast.

- `obj.DeepCopy (vtkAbstractArray aa)` - Deep copy of data. Copies data from different data arrays even if they are different types (using doubleing-point exchange).

- `obj.DeepCopy (vtkDataArray da)` - Deep copy of data. Copies data from different data arrays even if they are different types (using doubleing-point exchange).

- `obj.FillComponent (int j, double c)` - Fill a component of a data array with a specified value. This method sets the specified component to specified value for all tuples in the data array. This methods can be used to initialize or reinitialize a single component of a multi-component array.

- `obj.CopyComponent (int j, vtkDataArray from, int fromComponent)` - Copy a component from one data array into a component on this data array. This method copies the specified component ("fromComponent") from the specified data array ("from") to the specified component ("j") over all the tuples in this data array. This method can be used to extract a component (column) from one data array and paste that data into a component on this data array.

- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this data array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.

- `obj.CreateDefaultLookupTable ()` - Create default lookup table. Generally used to create one when none is available.

- `obj.SetLookupTable (vtkLookupTable lut)` - Set/get the lookup table associated with this scalar data, if any.

- `vtkLookupTable = obj.GetLookupTable ()` - Set/get the lookup table associated with this scalar data, if any.

- `obj.GetRange (double range[2], int comp)` - Return the range of the array values for the given component. Range is copied into the array provided. If comp is equal to -1, it returns the range of the magnitude (if the number of components is equal to 1 it still returns the range of component 0).

- `double = obj.GetRange (int comp)` - Return the range of the array values for the 0th component. Range is copied into the array provided.

- `double = obj.GetRange ()` - Return the range of the array values for the 0th component. Range is copied into the array provided.

- `obj.GetRange (double range[2])` - These methods return the Min and Max possible range of the native data type. For example if a vtkScalars consists of unsigned char data these will return (0,255).

- `obj.GetDataTypeRange (double range[2])` - These methods return the Min and Max possible range of the native data type. For example if a vtkScalars consists of unsigned char data these will return (0,255).

- `double = obj.GetDataTypeMin ()` - These methods return the Min and Max possible range of the native data type. For example if a vtkScalars consists of unsigned char data these will return (0,255).

- `double = obj.GetDataTypeMax ()` - These methods return the Min and Max possible range of the native data type. For example if a vtkScalars consists of unsigned char data these will return (0,255).

- `double = obj.GetMaxNorm ()` - Return the maximum norm for the tuples. Note that the max. is computed everytime GetMaxNorm is called.

- `int = obj.CopyInformation (vtkInformation infoFrom, int deep)` - Copy information instance. Arrays use information objects in a variety of ways. It is important to have flexibility in this regard because certain keys should not be coppied, while others must be. NOTE: Up to the implmeneter to make sure that keys not inteneded to be coppied are excluded here.

30.23 vtkDataArrayCollection

30.23.1 Usage

vtkDataArrayCollection is an object that creates and manipulates lists of datasets. See also vtkCollection and subclasses.

To create an instance of class vtkDataArrayCollection, simply invoke its constructor as follows

```
obj = vtkDataArrayCollection
```

30.23.2 Methods

The class vtkDataArrayCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataArrayCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataArrayCollection = obj.NewInstance ()`
- `vtkDataArrayCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkDataArray ds)` - Get the next dataarray in the list.
- `vtkDataArray = obj.GetNextItem ()` - Get the next dataarray in the list.
- `vtkDataArray = obj.GetItem (int i)` - Get the ith dataarray in the list.

30.24 vtkDataArrayCollectionIterator

30.24.1 Usage

vtkDataArrayCollectionIterator provides an implementation of vtkCollectionIterator which allows the items to be retrieved with the proper subclass pointer type for vtkDataArrayCollection.

To create an instance of class vtkDataArrayCollectionIterator, simply invoke its constructor as follows

```
obj = vtkDataArrayCollectionIterator
```

30.24.2 Methods

The class vtkDataArrayCollectionIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataArrayCollectionIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataArrayCollectionIterator = obj.NewInstance ()`
- `vtkDataArrayCollectionIterator = obj.SafeDownCast (vtkObject o)`
- `obj.SetCollection (vtkCollection )` - Set the collection over which to iterate.
- `obj.SetCollection (vtkDataArrayCollection )` - Set the collection over which to iterate.
- `vtkDataArray = obj.GetDataArray ()` - Get the item at the current iterator position. Valid only when IsDoneWithTraversal() returns 1.

30.25 vtkDataArraySelection

30.25.1 Usage

vtkDataArraySelection can be used by vtkSource subclasses to store on/off settings for whether each vtkDataArray in its input should be passed in the source's output. This is primarily intended to allow file readers to configure what data arrays are read from the file.

To create an instance of class vtkDataArraySelection, simply invoke its constructor as follows

```
obj = vtkDataArraySelection
```

30.25.2 Methods

The class vtkDataArraySelection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataArraySelection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataArraySelection = obj.NewInstance ()`
- `vtkDataArraySelection = obj.SafeDownCast (vtkObject o)`
- `obj.EnableArray (string name)` - Enable the array with the given name. Creates a new entry if none exists.
- `obj.DisableArray (string name)` - Disable the array with the given name. Creates a new entry if none exists.
- `int = obj.ArrayIsEnabled (string name)` - Return whether the array with the given name is enabled. If there is no entry, the array is assumed to be disabled.
- `int = obj.ArrayExists (string name)` - Return whether the array with the given name exists.
- `obj.EnableAllArrays ()` - Enable all arrays that currently have an entry.
- `obj.DisableAllArrays ()` - Disable all arrays that currently have an entry.
- `int = obj.GetNumberOfArrays ()` - Get the number of arrays that currently have an entry.
- `int = obj.GetNumberOfArraysEnabled ()` - Get the number of arrays that are enabled.
- `string = obj.GetArrayName (int index)` - Get the name of the array entry at the given index.
- `int = obj.GetArrayIndex (string name)` - Get an index of the array containing name within the enabled arrays
- `int = obj.GetEnabledArrayIndex (string name)` - Get the index of an array with the given name among those that are enabled. Returns -1 if the array is not enabled.
- `int = obj.GetArraySetting (string name)` - Get whether the array at the given index is enabled.
- `int = obj.GetArraySetting (int index)` - Get whether the array at the given index is enabled.
- `obj.RemoveAllArrays ()` - Remove all array entries.
- `obj.CopySelections (vtkDataArraySelection selections)` - Copy the selections from the given vtkDataArraySelection instance.

30.26 vtkDebugLeaks

30.26.1 Usage

vtkDebugLeaks is used to report memory leaks at the exit of the program. It uses the vtkObjectFactory to intercept the construction of all VTK objects. It uses the UnRegister method of vtkObject to intercept the destruction of all objects. A table of object name to number of instances is kept. At the exit of the program if there are still VTK objects around it will print them out. To enable this class add the flag -DVTK_DEBUG_LEAKS to the compile line, and rebuild vtkObject and vtkObjectFactory.

To create an instance of class vtkDebugLeaks, simply invoke its constructor as follows

```
obj = vtkDebugLeaks
```

30.26.2 Methods

The class vtkDebugLeaks has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDebugLeaks class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDebugLeaks = obj.NewInstance ()`
- `vtkDebugLeaks = obj.SafeDownCast (vtkObject o)`

30.27 vtkDirectory

30.27.1 Usage

vtkDirectory provides a portable way of finding the names of the files in a system directory. It also provides methods of manipulating directories.

To create an instance of class vtkDirectory, simply invoke its constructor as follows

```
obj = vtkDirectory
```

30.27.2 Methods

The class vtkDirectory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDirectory class.

- `string = obj.GetClassName ()` - Return the class name as a string.
- `int = obj.IsA (string name)` - Return the class name as a string.
- `vtkDirectory = obj.NewInstance ()` - Return the class name as a string.
- `vtkDirectory = obj.SafeDownCast (vtkObject o)` - Return the class name as a string.
- `int = obj.Open (string dir)` - Open the specified directory and load the names of the files in that directory. 0 is returned if the directory can not be opened, 1 if it is opened.
- `vtkIdType = obj.GetNumberOfFiles ()` - Return the number of files in the current directory.
- `string = obj.GetFile (vtkIdType index)` - Return the file at the given index, the indexing is 0 based

- `int = obj.FileIsDirectory (string name)` - Return true if the file is a directory. If the file is not an absolute path, it is assumed to be relative to the opened directory. If no directory has been opened, it is assumed to be relative to the current working directory.
- `vtkStringArray = obj.GetFiles ()` - Get an array that contains all the file names.

30.28 vtkDoubleArray

30.28.1 Usage

vtkDoubleArray is an array of values of type double. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkDoubleArray, simply invoke its constructor as follows

```
obj = vtkDoubleArray
```

30.28.2 Methods

The class vtkDoubleArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDoubleArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDoubleArray = obj.NewInstance ()`
- `vtkDoubleArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, double tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, double tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, double tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (double tuple)` - Get the data at a particular index.
- `double = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, double value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, double f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (double f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.

- `obj.SetArray (double array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (double array, vtkIdType size, int save, int deleteMethod)`

30.29 vtkDynamicLoader

30.29.1 Usage

vtkDynamicLoader provides a portable interface to loading dynamic libraries into a process.

To create an instance of class vtkDynamicLoader, simply invoke its constructor as follows

```
obj = vtkDynamicLoader
```

30.29.2 Methods

The class vtkDynamicLoader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDynamicLoader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDynamicLoader = obj.NewInstance ()`
- `vtkDynamicLoader = obj.SafeDownCast (vtkObject o)`

30.30 vtkEdgeTable

30.30.1 Usage

vtkEdgeTable is a general object for keeping track of lists of edges. An edge is defined by the pair of point id's (p1,p2). Methods are available to insert edges, check if edges exist, and traverse the list of edges. Also, it's possible to associate attribute information with each edge. The attribute information may take the form of vtkIdType id's, void* pointers, or points. To store attributes, make sure that InitEdgeInsertion() is invoked with the storeAttributes flag set properly. If points are inserted, use the methods InitPointInsertion() and InsertUniquePoint().

To create an instance of class vtkEdgeTable, simply invoke its constructor as follows

```
obj = vtkEdgeTable
```

30.30.2 Methods

The class vtkEdgeTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgeTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgeTable = obj.NewInstance ()`

- `vtkEdgeTable = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Free memory and return to the initially instantiated state.
- `int = obj.InitEdgeInsertion (vtkIdType numPoints, int storeAttributes)` - Initialize the edge insertion process. Provide an estimate of the number of points in a dataset (the maximum range value of p1 or p2). The storeAttributes variable controls whether attributes are to be stored with the edge, and what type of attributes. If storeAttributes==1, then attributes of vtkIdType can be stored. If storeAttributes==2, then attributes of type void* can be stored. In either case, additional memory will be required by the data structure to store attribute data per each edge. This method is used in conjunction with one of the three InsertEdge() methods described below (don't mix the InsertEdge() methods—make sure that the one used is consistent with the storeAttributes flag set in InitEdgeInsertion()).
- `vtkIdType = obj.InsertEdge (vtkIdType p1, vtkIdType p2)` - Insert the edge (p1,p2) into the table. It is the user's responsibility to check if the edge has already been inserted (use IsEdge()). If the storeAttributes flag in InitEdgeInsertion() has been set, then the method returns a unique integer id (i.e., the edge id) that can be used to set and get edge attributes. Otherwise, the method will return 1. Do not mix this method with the InsertEdge() method that follows.
- `obj.InsertEdge (vtkIdType p1, vtkIdType p2, vtkIdType attributeId)` - Insert the edge (p1,p2) into the table with the attribute id specified (make sure the attributeId ¿= 0). Note that the attributeId is ignored if the storeAttributes variable was set to 0 in the InitEdgeInsertion() method. It is the user's responsibility to check if the edge has already been inserted (use IsEdge()). Do not mix this method with the other two InsertEdge() methods.
- `vtkIdType = obj.IsEdge (vtkIdType p1, vtkIdType p2)` - Return an integer id for the edge, or an attribute id of the edge (p1,p2) if the edge has been previously defined (it depends upon which version of InsertEdge() is being used); otherwise -1. The unique integer id can be used to set and retrieve attributes to the edge.
- `int = obj.InitPointInsertion (vtkPoints newPts, vtkIdType estSize)` - Initialize the point insertion process. The newPts is an object representing point coordinates into which incremental insertion methods place their data. The points are associated with the edge.
- `vtkIdType = obj.GetNumberOfEdges ()` - Return the number of edges that have been inserted thus far.
- `obj.InitTraversal ()` - Intialize traversal of edges in table.
- `obj.Reset ()` - Reset the object and prepare for reinsertion of edges. Does not delete memory like the Initialize() method.

30.31 vtkExtentSplitter

30.31.1 Usage

vtkExtentSplitter splits each input extent into non-overlapping sub-extents that are completely contained within other "source extents". A source extent corresponds to some resource providing an extent. Each source extent has an integer identifier, integer priority, and an extent. The input extents are split into sub-extents according to priority, availability, and amount of overlap of the source extents. This can be used by parallel data readers to read as few piece files as possible.

To create an instance of class vtkExtentSplitter, simply invoke its constructor as follows

```
obj = vtkExtentSplitter
```

30.31.2 Methods

The class vtkExtentSplitter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtentSplitter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtentSplitter = obj.NewInstance ()`
- `vtkExtentSplitter = obj.SafeDownCast (vtkObject o)`
- `obj.AddExtentSource (int id, int priority, int x0, int x1, int y0, int y1, int z0, int z1)` - Add/Remove a source providing the given extent. Sources with higher priority numbers are favored. Source id numbers and priorities must be non-negative.
- `obj.AddExtentSource (int id, int priority, int extent)` - Add/Remove a source providing the given extent. Sources with higher priority numbers are favored. Source id numbers and priorities must be non-negative.
- `obj.RemoveExtentSource (int id)` - Add/Remove a source providing the given extent. Sources with higher priority numbers are favored. Source id numbers and priorities must be non-negative.
- `obj.RemoveAllExtentSources ()` - Add/Remove a source providing the given extent. Sources with higher priority numbers are favored. Source id numbers and priorities must be non-negative.
- `obj.AddExtent (int x0, int x1, int y0, int y1, int z0, int z1)` - Add an extent to the queue of extents to be split among the available sources.
- `obj.AddExtent (int extent)` - Add an extent to the queue of extents to be split among the available sources.
- `int = obj.ComputeSubExtents ()` - Split the extents currently in the queue among the available sources. The queue is empty when this returns. Returns 1 if all extents could be read. Returns 0 if any portion of any extent was not available through any source.
- `int = obj.GetNumberOfSubExtents ()` - Get the number of sub-extents into which the original set of extents have been split across the available sources. Valid after a call to ComputeSubExtents.
- `int = obj.GetSubExtent (int index)` - Get the sub-extent associated with the given index. Use GetSubExtentSource to get the id of the source from which this sub-extent should be read. Valid after a call to ComputeSubExtents.
- `obj.GetSubExtent (int index, int extent)` - Get the sub-extent associated with the given index. Use GetSubExtentSource to get the id of the source from which this sub-extent should be read. Valid after a call to ComputeSubExtents.
- `int = obj.GetSubExtentSource (int index)` - Get the id of the source from which the sub-extent associated with the given index should be read. Returns -1 if no source provides the sub-extent.
- `int = obj.GetPointMode ()` - Get/Set whether "point mode" is on. In point mode, sub-extents are generated to ensure every point in the update request is read, but not necessarily every cell. This can be used when point data are stored in a planar slice per piece with no cell data. The default is OFF.
- `obj.SetPointMode (int )` - Get/Set whether "point mode" is on. In point mode, sub-extents are generated to ensure every point in the update request is read, but not necessarily every cell. This can be used when point data are stored in a planar slice per piece with no cell data. The default is OFF.

- `obj.PointModeOn ()` - Get/Set whether "point mode" is on. In point mode, sub-extents are generated to ensure every point in the update request is read, but not necessarily every cell. This can be used when point data are stored in a planar slice per piece with no cell data. The default is OFF.
- `obj.PointModeOff ()` - Get/Set whether "point mode" is on. In point mode, sub-extents are generated to ensure every point in the update request is read, but not necessarily every cell. This can be used when point data are stored in a planar slice per piece with no cell data. The default is OFF.

30.32 vtkExtentTranslator

30.32.1 Usage

vtkExtentTranslator generates a structured extent from an unstructured extent. It uses a recursive scheme that splits the largest axis. A hard coded extent can be used for a starting point.

To create an instance of class vtkExtentTranslator, simply invoke its constructor as follows

```
obj = vtkExtentTranslator
```

30.32.2 Methods

The class vtkExtentTranslator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExtentTranslator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExtentTranslator = obj.NewInstance ()`
- `vtkExtentTranslator = obj.SafeDownCast (vtkObject o)`
- `obj.SetWholeExtent (int , int , int , int , int , int )` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `obj.SetWholeExtent (int a[6])` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `int = obj. GetWholeExtent ()` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `obj.SetExtent (int , int , int , int , int , int )` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `obj.SetExtent (int a[6])` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `int = obj. GetExtent ()` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `obj.SetPiece (int )` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `int = obj.GetPiece ()` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `obj.SetNumberOfPieces (int )` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.

- `int = obj.GetNumberOfPieces ()` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `obj.SetGhostLevel (int )` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `int = obj.GetGhostLevel ()` - Set the Piece/NumPieces. Set the WholeExtent and then call PieceToExtent. The result can be obtained from the Extent ivar.
- `int = obj.PieceToExtent ()` - These are the main methods that should be called. These methods are responsible for converting a piece to an extent. The signatures without arguments are only thread safe when each thread accesses a different instance. The signatures with arguements are fully thread safe.
- `int = obj.PieceToExtentByPoints ()` - These are the main methods that should be called. These methods are responsible for converting a piece to an extent. The signatures without arguments are only thread safe when each thread accesses a different instance. The signatures with arguements are fully thread safe.
- `int = obj.PieceToExtentThreadSafe (int piece, int numPieces, int ghostLevel, int wholeExtent, int r` - These are the main methods that should be called. These methods are responsible for converting a piece to an extent. The signatures without arguments are only thread safe when each thread accesses a different instance. The signatures with arguements are fully thread safe.
- `obj.SetSplitModeToBlock ()` - How should the streamer break up extents. Block mode tries to break an extent up into cube blocks. It always chooses the largest axis to split. Slab mode first breaks up the Z axis. If it gets to one slice, then it starts breaking up other axes.
- `obj.SetSplitModeToXSlab ()` - How should the streamer break up extents. Block mode tries to break an extent up into cube blocks. It always chooses the largest axis to split. Slab mode first breaks up the Z axis. If it gets to one slice, then it starts breaking up other axes.
- `obj.SetSplitModeToYSlab ()` - How should the streamer break up extents. Block mode tries to break an extent up into cube blocks. It always chooses the largest axis to split. Slab mode first breaks up the Z axis. If it gets to one slice, then it starts breaking up other axes.
- `obj.SetSplitModeToZSlab ()` - How should the streamer break up extents. Block mode tries to break an extent up into cube blocks. It always chooses the largest axis to split. Slab mode first breaks up the Z axis. If it gets to one slice, then it starts breaking up other axes.
- `int = obj.GetSplitMode ()` - How should the streamer break up extents. Block mode tries to break an extent up into cube blocks. It always chooses the largest axis to split. Slab mode first breaks up the Z axis. If it gets to one slice, then it starts breaking up other axes.
- `obj.SetSplitPath (int len, int splitpath)`

30.33 vtkFastNumericConversion

30.33.1 Usage

vtkFastNumericConversion uses a portable (assuming IEEE format) method for converting single and double precision floating point values to a fixed point representation. This allows fast integer floor operations on platforms, such as Intel X86, in which CPU floating point conversion algorithms are very slow. It is based on the techniques described in Chris Hecker's article, "Let's Get to the (Floating) Point", in Game Developer Magazine, Feb/Mar 1996, and the techniques described in Michael Herf's website, http://www.stereopsis.com/FPU.html. The Hecker article can be found at http://www.d6.com/users/checker/pdfs/gdmfp.pd Unfortunately, each of these techniques is incomplete, and doesn't convert properly, in a way that depends on how many bits are reserved for fixed point fractional use, due to failing to properly account for the default

round-towards-even rounding mode of the X86. Thus, my implementation incorporates some rounding correction that undoes the rounding that the FPU performs during denormalization of the floating point value. Note that the rounding affect I'm talking about here is not the effect on the fistp instruction, but rather the effect that occurs during the denormalization of a value that occurs when adding it to a much larger value. The bits must be shifted to the right, and when a "1" bit falls off the edge, the rounding mode determines what happens next, in order to avoid completely "losing" the 1-bit. Furthermore, my implementation works on Linux, where the default precision mode is 64-bit extended precision.

To create an instance of class vtkFastNumericConversion, simply invoke its constructor as follows

```
obj = vtkFastNumericConversion
```

30.33.2 Methods

The class vtkFastNumericConversion has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFastNumericConversion class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFastNumericConversion = obj.NewInstance ()`
- `vtkFastNumericConversion = obj.SafeDownCast (vtkObject o)`
- `int = obj.TestQuickFloor (double val)` - Wrappable method for script-testing of correct cross-platform functionality
- `int = obj.TestSafeFloor (double val)` - Wrappable method for script-testing of correct cross-platform functionality
- `int = obj.TestRound (double val)` - Wrappable method for script-testing of correct cross-platform functionality
- `int = obj.TestConvertFixedPointIntPart (double val)` - Wrappable method for script-testing of correct cross-platform functionality
- `int = obj.TestConvertFixedPointFracPart (double val)` - Wrappable method for script-testing of correct cross-platform functionality
- `obj.SetReservedFracBits (int bits)` - Set the number of bits reserved for fractional precision that are maintained as part of the flooring process. This number affects the flooring arithmetic. It may be useful if the factional part is to be used to index into a lookup table of some sort. However, if you are only interested in knowing the fractional remainder after flooring, there doesn't appear to be any advantage to using these bits, either in terms of a lookup table, or by directly multiplying by some unit fraction, over simply subtracting the floored value from the original value. Note that since only 32 bits are used for the entire fixed point representation, increasing the number of reserved fractional bits reduces the range of integer values that can be floored to. Add one to the requested number of fractional bits, to make the conversion safe with respect to rounding mode. This is the same as the difference between QuickFloor and SafeFloor.
- `obj.PerformanceTests (void )` - Conduct timing tests so that the usefulness of this class can be ascertained on whatever platform it is being used. Output can be retrieved via Print method.

30.34 vtkFileOutputWindow

30.34.1 Usage

Writes debug/warning/error output to a log file instead of the console. To use this class, instantiate it and then call SetInstance(this).

To create an instance of class vtkFileOutputWindow, simply invoke its constructor as follows

```
obj = vtkFileOutputWindow
```

30.34.2 Methods

The class vtkFileOutputWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFileOutputWindow class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFileOutputWindow = obj.NewInstance ()`
- `vtkFileOutputWindow = obj.SafeDownCast (vtkObject o)`
- `obj.DisplayText (string )` - Put the text into the log file. New lines are converted to carriage return new lines.
- `obj.SetFileName (string )` - Sets the name for the log file.
- `string = obj.GetFileName ()` - Sets the name for the log file.
- `obj.SetFlush (int )` - Turns on buffer flushing for the output to the log file.
- `int = obj.GetFlush ()` - Turns on buffer flushing for the output to the log file.
- `obj.FlushOn ()` - Turns on buffer flushing for the output to the log file.
- `obj.FlushOff ()` - Turns on buffer flushing for the output to the log file.
- `obj.SetAppend (int )` - Setting append will cause the log file to be opened in append mode. Otherwise, if the log file exists, it will be overwritten each time the vtkFileOutputWindow is created.
- `int = obj.GetAppend ()` - Setting append will cause the log file to be opened in append mode. Otherwise, if the log file exists, it will be overwritten each time the vtkFileOutputWindow is created.
- `obj.AppendOn ()` - Setting append will cause the log file to be opened in append mode. Otherwise, if the log file exists, it will be overwritten each time the vtkFileOutputWindow is created.
- `obj.AppendOff ()` - Setting append will cause the log file to be opened in append mode. Otherwise, if the log file exists, it will be overwritten each time the vtkFileOutputWindow is created.

30.35 vtkFloatArray

30.35.1 Usage

vtkFloatArray is an array of values of type float. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkFloatArray, simply invoke its constructor as follows

```
obj = vtkFloatArray
```

30.35.2 Methods

The class vtkFloatArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFloatArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFloatArray = obj.NewInstance ()`
- `vtkFloatArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, float tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, float tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, float tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (float tuple)` - Get the data at a particular index.
- `float = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, float value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, float f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (float f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (float array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (float array, vtkIdType size, int save, int deleteMethod)`

30.36 vtkFunctionParser

30.36.1 Usage

vtkFunctionParser is a class that takes in a mathematical expression as a char string, parses it, and evaluates it at the specified values of the variables in the input string.

You can use the "if" operator to create conditional expressions such as if (test, trueresult, falseresult). These evaluate the boolean valued test expression and then evaluate either the trueresult or the falseresult

expression to produce a final (scalar or vector valued) value. "test" may contain ¡,¿,=,—,&, and () and all three subexpressions can evaluate arbitrary function operators (ln, cos, +, if, etc)

.SECTION Thanks Thomas Dunne (thomas.dunne@iwr.uni-heidelberg.de) for adding code for two-parameter-parsing and a few functions (sign, min, max).

Sid Sydoriak (sxs@lanl.gov) for adding boolean operations and conditional expressions and for fixing a variety of bugs.

To create an instance of class vtkFunctionParser, simply invoke its constructor as follows

```
obj = vtkFunctionParser
```

30.36.2 Methods

The class vtkFunctionParser has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFunctionParser class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFunctionParser = obj.NewInstance ()`
- `vtkFunctionParser = obj.SafeDownCast (vtkObject o)`
- `obj.SetFunction (string function)`
- `string = obj.GetFunction ()`
- `int = obj.IsScalarResult ()` - Check whether the result is a scalar result. If it isn't, then either the result is a vector or an error has occurred.
- `int = obj.IsVectorResult ()` - Check whether the result is a vector result. If it isn't, then either the result is scalar or an error has occurred.
- `double = obj.GetScalarResult ()` - Get a scalar result from evaluating the input function.
- `double = obj.GetVectorResult ()` - Get a vector result from evaluating the input function.
- `obj.GetVectorResult (double result[3])` - Get a vector result from evaluating the input function.
- `obj.SetScalarVariableValue (string variableName, double value)` - Set the value of a scalar variable. If a variable with this name exists, then its value will be set to the new value. If there is not already a variable with this name, variableName will be added to the list of variables, and its value will be set to the new value.
- `obj.SetScalarVariableValue (int i, double value)` - Set the value of a scalar variable. If a variable with this name exists, then its value will be set to the new value. If there is not already a variable with this name, variableName will be added to the list of variables, and its value will be set to the new value.
- `double = obj.GetScalarVariableValue (string variableName)` - Get the value of a scalar variable.
- `double = obj.GetScalarVariableValue (int i)` - Get the value of a scalar variable.
- `obj.SetVectorVariableValue (string variableName, double xValue, double yValue, double zValue)` - Set the value of a vector variable. If a variable with this name exists, then its value will be set to the new value. If there is not already a variable with this name, variableName will be added to the list of variables, and its value will be set to the new value.

- `obj.SetVectorVariableValue (string variableName, double values[3])` - Set the value of a vector variable. If a variable with this name exists, then its value will be set to the new value. If there is not already a variable with this name, variableName will be added to the list of variables, and its value will be set to the new value.
- `obj.SetVectorVariableValue (int i, double xValue, double yValue, double zValue)` - Set the value of a vector variable. If a variable with this name exists, then its value will be set to the new value. If there is not already a variable with this name, variableName will be added to the list of variables, and its value will be set to the new value.
- `obj.SetVectorVariableValue (int i, double values[3])` - Set the value of a vector variable. If a variable with this name exists, then its value will be set to the new value. If there is not already a variable with this name, variableName will be added to the list of variables, and its value will be set to the new value.
- `double = obj.GetVectorVariableValue (string variableName)` - Get the value of a vector variable.
- `obj.GetVectorVariableValue (string variableName, double value[3])` - Get the value of a vector variable.
- `double = obj.GetVectorVariableValue (int i)` - Get the value of a vector variable.
- `obj.GetVectorVariableValue (int i, double value[3])` - Get the value of a vector variable.
- `int = obj.GetNumberOfScalarVariables ()` - Get the number of scalar variables.
- `int = obj.GetNumberOfVectorVariables ()` - Get the number of vector variables.
- `string = obj.GetScalarVariableName (int i)` - Get the ith scalar variable name.
- `string = obj.GetVectorVariableName (int i)` - Get the ith vector variable name.
- `obj.RemoveAllVariables ()` - Remove all the current variables.
- `obj.RemoveScalarVariables ()` - Remove all the scalar variables.
- `obj.RemoveVectorVariables ()` - Remove all the vector variables.
- `obj.SetReplaceInvalidValues (int )` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `int = obj.GetReplaceInvalidValues ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `obj.ReplaceInvalidValuesOn ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `obj.ReplaceInvalidValuesOff ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `obj.SetReplacementValue (double )` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported
- `double = obj.GetReplacementValue ()` - When ReplaceInvalidValues is on, all invalid values (such as sqrt(-2), note that function parser does not handle complex numbers) will be replaced by ReplacementValue. Otherwise an error will be reported

30.37 vtkFunctionSet

30.37.1 Usage

vtkFunctionSet specifies an abstract interface for set of functions of the form F_i = F_i(x_j) where F (with i=1..m) are the functions and x (with j=1..n) are the independent variables. The only supported operation is the function evaluation at x_j.

To create an instance of class vtkFunctionSet, simply invoke its constructor as follows

```
obj = vtkFunctionSet
```

30.37.2 Methods

The class vtkFunctionSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFunctionSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFunctionSet = obj.NewInstance ()`
- `vtkFunctionSet = obj.SafeDownCast (vtkObject o)`
- `int = obj.FunctionValues (double x, double f)` - Evaluate functions at x_j. x and f have to point to valid double arrays of appropriate sizes obtained with GetNumberOfFunctions() and GetNumberOfIndependentVariables.
- `int = obj.GetNumberOfFunctions ()` - Return the number of independent variables. Note that this is constant for a given type of set of functions and can not be changed at run time.
- `int = obj.GetNumberOfIndependentVariables ()`

30.38 vtkGarbageCollector

30.38.1 Usage

vtkGarbageCollector is used by VTK classes that may be involved in reference counting loops (such as Algorithm ¡-¿ Executive). It detects strongly connected components of the reference graph that have been leaked deletes them. The garbage collector uses the ReportReferences method to search the reference graph and construct a net reference count for each connected component. If the net reference count is zero the entire set of objects is deleted. Deleting each component may leak other components, which are then collected recursively.

To enable garbage collection for a class, add these members:

```
public:
 virtual void Register(vtkObjectBase* o)
   {
   this->RegisterInternal(o, 1);
   }
 virtual void UnRegister(vtkObjectBase* o)
   {
   this->UnRegisterInternal(o, 1);
   }
```

```
protected:

 virtual void ReportReferences(vtkGarbageCollector* collector)
   {
   // Report references held by this object that may be in a loop.
   this->Superclass::ReportReferences(collector);
   vtkGarbageCollectorReport(collector, this->OtherObject, ''Other Object'');
   }
```

The implementations should be in the .cxx file in practice. It is important that the reference be reported using the real pointer or smart pointer instance that holds the reference. When collecting the garbage collector will actually set this pointer to NULL. The destructor of the class should be written to deal with this. It is also expected that an invariant is maintained for any reference that is reported. The variable holding the reference must always either be NULL or refer to a fully constructed valid object. Therefore code like "this-¿Object-¿UnRegister(this)" must be avoided if "this-¿Object" is a reported reference because it is possible that the object is deleted before UnRegister returns but then "this-¿Object" will be left as a dangling pointer. Instead use code like

```
vtkObjectBase* obj = this->Object;
this->Object = 0;
obj->UnRegister(this);
```

so that the reported reference maintains the invariant.

If subclassing from a class that already supports garbage collection, one need only provide the ReportReferences method.

To create an instance of class vtkGarbageCollector, simply invoke its constructor as follows

```
obj = vtkGarbageCollector
```

30.38.2 Methods

The class vtkGarbageCollector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGarbageCollector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGarbageCollector = obj.NewInstance ()`
- `vtkGarbageCollector = obj.SafeDownCast (vtkObject o)`

30.39 vtkGaussianRandomSequence

30.39.1 Usage

vtkGaussianRandomSequence is a sequence of pseudo random numbers distributed according to the Gaussian/normal distribution (mean=0 and standard deviation=1)

This is just an interface.

To create an instance of class vtkGaussianRandomSequence, simply invoke its constructor as follows

```
obj = vtkGaussianRandomSequence
```

30.39.2 Methods

The class vtkGaussianRandomSequence has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGaussianRandomSequence class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGaussianRandomSequence = obj.NewInstance ()`
- `vtkGaussianRandomSequence = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetScaledValue (double mean, double standardDeviation)` - Convenient method to return a value given the mean and standard deviation of the Gaussian distribution from the the Gaussian distribution of mean=0 and standard deviation=1.0. There is an initial implementation that can be overridden by a subclass.

30.40 vtkGeneralTransform

30.40.1 Usage

vtkGeneralTransform is like vtkTransform and vtkPerspectiveTransform, but it will work with any vtkAbstractTransform as input. It is not as efficient as the other two, however, because arbitrary transformations cannot be concatenated by matrix multiplication. Transform concatenation is simulated by passing each input point through each transform in turn.

To create an instance of class vtkGeneralTransform, simply invoke its constructor as follows

```
obj = vtkGeneralTransform
```

30.40.2 Methods

The class vtkGeneralTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeneralTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeneralTransform = obj.NewInstance ()`
- `vtkGeneralTransform = obj.SafeDownCast (vtkObject o)`
- `obj.Identity ()` - Set this transformation to the identity transformation. If the transform has an Input, then the transformation will be reset so that it is the same as the Input.
- `obj.Inverse ()` - Invert the transformation. This will also set a flag so that the transformation will use the inverse of its Input, if an Input has been set.
- `obj.Translate (double x, double y, double z)` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Translate (double x[3])` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.

- `obj.Translate (float x[3])` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.RotateWXYZ (double angle, double x, double y, double z)` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateWXYZ (double angle, double axis[3])` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateWXYZ (double angle, float axis[3])` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateX (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.RotateY (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.RotateZ (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.Scale (double x, double y, double z)` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Scale (double s[3])` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Scale (float s[3])` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (vtkMatrix4x4 matrix)` - Concatenates the matrix with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (double elements[16])` - Concatenates the matrix with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (vtkAbstractTransform transform)` - Concatenate the specified transform with the current transformation according to PreMultiply or PostMultiply semantics. The concatenation is pipelined, meaning that if any of the transformations are changed, even after Concatenate() is called, those changes will be reflected when you call TransformPoint().
- `obj.PreMultiply ()` - Sets the internal state of the transform to PreMultiply. All subsequent operations will occur before those already represented in the current transformation. In homogeneous matrix notation, M = M*A where M is the current transformation matrix and A is the applied matrix. The default is PreMultiply.
- `obj.PostMultiply ()` - Sets the internal state of the transform to PostMultiply. All subsequent operations will occur after those already represented in the current transformation. In homogeneous matrix notation, M = A*M where M is the current transformation matrix and A is the applied matrix. The default is PreMultiply.
- `int = obj.GetNumberOfConcatenatedTransforms ()` - Get the total number of transformations that are linked into this one via Concatenate() operations or via SetInput().

- `vtkAbstractTransform = obj.GetConcatenatedTransform (int i)`
- `obj.SetInput (vtkAbstractTransform input)` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.
- `vtkAbstractTransform = obj.GetInput ()` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.
- `int = obj.GetInverseFlag ()` - Get the inverse flag of the transformation. This controls whether it is the Input or the inverse of the Input that is used as the base transformation. The InverseFlag is flipped every time Inverse() is called. The InverseFlag is off when a transform is first created.
- `obj.Push ()` - Pushes the current transformation onto the transformation stack.
- `obj.Pop ()` - Deletes the transformation on the top of the stack and sets the top to the next transformation on the stack.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `int = obj.CircuitCheck (vtkAbstractTransform transform)` - Check for self-reference. Will return true if concatenating with the specified transform, setting it to be our inverse, or setting it to be our input will create a circular reference. CircuitCheck is automatically called by SetInput(), SetInverse(), and Concatenate(vtkXTransform *). Avoid using this function, it is experimental.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.
- `long = obj.GetMTime ()` - Override GetMTime to account for input and concatenation.

30.41 vtkHeap

30.41.1 Usage

This class is a replacement for malloc/free and new/delete for software that has inherent memory leak or performance problems. For example, external software such as the PLY library (vtkPLY) and VRML importer (vtkVRMLImporter) are often written with lots of malloc() calls but without the corresponding free() invocations. The class vtkOrderedTriangulator may create and delete millions of new/delete calls. This class allows the overloading of the C++ new operator (or other memory allocation requests) by using the method AllocateMemory(). Memory is deleted with an invocation of CleanAll() (which deletes ALL memory; any given memory allocation cannot be deleted). Note: a block size can be used to control the size of each memory allocation. Requests for memory are fulfilled from the block until the block runs out, then a new block is created.

To create an instance of class vtkHeap, simply invoke its constructor as follows

```
obj = vtkHeap
```

30.41.2 Methods

The class vtkHeap has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHeap class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHeap = obj.NewInstance ()`
- `vtkHeap = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfBlocks ()` - Get the number of allocations thus far.
- `int = obj.GetNumberOfAllocations ()` - Get the number of allocations thus far.
- `obj.Reset ()` - This methods resets the current allocation location back to the beginning of the heap. This allows reuse of previously allocated memory which may be beneficial to performance in many cases.
- `string = obj.StringDup (string str)` - Convenience method performs string duplication.

30.42 vtkHomogeneousTransform

30.42.1 Usage

vtkHomogeneousTransform provides a generic interface for homogeneous transformations, i.e. transformations which can be represented by multiplying a 4x4 matrix with a homogeneous coordinate.

To create an instance of class vtkHomogeneousTransform, simply invoke its constructor as follows

```
obj = vtkHomogeneousTransform
```

30.42.2 Methods

The class vtkHomogeneousTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHomogeneousTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHomogeneousTransform = obj.NewInstance ()`
- `vtkHomogeneousTransform = obj.SafeDownCast (vtkObject o)`
- `obj.TransformPoints (vtkPoints inPts, vtkPoints outPts)` - Apply the transformation to a series of points, and append the results to outPts.
- `obj.TransformPointsNormalsVectors (vtkPoints inPts, vtkPoints outPts, vtkDataArray inNms, vtkDataAr` - Apply the transformation to a combination of points, normals and vectors.
- `obj.GetMatrix (vtkMatrix4x4 m)` - Get a copy of the internal transformation matrix. The transform is Updated first, to guarantee that the matrix is valid.
- `vtkMatrix4x4 = obj.GetMatrix ()` - Get a pointer to an internal vtkMatrix4x4 that represents the transformation. An Update() is called on the transform to ensure that the matrix is up-to-date when you get it. You should not store the matrix pointer anywhere because it might become stale.

- `vtkHomogeneousTransform = obj.GetHomogeneousInverse ()` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.

30.43 vtkIdentityTransform

30.43.1 Usage

vtkIdentityTransform is a transformation which will simply pass coordinate data unchanged. All other transform types can also do this, however, the vtkIdentityTransform does so with much greater efficiency.

To create an instance of class vtkIdentityTransform, simply invoke its constructor as follows

```
obj = vtkIdentityTransform
```

30.43.2 Methods

The class vtkIdentityTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIdentityTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIdentityTransform = obj.NewInstance ()`
- `vtkIdentityTransform = obj.SafeDownCast (vtkObject o)`
- `obj.TransformPoints (vtkPoints inPts, vtkPoints outPts)` - Apply the transformation to a series of points, and append the results to outPts.
- `obj.TransformNormals (vtkDataArray inNms, vtkDataArray outNms)` - Apply the transformation to a series of normals, and append the results to outNms.
- `obj.TransformVectors (vtkDataArray inVrs, vtkDataArray outVrs)` - Apply the transformation to a series of vectors, and append the results to outVrs.
- `obj.TransformPointsNormalsVectors (vtkPoints inPts, vtkPoints outPts, vtkDataArray inNms, vtkDataAr` - Apply the transformation to a combination of points, normals and vectors.
- `obj.Inverse ()`
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformNormal (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformNormal (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.

- `obj.InternalTransformVector (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformVector (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make a transform of the same type. This will actually return the same transform.

30.44 vtkIdList

30.44.1 Usage

vtkIdList is used to represent and pass data id's between objects. vtkIdList may represent any type of integer id, but usually represents point and cell ids.

To create an instance of class vtkIdList, simply invoke its constructor as follows

```
obj = vtkIdList
```

30.44.2 Methods

The class vtkIdList has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIdList class.

- `obj.Initialize ()`
- `int = obj.Allocate (vtkIdType sz, int strategy)`
- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIdList = obj.NewInstance ()`
- `vtkIdList = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetNumberOfIds ()` - Return the number of id's in the list.
- `vtkIdType = obj.GetId (vtkIdType i)` - Return the id at location i.
- `obj.SetNumberOfIds (vtkIdType number)` - Specify the number of ids for this object to hold. Does an allocation as well as setting the number of ids.
- `obj.SetId (vtkIdType i, vtkIdType vtkid)` - Set the id at location i. Doesn't do range checking so it's a bit faster than InsertId. Make sure you use SetNumberOfIds() to allocate memory prior to using SetId().
- `obj.InsertId (vtkIdType i, vtkIdType vtkid)` - Set the id at location i. Does range checking and allocates memory as necessary.
- `vtkIdType = obj.InsertNextId (vtkIdType vtkid)` - Add the id specified to the end of the list. Range checking is performed.
- `vtkIdType = obj.InsertUniqueId (vtkIdType vtkid)` - If id is not already in list, insert it and return location in list. Otherwise return just location in list.
- `vtkIdType = obj.GetPointer (vtkIdType i)` - Get a pointer to a particular data index.

- `vtkIdType = obj.WritePointer (vtkIdType i, vtkIdType number)` - Get a pointer to a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.Reset ()` - Reset to an empty state.
- `obj.Squeeze ()` - Free any unused memory.
- `obj.DeepCopy (vtkIdList ids)` - Copy an id list by explicitly copying the internal array.
- `obj.DeleteId (vtkIdType vtkid)` - Delete specified id from list. Will remove all occurrences of id in list.
- `vtkIdType = obj.IsId (vtkIdType vtkid)` - Return -1 if id specified is not contained in the list; otherwise return the position in the list.
- `obj.IntersectWith (vtkIdList \&otherIds)` - Intersect this list with another vtkIdList. Updates current list according to result of intersection operation.

30.45 vtkIdListCollection

30.45.1 Usage

vtkIdListCollection is an object that creates and manipulates lists of datasets. See also vtkCollection and subclasses.

To create an instance of class vtkIdListCollection, simply invoke its constructor as follows

```
obj = vtkIdListCollection
```

30.45.2 Methods

The class vtkIdListCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIdListCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIdListCollection = obj.NewInstance ()`
- `vtkIdListCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkIdList ds)` - Get the next dataset in the list.
- `vtkIdList = obj.GetNextItem ()` - Get the next dataset in the list.
- `vtkIdList = obj.GetItem (int i)` - Get the ith dataset in the list.

30.46 vtkIdTypeArray

30.46.1 Usage

vtkIdTypeArray is an array of values of type vtkIdType. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkIdTypeArray, simply invoke its constructor as follows

```
obj = vtkIdTypeArray
```

30.46.2 Methods

The class vtkIdTypeArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIdTypeArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIdTypeArray = obj.NewInstance ()`
- `vtkIdTypeArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `vtkIdType = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, vtkIdType value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, vtkIdType f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (vtkIdType f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `vtkIdType = obj.WritePointer (vtkIdType id, vtkIdType number)` - Get the address of a particular data index. Performs no checks to verify that the memory has been allocated etc.
- `vtkIdType = obj.GetPointer (vtkIdType id)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.

30.47 vtkImplicitFunction

30.47.1 Usage

vtkImplicitFunction specifies an abstract interface for implicit functions. Implicit functions are real valued functions defined in 3D space, w = F(x,y,z). Two primitive operations are required: the ability to evaluate the function, and the function gradient at a given point. The implicit function divides space into three regions: on the surface (F(x,y,z)=w), outside of the surface (F(x,y,z)¿c), and inside the surface (F(x,y,z)¡c). (When c is zero, positive values are outside, negative values are inside, and zero is on the surface. Note also that the function gradient points from inside to outside.)

Implicit functions are very powerful. It is possible to represent almost any type of geometry with the level sets w = const, especially if you use boolean combinations of implicit functions (see vtkImplicitBoolean).

vtkImplicitFunction provides a mechanism to transform the implicit function(s) via a vtkAbstractTransform. This capability can be used to translate, orient, scale, or warp implicit functions. For example, a sphere implicit function can be transformed into an oriented ellipse.

To create an instance of class vtkImplicitFunction, simply invoke its constructor as follows

```
obj = vtkImplicitFunction
```

30.47.2 Methods

The class vtkImplicitFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitFunction = obj.NewInstance ()`
- `vtkImplicitFunction = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Overload standard modified time function. If Transform is modified, then this object is modified as well.
- `double = obj.FunctionValue (double x[3])` - Evaluate function at position x-y-z and return value. Point x[3] is transformed through transform (if provided).
- `double = obj.FunctionValue (double x, double y, double z)` - Evaluate function at position x-y-z and return value. Point x[3] is transformed through transform (if provided).
- `obj.FunctionGradient (double x[3], double g[3])` - Evaluate function gradient at position x-y-z and pass back vector. Point x[3] is transformed through transform (if provided).
- `double = obj.FunctionGradient (double x[3])` - Evaluate function gradient at position x-y-z and pass back vector. Point x[3] is transformed through transform (if provided).
- `double = obj.FunctionGradient (double x, double y, double z)` - Evaluate function gradient at position x-y-z and pass back vector. Point x[3] is transformed through transform (if provided).
- `obj.SetTransform (vtkAbstractTransform )` - Set/Get a transformation to apply to input points before executing the implicit function.
- `obj.SetTransform (double elements[16])` - Set/Get a transformation to apply to input points before executing the implicit function.
- `vtkAbstractTransform = obj.GetTransform ()` - Set/Get a transformation to apply to input points before executing the implicit function.
- `double = obj.EvaluateFunction (double x[3])` - Evaluate function at position x-y-z and return value. You should generally not call this method directly, you should use FunctionValue() instead. This method must be implemented by any derived class.
- `double = obj.EvaluateFunction (double x, double y, double z)` - Evaluate function at position x-y-z and return value. You should generally not call this method directly, you should use FunctionValue() instead. This method must be implemented by any derived class.
- `obj.EvaluateGradient (double x[3], double g[3])` - Evaluate function gradient at position x-y-z and pass back vector. You should generally not call this method directly, you should use FunctionGradient() instead. This method must be implemented by any derived class.

30.48 vtkImplicitFunctionCollection

30.48.1 Usage

vtkImplicitFunctionCollection is an object that creates and manipulates lists of objects of type vtkImplicitFunction.

To create an instance of class vtkImplicitFunctionCollection, simply invoke its constructor as follows

```
obj = vtkImplicitFunctionCollection
```

30.48.2 Methods

The class vtkImplicitFunctionCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitFunctionCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitFunctionCollection = obj.NewInstance ()`
- `vtkImplicitFunctionCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkImplicitFunction )` - Add an implicit function to the list.
- `vtkImplicitFunction = obj.GetNextItem ()` - Get the next implicit function in the list.

30.49 vtkInformation

30.49.1 Usage

vtkInformation represents information and/or data for one input or one output of a vtkAlgorithm. It maps from keys to values of several data types. Instances of this class are collected in vtkInformationVector instances and passed to vtkAlgorithm::ProcessRequest calls. The information and data referenced by the instance on a particular input or output define the request made to the vtkAlgorithm instance.

To create an instance of class vtkInformation, simply invoke its constructor as follows

```
obj = vtkInformation
```

30.49.2 Methods

The class vtkInformation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformation = obj.NewInstance ()`
- `vtkInformation = obj.SafeDownCast (vtkObject o)`
- `obj.Modified ()` - Modified signature with no arguments that calls Modified on vtkObject superclass.
- `obj.Modified (vtkInformationKey key)` - Modified signature that takes an information key as an argument. Sets the new MTime and invokes a modified event with the information key as call data.
- `obj.Clear ()` - Clear all information entries.
- `int = obj.GetNumberOfKeys ()` - Return the number of keys in this information object (as would be returned by iterating over the keys).
- `obj.Copy (vtkInformation from, int deep)` - Copy all information entries from the given vtkInformation instance. Any previously existing entries are removed. If deep==1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).

- `obj.CopyEntry (vtkInformation from, vtkInformationKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationDataObjectKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationDoubleVectorKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationInformationKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationInformationVectorKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationIntegerKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationIntegerVectorKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationRequestKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationStringKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationStringVectorKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntry (vtkInformation from, vtkInformationUnsignedLongKey key, int deep)` - Copy the key/value pair associated with the given key in the given information object. If deep=1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.CopyEntries (vtkInformation from, vtkInformationKeyVectorKey key, int deep)` - Use the given key to lookup a list of other keys in the given information object. The key/value pairs associated with these other keys will be copied. If deep==1, a deep copy of the information structure is performed.

- `int = obj.Has (vtkInformationKey key)` - Check whether the given key appears in this information object.
- `obj.Remove (vtkInformationKey key)` - Remove the given key and its data from this information object.
- `obj.Set (vtkInformationRequestKey key)` - Get/Set a request-valued entry.
- `obj.Remove (vtkInformationRequestKey key)` - Get/Set a request-valued entry.
- `int = obj.Has (vtkInformationRequestKey key)` - Get/Set a request-valued entry.
- `obj.Set (vtkInformationIntegerKey key, int value)` - Get/Set an integer-valued entry.
- `int = obj.Get (vtkInformationIntegerKey key)` - Get/Set an integer-valued entry.
- `obj.Remove (vtkInformationIntegerKey key)` - Get/Set an integer-valued entry.
- `int = obj.Has (vtkInformationIntegerKey key)` - Get/Set an integer-valued entry.
- `obj.Set (vtkInformationIdTypeKey key, vtkIdType value)` - Get/Set a vtkIdType-valued entry.
- `vtkIdType = obj.Get (vtkInformationIdTypeKey key)` - Get/Set a vtkIdType-valued entry.
- `obj.Remove (vtkInformationIdTypeKey key)` - Get/Set a vtkIdType-valued entry.
- `int = obj.Has (vtkInformationIdTypeKey key)` - Get/Set a vtkIdType-valued entry.
- `obj.Set (vtkInformationDoubleKey key, double value)` - Get/Set an double-valued entry.
- `double = obj.Get (vtkInformationDoubleKey key)` - Get/Set an double-valued entry.
- `obj.Remove (vtkInformationDoubleKey key)` - Get/Set an double-valued entry.
- `int = obj.Has (vtkInformationDoubleKey key)` - Get/Set an double-valued entry.
- `obj.Append (vtkInformationIntegerVectorKey key, int value)` - Get/Set an integer-vector-valued entry.
- `obj.Set (vtkInformationIntegerVectorKey key, int value, int length)` - Get/Set an integer-vector-valued entry.
- `obj.Set (vtkInformationIntegerVectorKey key, int value1, int value2, int value3)` - Get/Set an integer-vector-valued entry.
- `obj.Set (vtkInformationIntegerVectorKey key, int value1, int value2, int value3, int value4, int va` - Get/Set an integer-vector-valued entry.
- `int = obj.Get (vtkInformationIntegerVectorKey key, int idx)` - Get/Set an integer-vector-valued entry.
- `obj.Get (vtkInformationIntegerVectorKey key, int value)` - Get/Set an integer-vector-valued entry.
- `int = obj.Length (vtkInformationIntegerVectorKey key)` - Get/Set an integer-vector-valued entry.
- `obj.Remove (vtkInformationIntegerVectorKey key)` - Get/Set an integer-vector-valued entry.
- `int = obj.Has (vtkInformationIntegerVectorKey key)` - Get/Set an integer-vector-valued entry.
- `obj.Append (vtkInformationStringVectorKey key, string value)` - Get/Set a string-vector-valued entry.

- `obj.Set (vtkInformationStringVectorKey key, string value, int idx)` - Get/Set a string-vector-valued entry.
- `string = obj.Get (vtkInformationStringVectorKey key, int idx)` - Get/Set a string-vector-valued entry.
- `int = obj.Length (vtkInformationStringVectorKey key)` - Get/Set a string-vector-valued entry.
- `obj.Remove (vtkInformationStringVectorKey key)` - Get/Set a string-vector-valued entry.
- `int = obj.Has (vtkInformationStringVectorKey key)` - Get/Set a string-vector-valued entry.
- `obj.Set (vtkInformationIntegerPointerKey key, int value, int length)` - Get/Set an integer-pointer-valued entry.
- `obj.Get (vtkInformationIntegerPointerKey key, int value)` - Get/Set an integer-pointer-valued entry.
- `int = obj.Length (vtkInformationIntegerPointerKey key)` - Get/Set an integer-pointer-valued entry.
- `obj.Remove (vtkInformationIntegerPointerKey key)` - Get/Set an integer-pointer-valued entry.
- `int = obj.Has (vtkInformationIntegerPointerKey key)` - Get/Set an integer-pointer-valued entry.
- `obj.Set (vtkInformationUnsignedLongKey key, long value)` - Get/Set an unsigned-long-valued entry.
- `long = obj.Get (vtkInformationUnsignedLongKey key)` - Get/Set an unsigned-long-valued entry.
- `obj.Remove (vtkInformationUnsignedLongKey key)` - Get/Set an unsigned-long-valued entry.
- `int = obj.Has (vtkInformationUnsignedLongKey key)` - Get/Set an unsigned-long-valued entry.
- `obj.Append (vtkInformationDoubleVectorKey key, double value)` - Get/Set an double-vector-valued entry.
- `obj.Set (vtkInformationDoubleVectorKey key, double value, int length)` - Get/Set an double-vector-valued entry.
- `obj.Set (vtkInformationDoubleVectorKey key, double value1, double value2, double value3)` - Get/Set an double-vector-valued entry.
- `obj.Set (vtkInformationDoubleVectorKey key, double value1, double value2, double value3, double val` - Get/Set an double-vector-valued entry.
- `double = obj.Get (vtkInformationDoubleVectorKey key, int idx)` - Get/Set an double-vector-valued entry.
- `obj.Get (vtkInformationDoubleVectorKey key, double value)` - Get/Set an double-vector-valued entry.
- `int = obj.Length (vtkInformationDoubleVectorKey key)` - Get/Set an double-vector-valued entry.
- `obj.Remove (vtkInformationDoubleVectorKey key)` - Get/Set an double-vector-valued entry.
- `int = obj.Has (vtkInformationDoubleVectorKey key)` - Get/Set an double-vector-valued entry.
- `obj.Append (vtkInformationKeyVectorKey key, vtkInformationKey value)` - Get/Set an InformationKey-vector-valued entry.

- `obj.AppendUnique (vtkInformationKeyVectorKey key, vtkInformationKey value)` - Get/Set an InformationKey-vector-valued entry.
- `obj.Remove (vtkInformationKeyVectorKey key, vtkInformationKey value)` - Get/Set an InformationKey-vector-valued entry.
- `vtkInformationKey = obj.Get (vtkInformationKeyVectorKey key, int idx)` - Get/Set an InformationKey-vector-valued entry.
- `int = obj.Length (vtkInformationKeyVectorKey key)` - Get/Set an InformationKey-vector-valued entry.
- `obj.Remove (vtkInformationKeyVectorKey key)` - Get/Set an InformationKey-vector-valued entry.
- `int = obj.Has (vtkInformationKeyVectorKey key)` - Get/Set an InformationKey-vector-valued entry.
- `obj.Set (vtkInformationStringKey key, string )` - Get/Set a string-valued entry.
- `string = obj.Get (vtkInformationStringKey key)` - Get/Set a string-valued entry.
- `obj.Remove (vtkInformationStringKey key)` - Get/Set a string-valued entry.
- `int = obj.Has (vtkInformationStringKey key)` - Get/Set a string-valued entry.
- `obj.Set (vtkInformationInformationKey key, vtkInformation )` - Get/Set an entry storing another vtkInformation instance.
- `vtkInformation = obj.Get (vtkInformationInformationKey key)` - Get/Set an entry storing another vtkInformation instance.
- `obj.Remove (vtkInformationInformationKey key)` - Get/Set an entry storing another vtkInformation instance.
- `int = obj.Has (vtkInformationInformationKey key)` - Get/Set an entry storing another vtkInformation instance.
- `obj.Set (vtkInformationInformationVectorKey key, vtkInformationVector )` - Get/Set an entry storing a vtkInformationVector instance.
- `vtkInformationVector = obj.Get (vtkInformationInformationVectorKey key)` - Get/Set an entry storing a vtkInformationVector instance.
- `obj.Remove (vtkInformationInformationVectorKey key)` - Get/Set an entry storing a vtkInformationVector instance.
- `int = obj.Has (vtkInformationInformationVectorKey key)` - Get/Set an entry storing a vtkInformationVector instance.
- `obj.Set (vtkInformationObjectBaseKey key, vtkObjectBase )` - Get/Set an entry storing a vtkObjectBase instance.
- `vtkObjectBase = obj.Get (vtkInformationObjectBaseKey key)` - Get/Set an entry storing a vtkObjectBase instance.
- `obj.Remove (vtkInformationObjectBaseKey key)` - Get/Set an entry storing a vtkObjectBase instance.
- `int = obj.Has (vtkInformationObjectBaseKey key)` - Get/Set an entry storing a vtkObjectBase instance.

- `obj.Set (vtkInformationDataObjectKey key, vtkDataObject )` - Get/Set an entry storing a vtkDataObject instance.
- `vtkDataObject = obj.Get (vtkInformationDataObjectKey key)` - Get/Set an entry storing a vtkDataObject instance.
- `obj.Remove (vtkInformationDataObjectKey key)` - Get/Set an entry storing a vtkDataObject instance.
- `int = obj.Has (vtkInformationDataObjectKey key)` - Get/Set an entry storing a vtkDataObject instance.
- `obj.Register (vtkObjectBase o)` - Initiate garbage collection when a reference is removed.
- `obj.UnRegister (vtkObjectBase o)` - Initiate garbage collection when a reference is removed.
- `obj.SetRequest (vtkInformationRequestKey request)` - Get/Set the Request ivar
- `vtkInformationRequestKey = obj.GetRequest ()` - Get/Set the Request ivar

30.50 vtkInformationDataObjectKey

30.50.1 Usage

vtkInformationDataObjectKey is used to represent keys in vtkInformation for values that are vtkDataObject instances.

To create an instance of class vtkInformationDataObjectKey, simply invoke its constructor as follows

```
obj = vtkInformationDataObjectKey
```

30.50.2 Methods

The class vtkInformationDataObjectKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationDataObjectKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationDataObjectKey = obj.NewInstance ()`
- `vtkInformationDataObjectKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationDataObjectKey = obj.(string name, string location)`
- `~vtkInformationDataObjectKey = obj.()`
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.Report (vtkInformation info, vtkGarbageCollector collector)` - Report a reference this key has in the given information object.

30.51 vtkInformationDoubleKey

30.51.1 Usage

vtkInformationDoubleKey is used to represent keys for double values in vtkInformation.

To create an instance of class vtkInformationDoubleKey, simply invoke its constructor as follows

```
obj = vtkInformationDoubleKey
```

30.51.2 Methods

The class vtkInformationDoubleKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationDoubleKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationDoubleKey = obj.NewInstance ()`
- `vtkInformationDoubleKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationDoubleKey = obj.(string name, string location)`
- `~vtkInformationDoubleKey = obj.()`
- `obj.Set (vtkInformation info, double )` - Get/Set the value associated with this key in the given information object.
- `double = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.52 vtkInformationDoubleVectorKey

30.52.1 Usage

vtkInformationDoubleVectorKey is used to represent keys for double vector values in vtkInformation.h

To create an instance of class vtkInformationDoubleVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationDoubleVectorKey
```

30.52.2 Methods

The class vtkInformationDoubleVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationDoubleVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationDoubleVectorKey = obj.NewInstance ()`

- `vtkInformationDoubleVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationDoubleVectorKey = obj.(string name, string location, int length)`
- `~vtkInformationDoubleVectorKey = obj.()`
- `obj.Append (vtkInformation info, double value)` - Get/Set the value associated with this key in the given information object.
- `obj.Set (vtkInformation info, double value, int length)` - Get/Set the value associated with this key in the given information object.
- `double = obj.Get (vtkInformation info, int idx)` - Get/Set the value associated with this key in the given information object.
- `obj.Get (vtkInformation info, double value)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Length (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.53 vtkInformationIdTypeKey

30.53.1 Usage

vtkInformationIdTypeKey is used to represent keys for vtkIdType values in vtkInformation.

To create an instance of class vtkInformationIdTypeKey, simply invoke its constructor as follows

```
obj = vtkInformationIdTypeKey
```

30.53.2 Methods

The class vtkInformationIdTypeKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationIdTypeKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationIdTypeKey = obj.NewInstance ()`
- `vtkInformationIdTypeKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationIdTypeKey = obj.(string name, string location)`
- `~vtkInformationIdTypeKey = obj.()`
- `obj.Set (vtkInformation info, vtkIdType )` - Get/Set the value associated with this key in the given information object.
- `vtkIdType = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.54 vtkInformationInformationKey

30.54.1 Usage

vtkInformationInformationKey is used to represent keys in vtkInformation for other information objects.

To create an instance of class vtkInformationInformationKey, simply invoke its constructor as follows

```
obj = vtkInformationInformationKey
```

30.54.2 Methods

The class vtkInformationInformationKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationInformationKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationInformationKey = obj.NewInstance ()`
- `vtkInformationInformationKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationInformationKey = obj.(string name, string location)`
- `~vtkInformationInformationKey = obj.()`
- `obj.Set (vtkInformation info, vtkInformation )` - Get/Set the value associated with this key in the given information object.
- `vtkInformation = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.DeepCopy (vtkInformation from, vtkInformation to)` - Duplicate (new instance created) the entry associated with this key from one information object to another (new instances of any contained vtkInformation and vtkInformationVector objects are created).

30.55 vtkInformationInformationVectorKey

30.55.1 Usage

vtkInformationInformationVectorKey is used to represent keys in vtkInformation for vectors of other vtkInformation objects.

To create an instance of class vtkInformationInformationVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationInformationVectorKey
```

30.55.2 Methods

The class vtkInformationInformationVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationInformationVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationInformationVectorKey = obj.NewInstance ()`
- `vtkInformationInformationVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationInformationVectorKey = obj.(string name, string location)`
- `~vtkInformationInformationVectorKey = obj.()`
- `obj.Set (vtkInformation info, vtkInformationVector )` - Get/Set the value associated with this key in the given information object.
- `vtkInformationVector = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.DeepCopy (vtkInformation from, vtkInformation to)` - Duplicate (new instance created) the entry associated with this key from one information object to another (new instances of any contained vtkInformation and vtkInformationVector objects are created).
- `obj.Report (vtkInformation info, vtkGarbageCollector collector)` - Report a reference this key has in the given information object.

30.56 vtkInformationIntegerKey

30.56.1 Usage

vtkInformationIntegerKey is used to represent keys for integer values in vtkInformation.

To create an instance of class vtkInformationIntegerKey, simply invoke its constructor as follows

```
obj = vtkInformationIntegerKey
```

30.56.2 Methods

The class vtkInformationIntegerKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationIntegerKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationIntegerKey = obj.NewInstance ()`
- `vtkInformationIntegerKey = obj.SafeDownCast (vtkObject o)`

- `vtkInformationIntegerKey = obj.(string name, string location)`
- `~vtkInformationIntegerKey = obj.()`
- `obj.Set (vtkInformation info, int )` - Get/Set the value associated with this key in the given information object.
- `int = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.57 vtkInformationIntegerPointerKey

30.57.1 Usage

vtkInformationIntegerPointerKey is used to represent keys for pointer to integer values in vtkInformation.h
To create an instance of class vtkInformationIntegerPointerKey, simply invoke its constructor as follows

```
obj = vtkInformationIntegerPointerKey
```

30.57.2 Methods

The class vtkInformationIntegerPointerKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationIntegerPointerKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationIntegerPointerKey = obj.NewInstance ()`
- `vtkInformationIntegerPointerKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationIntegerPointerKey = obj.(string name, string location, int length)`
- `~vtkInformationIntegerPointerKey = obj.()`
- `obj.Set (vtkInformation info, int value, int length)` - Get/Set the value associated with this key in the given information object.
- `obj.Get (vtkInformation info, int value)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Length (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.58 vtkInformationIntegerVectorKey

30.58.1 Usage

vtkInformationIntegerVectorKey is used to represent keys for integer vector values in vtkInformation.h

To create an instance of class vtkInformationIntegerVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationIntegerVectorKey
```

30.58.2 Methods

The class vtkInformationIntegerVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationIntegerVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationIntegerVectorKey = obj.NewInstance ()`
- `vtkInformationIntegerVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationIntegerVectorKey = obj.(string name, string location, int length)`
- `~vtkInformationIntegerVectorKey = obj.()`
- `obj.Append (vtkInformation info, int value)` - Get/Set the value associated with this key in the given information object.
- `obj.Set (vtkInformation info, int value, int length)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Get (vtkInformation info, int idx)` - Get/Set the value associated with this key in the given information object.
- `obj.Get (vtkInformation info, int value)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Length (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.59 vtkInformationIterator

30.59.1 Usage

vtkInformationIterator can be used to iterate over the keys of an information object. The corresponding values can then be directly obtained from the information object using the keys.

To create an instance of class vtkInformationIterator, simply invoke its constructor as follows

```
obj = vtkInformationIterator
```

30.59.2 Methods

The class vtkInformationIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationIterator = obj.NewInstance ()`
- `vtkInformationIterator = obj.SafeDownCast (vtkObject o)`
- `obj.SetInformation (vtkInformation )` - Set/Get the information to iterator over.
- `vtkInformation = obj.GetInformation ()` - Set/Get the information to iterator over.
- `obj.InitTraversal ()` - Move the iterator to the beginning of the collection.
- `obj.GoToFirstItem ()` - Move the iterator to the beginning of the collection.
- `obj.GoToNextItem ()` - Move the iterator to the next item in the collection.
- `int = obj.IsDoneWithTraversal ()` - Test whether the iterator is currently pointing to a valid item. Returns 1 for yes, 0 for no.
- `vtkInformationKey = obj.GetCurrentKey ()` - Get the current item. Valid only when IsDoneWith-Traversal() returns 1.

30.60 vtkInformationKey

30.60.1 Usage

vtkInformationKey is the superclass for all keys used to access the map represented by vtkInformation. The vtkInformation::Set and vtkInformation::Get methods of vtkInformation are accessed by information keys. A key is a pointer to an instance of a subclass of vtkInformationKey. The type of the subclass determines the overload of Set/Get that is selected. This ensures that the type of value stored in a vtkInformation instance corresponding to a given key matches the type expected for that key.

To create an instance of class vtkInformationKey, simply invoke its constructor as follows

```
obj = vtkInformationKey
```

30.60.2 Methods

The class vtkInformationKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationKey = obj.NewInstance ()`
- `vtkInformationKey = obj.SafeDownCast (vtkObject o)`
- `obj.Register (vtkObjectBase )` - Prevent normal vtkObject reference counting behavior.

- `obj.UnRegister (vtkObjectBase )` - Prevent normal vtkObject reference counting behavior.
- `string = obj.GetName ()` - Get the name of the key. This is not the type of the key, but the name of the key instance.
- `string = obj.GetLocation ()` - Get the location of the key. This is the name of the class in which the key is defined.
- `vtkInformationKey = obj.(string name, string location)` - Key instances are static data that need to be created and destroyed. The constructor and destructor must be public. The name of the static instance and the class in which it is defined should be passed to the constructor. They must be string literals because the strings are not copied.
- `~vtkInformationKey = obj.()` - Key instances are static data that need to be created and destroyed. The constructor and destructor must be public. The name of the static instance and the class in which it is defined should be passed to the constructor. They must be string literals because the strings are not copied.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.DeepCopy (vtkInformation from, vtkInformation to)` - Check whether this key appears in the given information object.
- `int = obj.Has (vtkInformation info)` - Check whether this key appears in the given information object.
- `obj.Remove (vtkInformation info)` - Remove this key from the given information object.
- `obj.Report (vtkInformation info, vtkGarbageCollector collector)` - Report a reference this key has in the given information object.

30.61 vtkInformationKeyVectorKey

30.61.1 Usage

vtkInformationKeyVectorKey is used to represent keys for vector-of-keys values in vtkInformation.

To create an instance of class vtkInformationKeyVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationKeyVectorKey
```

30.61.2 Methods

The class vtkInformationKeyVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationKeyVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationKeyVectorKey = obj.NewInstance ()`
- `vtkInformationKeyVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationKeyVectorKey = obj.(string name, string location)`
- `~vtkInformationKeyVectorKey = obj.()`

- `obj.Append (vtkInformation info, vtkInformationKey value)` - Get/Set the value associated with this key in the given information object.
- `obj.AppendUnique (vtkInformation info, vtkInformationKey value)` - Get/Set the value associated with this key in the given information object.
- `obj.RemoveItem (vtkInformation info, vtkInformationKey value)` - Get/Set the value associated with this key in the given information object.
- `vtkInformationKey = obj.Get (vtkInformation info, int idx)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Length (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.62 vtkInformationObjectBaseKey

30.62.1 Usage

vtkInformationObjectBaseKey is used to represent keys in vtkInformation for values that are vtkObjectBase instances.

To create an instance of class vtkInformationObjectBaseKey, simply invoke its constructor as follows

```
obj = vtkInformationObjectBaseKey
```

30.62.2 Methods

The class vtkInformationObjectBaseKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationObjectBaseKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationObjectBaseKey = obj.NewInstance ()`
- `vtkInformationObjectBaseKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationObjectBaseKey = obj.(string name, string location, string requiredClass)`
- `~vtkInformationObjectBaseKey = obj.()`
- `obj.Set (vtkInformation info, vtkObjectBase )` - Get/Set the value associated with this key in the given information object.
- `vtkObjectBase = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.Report (vtkInformation info, vtkGarbageCollector collector)` - Report a reference this key has in the given information object.

30.63 vtkInformationObjectBaseVectorKey

30.63.1 Usage

vtkInformationObjectBaseVectorKey is used to represent keys for double vector values in vtkInformation.h. NOTE the interface in this key differs from that in other similar keys because of our internal use of smart pointers.

To create an instance of class vtkInformationObjectBaseVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationObjectBaseVectorKey
```

30.63.2 Methods

The class vtkInformationObjectBaseVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationObjectBaseVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationObjectBaseVectorKey = obj.NewInstance ()`
- `vtkInformationObjectBaseVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationObjectBaseVectorKey = obj.(string name, string location, string requiredClass)` - The name of the static instance and the class in which it is defined(location) should be passed to the constructor. Providing "requiredClass" name one can insure that only objects of type "requiredClass" are stored in vectors associated with the instance of this key type created. These should be string literals as they are not coppied.
- `~vtkInformationObjectBaseVectorKey = obj.()` - The name of the static instance and the class in which it is defined(location) should be passed to the constructor. Providing "requiredClass" name one can insure that only objects of type "requiredClass" are stored in vectors associated with the instance of this key type created. These should be string literals as they are not coppied.
- `obj.Clear (vtkInformation info)` - Clear the vector.
- `obj.Resize (vtkInformation info, int n)` - Resize (extend) the vector to hold n objects. Any new elements created will be null initialized.
- `int = obj.Size (vtkInformation info)` - Get the vector's length.
- `int = obj.Length (vtkInformation info)` - Put the value on the back of the vector, with ref counting.
- `obj.Append (vtkInformation info, vtkObjectBase value)` - Put the value on the back of the vector, with ref counting.
- `obj.Set (vtkInformation info, vtkObjectBase value, int i)` - Set element i of the vector to value. Resizes the vector if needed.
- `vtkObjectBase = obj.Get (vtkInformation info, int idx)` - Get the vtkObjectBase at a specific location in the vector.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.64 vtkInformationQuadratureSchemeDefinitionVectorKey

30.64.1 Usage

vtkInformationQuadratureSchemeDefinitionVectorKey is used to represent keys for double vector values in vtkInformation.h. NOTE the interface in this key differs from that in other similar keys because of our internal use of smart pointers.

To create an instance of class vtkInformationQuadratureSchemeDefinitionVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationQuadratureSchemeDefinitionVectorKey
```

30.64.2 Methods

The class vtkInformationQuadratureSchemeDefinitionVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationQuadratureSchemeDefinitionVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationQuadratureSchemeDefinitionVectorKey = obj.NewInstance ()`
- `vtkInformationQuadratureSchemeDefinitionVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationQuadratureSchemeDefinitionVectorKey = obj.(string name, string location)` - The name of the static instance and the class in which it is defined(location) should be passed to the constructor.
- `~vtkInformationQuadratureSchemeDefinitionVectorKey = obj.()` - The name of the static instance and the class in which it is defined(location) should be passed to the constructor.
- `obj.Clear (vtkInformation info)` - Clear the vector.
- `obj.Resize (vtkInformation info, int n)` - Resize (extend) the vector to hold n objects. Any new elements created will be null initialized.
- `int = obj.Size (vtkInformation info)` - Get the vector's length.
- `int = obj.Length (vtkInformation info)` - Put the value on the back of the vector, with reference counting.
- `obj.Append (vtkInformation info, vtkQuadratureSchemeDefinition value)` - Put the value on the back of the vector, with reference counting.
- `obj.Set (vtkInformation info, vtkQuadratureSchemeDefinition value, int i)` - Set element i of the vector to value. Resizes the vector if needed.
- `vtkQuadratureSchemeDefinition = obj.Get (vtkInformation info, int idx)` - Get the vtkQuadratureSchemeDefinition at a specific location in the vector.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.DeepCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

- `int = obj.SaveState (vtkInformation info, vtkXMLDataElement element)` - Generate an XML representation of the object. Each key/value pair will be nested in the resulting XML hierarchy. The element passed in is assumed to be empty.
- `int = obj.RestoreState (vtkInformation info, vtkXMLDataElement element)` - Load key/value pairs from an XML state representation created with SaveState. Duplicate keys will generate a fatal error.

30.65 vtkInformationRequestKey

30.65.1 Usage

vtkInformationRequestKey is used to represent keys for pointer to pointer values in vtkInformation.h

To create an instance of class vtkInformationRequestKey, simply invoke its constructor as follows

```
obj = vtkInformationRequestKey
```

30.65.2 Methods

The class vtkInformationRequestKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationRequestKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationRequestKey = obj.NewInstance ()`
- `vtkInformationRequestKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationRequestKey = obj.(string name, string location)`
- `~vtkInformationRequestKey = obj.()`
- `obj.Set (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.Remove (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Has (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.66 vtkInformationStringKey

30.66.1 Usage

vtkInformationStringKey is used to represent keys for string values in vtkInformation.

To create an instance of class vtkInformationStringKey, simply invoke its constructor as follows

```
obj = vtkInformationStringKey
```

30.66.2 Methods

The class vtkInformationStringKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationStringKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationStringKey = obj.NewInstance ()`
- `vtkInformationStringKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationStringKey = obj.(string name, string location)`
- `~vtkInformationStringKey = obj.()`
- `obj.Set (vtkInformation info, string )` - Get/Set the value associated with this key in the given information object.
- `string = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.67 vtkInformationStringVectorKey

30.67.1 Usage

vtkInformationStringVectorKey is used to represent keys for String vector values in vtkInformation.h

To create an instance of class vtkInformationStringVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationStringVectorKey
```

30.67.2 Methods

The class vtkInformationStringVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationStringVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationStringVectorKey = obj.NewInstance ()`
- `vtkInformationStringVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationStringVectorKey = obj.(string name, string location, int length)`
- `~vtkInformationStringVectorKey = obj.()`
- `obj.Append (vtkInformation info, string value)` - Get/Set the value associated with this key in the given information object.

- `obj.Set (vtkInformation info, string value, int idx)` - Get/Set the value associated with this key in the given information object.
- `string = obj.Get (vtkInformation info, int idx)` - Get/Set the value associated with this key in the given information object.
- `int = obj.Length (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.68 vtkInformationUnsignedLongKey

30.68.1 Usage

vtkInformationUnsignedLongKey is used to represent keys for unsigned long values in vtkInformation.

To create an instance of class vtkInformationUnsignedLongKey, simply invoke its constructor as follows

```
obj = vtkInformationUnsignedLongKey
```

30.68.2 Methods

The class vtkInformationUnsignedLongKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationUnsignedLongKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationUnsignedLongKey = obj.NewInstance ()`
- `vtkInformationUnsignedLongKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationUnsignedLongKey = obj.(string name, string location)`
- `~vtkInformationUnsignedLongKey = obj.()`
- `obj.Set (vtkInformation info, long )` - Get/Set the value associated with this key in the given information object.
- `long = obj.Get (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.

30.69 vtkInformationVector

30.69.1 Usage

To create an instance of class vtkInformationVector, simply invoke its constructor as follows

```
obj = vtkInformationVector
```

30.69.2 Methods

The class vtkInformationVector has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationVector class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationVector = obj.NewInstance ()`
- `vtkInformationVector = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfInformationObjects ()` - Get/Set the number of information objects in the vector. Setting the number to larger than the current number will create empty vtkInformation instances. Setting the number to smaller than the current number will remove entries from higher indices.
- `obj.SetNumberOfInformationObjects (int n)` - Get/Set the number of information objects in the vector. Setting the number to larger than the current number will create empty vtkInformation instances. Setting the number to smaller than the current number will remove entries from higher indices.
- `obj.SetInformationObject (int index, vtkInformation info)` - Get/Set the vtkInformation instance stored at the given index in the vector. The vector will automatically expand to include the index given if necessary. Missing entries in-between will be filled with empty vtkInformation instances.
- `vtkInformation = obj.GetInformationObject (int index)` - Get/Set the vtkInformation instance stored at the given index in the vector. The vector will automatically expand to include the index given if necessary. Missing entries in-between will be filled with empty vtkInformation instances.
- `obj.Append (vtkInformation info)` - Append/Remove an information object.
- `obj.Remove (vtkInformation info)` - Append/Remove an information object.
- `obj.Register (vtkObjectBase o)` - Initiate garbage collection when a reference is removed.
- `obj.UnRegister (vtkObjectBase o)` - Initiate garbage collection when a reference is removed.
- `obj.Copy (vtkInformationVector from, int deep)` - Copy all information entries from the given vtkInformation instance. Any previously existing entries are removed. If deep==1, a deep copy of the information structure is performed (new instances of any contained vtkInformation and vtkInformationVector objects are created).

30.70 vtkInitialValueProblemSolver

30.70.1 Usage

Given a vtkFunctionSet which returns dF_i(x_j, t)/dt given x_j and t, vtkInitialValueProblemSolver computes the value of F_i at t+deltat.

To create an instance of class vtkInitialValueProblemSolver, simply invoke its constructor as follows

```
obj = vtkInitialValueProblemSolver
```

30.70.2 Methods

The class vtkInitialValueProblemSolver has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInitialValueProblemSolver class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInitialValueProblemSolver = obj.NewInstance ()`
- `vtkInitialValueProblemSolver = obj.SafeDownCast (vtkObject o)`
- `obj.SetFunctionSet (vtkFunctionSet functionset)` - Set / get the dataset used for the implicit function evaluation.
- `vtkFunctionSet = obj.GetFunctionSet ()` - Set / get the dataset used for the implicit function evaluation.
- `int = obj.IsAdaptive ()`

30.71 vtkInstantiator

30.71.1 Usage

vtkInstantiator provides an interface to create an instance of any VTK class from its name. Instances are created through registered pointers to functions returning the objects. New classes can also be registered with the creator. VTK libraries automatically register their classes with the creator when they are loaded. Instances are created using the static New() method, so the normal vtkObjectFactory mechanism is still invoked.

When using this class from language wrappers (Tcl, Python, or Java), the vtkInstantiator should be able to create any class from any kit that has been loaded.

In C++ code, one should include the header for each kit from which one wishes to create instances through vtkInstantiator. This is necessary to ensure proper linking when building static libraries. Be careful, though, because including each kit's header means every class from that kit will be linked into your executable whether or not the class is used. The headers are:

vtkCommon - vtkCommonInstantiator.h vtkFiltering - vtkFilteringInstantiator.h vtkIO - vtkIOInstantiator.h vtkImaging - vtkImagingInstantiator.h vtkGraphics - vtkGraphicsInstantiator.h vtkRendering - vtkRenderingInstantiator.h vtkVolumeRendering - vtkVolumeRenderingInstantiator.h vtkHybrid - vtkHybridInstantiator.h vtkParallel - vtkParallelInstantiator.h

The VTK_MAKE_INSTANTIATOR() command in CMake is used to automatically generate the creator registration for each VTK library. It can also be used to create registration code for VTK-style user libraries that are linked to vtkCommon. After using this command to register classes from a new library, the generated header must be included.

To create an instance of class vtkInstantiator, simply invoke its constructor as follows

```
obj = vtkInstantiator
```

30.71.2 Methods

The class vtkInstantiator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInstantiator class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkInstantiator = obj.NewInstance ()`
- `vtkInstantiator = obj.SafeDownCast (vtkObject o)`

30.72 vtkIntArray

30.72.1 Usage

vtkIntArray is an array of values of type int. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkIntArray, simply invoke its constructor as follows

```
obj = vtkIntArray
```

30.72.2 Methods

The class vtkIntArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIntArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIntArray = obj.NewInstance ()`
- `vtkIntArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, int tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, int tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, int tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (int tuple)` - Get the data at a particular index.
- `int = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, int value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, int f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (int f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.

- `obj.SetArray (int array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (int array, vtkIdType size, int save, int deleteMethod)`

30.73 vtkLinearTransform

30.73.1 Usage

vtkLinearTransform provides a generic interface for linear (affine or 12 degree-of-freedom) geometric transformations.

To create an instance of class vtkLinearTransform, simply invoke its constructor as follows

```
obj = vtkLinearTransform
```

30.73.2 Methods

The class vtkLinearTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLinearTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLinearTransform = obj.NewInstance ()`
- `vtkLinearTransform = obj.SafeDownCast (vtkObject o)`
- `obj.TransformNormal (float in[3], float out[3])` - Apply the transformation to a normal. You can use the same array to store both the input and output.
- `obj.TransformNormal (double in[3], double out[3])` - Apply the transformation to a double-precision normal. You can use the same array to store both the input and output.
- `double = obj.TransformNormal (double x, double y, double z)` - Synonymous with TransformDoubleNormal(x,y,z). Use this if you are programming in python, tcl or Java.
- `double = obj.TransformNormal (double normal[3])` - Synonymous with TransformDoubleNormal(x,y,z). Use this if you are programming in python, tcl or Java.
- `float = obj.TransformFloatNormal (float x, float y, float z)` - Apply the transformation to an (x,y,z) normal. Use this if you are programming in python, tcl or Java.
- `float = obj.TransformFloatNormal (float normal[3])` - Apply the transformation to an (x,y,z) normal. Use this if you are programming in python, tcl or Java.
- `double = obj.TransformDoubleNormal (double x, double y, double z)` - Apply the transformation to a double-precision (x,y,z) normal. Use this if you are programming in python, tcl or Java.
- `double = obj.TransformDoubleNormal (double normal[3])` - Apply the transformation to a double-precision (x,y,z) normal. Use this if you are programming in python, tcl or Java.
- `double = obj.TransformVector (double x, double y, double z)` - Synonymous with TransformDoubleVector(x,y,z). Use this if you are programming in python, tcl or Java.

- `double = obj.TransformVector (double normal[3])` - Synonymous with TransformDoubleVector(x,y,z). Use this if you are programming in python, tcl or Java.
- `obj.TransformVector (float in[3], float out[3])` - Apply the transformation to a vector. You can use the same array to store both the input and output.
- `obj.TransformVector (double in[3], double out[3])` - Apply the transformation to a double-precision vector. You can use the same array to store both the input and output.
- `float = obj.TransformFloatVector (float x, float y, float z)` - Apply the transformation to an (x,y,z) vector. Use this if you are programming in python, tcl or Java.
- `float = obj.TransformFloatVector (float vec[3])` - Apply the transformation to an (x,y,z) vector. Use this if you are programming in python, tcl or Java.
- `double = obj.TransformDoubleVector (double x, double y, double z)` - Apply the transformation to a double-precision (x,y,z) vector. Use this if you are programming in python, tcl or Java.
- `double = obj.TransformDoubleVector (double vec[3])` - Apply the transformation to a double-precision (x,y,z) vector. Use this if you are programming in python, tcl or Java.
- `obj.TransformPoints (vtkPoints inPts, vtkPoints outPts)` - Apply the transformation to a series of points, and append the results to outPts.
- `obj.TransformNormals (vtkDataArray inNms, vtkDataArray outNms)` - Apply the transformation to a series of normals, and append the results to outNms.
- `obj.TransformVectors (vtkDataArray inVrs, vtkDataArray outVrs)` - Apply the transformation to a series of vectors, and append the results to outVrs.
- `obj.TransformPointsNormalsVectors (vtkPoints inPts, vtkPoints outPts, vtkDataArray inNms, vtkDataAr` - Apply the transformation to a combination of points, normals and vectors.
- `vtkLinearTransform = obj.GetLinearInverse ()` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformNormal (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformNormal (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformVector (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformVector (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.

30.74 vtkLogLookupTable

30.74.1 Usage

This class is an empty shell. Use vtkLookupTable with SetScaleToLog10() instead.

To create an instance of class vtkLogLookupTable, simply invoke its constructor as follows

```
obj = vtkLogLookupTable
```

30.74.2 Methods

The class vtkLogLookupTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLogLookupTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLogLookupTable = obj.NewInstance ()`
- `vtkLogLookupTable = obj.SafeDownCast (vtkObject o)`

30.75 vtkLongArray

30.75.1 Usage

vtkLongArray is an array of values of type long. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkLongArray, simply invoke its constructor as follows

```
obj = vtkLongArray
```

30.75.2 Methods

The class vtkLongArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLongArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLongArray = obj.NewInstance ()`
- `vtkLongArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, long tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, long tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, long tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (long tuple)` - Get the data at a particular index.
- `long = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, long value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.

- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, long f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (long f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (long array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (long array, vtkIdType size, int save, int deleteMethod)`

30.76 vtkLongLongArray

30.76.1 Usage

vtkLongLongArray is an array of values of type long long. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkLongLongArray, simply invoke its constructor as follows

```
obj = vtkLongLongArray
```

30.76.2 Methods

The class vtkLongLongArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLongLongArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLongLongArray = obj.NewInstance ()`
- `vtkLongLongArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `long = obj.long GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, long long value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, long long f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (long long f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.

- `long = obj.long WritePointer (vtkIdType id, vtkIdType number)` - Get the address of a particular data index. Performs no checks to verify that the memory has been allocated etc.
- `long = obj.long GetPointer (vtkIdType id)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.

30.77 vtkLookupTable

30.77.1 Usage

vtkLookupTable is an object that is used by mapper objects to map scalar values into rgba (red-green-blue-alpha transparency) color specification, or rgba into scalar values. The color table can be created by direct insertion of color values, or by specifying hue, saturation, value, and alpha range and generating a table.

To create an instance of class vtkLookupTable, simply invoke its constructor as follows

```
obj = vtkLookupTable
```

30.77.2 Methods

The class vtkLookupTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLookupTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLookupTable = obj.NewInstance ()`
- `vtkLookupTable = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsOpaque ()` - Return true if all of the values defining the mapping have an opacity equal to 1. Default implementation return true.
- `int = obj.Allocate (int sz, int ext)` - Allocate a color table of specified size.
- `obj.Build ()` - Generate lookup table from hue, saturation, value, alpha min/max values. Table is built from linear ramp of each value.
- `obj.ForceBuild ()` - Force the lookup table to regenerate from hue, saturation, value, and alpha min/max values. Table is built from a linear ramp of each value. ForceBuild() is useful if a lookup table has been defined manually (using SetTableValue) and then an application decides to rebuild the lookup table using the implicit process.
- `obj.SetRamp (int )` - Set the shape of the table ramp to either linear or S-curve. The default is S-curve, which tails off gradually at either end. The equation used for the S-curve is y = (sin((x - 1/2)*pi) + 1)/2, while the equation for the linear ramp is simply y = x. For an S-curve greyscale ramp, you should set NumberOfTableValues to 402 (which is 256*pi/2) to provide room for the tails of the ramp. The equation for the SQRT is y = sqrt(x).
- `obj.SetRampToLinear ()` - Set the shape of the table ramp to either linear or S-curve. The default is S-curve, which tails off gradually at either end. The equation used for the S-curve is y = (sin((x - 1/2)*pi) + 1)/2, while the equation for the linear ramp is simply y = x. For an S-curve greyscale ramp, you should set NumberOfTableValues to 402 (which is 256*pi/2) to provide room for the tails of the ramp. The equation for the SQRT is y = sqrt(x).

- `obj.SetRampToSCurve ()` - Set the shape of the table ramp to either linear or S-curve. The default is S-curve, which tails off gradually at either end. The equation used for the S-curve is y = (sin((x - 1/2)*pi) + 1)/2, while the equation for the linear ramp is simply y = x. For an S-curve greyscale ramp, you should set NumberOfTableValues to 402 (which is 256*pi/2) to provide room for the tails of the ramp. The equation for the SQRT is y = sqrt(x).

- `obj.SetRampToSQRT ()` - Set the shape of the table ramp to either linear or S-curve. The default is S-curve, which tails off gradually at either end. The equation used for the S-curve is y = (sin((x - 1/2)*pi) + 1)/2, while the equation for the linear ramp is simply y = x. For an S-curve greyscale ramp, you should set NumberOfTableValues to 402 (which is 256*pi/2) to provide room for the tails of the ramp. The equation for the SQRT is y = sqrt(x).

- `int = obj.GetRamp ()` - Set the shape of the table ramp to either linear or S-curve. The default is S-curve, which tails off gradually at either end. The equation used for the S-curve is y = (sin((x - 1/2)*pi) + 1)/2, while the equation for the linear ramp is simply y = x. For an S-curve greyscale ramp, you should set NumberOfTableValues to 402 (which is 256*pi/2) to provide room for the tails of the ramp. The equation for the SQRT is y = sqrt(x).

- `obj.SetScale (int scale)` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, then the TableRange must not cross the value zero.

- `obj.SetScaleToLinear ()` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, then the TableRange must not cross the value zero.

- `obj.SetScaleToLog10 ()` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, then the TableRange must not cross the value zero.

- `int = obj.GetScale ()` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, then the TableRange must not cross the value zero.

- `obj.SetTableRange (double r[2])` - Set/Get the minimum/maximum scalar values for scalar mapping. Scalar values less than minimum range value are clamped to minimum range value. Scalar values greater than maximum range value are clamped to maximum range value.

- `obj.SetTableRange (double min, double max)` - Set/Get the minimum/maximum scalar values for scalar mapping. Scalar values less than minimum range value are clamped to minimum range value. Scalar values greater than maximum range value are clamped to maximum range value.

- `double = obj. GetTableRange ()` - Set/Get the minimum/maximum scalar values for scalar mapping. Scalar values less than minimum range value are clamped to minimum range value. Scalar values greater than maximum range value are clamped to maximum range value.

- `obj.SetHueRange (double , double )` - Set the range in hue (using automatic generation). Hue ranges between [0,1].

- `obj.SetHueRange (double a[2])` - Set the range in hue (using automatic generation). Hue ranges between [0,1].

- `double = obj. GetHueRange ()` - Set the range in hue (using automatic generation). Hue ranges between [0,1].

- `obj.SetSaturationRange (double , double )` - Set the range in saturation (using automatic generation). Saturation ranges between [0,1].

- `obj.SetSaturationRange (double a[2])` - Set the range in saturation (using automatic generation). Saturation ranges between [0,1].

- `double = obj. GetSaturationRange ()` - Set the range in saturation (using automatic generation). Saturation ranges between [0,1].

- `obj.SetValueRange (double , double )` - Set the range in value (using automatic generation). Value ranges between [0,1].
- `obj.SetValueRange (double  a[2])` - Set the range in value (using automatic generation). Value ranges between [0,1].
- `double = obj. GetValueRange ()` - Set the range in value (using automatic generation). Value ranges between [0,1].
- `obj.SetAlphaRange (double , double )` - Set the range in alpha (using automatic generation). Alpha ranges from [0,1].
- `obj.SetAlphaRange (double  a[2])` - Set the range in alpha (using automatic generation). Alpha ranges from [0,1].
- `double = obj. GetAlphaRange ()` - Set the range in alpha (using automatic generation). Alpha ranges from [0,1].
- `obj.GetColor (double x, double rgb[3])` - Map one value through the lookup table and return the color as an RGB array of doubles between 0 and 1.
- `double = obj.GetOpacity (double v)` - Map one value through the lookup table and return the alpha value (the opacity) as a double between 0 and 1.
- `vtkIdType = obj.GetIndex (double v)` - Return the table index associated with a particular value.
- `obj.SetNumberOfTableValues (vtkIdType number)` - Specify the number of values (i.e., colors) in the lookup table.
- `vtkIdType = obj.GetNumberOfTableValues ()` - Specify the number of values (i.e., colors) in the lookup table.
- `obj.SetTableValue (vtkIdType indx, double rgba[4])` - Directly load color into lookup table. Use [0,1] double values for color component specification. Make sure that you've either used the Build() method or used SetNumberOfTableValues() prior to using this method.
- `obj.SetTableValue (vtkIdType indx, double r, double g, double b, double a)` - Directly load color into lookup table. Use [0,1] double values for color component specification.
- `double = obj.GetTableValue (vtkIdType id)` - Return a rgba color value for the given index into the lookup table. Color components are expressed as [0,1] double values.
- `obj.GetTableValue (vtkIdType id, double rgba[4])` - Return a rgba color value for the given index into the lookup table. Color components are expressed as [0,1] double values.
- `double = obj.GetRange ()` - Sets/Gets the range of scalars which will be mapped. This is a duplicate of Get/SetTableRange.
- `obj.SetRange (double min, double max)` - Sets/Gets the range of scalars which will be mapped. This is a duplicate of Get/SetTableRange.
- `obj.SetRange (double rng[2])` - Sets/Gets the range of scalars which will be mapped. This is a duplicate of Get/SetTableRange.
- `obj.SetNumberOfColors (vtkIdType )` - Set the number of colors in the lookup table. Use SetNumberOfTableValues() instead, it can be used both before and after the table has been built whereas SetNumberOfColors() has no effect after the table has been built.
- `vtkIdType = obj.GetNumberOfColorsMinValue ()` - Set the number of colors in the lookup table. Use SetNumberOfTableValues() instead, it can be used both before and after the table has been built whereas SetNumberOfColors() has no effect after the table has been built.

- `vtkIdType = obj.GetNumberOfColorsMaxValue ()` - Set the number of colors in the lookup table. Use SetNumberOfTableValues() instead, it can be used both before and after the table has been built whereas SetNumberOfColors() has no effect after the table has been built.

- `vtkIdType = obj.GetNumberOfColors ()` - Set the number of colors in the lookup table. Use SetNumberOfTableValues() instead, it can be used both before and after the table has been built whereas SetNumberOfColors() has no effect after the table has been built.

- `obj.SetTable (vtkUnsignedCharArray )` - Set/Get the internal table array that is used to map the scalars to colors. The table array is an unsigned char array with 4 components representing RGBA.

- `vtkUnsignedCharArray = obj.GetTable ()` - Set/Get the internal table array that is used to map the scalars to colors. The table array is an unsigned char array with 4 components representing RGBA.

- `obj.DeepCopy (vtkLookupTable lut)` - Copy the contents from another LookupTable

- `int = obj.UsingLogScale ()`

30.78 vtkLookupTableWithEnabling

30.78.1 Usage

vtkLookupTableWithEnabling "disables" or "grays out" output colors based on whether the given value in EnabledArray is "0" or not.

To create an instance of class vtkLookupTableWithEnabling, simply invoke its constructor as follows

```
obj = vtkLookupTableWithEnabling
```

30.78.2 Methods

The class vtkLookupTableWithEnabling has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLookupTableWithEnabling class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkLookupTableWithEnabling = obj.NewInstance ()`

- `vtkLookupTableWithEnabling = obj.SafeDownCast (vtkObject o)`

- `vtkDataArray = obj.GetEnabledArray ()` - This must be set before MapScalars() is called. Indices of this array must map directly to those in the scalars array passed to MapScalars(). Values of 0 in the array indicate the color should be desaturatated.

- `obj.SetEnabledArray (vtkDataArray enabledArray)` - This must be set before MapScalars() is called. Indices of this array must map directly to those in the scalars array passed to MapScalars(). Values of 0 in the array indicate the color should be desaturatated.

- `obj.DisableColor (char r, char g, char b, string rd, string gd, string bd)` - A convenience method for taking a color and desaturating it.

30.79 vtkMath

30.79.1 Usage

vtkMath provides methods to perform common math operations. These include providing constants such as Pi; conversion from degrees to radians; vector operations such as dot and cross products and vector norm; matrix determinant for 2x2 and 3x3 matrices; univariate polynomial solvers; and for random number generation (for backward compatibility only).

To create an instance of class vtkMath, simply invoke its constructor as follows

```
obj = vtkMath
```

30.79.2 Methods

The class vtkMath has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMath class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMath = obj.NewInstance ()`
- `vtkMath = obj.SafeDownCast (vtkObject o)`

30.80 vtkMatrix3x3

30.80.1 Usage

vtkMatrix3x3 is a class to represent and manipulate 3x3 matrices. Specifically, it is designed to work on 3x3 transformation matrices found in 2D rendering using homogeneous coordinates [x y w].

To create an instance of class vtkMatrix3x3, simply invoke its constructor as follows

```
obj = vtkMatrix3x3
```

30.80.2 Methods

The class vtkMatrix3x3 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMatrix3x3 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMatrix3x3 = obj.NewInstance ()`
- `vtkMatrix3x3 = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkMatrix3x3 source)` - Non-static member function. Assigns *from* elements array
- `obj.DeepCopy (double Elements[9])` - Set all of the elements to zero.
- `obj.Zero ()` - Set equal to Identity matrix
- `obj.Identity ()` - Matrix Inversion (adapted from Richard Carling in "Graphics Gems," Academic Press, 1990).

- `obj.Invert ()` - Transpose the matrix and put it into out.
- `obj.Transpose ()` - Multiply a homogeneous coordinate by this matrix, i.e. out = A*in. The in[3] and out[3] can be the same array.
- `obj.MultiplyPoint (float in[3], float out[3])` - Multiply a homogeneous coordinate by this matrix, i.e. out = A*in. The in[3] and out[3] can be the same array.
- `obj.MultiplyPoint (double in[3], double out[3])` - Multiplies matrices a and b and stores the result in c (c=a*b).
- `obj.Adjoint (vtkMatrix3x3 in, vtkMatrix3x3 out)` - Compute the determinant of the matrix and return it.
- `double = obj.Determinant ()` - Sets the element i,j in the matrix.
- `obj.SetElement (int i, int j, double value)` - Sets the element i,j in the matrix.
- `double = obj.GetElement (int i, int j) const`
- `bool = obj.IsIdentity ()`

30.81 vtkMatrix4x4

30.81.1 Usage

vtkMatrix4x4 is a class to represent and manipulate 4x4 matrices. Specifically, it is designed to work on 4x4 transformation matrices found in 3D rendering using homogeneous coordinates [x y z w].

To create an instance of class vtkMatrix4x4, simply invoke its constructor as follows

```
obj = vtkMatrix4x4
```

30.81.2 Methods

The class vtkMatrix4x4 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMatrix4x4 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMatrix4x4 = obj.NewInstance ()`
- `vtkMatrix4x4 = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkMatrix4x4 source)` - Non-static member function. Assigns *from* elements array
- `obj.DeepCopy (double Elements[16])` - Set all of the elements to zero.
- `obj.Zero ()` - Set equal to Identity matrix
- `obj.Identity ()` - Matrix Inversion (adapted from Richard Carling in "Graphics Gems," Academic Press, 1990).
- `obj.Invert ()` - Transpose the matrix and put it into out.
- `obj.Transpose ()` - Multiply a homogeneous coordinate by this matrix, i.e. out = A*in. The in[4] and out[4] can be the same array.

- `obj.MultiplyPoint (float in[4], float out[4])` - Multiply a homogeneous coordinate by this matrix, i.e. out = A*in. The in[4] and out[4] can be the same array.
- `obj.MultiplyPoint (double in[4], double out[4])` - For use in Java, Python or Tcl. The default MultiplyPoint() uses a single-precision point.
- `float = obj.MultiplyPoint (float in[4])` - For use in Java, Python or Tcl. The default MultiplyPoint() uses a single-precision point.
- `float = obj.MultiplyFloatPoint (float in[4])` - For use in Java, Python or Tcl. The default MultiplyPoint() uses a single-precision point.
- `double = obj.MultiplyDoublePoint (double in[4])` - Multiplies matrices a and b and stores the result in c.
- `obj.Adjoint (vtkMatrix4x4 in, vtkMatrix4x4 out)` - Compute the determinant of the matrix and return it.
- `double = obj.Determinant ()` - Sets the element i,j in the matrix.
- `obj.SetElement (int i, int j, double value)` - Sets the element i,j in the matrix.
- `double = obj.GetElement (int i, int j) const`

30.82 vtkMatrixToHomogeneousTransform

30.82.1 Usage

This is a very simple class which allows a vtkMatrix4x4 to be used in place of a vtkHomogeneousTransform or vtkAbstractTransform. For example, if you use it as a proxy between a matrix and vtkTransformPolyDataFilter then any modifications to the matrix will automatically be reflected in the output of the filter.

To create an instance of class vtkMatrixToHomogeneousTransform, simply invoke its constructor as follows

```
obj = vtkMatrixToHomogeneousTransform
```

30.82.2 Methods

The class vtkMatrixToHomogeneousTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMatrixToHomogeneousTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMatrixToHomogeneousTransform = obj.NewInstance ()`
- `vtkMatrixToHomogeneousTransform = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkMatrix4x4 )`
- `vtkMatrix4x4 = obj.GetInput ()`
- `obj.Inverse ()` - The input matrix is left as-is, but the transformation matrix is inverted.
- `long = obj.GetMTime ()` - Get the MTime: this is the bit of magic that makes everything work.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make a new transform of the same type.
- `obj.SetMatrix (vtkMatrix4x4 matrix)` - @deprecated This method is deprecated.

30.83 vtkMatrixToLinearTransform

30.83.1 Usage

This is a very simple class which allows a vtkMatrix4x4 to be used in place of a vtkLinearTransform or vtkAbstractTransform. For example, if you use it as a proxy between a matrix and vtkTransformPolyDataFilter then any modifications to the matrix will automatically be reflected in the output of the filter.

To create an instance of class vtkMatrixToLinearTransform, simply invoke its constructor as follows

```
obj = vtkMatrixToLinearTransform
```

30.83.2 Methods

The class vtkMatrixToLinearTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMatrixToLinearTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMatrixToLinearTransform = obj.NewInstance ()`
- `vtkMatrixToLinearTransform = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkMatrix4x4 )` - Set the input matrix. Any modifications to the matrix will be reflected in the transformation.
- `vtkMatrix4x4 = obj.GetInput ()` - Set the input matrix. Any modifications to the matrix will be reflected in the transformation.
- `obj.Inverse ()` - The input matrix is left as-is, but the transformation matrix is inverted.
- `long = obj.GetMTime ()` - Get the MTime: this is the bit of magic that makes everything work.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make a new transform of the same type.
- `obj.SetMatrix (vtkMatrix4x4 matrix)` - @deprecated This method is deprecated.

30.84 vtkMinimalStandardRandomSequence

30.84.1 Usage

vtkMinimalStandardRandomSequence is a sequence of statistically independent pseudo random numbers uniformly distributed between 0.0 and 1.0.

The sequence is generated by a prime modulus multiplicative linear congruential generator (PMMLCG) or "Lehmer generator" with multiplier 16807 and prime modulus 2$\hat{}$(31)-1. The authors calls it "minimal standard random number generator"

ref: "Random Number Generators: Good Ones are Hard to Find," by Stephen K. Park and Keith W. Miller in Communications of the ACM, 31, 10 (Oct. 1988) pp. 1192-1201. Code is at page 1195, "Integer version 2"

Correctness test is described in first column, page 1195: A seed of 1 at step 1 should give a seed of 1043618065 at step 10001.

To create an instance of class vtkMinimalStandardRandomSequence, simply invoke its constructor as follows

```
obj = vtkMinimalStandardRandomSequence
```

30.84.2 Methods

The class vtkMinimalStandardRandomSequence has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMinimalStandardRandomSequence class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMinimalStandardRandomSequence = obj.NewInstance ()`
- `vtkMinimalStandardRandomSequence = obj.SafeDownCast (vtkObject o)`
- `obj.SetSeed (int value)` - Set the seed of the random sequence. The following pre-condition is stated page 1197, second column: valid_seed: value¿=1 && value¡=2147483646 2147483646=(2$\hat{}$31)-2 This method does not have this criterium as a pre-condition (ie it will not fail if an incorrect seed value is passed) but the value is silently changed to fit in the valid range [1,2147483646]. 2147483646 is added to a null or negative value. 2147483647 is changed to be 1 (ie 2147483646 is substracted). Implementation note: it also performs 3 calls to Next() to avoid the bad property that the first random number is proportional to the seed value.
- `obj.SetSeedOnly (int value)` - Set the seed of the random sequence. There is no extra internal ajustment. Only useful for writing correctness test. The following pre-condition is stated page 1197, second column 2147483646=(2$\hat{}$31)-2 This method does not have this criterium as a pre-condition (ie it will not fail if an incorrect seed value is passed) but the value is silently changed to fit in the valid range [1,2147483646]. 2147483646 is added to a null or negative value. 2147483647 is changed to be 1 (ie 2147483646 is substracted).
- `int = obj.GetSeed ()` - Get the seed of the random sequence. Only useful for writing correctness test.
- `double = obj.GetValue ()` - Current value
- `obj.Next ()` - Move to the next number in the random sequence.
- `double = obj.GetRangeValue (double rangeMin, double rangeMax)` - Convenient method to return a value in a specific range from the range [0,1. There is an initial implementation that can be overridden by a subclass. There is no pre-condition on the range: - it can be in increasing order: rangeMin¡rangeMax - it can be empty: rangeMin=rangeMax - it can be in decreasing order: rangeMin¿rangeMax

  (rangeMin¡=rangeMax && result¿=rangeMin && result¡=rangeMax) —— (rangeMax¡=rangeMin && result¿=rangeMax && result¡=rangeMin)

30.85 vtkMultiThreader

30.85.1 Usage

vtkMultithreader is a class that provides support for multithreaded execution using sproc() on an SGI, or pthread_create on any platform supporting POSIX threads. This class can be used to execute a single method on multiple threads, or to specify a method per thread.

To create an instance of class vtkMultiThreader, simply invoke its constructor as follows

```
obj = vtkMultiThreader
```

30.85.2 Methods

The class vtkMultiThreader has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiThreader class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiThreader = obj.NewInstance ()`
- `vtkMultiThreader = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfThreads (int )` - Get/Set the number of threads to create. It will be clamped to the range 1 - VTK_MAX_THREADS, so the caller of this method should check that the requested number of threads was accepted.
- `int = obj.GetNumberOfThreadsMinValue ()` - Get/Set the number of threads to create. It will be clamped to the range 1 - VTK_MAX_THREADS, so the caller of this method should check that the requested number of threads was accepted.
- `int = obj.GetNumberOfThreadsMaxValue ()` - Get/Set the number of threads to create. It will be clamped to the range 1 - VTK_MAX_THREADS, so the caller of this method should check that the requested number of threads was accepted.
- `int = obj.GetNumberOfThreads ()` - Get/Set the number of threads to create. It will be clamped to the range 1 - VTK_MAX_THREADS, so the caller of this method should check that the requested number of threads was accepted.

30.86 vtkMutexLock

30.86.1 Usage

vtkMutexLock allows the locking of variables which are accessed through different threads. This header file also defines vtkSimpleMutexLock which is not a subclass of vtkObject.

To create an instance of class vtkMutexLock, simply invoke its constructor as follows

```
obj = vtkMutexLock
```

30.86.2 Methods

The class vtkMutexLock has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMutexLock class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMutexLock = obj.NewInstance ()`
- `vtkMutexLock = obj.SafeDownCast (vtkObject o)`
- `obj.Lock (void )` - Lock the vtkMutexLock
- `obj.Unlock (void )` - Unlock the vtkMutexLock

30.87 vtkObject

30.87.1 Usage

vtkObject is the base class for most objects in the visualization toolkit. vtkObject provides methods for tracking modification time, debugging, printing, and event callbacks. Most objects created within the VTK framework should be a subclass of vtkObject or one of its children. The few exceptions tend to be very small helper classes that usually never get instantiated or situations where multiple inheritance gets in the way. vtkObject also performs reference counting: objects that are reference counted exist as long as another object uses them. Once the last reference to a reference counted object is removed, the object will spontaneously destruct.

To create an instance of class vtkObject, simply invoke its constructor as follows

```
obj = vtkObject
```

30.87.2 Methods

The class vtkObject has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkObject class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkObject = obj.NewInstance ()`
- `vtkObject = obj.SafeDownCast (vtkObject o)`
- `obj.DebugOn ()` - Turn debugging output on.
- `obj.DebugOff ()` - Turn debugging output off.
- `char = obj.GetDebug ()` - Get the value of the debug flag.
- `obj.SetDebug (char debugFlag)` - Set the value of the debug flag. A non-zero value turns debugging on.
- `obj.Modified ()` - Update the modification time for this object. Many filters rely on the modification time to determine if they need to recompute their data. The modification time is a unique monotonically increasing unsigned long integer.
- `long = obj.GetMTime ()` - Return this object's modified time.
- `obj.RemoveObserver (long tag)` - Allow people to add/remove/invoke observers (callbacks) to any VTK object. This is an implementation of the subject/observer design pattern. An observer is added by specifying an event to respond to and a vtkCommand to execute. It returns an unsigned long tag which can be used later to remove the event or retrieve the command. When events are invoked, the observers are called in the order they were added. If a priority value is specified, then the higher priority commands are called first. A command may set an abort flag to stop processing of the event. (See vtkCommand.h for more information.)
- `obj.RemoveObservers (long event)` - Allow people to add/remove/invoke observers (callbacks) to any VTK object. This is an implementation of the subject/observer design pattern. An observer is added by specifying an event to respond to and a vtkCommand to execute. It returns an unsigned long tag which can be used later to remove the event or retrieve the command. When events are invoked, the observers are called in the order they were added. If a priority value is specified, then the higher priority commands are called first. A command may set an abort flag to stop processing of the event. (See vtkCommand.h for more information.)

- `obj.RemoveObservers (string event)` - Allow people to add/remove/invoke observers (callbacks) to any VTK object. This is an implementation of the subject/observer design pattern. An observer is added by specifying an event to respond to and a vtkCommand to execute. It returns an unsigned long tag which can be used later to remove the event or retrieve the command. When events are invoked, the observers are called in the order they were added. If a priority value is specified, then the higher priority commands are called first. A command may set an abort flag to stop processing of the event. (See vtkCommand.h for more information.)
- `obj.RemoveAllObservers ()` - Allow people to add/remove/invoke observers (callbacks) to any VTK object. This is an implementation of the subject/observer design pattern. An observer is added by specifying an event to respond to and a vtkCommand to execute. It returns an unsigned long tag which can be used later to remove the event or retrieve the command. When events are invoked, the observers are called in the order they were added. If a priority value is specified, then the higher priority commands are called first. A command may set an abort flag to stop processing of the event. (See vtkCommand.h for more information.)
- `int = obj.HasObserver (long event)` - Allow people to add/remove/invoke observers (callbacks) to any VTK object. This is an implementation of the subject/observer design pattern. An observer is added by specifying an event to respond to and a vtkCommand to execute. It returns an unsigned long tag which can be used later to remove the event or retrieve the command. When events are invoked, the observers are called in the order they were added. If a priority value is specified, then the higher priority commands are called first. A command may set an abort flag to stop processing of the event. (See vtkCommand.h for more information.)
- `int = obj.HasObserver (string event)` - Allow people to add/remove/invoke observers (callbacks) to any VTK object. This is an implementation of the subject/observer design pattern. An observer is added by specifying an event to respond to and a vtkCommand to execute. It returns an unsigned long tag which can be used later to remove the event or retrieve the command. When events are invoked, the observers are called in the order they were added. If a priority value is specified, then the higher priority commands are called first. A command may set an abort flag to stop processing of the event. (See vtkCommand.h for more information.)
- `int = obj.InvokeEvent (long event)`
- `int = obj.InvokeEvent (string event)`

30.88 vtkObjectBase

30.88.1 Usage

vtkObjectBase is the base class for all reference counted classes in the VTK. These classes include vtkCommand classes, vtkInformationKey classes, and vtkObject classes.

vtkObjectBase performs reference counting: objects that are reference counted exist as long as another object uses them. Once the last reference to a reference counted object is removed, the object will spontaneously destruct.

Constructor and destructor of the subclasses of vtkObjectBase should be protected, so that only New() and UnRegister() actually call them. Debug leaks can be used to see if there are any objects left with nonzero reference count.

To create an instance of class vtkObjectBase, simply invoke its constructor as follows

```
obj = vtkObjectBase
```

30.88.2 Methods

The class vtkObjectBase has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When

in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkObjectBase class.

- `string = obj.GetClassName () const` - Return the class name as a string. This method is defined in all subclasses of vtkObjectBase with the vtkTypeRevisionMacro found in vtkSetGet.h.
- `int = obj.IsA (string name)` - Return 1 if this class is the same type of (or a subclass of) the named class. Returns 0 otherwise. This method works in combination with vtkTypeRevisionMacro found in vtkSetGet.h.
- `obj.Delete ()` - Delete a VTK object. This method should always be used to delete an object when the New() method was used to create it. Using the C++ delete method will not work with reference counting.
- `obj.FastDelete ()` - Delete a reference to this object. This version will not invoke garbage collection and can potentially leak the object if it is part of a reference loop. Use this method only when it is known that the object has another reference and would not be collected if a full garbage collection check were done.
- `obj.Register (vtkObjectBase o)` - Increase the reference count (mark as used by another object).
- `obj.UnRegister (vtkObjectBase o)` - Decrease the reference count (release by another object). This has the same effect as invoking Delete() (i.e., it reduces the reference count by 1).
- `int = obj.GetReferenceCount ()` - Sets the reference count. (This is very dangerous, use with care.)
- `obj.SetReferenceCount (int )` - Sets the reference count. (This is very dangerous, use with care.)

30.89 vtkObjectFactory

30.89.1 Usage

vtkObjectFactory is used to create vtk objects. The base class vtkObjectFactory contains a static method CreateInstance which is used to create vtk objects from the list of registered vtkObjectFactory sub-classes. The first time CreateInstance is called, all dll's or shared libraries in the environment variable VTK_AUTOLOAD_PATH are loaded into the current process. The C functions vtkLoad, vtkGetFactoryCompilerUsed, and vtkGetFactoryVersion are called on each dll. To implement these functions in a shared library or dll, use the macro: VTK_FACTORY_INTERFACE_IMPLEMENT. VTK_AUTOLOAD_PATH is an environment variable containing a colon separated (semi-colon on win32) list of paths.

The vtkObjectFactory can be use to override the creation of any object in VTK with a sub-class of that object. The factories can be registered either at run time with the VTK_AUTOLOAD_PATH, or at compile time with the vtkObjectFactory::RegisterFactory method.

To create an instance of class vtkObjectFactory, simply invoke its constructor as follows

```
obj = vtkObjectFactory
```

30.89.2 Methods

The class vtkObjectFactory has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkObjectFactory class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkObjectFactory = obj.NewInstance ()`

- `vtkObjectFactory = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetVTKSourceVersion ()` - All sub-classes of vtkObjectFactory should must return the version of VTK they were built with. This should be implemented with the macro VTK_SOURCE_VERSION and NOT a call to vtkVersion::GetVTKSourceVersion. As the version needs to be compiled into the file as a string constant. This is critical to determine possible incompatible dynamic factory loads.
- `string = obj.GetDescription ()` - Return a descriptive string describing the factory.
- `int = obj.GetNumberOfOverrides ()` - Return number of overrides this factory can create.
- `string = obj.GetClassOverrideName (int index)` - Return the name of a class override at the given index.
- `string = obj.GetClassOverrideWithName (int index)` - Return the name of the class that will override the class at the given index
- `int = obj.GetEnableFlag (int index)` - Return the enable flag for the class at the given index.
- `string = obj.GetOverrideDescription (int index)` - Return the description for a the class override at the given index.
- `obj.SetEnableFlag (int flag, string className, string subclassName)` - Set and Get the Enable flag for the specific override of className. if subclassName is null, then it is ignored.
- `int = obj.GetEnableFlag (string className, string subclassName)` - Set and Get the Enable flag for the specific override of className. if subclassName is null, then it is ignored.
- `int = obj.HasOverride (string className)` - Return 1 if this factory overrides the given class name, 0 otherwise.
- `int = obj.HasOverride (string className, string subclassName)` - Return 1 if this factory overrides the given class name, 0 otherwise.
- `obj.Disable (string className)` - Set all enable flags for the given class to 0. This will mean that the factory will stop producing class with the given name.
- `string = obj.GetLibraryPath ()` - This returns the path to a dynamically loaded factory.

30.90 vtkObjectFactoryCollection

30.90.1 Usage

vtkObjectFactoryCollection is an object that creates and manipulates lists of object of type vtkObjectFactory.

To create an instance of class vtkObjectFactoryCollection, simply invoke its constructor as follows

```
obj = vtkObjectFactoryCollection
```

30.90.2 Methods

The class vtkObjectFactoryCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkObjectFactoryCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkObjectFactoryCollection = obj.NewInstance ()`
- `vtkObjectFactoryCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkObjectFactory t)` - Get the next ObjectFactory in the list. Return NULL when the end of the list is reached.
- `vtkObjectFactory = obj.GetNextItem ()`

30.91 vtkOutputWindow

30.91.1 Usage

This class is used to encapsulate all text output, so that it will work with operating systems that have a stdout and stderr, and ones that do not. (i.e windows does not). Sub-classes can be provided which can redirect the output to a window.

To create an instance of class vtkOutputWindow, simply invoke its constructor as follows

```
obj = vtkOutputWindow
```

30.91.2 Methods

The class vtkOutputWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutputWindow class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutputWindow = obj.NewInstance ()`
- `vtkOutputWindow = obj.SafeDownCast (vtkObject o)`
- `obj.DisplayText (string )` - Display the text. Four virtual methods exist, depending on the type of message to display. This allows redirection or reformatting of the messages. The default implementation uses DisplayText for all.
- `obj.DisplayErrorText (string )` - Display the text. Four virtual methods exist, depending on the type of message to display. This allows redirection or reformatting of the messages. The default implementation uses DisplayText for all.
- `obj.DisplayWarningText (string )` - Display the text. Four virtual methods exist, depending on the type of message to display. This allows redirection or reformatting of the messages. The default implementation uses DisplayText for all.
- `obj.DisplayGenericWarningText (string )` - Display the text. Four virtual methods exist, depending on the type of message to display. This allows redirection or reformatting of the messages. The default implementation uses DisplayText for all.
- `obj.DisplayDebugText (string )`
- `obj.PromptUserOn ()` - If PromptUser is set to true then each time a line of text is displayed, the user is asked if they want to keep getting messages.
- `obj.PromptUserOff ()` - If PromptUser is set to true then each time a line of text is displayed, the user is asked if they want to keep getting messages.
- `obj.SetPromptUser (int )` - If PromptUser is set to true then each time a line of text is displayed, the user is asked if they want to keep getting messages.

30.92 vtkOverrideInformation

30.92.1 Usage

vtkOverrideInformation is used to represent the information about a class which is overriden in a vtkObjectFactory.

To create an instance of class vtkOverrideInformation, simply invoke its constructor as follows

```
obj = vtkOverrideInformation
```

30.92.2 Methods

The class vtkOverrideInformation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOverrideInformation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOverrideInformation = obj.NewInstance ()`
- `vtkOverrideInformation = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetClassOverrideName ()` - Returns the name of the class that will override the class. For example, if you had a factory that provided an override for vtkVertex called vtkMyVertex, then this would return "vtkMyVertex"
- `string = obj.GetClassOverrideWithName ()` - Return a human readable or GUI displayable description of this override.
- `string = obj.GetDescription ()` - Return the specific object factory that this override occurs in.
- `vtkObjectFactory = obj.GetObjectFactory ()` - Set the class override name
- `obj.SetClassOverrideName (string )` - Set the class override name
- `obj.SetClassOverrideWithName (string )` - Set the class override name Set the class override with name
- `obj.SetDescription (string )` - Set the class override name Set the class override with name Set the description

30.93 vtkOverrideInformationCollection

30.93.1 Usage

vtkOverrideInformationCollection is an object that creates and manipulates lists of objects of type vtkOverrideInformation.

To create an instance of class vtkOverrideInformationCollection, simply invoke its constructor as follows

```
obj = vtkOverrideInformationCollection
```

30.93.2 Methods

The class vtkOverrideInformationCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOverrideInformationCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOverrideInformationCollection = obj.NewInstance ()`
- `vtkOverrideInformationCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkOverrideInformation )` - Add a OverrideInformation to the list.
- `vtkOverrideInformation = obj.GetNextItem ()` - Get the next OverrideInformation in the list.

30.94 vtkParametricBoy

30.94.1 Usage

vtkParametricBoy generates Boy's surface. This is a Model of the projective plane without singularities. It was found by Werner Boy on assignment from David Hilbert.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricBoy, simply invoke its constructor as follows

```
obj = vtkParametricBoy
```

30.94.2 Methods

The class vtkParametricBoy has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricBoy class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricBoy = obj.NewInstance ()`
- `vtkParametricBoy = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Set/Get the scale factor for the z-coordinate. Default = 1/8, giving a nice shape.
- `obj.SetZScale (double )` - Set/Get the scale factor for the z-coordinate. Default = 1/8, giving a nice shape.
- `double = obj.GetZScale ()` - Set/Get the scale factor for the z-coordinate. Default = 1/8, giving a nice shape.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - Boy's surface.

  This function performs the mapping $f(u, v) \rightarrow (x, y, x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x, y, z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.95 vtkParametricConicSpiral

30.95.1 Usage

vtkParametricConicSpiral generates conic spiral surfaces. These can resemble sea shells, or may look like a torus "eating" its own tail.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricConicSpiral, simply invoke its constructor as follows

```
obj = vtkParametricConicSpiral
```

30.95.2 Methods

The class vtkParametricConicSpiral has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricConicSpiral class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricConicSpiral = obj.NewInstance ()`
- `vtkParametricConicSpiral = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Set/Get the scale factor. Default = 0.2
- `obj.SetA (double )` - Set/Get the scale factor. Default = 0.2
- `double = obj.GetA ()` - Set/Get the scale factor. Default = 0.2
- `obj.SetB (double )` - Set/Get the A function coefficient (see equation below). Default = 1.
- `double = obj.GetB ()` - Set/Get the A function coefficient (see equation below). Default = 1.
- `obj.SetC (double )` - Set/Get the B function coefficient (see equation below). Default = 0.1.
- `double = obj.GetC ()` - Set/Get the B function coefficient (see equation below). Default = 0.1.
- `obj.SetN (double )` - Set/Get the C function coefficient (see equation below). Default = 2.
- `double = obj.GetN ()` - Set/Get the C function coefficient (see equation below). Default = 2.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A conic spiral surface.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.96 vtkParametricCrossCap

30.96.1 Usage

vtkParametricCrossCap generates a cross-cap which is a non-orientable self-intersecting single-sided surface. This is one possible image of a projective plane in three-space.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricCrossCap, simply invoke its constructor as follows

```
obj = vtkParametricCrossCap
```

30.96.2 Methods

The class vtkParametricCrossCap has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricCrossCap class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricCrossCap = obj.NewInstance ()`
- `vtkParametricCrossCap = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - A cross-cap.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A cross-cap.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.97 vtkParametricDini

30.97.1 Usage

vtkParametricDini generates Dini's surface. Dini's surface is a surface that posesses constant negative Gaussian curvature

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricDini, simply invoke its constructor as follows

```
obj = vtkParametricDini
```

30.97.2 Methods

The class vtkParametricDini has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricDini class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricDini = obj.NewInstance ()`
- `vtkParametricDini = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Set/Get the scale factor. Default = 1.
- `obj.SetA (double )` - Set/Get the scale factor. Default = 1.
- `double = obj.GetA ()` - Set/Get the scale factor. Default = 1.
- `obj.SetB (double )` - Set/Get the scale factor. Default = 0.2
- `double = obj.GetB ()` - Set/Get the scale factor. Default = 0.2
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - Dini's surface.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.98 vtkParametricEllipsoid

30.98.1 Usage

vtkParametricEllipsoid generates an ellipsoid. If all the radii are the same, we have a sphere. An oblate spheroid occurs if RadiusX = RadiusY ¿ RadiusZ. Here the Z-axis forms the symmetry axis. To a first approximation, this is the shape of the earth. A prolate spheroid occurs if RadiusX = RadiusY ¡ RadiusZ.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricEllipsoid, simply invoke its constructor as follows

```
obj = vtkParametricEllipsoid
```

30.98.2 Methods

The class vtkParametricEllipsoid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricEllipsoid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricEllipsoid = obj.NewInstance ()`
- `vtkParametricEllipsoid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Set/Get the scaling factor for the x-axis. Default = 1.
- `obj.SetXRadius (double )` - Set/Get the scaling factor for the x-axis. Default = 1.
- `double = obj.GetXRadius ()` - Set/Get the scaling factor for the x-axis. Default = 1.
- `obj.SetYRadius (double )` - Set/Get the scaling factor for the y-axis. Default = 1.
- `double = obj.GetYRadius ()` - Set/Get the scaling factor for the y-axis. Default = 1.
- `obj.SetZRadius (double )` - Set/Get the scaling factor for the z-axis. Default = 1.
- `double = obj.GetZRadius ()` - Set/Get the scaling factor for the z-axis. Default = 1.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - An ellipsoid.

  This function performs the mapping $f(u, v) \rightarrow (x, y, x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x, y, z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.99 vtkParametricEnneper

30.99.1 Usage

vtkParametricEnneper generates Enneper's surface. Enneper's surface is a a self-intersecting minimal surface posessing constant negative Gaussian curvature

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricEnneper, simply invoke its constructor as follows

```
obj = vtkParametricEnneper
```

30.99.2 Methods

The class vtkParametricEnneper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricEnneper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricEnneper = obj.NewInstance ()`
- `vtkParametricEnneper = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Enneper's surface.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - Enneper's surface.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uv are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.100 vtkParametricFigure8Klein

30.100.1 Usage

vtkParametricFigure8Klein generates a figure-8 Klein bottle. A Klein bottle is a closed surface with no interior and only one surface. It is unrealisable in 3 dimensions without intersecting surfaces. It can be realised in 4 dimensions by considering the map $F : R^2 \rightarrow R^4$ given by:

- $f(u,v) = ((r * cos(v) + a) * cos(u), (r * cos(v) + a) * sin(u), r * sin(v) * cos(u/2), r * sin(v) * sin(u/2))$

This representation of the immersion in R^3 is formed by taking two Mobius strips and joining them along their boundaries, this is the so called "Figure-8 Klein Bottle"

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricFigure8Klein, simply invoke its constructor as follows

```
obj = vtkParametricFigure8Klein
```

30.100.2 Methods

The class vtkParametricFigure8Klein has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricFigure8Klein class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricFigure8Klein = obj.NewInstance ()`
- `vtkParametricFigure8Klein = obj.SafeDownCast (vtkObject o)`
- `obj.SetRadius (double )` - Set/Get the radius of the bottle.
- `double = obj.GetRadius ()` - Set/Get the radius of the bottle.
- `int = obj.GetDimension ()` - A Figure-8 Klein bottle.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A Figure-8 Klein bottle.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.101 vtkParametricFunction

30.101.1 Usage

vtkParametricFunction is an abstract interface for functions defined by parametric mapping i.e. f(u,v,w)-¿(x,y,z) where u_min ¡= u ¡ u_max, v_min ¡= v ¡ v_max, w_min ¡= w ¡ w_max. (For notational convenience, we will write f(u)-¿x and assume that u means (u,v,w) and x means (x,y,z).)

The interface contains the pure virtual function, Evaluate(), that generates a point and the derivatives at that point which are then used to construct the surface. A second pure virtual function, EvaluateScalar(), can be used to generate a scalar for the surface. Finally, the GetDimension() virtual function is used to differentiate 1D, 2D, and 3D parametric functions. Since this abstract class defines a pure virtual API, its subclasses must implement the pure virtual functions GetDimension(), Evaluate() and EvaluateScalar().

This class has also methods for defining a range of parametric values (u,v,w).
.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.
To create an instance of class vtkParametricFunction, simply invoke its constructor as follows

```
obj = vtkParametricFunction
```

30.101.2 Methods

The class vtkParametricFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricFunction = obj.NewInstance ()`
- `vtkParametricFunction = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()`
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - Performs the mapping $f(uvw)-¿(Pt,Duvw)$f. This is a pure virtual function that must be instantiated in a derived class.

  uvw are the parameters, with u corresponding to uvw[0], v to uvw[1] and w to uvw[2] respectively. Pt is the returned Cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Note that the first three values in Duvw are Du, the next three are Dv, and the final three are Dw. Du Dv Dw are the partial derivatives of the function at the point Pt with respect to u, v and w respectively.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw. This is a pure virtual function that must be instantiated in a derived class.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v, and w. Pt, Duvw are obtained from Evaluate().
- `obj.SetMinimumU (double )` - Set/Get the minimum u-value.
- `double = obj.GetMinimumU ()` - Set/Get the minimum u-value.
- `obj.SetMaximumU (double )` - Set/Get the maximum u-value.
- `double = obj.GetMaximumU ()` - Set/Get the maximum u-value.
- `obj.SetMinimumV (double )` - Set/Get the minimum v-value.
- `double = obj.GetMinimumV ()` - Set/Get the minimum v-value.
- `obj.SetMaximumV (double )` - Set/Get the maximum v-value.
- `double = obj.GetMaximumV ()` - Set/Get the maximum v-value.
- `obj.SetMinimumW (double )` - Set/Get the minimum w-value.
- `double = obj.GetMinimumW ()` - Set/Get the minimum w-value.
- `obj.SetMaximumW (double )` - Set/Get the maximum w-value.
- `double = obj.GetMaximumW ()` - Set/Get the maximum w-value.
- `obj.SetJoinU (int )` - Set/Get the flag which joins the first triangle strip to the last one.

- `int = obj.GetJoinU ()` - Set/Get the flag which joins the first triangle strip to the last one.
- `obj.JoinUOn ()` - Set/Get the flag which joins the first triangle strip to the last one.
- `obj.JoinUOff ()` - Set/Get the flag which joins the first triangle strip to the last one.
- `obj.SetJoinV (int )` - Set/Get the flag which joins the the ends of the triangle strips.
- `int = obj.GetJoinV ()` - Set/Get the flag which joins the the ends of the triangle strips.
- `obj.JoinVOn ()` - Set/Get the flag which joins the the ends of the triangle strips.
- `obj.JoinVOff ()` - Set/Get the flag which joins the the ends of the triangle strips.
- `obj.SetTwistU (int )` - Set/Get the flag which joins the first triangle strip to the last one with a twist. JoinU must also be set if this is set. Used when building some non-orientable surfaces.
- `int = obj.GetTwistU ()` - Set/Get the flag which joins the first triangle strip to the last one with a twist. JoinU must also be set if this is set. Used when building some non-orientable surfaces.
- `obj.TwistUOn ()` - Set/Get the flag which joins the first triangle strip to the last one with a twist. JoinU must also be set if this is set. Used when building some non-orientable surfaces.
- `obj.TwistUOff ()` - Set/Get the flag which joins the first triangle strip to the last one with a twist. JoinU must also be set if this is set. Used when building some non-orientable surfaces.
- `obj.SetTwistV (int )` - Set/Get the flag which joins the ends of the triangle strips with a twist. JoinV must also be set if this is set. Used when building some non-orientable surfaces.
- `int = obj.GetTwistV ()` - Set/Get the flag which joins the ends of the triangle strips with a twist. JoinV must also be set if this is set. Used when building some non-orientable surfaces.
- `obj.TwistVOn ()` - Set/Get the flag which joins the ends of the triangle strips with a twist. JoinV must also be set if this is set. Used when building some non-orientable surfaces.
- `obj.TwistVOff ()` - Set/Get the flag which joins the ends of the triangle strips with a twist. JoinV must also be set if this is set. Used when building some non-orientable surfaces.
- `obj.SetClockwiseOrdering (int )` - Set/Get the flag which determines the ordering of the the vertices forming the triangle strips. The ordering of the points being inserted into the triangle strip is important because it determines the direction of the normals for the lighting. If set, the ordering is clockwise, otherwise the ordering is anti-clockwise. Default is true (i.e. clockwise ordering).
- `int = obj.GetClockwiseOrdering ()` - Set/Get the flag which determines the ordering of the the vertices forming the triangle strips. The ordering of the points being inserted into the triangle strip is important because it determines the direction of the normals for the lighting. If set, the ordering is clockwise, otherwise the ordering is anti-clockwise. Default is true (i.e. clockwise ordering).
- `obj.ClockwiseOrderingOn ()` - Set/Get the flag which determines the ordering of the the vertices forming the triangle strips. The ordering of the points being inserted into the triangle strip is important because it determines the direction of the normals for the lighting. If set, the ordering is clockwise, otherwise the ordering is anti-clockwise. Default is true (i.e. clockwise ordering).
- `obj.ClockwiseOrderingOff ()` - Set/Get the flag which determines the ordering of the the vertices forming the triangle strips. The ordering of the points being inserted into the triangle strip is important because it determines the direction of the normals for the lighting. If set, the ordering is clockwise, otherwise the ordering is anti-clockwise. Default is true (i.e. clockwise ordering).
- `obj.SetDerivativesAvailable (int )` - Set/Get the flag which determines whether derivatives are available from the parametric function (i.e., whether the Evaluate() method returns valid derivatives).

- `int = obj.GetDerivativesAvailable ()` - Set/Get the flag which determines whether derivatives are available from the parametric function (i.e., whether the Evaluate() method returns valid derivatives).
- `obj.DerivativesAvailableOn ()` - Set/Get the flag which determines whether derivatives are available from the parametric function (i.e., whether the Evaluate() method returns valid derivatives).
- `obj.DerivativesAvailableOff ()` - Set/Get the flag which determines whether derivatives are available from the parametric function (i.e., whether the Evaluate() method returns valid derivatives).

30.102 vtkParametricKlein

30.102.1 Usage

vtkParametricKlein generates a "classical" representation of a Klein bottle. A Klein bottle is a closed surface with no interior and only one surface. It is unrealisable in 3 dimensions without intersecting surfaces. It can be realised in 4 dimensions by considering the map $F : R^2 \rightarrow R^4$ given by:

- $f(u, v) = ((r * cos(v) + a) * cos(u), (r * cos(v) + a) * sin(u), r * sin(v) * cos(u/2), r * sin(v) * sin(u/2))$

The classical representation of the immersion in R^3 is returned by this function.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricKlein, simply invoke its constructor as follows

```
obj = vtkParametricKlein
```

30.102.2 Methods

The class vtkParametricKlein has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricKlein class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricKlein = obj.NewInstance ()`
- `vtkParametricKlein = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - A Klein bottle.

  This function performs the mapping $f(u, v) \rightarrow (x, y, x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x, y, z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A Klein bottle.

  This function performs the mapping $f(u, v) \rightarrow (x, y, x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x, y, z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.103 vtkParametricMobius

30.103.1 Usage

vtkParametricMobius generates a Mobius strip.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Du, Dv are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.104 vtkParametricRandomHills

30.104.1 Usage

vtkParametricRandomHills generates a surface covered with randomly placed hills.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.
To create an instance of class vtkParametricRandomHills, simply invoke its constructor as follows

```
obj = vtkParametricRandomHills
```

30.104.2 Methods

The class vtkParametricRandomHills has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricRandomHills class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricRandomHills = obj.NewInstance ()`
- `vtkParametricRandomHills = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Construct a surface of random hills with the following parameters: MinimumU = -10, MaximumU = 10, MinimumV = -10, MaximumV = 10, JoinU = 0, JoinV = 0, TwistU = 0, TwistV = 0; ClockwiseOrdering = 1, DerivativesAvailable = 0, Number of hills = 30, Variance of the hills 2.5 in both x- and y- directions, Scaling factor for the variances 1/3 in both x- and y- directions, Amplitude of each hill = 1, Scaling factor for the amplitude = 1/3, RandomSeed = 1, AllowRandomGeneration = 1.
- `obj.SetNumberOfHills (int )` - Set/Get the number of hills. Default is 30.
- `int = obj.GetNumberOfHills ()` - Set/Get the number of hills. Default is 30.
- `obj.SetHillXVariance (double )` - Set/Get the hill variance in the x-direction. Default is 2.5.
- `double = obj.GetHillXVariance ()` - Set/Get the hill variance in the x-direction. Default is 2.5.
- `obj.SetHillYVariance (double )` - Set/Get the hill variance in the y-direction. Default is 2.5.
- `double = obj.GetHillYVariance ()` - Set/Get the hill variance in the y-direction. Default is 2.5.
- `obj.SetHillAmplitude (double )` - Set/Get the hill amplitude (height). Default is 2.
- `double = obj.GetHillAmplitude ()` - Set/Get the hill amplitude (height). Default is 2.
- `obj.SetRandomSeed (int )` - Set/Get the Seed for the random number generator, a value of 1 will initialize the random number generator, a negative value will initialize it with the system time. Default is 1.
- `int = obj.GetRandomSeed ()` - Set/Get the Seed for the random number generator, a value of 1 will initialize the random number generator, a negative value will initialize it with the system time. Default is 1.
- `obj.SetAllowRandomGeneration (int )` - Set/Get the random generation flag. A value of 0 will disable the generation of random hills on the surface. This allows a reproducible shape to be generated. Any other value means that the generation of the hills will be done randomly. Default is 1.
- `int = obj.GetAllowRandomGeneration ()` - Set/Get the random generation flag. A value of 0 will disable the generation of random hills on the surface. This allows a reproducible shape to be generated. Any other value means that the generation of the hills will be done randomly. Default is 1.
- `obj.AllowRandomGenerationOn ()` - Set/Get the random generation flag. A value of 0 will disable the generation of random hills on the surface. This allows a reproducible shape to be generated. Any other value means that the generation of the hills will be done randomly. Default is 1.

- `obj.AllowRandomGenerationOff ()` - Set/Get the random generation flag. A value of 0 will disable the generation of random hills on the surface. This allows a reproducible shape to be generated. Any other value means that the generation of the hills will be done randomly. Default is 1.
- `obj.SetXVarianceScaleFactor (double )` - Set/Get the scaling factor for the variance in the x-direction. Default is 1/3.
- `double = obj.GetXVarianceScaleFactor ()` - Set/Get the scaling factor for the variance in the x-direction. Default is 1/3.
- `obj.SetYVarianceScaleFactor (double )` - Set/Get the scaling factor for the variance in the y-direction. Default is 1/3.
- `double = obj.GetYVarianceScaleFactor ()` - Set/Get the scaling factor for the variance in the y-direction. Default is 1/3.
- `obj.SetAmplitudeScaleFactor (double )` - Set/Get the scaling factor for the amplitude. Default is 1/3.
- `double = obj.GetAmplitudeScaleFactor ()` - Set/Get the scaling factor for the amplitude. Default is 1/3.
- `obj.GenerateTheHills (void )` - Generate the centers of the hills, their standard deviations and their amplitudes. This function creates a series of vectors representing the u, v coordinates of each hill, its variance in the u, v directions and the amplitude.

  NOTE: This function must be called whenever any of the parameters are changed.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - Construct a terrain consisting of randomly placed hills on a surface.

  It is assumed that the function GenerateTheHills() has been executed to build the vectors of coordinates required to generate the point Pt. Pt represents the sum of all the amplitudes over the space.

  This function performs the mapping $f(u, v) \rightarrow (x, y, x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x, y, z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the Cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.105 vtkParametricRoman

30.105.1 Usage

vtkParametricRoman generates Steiner's Roman Surface.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricRoman, simply invoke its constructor as follows

```
obj = vtkParametricRoman
```

30.105.2 Methods

The class vtkParametricRoman has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricRoman class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricRoman = obj.NewInstance ()`
- `vtkParametricRoman = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Construct Steiner's Roman Surface with the following parameters: MinimumU = 0, MaximumU = Pi, MinimumV = 0, MaximumV = Pi, JoinU = 1, JoinV = 1, TwistU = 1, TwistV = 0; ClockwiseOrdering = 1, DerivativesAvailable = 1, Radius = 1
- `obj.SetRadius (double )` - Set/Get the radius.
- `double = obj.GetRadius ()` - Set/Get the radius.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - Steiner's Roman Surface

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the Cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.106 vtkParametricSuperEllipsoid

30.106.1 Usage

vtkParametricSuperEllipsoid generates a superellipsoid. A superellipsoid is a versatile primitive that is controlled by two parameters n1 and n2. As special cases it can represent a sphere, square box, and closed cylindrical can.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

Also see: http://astronomy.swin.edu.au/ pbourke/surfaces/

To create an instance of class vtkParametricSuperEllipsoid, simply invoke its constructor as follows

```
obj = vtkParametricSuperEllipsoid
```

30.106.2 Methods

The class vtkParametricSuperEllipsoid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricSuperEllipsoid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricSuperEllipsoid = obj.NewInstance ()`
- `vtkParametricSuperEllipsoid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Set/Get the scaling factor for the x-axis. Default = 1.
- `obj.SetXRadius (double )` - Set/Get the scaling factor for the x-axis. Default = 1.
- `double = obj.GetXRadius ()` - Set/Get the scaling factor for the x-axis. Default = 1.
- `obj.SetYRadius (double )` - Set/Get the scaling factor for the y-axis. Default = 1.
- `double = obj.GetYRadius ()` - Set/Get the scaling factor for the y-axis. Default = 1.
- `obj.SetZRadius (double )` - Set/Get the scaling factor for the z-axis. Default = 1.
- `double = obj.GetZRadius ()` - Set/Get the scaling factor for the z-axis. Default = 1.
- `obj.SetN1 (double )` - Set/Get the "squareness" parameter in the z axis. Default = 1.
- `double = obj.GetN1 ()` - Set/Get the "squareness" parameter in the z axis. Default = 1.
- `obj.SetN2 (double )` - Set/Get the "squareness" parameter in the x-y plane. Default = 1.
- `double = obj.GetN2 ()` - Set/Get the "squareness" parameter in the x-y plane. Default = 1.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A superellipsoid.

  This function performs the mapping $f(u, v) \rightarrow (x, y, x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x, y, z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.107 vtkParametricSuperToroid

30.107.1 Usage

vtkParametricSuperToroid generates a supertoroid. Essentially a supertoroid is a torus with the sine and cosine terms raised to a power. A supertoroid is a versatile primitive that is controlled by four parameters r0, r1, n1 and n2. r0, r1 determine the type of torus whilst the value of n1 determines the shape of the torus ring and n2 determines the shape of the cross section of the ring. It is the different values of these powers which give rise to a family of 3D shapes that are all basically toroidal in shape.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

To create an instance of class vtkParametricSuperToroid, simply invoke its constructor as follows

```
obj = vtkParametricSuperToroid
```

30.107.2 Methods

The class vtkParametricSuperToroid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricSuperToroid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricSuperToroid = obj.NewInstance ()`
- `vtkParametricSuperToroid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Set/Get the radius from the center to the middle of the ring of the supertoroid. Default = 1.
- `obj.SetRingRadius (double )` - Set/Get the radius from the center to the middle of the ring of the supertoroid. Default = 1.
- `double = obj.GetRingRadius ()` - Set/Get the radius from the center to the middle of the ring of the supertoroid. Default = 1.
- `obj.SetCrossSectionRadius (double )` - Set/Get the radius of the cross section of ring of the supertoroid. Default = 0.5.
- `double = obj.GetCrossSectionRadius ()` - Set/Get the radius of the cross section of ring of the supertoroid. Default = 0.5.
- `obj.SetXRadius (double )` - Set/Get the scaling factor for the x-axis. Default = 1.
- `double = obj.GetXRadius ()` - Set/Get the scaling factor for the x-axis. Default = 1.
- `obj.SetYRadius (double )` - Set/Get the scaling factor for the y-axis. Default = 1.
- `double = obj.GetYRadius ()` - Set/Get the scaling factor for the y-axis. Default = 1.
- `obj.SetZRadius (double )` - Set/Get the scaling factor for the z-axis. Default = 1.
- `double = obj.GetZRadius ()` - Set/Get the scaling factor for the z-axis. Default = 1.
- `obj.SetN1 (double )` - Set/Get the shape of the torus ring. Default = 1.
- `double = obj.GetN1 ()` - Set/Get the shape of the torus ring. Default = 1.
- `obj.SetN2 (double )` - Set/Get the shape of the cross section of the ring. Default = 1.
- `double = obj.GetN2 ()` - Set/Get the shape of the cross section of the ring. Default = 1.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A supertoroid.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.108 vtkParametricTorus

30.108.1 Usage

vtkParametricTorus generates a torus.

For further information about this surface, please consult the technical description "Parametric surfaces" in http://www.vtk.org/documents.php in the "VTK Technical Documents" section in the VTk.org web pages.

.SECTION Thanks Andrew Maclean a.maclean@cas.edu.au for creating and contributing the class.

To create an instance of class vtkParametricTorus, simply invoke its constructor as follows

```
obj = vtkParametricTorus
```

30.108.2 Methods

The class vtkParametricTorus has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricTorus class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricTorus = obj.NewInstance ()`
- `vtkParametricTorus = obj.SafeDownCast (vtkObject o)`
- `obj.SetRingRadius (double )` - Set/Get the radius from the center to the middle of the ring of the torus. The default value is 1.0.
- `double = obj.GetRingRadius ()` - Set/Get the radius from the center to the middle of the ring of the torus. The default value is 1.0.
- `obj.SetCrossSectionRadius (double )` - Set/Get the radius of the cross section of ring of the torus. The default value is 0.5.
- `double = obj.GetCrossSectionRadius ()` - Set/Get the radius of the cross section of ring of the torus. The default value is 0.5.
- `int = obj.GetDimension ()` - A torus.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `obj.Evaluate (double uvw[3], double Pt[3], double Duvw[9])` - A torus.

  This function performs the mapping $f(u,v) \rightarrow (x,y,x)$, returning it as Pt. It also returns the partial derivatives Du and Dv. $Pt = (x,y,z), Du = (dx/du, dy/du, dz/du), Dv = (dx/dv, dy/dv, dz/dv)$. Then the normal is $N = DuXDv$.
- `double = obj.EvaluateScalar (double uvw[3], double Pt[3], double Duvw[9])` - Calculate a user defined scalar using one or all of uvw, Pt, Duvw.

  uvw are the parameters with Pt being the the Cartesian point, Duvw are the derivatives of this point with respect to u, v and w. Pt, Duvw are obtained from Evaluate().

  This function is only called if the ScalarMode has the value vtkParametricFunctionSource::SCALAR_FUNCTION_DEFI

  If the user does not need to calculate a scalar, then the instantiated function should return zero.

30.109 vtkPerspectiveTransform

30.109.1 Usage

A vtkPerspectiveTransform can be used to describe the full range of homogeneous transformations. It was designed in particular to describe a camera-view of a scene. ¡P¿The order in which you set up the display coordinates (via AdjustZBuffer() and AdjustViewport()), the projection (via Perspective(), Frustum(), or Ortho()) and the camera view (via SetupCamera()) are important. If the transform is in PreMultiply mode, which is the default, set the Viewport and ZBuffer first, then the projection, and finally the camera view. Once the view is set up, the Translate and Rotate methods can be used to move the camera around in world coordinates. If the Oblique() or Stereo() methods are used, they should be called just before SetupCamera(). ¡P¿In PostMultiply mode, you must perform all transformations in the opposite order. This is necessary, for example, if you already have a perspective transformation set up but must adjust the viewport. Another example is if you have a view transformation, and wish to perform translations and rotations in the camera's coordinate system rather than in world coordinates. ¡P¿The SetInput and Concatenate methods can be used to create a transformation pipeline with vtkPerspectiveTransform. See vtkTransform for more information on the transformation pipeline.

To create an instance of class vtkPerspectiveTransform, simply invoke its constructor as follows

```
obj = vtkPerspectiveTransform
```

30.109.2 Methods

The class vtkPerspectiveTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPerspectiveTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPerspectiveTransform = obj.NewInstance ()`
- `vtkPerspectiveTransform = obj.SafeDownCast (vtkObject o)`
- `obj.Identity ()` - Set this transformation to the identity transformation. If the transform has an Input, then the transformation will be reset so that it is the same as the Input.
- `obj.Inverse ()` - Invert the transformation. This will also set a flag so that the transformation will use the inverse of its Input, if an Input has been set.
- `obj.AdjustViewport (double oldXMin, double oldXMax, double oldYMin, double oldYMax, double newXMin,` - Perform an adjustment to the viewport coordinates. By default Ortho, Frustum, and Perspective provide a window of ([-1,+1],[-1,+1]). In PreMultiply mode, you call this method before calling Ortho, Frustum, or Perspective. In PostMultiply mode you can call it after. Note that if you must apply both AdjustZBuffer and AdjustViewport, it makes no difference which order you apply them in.
- `obj.AdjustZBuffer (double oldNearZ, double oldFarZ, double newNearZ, double newFarZ)` - Perform an adjustment to the Z-Buffer range that the near and far clipping planes map to. By default Ortho, Frustum, and Perspective map the near clipping plane to -1 and the far clipping plane to +1. In PreMultiply mode, you call this method before calling Ortho, Frustum, or Perspective. In PostMultiply mode you can call it after.
- `obj.Ortho (double xmin, double xmax, double ymin, double ymax, double znear, double zfar)` - Create an orthogonal projection matrix and concatenate it by the current transformation. The matrix maps [xmin,xmax], [ymin,ymax], [-znear,-zfar] to [-1,+1], [-1,+1], [+1,-1].

- `obj.Frustum (double xmin, double xmax, double ymin, double ymax, double znear, double zfar)` - Create an perspective projection matrix and concatenate it by the current transformation. The matrix maps a frustum with a back plane at -zfar and a front plane at -znear with extent [xmin,xmax],[ymin,ymax] to [-1,+1], [-1,+1], [+1,-1].
- `obj.Perspective (double angle, double aspect, double znear, double zfar)` - Create a perspective projection matrix by specifying the view angle (this angle is in the y direction), the aspect ratio, and the near and far clipping range. The projection matrix is concatenated with the current transformation. This method works via Frustum.
- `obj.Shear (double dxdz, double dydz, double zplane)` - Create a shear transformation about a plane at distance z from the camera. The values dxdz (i.e. dx/dz) and dydz specify the amount of shear in the x and y directions. The 'zplane' specifies the distance from the camera to the plane at which the shear causes zero displacement. Generally you want this plane to be the focal plane. This transformation can be used in combination with Ortho to create an oblique projection. It can also be used in combination with Perspective to provide correct stereo views when the eye is at arbitrary but known positions relative to the center of a flat viewing screen.
- `obj.Stereo (double angle, double focaldistance)` - Create a stereo shear matrix and concatenate it with the current transformation. This can be applied in conjunction with either a perspective transformation (via Frustum or Projection) or an orthographic projection. You must specify the distance from the camera plane to the focal plane, and the angle between the distance vector and the eye. The angle should be negative for the left eye, and positive for the right. This method works via Oblique.
- `obj.SetupCamera (double position[3], double focalpoint[3], double viewup[3])` - Set a view transformation matrix for the camera (this matrix does not contain any perspective) and concatenate it with the current transformation.
- `obj.SetupCamera (double p0, double p1, double p2, double fp0, double fp1, double fp2, double vup0,`
- `obj.Translate (double x, double y, double z)` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Translate (double x[3])` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Translate (float x[3])` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.RotateWXYZ (double angle, double x, double y, double z)` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateWXYZ (double angle, double axis[3])` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateWXYZ (double angle, float axis[3])` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateX (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.RotateY (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.

- `obj.RotateZ (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.Scale (double x, double y, double z)` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Scale (double s[3])` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Scale (float s[3])` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.SetMatrix (vtkMatrix4x4 matrix)` - Set the current matrix directly. This actually calls Identity(), followed by Concatenate(matrix).
- `obj.SetMatrix (double elements[16])` - Set the current matrix directly. This actually calls Identity(), followed by Concatenate(matrix).
- `obj.Concatenate (vtkMatrix4x4 matrix)` - Concatenates the matrix with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (double elements[16])` - Concatenates the matrix with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (vtkHomogeneousTransform transform)` - Concatenate the specified transform with the current transformation according to PreMultiply or PostMultiply semantics. The concatenation is pipelined, meaning that if any of the transformations are changed, even after Concatenate() is called, those changes will be reflected when you call TransformPoint().
- `obj.PreMultiply ()` - Sets the internal state of the transform to PreMultiply. All subsequent operations will occur before those already represented in the current transformation. In homogeneous matrix notation, M = M*A where M is the current transformation matrix and A is the applied matrix. The default is PreMultiply.
- `obj.PostMultiply ()` - Sets the internal state of the transform to PostMultiply. All subsequent operations will occur after those already represented in the current transformation. In homogeneous matrix notation, M = A*M where M is the current transformation matrix and A is the applied matrix. The default is PreMultiply.
- `int = obj.GetNumberOfConcatenatedTransforms ()` - Get the total number of transformations that are linked into this one via Concatenate() operations or via SetInput().
- `vtkHomogeneousTransform = obj.GetConcatenatedTransform (int i)` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.
- `obj.SetInput (vtkHomogeneousTransform input)` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.
- `vtkHomogeneousTransform = obj.GetInput ()` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the

InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.

- `int = obj.GetInverseFlag ()` - Get the inverse flag of the transformation. This controls whether it is the Input or the inverse of the Input that is used as the base transformation. The InverseFlag is flipped every time Inverse() is called. The InverseFlag is off when a transform is first created.
- `obj.Push ()` - Pushes the current transformation onto the transformation stack.
- `obj.Pop ()` - Deletes the transformation on the top of the stack and sets the top to the next transformation on the stack.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make a new transform of the same type – you are responsible for deleting the transform when you are done with it.
- `int = obj.CircuitCheck (vtkAbstractTransform transform)` - Check for self-reference. Will return true if concatenating with the specified transform, setting it to be our inverse, or setting it to be our input will create a circular reference. CircuitCheck is automatically called by SetInput(), SetInverse(), and Concatenate(vtkXTransform *). Avoid using this function, it is experimental.
- `long = obj.GetMTime ()` - Override GetMTime to account for input and concatenation.

30.110 vtkPlane

30.110.1 Usage

vtkPlane provides methods for various plane computations. These include projecting points onto a plane, evaluating the plane equation, and returning plane normal. vtkPlane is a concrete implementation of the abstract class vtkImplicitFunction.

To create an instance of class vtkPlane, simply invoke its constructor as follows

```
obj = vtkPlane
```

30.110.2 Methods

The class vtkPlane has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlane class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPlane = obj.NewInstance ()`
- `vtkPlane = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double g[3])`
- `obj.SetNormal (double , double , double )` - Set/get plane normal. Plane is defined by point and normal.
- `obj.SetNormal (double  a[3])` - Set/get plane normal. Plane is defined by point and normal.
- `double = obj. GetNormal ()` - Set/get plane normal. Plane is defined by point and normal.

- `obj.SetOrigin (double , double , double )` - Set/get point through which plane passes. Plane is defined by point and normal.
- `obj.SetOrigin (double a[3])` - Set/get point through which plane passes. Plane is defined by point and normal.
- `double = obj. GetOrigin ()` - Set/get point through which plane passes. Plane is defined by point and normal.
- `obj.Push (double distance)` - Translate the plane in the direction of the normal by the distance specified. Negative values move the plane in the opposite direction.
- `obj.ProjectPoint (double x[3], double xproj[3])`
- `obj.GeneralizedProjectPoint (double x[3], double xproj[3])`
- `double = obj.DistanceToPlane (double x[3])` - Return the distance of a point x to a plane defined by n(x-p0) = 0. The normal n[3] must be magnitude=1.

30.111 vtkPlaneCollection

30.111.1 Usage

vtkPlaneCollection is an object that creates and manipulates lists of objects of type vtkPlane.

To create an instance of class vtkPlaneCollection, simply invoke its constructor as follows

```
obj = vtkPlaneCollection
```

30.111.2 Methods

The class vtkPlaneCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlaneCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPlaneCollection = obj.NewInstance ()`
- `vtkPlaneCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkPlane )` - Add a plane to the list.
- `vtkPlane = obj.GetNextItem ()` - Get the next plane in the list.
- `vtkPlane = obj.GetItem (int i)` - Get the ith plane in the list.

30.112 vtkPlanes

30.112.1 Usage

vtkPlanes computes the implicit function and function gradient for a set of planes. The planes must define a convex space.

The function value is the closest first order distance of a point to the convex region defined by the planes. The function gradient is the plane normal at the function value. Note that the normals must point outside of the convex region. Thus, a negative function value means that a point is inside the convex region.

There are several methods to define the set of planes. The most general is to supply an instance of vtkPoints and an instance of vtkDataArray. (The points define a point on the plane, and the normals corresponding plane normals.) Two other specialized ways are to 1) supply six planes defining the view frustrum of a camera, and 2) provide a bounding box.

To create an instance of class vtkPlanes, simply invoke its constructor as follows

```
obj = vtkPlanes
```

30.112.2 Methods

The class vtkPlanes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlanes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPlanes = obj.NewInstance ()`
- `vtkPlanes = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double n[3])`
- `obj.SetPoints (vtkPoints )` - Specify a list of points defining points through which the planes pass.
- `vtkPoints = obj.GetPoints ()` - Specify a list of points defining points through which the planes pass.
- `obj.SetNormals (vtkDataArray normals)` - Specify a list of normal vectors for the planes. There is a one-to-one correspondence between plane points and plane normals.
- `vtkDataArray = obj.GetNormals ()` - Specify a list of normal vectors for the planes. There is a one-to-one correspondence between plane points and plane normals.
- `obj.SetFrustumPlanes (double planes[24])` - An alternative method to specify six planes defined by the camera view frustrum. See vtkCamera::GetFrustumPlanes() documentation.
- `obj.SetBounds (double bounds[6])` - An alternative method to specify six planes defined by a bounding box. The bounding box is a six-vector defined as (xmin,xmax,ymin,ymax,zmin,zmax). It defines six planes orthogonal to the x-y-z coordinate axes.
- `obj.SetBounds (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax)` - An alternative method to specify six planes defined by a bounding box. The bounding box is a six-vector defined as (xmin,xmax,ymin,ymax,zmin,zmax). It defines six planes orthogonal to the x-y-z coordinate axes.
- `int = obj.GetNumberOfPlanes ()` - Return the number of planes in the set of planes.
- `vtkPlane = obj.GetPlane (int i)` - Create and return a pointer to a vtkPlane object at the ith position. Asking for a plane outside the allowable range returns NULL. This method always returns the same object. Use GetPlane(int i, vtkPlane *plane) instead
- `obj.GetPlane (int i, vtkPlane plane)` - Create and return a pointer to a vtkPlane object at the ith position. Asking for a plane outside the allowable range returns NULL. This method always returns the same object. Use GetPlane(int i, vtkPlane *plane) instead

30.113 vtkPoints

30.113.1 Usage

vtkPoints represents 3D points. The data model for vtkPoints is an array of vx-vy-vz triplets accessible by (point or cell) id.

To create an instance of class vtkPoints, simply invoke its constructor as follows

```
obj = vtkPoints
```

30.113.2 Methods

The class vtkPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPoints = obj.NewInstance ()`
- `vtkPoints = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate initial memory size.
- `obj.Initialize ()` - Return object to instantiated state.
- `obj.SetData (vtkDataArray )` - Set/Get the underlying data array. This function must be implemented in a concrete subclass to check for consistency. (The tuple size must match the type of data. For example, 3-tuple data array can be assigned to a vector, normal, or points object, but not a tensor object, which has a tuple dimension of 9. Scalars, on the other hand, can have tuple dimension from 1-4, depending on the type of scalar.)
- `vtkDataArray = obj.GetData ()` - Set/Get the underlying data array. This function must be implemented in a concrete subclass to check for consistency. (The tuple size must match the type of data. For example, 3-tuple data array can be assigned to a vector, normal, or points object, but not a tensor object, which has a tuple dimension of 9. Scalars, on the other hand, can have tuple dimension from 1-4, depending on the type of scalar.)
- `int = obj.GetDataType ()` - Return the underlying data type. An integer indicating data type is returned as specified in vtkSetGet.h.
- `obj.SetDataType (int dataType)` - Specify the underlying data type of the object.
- `obj.SetDataTypeToBit ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToChar ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedChar ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToShort ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedShort ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToInt ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedInt ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToLong ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedLong ()` - Specify the underlying data type of the object.

- `obj.SetDataTypeToFloat ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToDouble ()` - Specify the underlying data type of the object.
- `obj.Squeeze ()` - Reclaim any extra memory.
- `obj.Reset ()` - Make object look empty but do not delete memory.
- `obj.DeepCopy (vtkPoints ad)` - Different ways to copy data. Shallow copy does reference count (i.e., assigns pointers and updates reference count); deep copy runs through entire data array assigning values.
- `obj.ShallowCopy (vtkPoints ad)` - Different ways to copy data. Shallow copy does reference count (i.e., assigns pointers and updates reference count); deep copy runs through entire data array assigning values.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this attribute data. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `vtkIdType = obj.GetNumberOfPoints ()` - Return number of points in array.
- `double = obj.GetPoint (vtkIdType id)` - Return a pointer to a double point x[3] for a specific id. WARNING: Just don't use this error-prone method, the returned pointer and its values are only valid as long as another method invocation is not performed. Prefer GetPoint() with the return value in argument.
- `obj.GetPoint (vtkIdType id, double x[3])` - Copy point components into user provided array v[3] for specified id.
- `obj.SetPoint (vtkIdType id, float x[3])` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.SetPoint (vtkIdType id, double x[3])` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.SetPoint (vtkIdType id, double x, double y, double z)` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.InsertPoint (vtkIdType id, float x[3])` - Insert point into object. Range checking performed and memory allocated as necessary.
- `obj.InsertPoint (vtkIdType id, double x[3])` - Insert point into object. Range checking performed and memory allocated as necessary.
- `obj.InsertPoint (vtkIdType id, double x, double y, double z)` - Insert point into object. Range checking performed and memory allocated as necessary.
- `vtkIdType = obj.InsertNextPoint (float x[3])` - Insert point into next available slot. Returns id of slot.
- `vtkIdType = obj.InsertNextPoint (double x[3])` - Insert point into next available slot. Returns id of slot.
- `vtkIdType = obj.InsertNextPoint (double x, double y, double z)` - Insert point into next available slot. Returns id of slot.

- `obj.SetNumberOfPoints (vtkIdType number)` - Specify the number of points for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetPoint() method for fast insertion.
- `obj.GetPoints (vtkIdList ptId, vtkPoints fp)` - Given a list of pt ids, return an array of points.
- `obj.ComputeBounds ()` - Determine (xmin,xmax, ymin,ymax, zmin,zmax) bounds of points.
- `double = obj.GetBounds ()` - Return the bounds of the points.
- `obj.GetBounds (double bounds[6])` - Return the bounds of the points.

30.114 vtkPoints2D

30.114.1 Usage

vtkPoints2D represents 2D points. The data model for vtkPoints2D is an array of vx-vy doublets accessible by (point or cell) id.

To create an instance of class vtkPoints2D, simply invoke its constructor as follows

```
obj = vtkPoints2D
```

30.114.2 Methods

The class vtkPoints2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPoints2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPoints2D = obj.NewInstance ()`
- `vtkPoints2D = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate initial memory size.
- `obj.Initialize ()` - Return object to instantiated state.
- `obj.SetData (vtkDataArray )` - Set/Get the underlying data array. This function must be implemented in a concrete subclass to check for consistency. (The tuple size must match the type of data. For example, 3-tuple data array can be assigned to a vector, normal, or points object, but not a tensor object, which has a tuple dimension of 9. Scalars, on the other hand, can have tuple dimension from 1-4, depending on the type of scalar.)
- `vtkDataArray = obj.GetData ()` - Return the underlying data type. An integer indicating data type is returned as specified in vtkSetGet.h.
- `int = obj.GetDataType ()` - Return the underlying data type. An integer indicating data type is returned as specified in vtkSetGet.h.
- `obj.SetDataType (int dataType)` - Specify the underlying data type of the object.
- `obj.SetDataTypeToBit ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToChar ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedChar ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToShort ()` - Specify the underlying data type of the object.

- `obj.SetDataTypeToUnsignedShort ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToInt ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedInt ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToLong ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToUnsignedLong ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToFloat ()` - Specify the underlying data type of the object.
- `obj.SetDataTypeToDouble ()` - Return a void pointer. For image pipeline interface and other special pointer manipulation.
- `obj.Squeeze ()` - Reclaim any extra memory.
- `obj.Reset ()` - Make object look empty but do not delete memory.
- `obj.DeepCopy (vtkPoints2D ad)` - Different ways to copy data. Shallow copy does reference count (i.e., assigns pointers and updates reference count); deep copy runs through entire data array assigning values.
- `obj.ShallowCopy (vtkPoints2D ad)` - Different ways to copy data. Shallow copy does reference count (i.e., assigns pointers and updates reference count); deep copy runs through entire data array assigning values.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this attribute data. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `vtkIdType = obj.GetNumberOfPoints ()` - Return a pointer to a double point x[2] for a specific id. WARNING: Just don't use this error-prone method, the returned pointer and its values are only valid as long as another method invocation is not performed. Prefer GetPoint() with the return value in argument.
- `obj.GetPoint (vtkIdType id, double x[2])` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.SetPoint (vtkIdType id, float x[2])` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.SetPoint (vtkIdType id, double x[2])` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.SetPoint (vtkIdType id, double x, double y)` - Insert point into object. No range checking performed (fast!). Make sure you use SetNumberOfPoints() to allocate memory prior to using SetPoint().
- `obj.InsertPoint (vtkIdType id, float x[2])` - Insert point into object. Range checking performed and memory allocated as necessary.
- `obj.InsertPoint (vtkIdType id, double x[2])` - Insert point into object. Range checking performed and memory allocated as necessary.
- `obj.InsertPoint (vtkIdType id, double x, double y)` - Insert point into object. Range checking performed and memory allocated as necessary.
- `vtkIdType = obj.InsertNextPoint (float x[2])` - Insert point into next available slot. Returns id of slot.

- `vtkIdType = obj.InsertNextPoint (double x[2])` - Insert point into next available slot. Returns id of slot.
- `vtkIdType = obj.InsertNextPoint (double x, double y)` - Insert point into next available slot. Returns id of slot.
- `obj.SetNumberOfPoints (vtkIdType number)` - Specify the number of points for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetPoint() method for fast insertion.
- `obj.GetPoints (vtkIdList ptId, vtkPoints2D fp)` - Given a list of pt ids, return an array of points.
- `obj.ComputeBounds ()` - Determine (xmin,xmax, ymin,ymax) bounds of points.
- `obj.GetBounds (double bounds[4])` - Return the bounds of the points.

30.115 vtkPolynomialSolversUnivariate

30.115.1 Usage

vtkPolynomialSolversUnivariate provides solvers for univariate polynomial equations with real coefficients. The Tartaglia-Cardan and Ferrari solvers work on polynomials of fixed degree 3 and 4, respectively. The Lin-Bairstow and Sturm solvers work on polynomials of arbitrary degree. The Sturm solver is the most robust solver but only reports roots within an interval and does not report multiplicities. The Lin-Bairstow solver reports multiplicities.

For difficult polynomials, you may wish to use FilterRoots to eliminate some of the roots reported by the Sturm solver. FilterRoots evaluates the derivatives near each root to eliminate cases where a local minimum or maximum is close to zero.

.SECTION Thanks Thanks to Philippe Pebay, Korben Rusek, David Thompson, and Maurice Rojas for implementing these solvers.

To create an instance of class vtkPolynomialSolversUnivariate, simply invoke its constructor as follows

```
obj = vtkPolynomialSolversUnivariate
```

30.115.2 Methods

The class vtkPolynomialSolversUnivariate has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolynomialSolversUnivariate class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolynomialSolversUnivariate = obj.NewInstance ()`
- `vtkPolynomialSolversUnivariate = obj.SafeDownCast (vtkObject o)`

30.116 vtkPriorityQueue

30.116.1 Usage

vtkPriorityQueue is a general object for creating and manipulating lists of object ids (e.g., point or cell ids). Object ids are sorted according to a user-specified priority, where entries at the top of the queue have the smallest values.

This implementation provides a feature beyond the usual ability to insert and retrieve (or pop) values from the queue. It is also possible to pop any item in the queue given its id number. This allows you to delete entries in the queue which can useful for reinserting an item into the queue.

To create an instance of class vtkPriorityQueue, simply invoke its constructor as follows

```
obj = vtkPriorityQueue
```

30.116.2 Methods

The class vtkPriorityQueue has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPriorityQueue class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPriorityQueue = obj.NewInstance ()`
- `vtkPriorityQueue = obj.SafeDownCast (vtkObject o)`
- `obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate initial space for priority queue.
- `obj.Insert (double priority, vtkIdType id)` - Insert id with priority specified. The id is generally an index like a point id or cell id.
- `vtkIdType = obj.Pop (vtkIdType location)` - Same as above but simplified for easier wrapping into interpreted languages.
- `vtkIdType = obj.Peek (vtkIdType location)` - Peek into the queue without actually removing anything. Returns the id.
- `double = obj.DeleteId (vtkIdType id)` - Delete entry in queue with specified id. Returns priority value associated with that id; or VTK_DOUBLE_MAX if not in queue.
- `double = obj.GetPriority (vtkIdType id)` - Get the priority of an entry in the queue with specified id. Returns priority value of that id or VTK_DOUBLE_MAX if not in queue.
- `vtkIdType = obj.GetNumberOfItems ()` - Return the number of items in this queue.
- `obj.Reset ()` - Empty the queue but without releasing memory. This avoids the overhead of memory allocation/deletion.

30.117 vtkProp

30.117.1 Usage

vtkProp is an abstract superclass for any objects that can exist in a rendered scene (either 2D or 3D). Instances of vtkProp may respond to various render methods (e.g., RenderOpaqueGeometry()). vtkProp also defines the API for picking, LOD manipulation, and common instance variables that control visibility, picking, and dragging.

To create an instance of class vtkProp, simply invoke its constructor as follows

```
obj = vtkProp
```

30.117.2 Methods

The class vtkProp has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProp class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProp = obj.NewInstance ()`
- `vtkProp = obj.SafeDownCast (vtkObject o)`
- `obj.GetActors (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `obj.GetActors2D (vtkPropCollection )` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `obj.GetVolumes (vtkPropCollection )` - Set/Get visibility of this vtkProp. Initial value is true.
- `obj.SetVisibility (int )` - Set/Get visibility of this vtkProp. Initial value is true.
- `int = obj.GetVisibility ()` - Set/Get visibility of this vtkProp. Initial value is true.
- `obj.VisibilityOn ()` - Set/Get visibility of this vtkProp. Initial value is true.
- `obj.VisibilityOff ()` - Set/Get visibility of this vtkProp. Initial value is true.
- `obj.SetPickable (int )` - Set/Get the pickable instance variable. This determines if the vtkProp can be picked (typically using the mouse). Also see dragable. Initial value is true.
- `int = obj.GetPickable ()` - Set/Get the pickable instance variable. This determines if the vtkProp can be picked (typically using the mouse). Also see dragable. Initial value is true.
- `obj.PickableOn ()` - Set/Get the pickable instance variable. This determines if the vtkProp can be picked (typically using the mouse). Also see dragable. Initial value is true.
- `obj.PickableOff ()` - Set/Get the pickable instance variable. This determines if the vtkProp can be picked (typically using the mouse). Also see dragable. Initial value is true.
- `obj.Pick ()` - Method fires PickEvent if the prop is picked.
- `obj.SetDragable (int )` - Set/Get the value of the dragable instance variable. This determines if an Prop, once picked, can be dragged (translated) through space. This is typically done through an interactive mouse interface. This does not affect methods such as SetPosition, which will continue to work. It is just intended to prevent some vtkProp'ss from being dragged from within a user interface. Initial value is true.
- `int = obj.GetDragable ()` - Set/Get the value of the dragable instance variable. This determines if an Prop, once picked, can be dragged (translated) through space. This is typically done through an interactive mouse interface. This does not affect methods such as SetPosition, which will continue to work. It is just intended to prevent some vtkProp'ss from being dragged from within a user interface. Initial value is true.
- `obj.DragableOn ()` - Set/Get the value of the dragable instance variable. This determines if an Prop, once picked, can be dragged (translated) through space. This is typically done through an interactive mouse interface. This does not affect methods such as SetPosition, which will continue to work. It is just intended to prevent some vtkProp'ss from being dragged from within a user interface. Initial value is true.

- `obj.DragableOff ()` - Set/Get the value of the dragable instance variable. This determines if an Prop, once picked, can be dragged (translated) through space. This is typically done through an interactive mouse interface. This does not affect methods such as SetPosition, which will continue to work. It is just intended to prevent some vtkProp'ss from being dragged from within a user interface. Initial value is true.

- `long = obj.GetRedrawMTime ()` - In case the Visibility flag is true, tell if the bounds of this prop should be taken into account or ignored during the computation of other bounding boxes, like in vtkRenderer::ResetCamera(). Initial value is true.

- `obj.SetUseBounds (bool )` - In case the Visibility flag is true, tell if the bounds of this prop should be taken into account or ignored during the computation of other bounding boxes, like in vtkRenderer::ResetCamera(). Initial value is true.

- `bool = obj.GetUseBounds ()` - In case the Visibility flag is true, tell if the bounds of this prop should be taken into account or ignored during the computation of other bounding boxes, like in vtkRenderer::ResetCamera(). Initial value is true.

- `obj.UseBoundsOn ()` - In case the Visibility flag is true, tell if the bounds of this prop should be taken into account or ignored during the computation of other bounding boxes, like in vtkRenderer::ResetCamera(). Initial value is true.

- `obj.UseBoundsOff ()` - In case the Visibility flag is true, tell if the bounds of this prop should be taken into account or ignored during the computation of other bounding boxes, like in vtkRenderer::ResetCamera(). Initial value is true.

- `double = obj.GetBounds ()` - Shallow copy of this vtkProp.

- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this vtkProp.

- `obj.InitPathTraversal ()` - vtkProp and its subclasses can be picked by subclasses of vtkAbstractPicker (e.g., vtkPropPicker). The following methods interface with the picking classes and return "pick paths". A pick path is a hierarchical, ordered list of props that form an assembly. Most often, when a vtkProp is picked, its path consists of a single node (i.e., the prop). However, classes like vtkAssembly and vtkPropAssembly can return more than one path, each path being several layers deep. (See vtkAssemblyPath for more information.) To use these methods - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted.

- `vtkAssemblyPath = obj.GetNextPath ()` - vtkProp and its subclasses can be picked by subclasses of vtkAbstractPicker (e.g., vtkPropPicker). The following methods interface with the picking classes and return "pick paths". A pick path is a hierarchical, ordered list of props that form an assembly. Most often, when a vtkProp is picked, its path consists of a single node (i.e., the prop). However, classes like vtkAssembly and vtkPropAssembly can return more than one path, each path being several layers deep. (See vtkAssemblyPath for more information.) To use these methods - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted.

- `int = obj.GetNumberOfPaths ()` - These methods are used by subclasses to place a matrix (if any) in the prop prior to rendering. Generally used only for picking. See vtkProp3D for more information.

- `obj.PokeMatrix (vtkMatrix4x4 )` - These methods are used by subclasses to place a matrix (if any) in the prop prior to rendering. Generally used only for picking. See vtkProp3D for more information.

- `vtkMatrix4x4 = obj.GetMatrix ()` - Set/Get property keys. Property keys can be digest by some rendering passes. For instance, the user may mark a prop as a shadow caster for a shadow mapping render pass. Keys are documented in render pass classes. Initial value is NULL.

- `vtkInformation = obj.GetPropertyKeys ()` - Set/Get property keys. Property keys can be digest by some rendering passes. For instance, the user may mark a prop as a shadow caster for a shadow mapping render pass. Keys are documented in render pass classes. Initial value is NULL.

- `obj.SetPropertyKeys (vtkInformation keys)` - Set/Get property keys. Property keys can be digest by some rendering passes. For instance, the user may mark a prop as a shadow caster for a shadow mapping render pass. Keys are documented in render pass classes. Initial value is NULL.

- `bool = obj.HasKeys (vtkInformation requiredKeys)` - Tells if the prop has all the required keys.

30.118 vtkPropCollection

30.118.1 Usage

vtkPropCollection represents and provides methods to manipulate a list of Props (i.e., vtkProp and subclasses). The list is unsorted and duplicate entries are not prevented.

To create an instance of class vtkPropCollection, simply invoke its constructor as follows

```
obj = vtkPropCollection
```

30.118.2 Methods

The class vtkPropCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPropCollection class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkPropCollection = obj.NewInstance ()`

- `vtkPropCollection = obj.SafeDownCast (vtkObject o)`

- `obj.AddItem (vtkProp a)` - Add an Prop to the list.

- `vtkProp = obj.GetNextProp ()` - Get the next Prop in the list.

- `vtkProp = obj.GetLastProp ()` - Get the last Prop in the list.

- `int = obj.GetNumberOfPaths ()` - Get the number of paths contained in this list. (Recall that a vtkProp can consist of multiple parts.) Used in picking and other activities to get the parts of composite entities like vtkAssembly or vtkPropAssembly.

30.119 vtkProperty2D

30.119.1 Usage

vtkProperty2D contains properties used to render two dimensional images and annotations.

To create an instance of class vtkProperty2D, simply invoke its constructor as follows

```
obj = vtkProperty2D
```

30.119.2 Methods

The class vtkProperty2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProperty2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProperty2D = obj.NewInstance ()`
- `vtkProperty2D = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkProperty2D p)` - Assign one property to another.
- `obj.SetColor (double , double , double )` - Set/Get the RGB color of this property.
- `obj.SetColor (double  a[3])` - Set/Get the RGB color of this property.
- `double = obj. GetColor ()` - Set/Get the RGB color of this property.
- `double = obj.GetOpacity ()` - Set/Get the Opacity of this property.
- `obj.SetOpacity (double )` - Set/Get the Opacity of this property.
- `obj.SetPointSize (float )` - Set/Get the diameter of a Point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetPointSizeMinValue ()` - Set/Get the diameter of a Point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetPointSizeMaxValue ()` - Set/Get the diameter of a Point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetPointSize ()` - Set/Get the diameter of a Point. The size is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `obj.SetLineWidth (float )` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetLineWidthMinValue ()` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetLineWidthMaxValue ()` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `float = obj.GetLineWidth ()` - Set/Get the width of a Line. The width is expressed in screen units. This is only implemented for OpenGL. The default is 1.0.
- `obj.SetLineStipplePattern (int )` - Set/Get the stippling pattern of a Line, as a 16-bit binary pattern (1 = pixel on, 0 = pixel off). This is only implemented for OpenGL. The default is 0xFFFF.
- `int = obj.GetLineStipplePattern ()` - Set/Get the stippling pattern of a Line, as a 16-bit binary pattern (1 = pixel on, 0 = pixel off). This is only implemented for OpenGL. The default is 0xFFFF.
- `obj.SetLineStippleRepeatFactor (int )` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.

- `int = obj.GetLineStippleRepeatFactorMinValue ()` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `int = obj.GetLineStippleRepeatFactorMaxValue ()` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `int = obj.GetLineStippleRepeatFactor ()` - Set/Get the stippling repeat factor of a Line, which specifies how many times each bit in the pattern is to be repeated. This is only implemented for OpenGL. The default is 1.
- `obj.SetDisplayLocation (int )` - The DisplayLocation is either background or foreground. If it is background, then this 2D actor will be drawn behind all 3D props or foreground 2D actors. If it is background, then this 2D actor will be drawn in front of all 3D props and background 2D actors. Within 2D actors of the same DisplayLocation type, order is determined by the order in which the 2D actors were added to the viewport.
- `int = obj.GetDisplayLocationMinValue ()` - The DisplayLocation is either background or foreground. If it is background, then this 2D actor will be drawn behind all 3D props or foreground 2D actors. If it is background, then this 2D actor will be drawn in front of all 3D props and background 2D actors. Within 2D actors of the same DisplayLocation type, order is determined by the order in which the 2D actors were added to the viewport.
- `int = obj.GetDisplayLocationMaxValue ()` - The DisplayLocation is either background or foreground. If it is background, then this 2D actor will be drawn behind all 3D props or foreground 2D actors. If it is background, then this 2D actor will be drawn in front of all 3D props and background 2D actors. Within 2D actors of the same DisplayLocation type, order is determined by the order in which the 2D actors were added to the viewport.
- `int = obj.GetDisplayLocation ()` - The DisplayLocation is either background or foreground. If it is background, then this 2D actor will be drawn behind all 3D props or foreground 2D actors. If it is background, then this 2D actor will be drawn in front of all 3D props and background 2D actors. Within 2D actors of the same DisplayLocation type, order is determined by the order in which the 2D actors were added to the viewport.
- `obj.SetDisplayLocationToBackground ()` - The DisplayLocation is either background or foreground. If it is background, then this 2D actor will be drawn behind all 3D props or foreground 2D actors. If it is background, then this 2D actor will be drawn in front of all 3D props and background 2D actors. Within 2D actors of the same DisplayLocation type, order is determined by the order in which the 2D actors were added to the viewport.
- `obj.SetDisplayLocationToForeground ()` - The DisplayLocation is either background or foreground. If it is background, then this 2D actor will be drawn behind all 3D props or foreground 2D actors. If it is background, then this 2D actor will be drawn in front of all 3D props and background 2D actors. Within 2D actors of the same DisplayLocation type, order is determined by the order in which the 2D actors were added to the viewport.

30.120 vtkQuadratureSchemeDefinition

30.120.1 Usage

An Elemental data type that holds a definition of a numerical quadrature scheme. The definition contains the requisite information to interpolate to the so called quadrature points of the specific scheme. namely:

```
1)
A matrix of shape function weights(shape functions evaluated
```

```
at parametric coordinates of the quadrature points).

2)
The number of quadrature points and cell nodes. These parameters
size the matrix, and allow for convinent evaluation by users
of the definition.
```

To create an instance of class vtkQuadratureSchemeDefinition, simply invoke its constructor as follows

```
obj = vtkQuadratureSchemeDefinition
```

30.120.2 Methods

The class vtkQuadratureSchemeDefinition has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadratureSchemeDefinition class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadratureSchemeDefinition = obj.NewInstance ()`
- `vtkQuadratureSchemeDefinition = obj.SafeDownCast (vtkObject o)`
- `int = obj.DeepCopy (vtkQuadratureSchemeDefinition other)` - Deep copy.
- `int = obj.SaveState (vtkXMLDataElement e)` - Put the object into an XML representation. The element passed in is assumed to be empty.
- `int = obj.RestoreState (vtkXMLDataElement e)` - Restore the object from an XML representation.
- `obj.Clear ()` - Release all allocated resources and set the object to an unitialized state.
- `obj.Initialize (int cellType, int numberOfNodes, int numberOfQuadraturePoints, double shapeFunctior` - Initialize the object allocating resources as needed.
- `obj.Initialize (int cellType, int numberOfNodes, int numberOfQuadraturePoints, double shapeFunctior` - Initialize the object allocating resources as needed.
- `int = obj.GetCellType () const` - Access to an alternative key.
- `int = obj.GetQuadratureKey () const` - Get the number of nodes associated with the interpolation.
- `int = obj.GetNumberOfNodes () const` - Get the number of quadrature points associated with the scheme.
- `int = obj.GetNumberOfQuadraturePoints () const` - Get the array of shape function weights. Shape function weights are the shape functions evaluated at the quadrature points. There are "NumberOfNodes" weights for each quadrature point.

30.121 vtkQuadric

30.121.1 Usage

vtkQuadric evaluates the quadric function F(x,y,z) = a0*x$\hat{2}$ + a1*y$\hat{2}$ + a2*z$\hat{2}$ + a3*x*y + a4*y*z + a5*x*z + a6*x + a7*y + a8*z + a9. vtkQuadric is a concrete implementation of vtkImplicitFunction.

To create an instance of class vtkQuadric, simply invoke its constructor as follows

```
obj = vtkQuadric
```

30.121.2 Methods

The class vtkQuadric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadric class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadric = obj.NewInstance ()`
- `vtkQuadric = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double g[3])`
- `obj.SetCoefficients (double a[10])`
- `obj.SetCoefficients (double a0, double a1, double a2, double a3, double a4, double a5, double a6, d`
- `double = obj. GetCoefficients ()`

30.122 vtkRandomSequence

30.122.1 Usage

vtkRandomSequence defines the interface of any sequence of random numbers.

At this level of abstraction, there is no assumption about the distribution of the numbers or about the quality of the sequence of numbers to be statistically independent. There is no assumption about the range of values.

To the question about why a random "sequence" class instead of a random "generator" class or to a random "number" class?, see the OOSC book: "Object-Oriented Software Construction", 2nd Edition, by Bertrand Meyer. chapter 23, "Principles of class design", "Pseudo-random number generators: a design exercise", page 754–755.

To create an instance of class vtkRandomSequence, simply invoke its constructor as follows

```
obj = vtkRandomSequence
```

30.122.2 Methods

The class vtkRandomSequence has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRandomSequence class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRandomSequence = obj.NewInstance ()`
- `vtkRandomSequence = obj.SafeDownCast (vtkObject o)`
- `double = obj.GetValue ()` - Current value
- `obj.Next ()` - Move to the next number in the random sequence.

30.123 vtkReferenceCount

30.123.1 Usage

vtkReferenceCount functionality has now been moved into vtkObject

To create an instance of class vtkReferenceCount, simply invoke its constructor as follows

```
obj = vtkReferenceCount
```

30.123.2 Methods

The class vtkReferenceCount has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkReferenceCount class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkReferenceCount = obj.NewInstance ()`
- `vtkReferenceCount = obj.SafeDownCast (vtkObject o)`

30.124 vtkRungeKutta2

30.124.1 Usage

This is a concrete sub-class of vtkInitialValueProblemSolver. It uses a 2nd order Runge-Kutta method to obtain the values of a set of functions at the next time step.

To create an instance of class vtkRungeKutta2, simply invoke its constructor as follows

```
obj = vtkRungeKutta2
```

30.124.2 Methods

The class vtkRungeKutta2 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRungeKutta2 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRungeKutta2 = obj.NewInstance ()`
- `vtkRungeKutta2 = obj.SafeDownCast (vtkObject o)`

30.125 vtkRungeKutta4

30.125.1 Usage

This is a concrete sub-class of vtkInitialValueProblemSolver. It uses a 4th order Runge-Kutta method to obtain the values of a set of functions at the next time step.

To create an instance of class vtkRungeKutta4, simply invoke its constructor as follows

```
obj = vtkRungeKutta4
```

30.125.2 Methods

The class vtkRungeKutta4 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRungeKutta4 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRungeKutta4 = obj.NewInstance ()`
- `vtkRungeKutta4 = obj.SafeDownCast (vtkObject o)`

30.126 vtkRungeKutta45

30.126.1 Usage

This is a concrete sub-class of vtkInitialValueProblemSolver. It uses a 5th order Runge-Kutta method with stepsize control to obtain the values of a set of functions at the next time step. The stepsize is adjusted by calculating an estimated error using an embedded 4th order Runge-Kutta formula: Press, W. H. et al., 1992, Numerical Recipes in Fortran, Second Edition, Cambridge University Press Cash, J.R. and Karp, A.H. 1990, ACM Transactions on Mathematical Software, vol 16, pp 201-222

To create an instance of class vtkRungeKutta45, simply invoke its constructor as follows

```
obj = vtkRungeKutta45
```

30.126.2 Methods

The class vtkRungeKutta45 has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRungeKutta45 class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRungeKutta45 = obj.NewInstance ()`
- `vtkRungeKutta45 = obj.SafeDownCast (vtkObject o)`

30.127 vtkScalarsToColors

30.127.1 Usage

vtkScalarsToColors is a general purpose superclass for objects that convert scalars to colors. This include vtkLookupTable classes and color transfer functions.

The scalars to color mapping can be augmented with an additional uniform alpha blend. This is used, for example, to blend a vtkActor's opacity with the lookup table values.

To create an instance of class vtkScalarsToColors, simply invoke its constructor as follows

```
obj = vtkScalarsToColors
```

30.127.2 Methods

The class vtkScalarsToColors has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScalarsToColors class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScalarsToColors = obj.NewInstance ()`
- `vtkScalarsToColors = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsOpaque ()` - Return true if all of the values defining the mapping have an opacity equal to 1. Default implementation return true.
- `obj.Build ()` - Perform any processing required (if any) before processing scalars.
- `double = obj.GetRange ()` - Sets/Gets the range of scalars which will be mapped.
- `obj.SetRange (double min, double max)` - Sets/Gets the range of scalars which will be mapped.
- `obj.SetRange (double rng[2])` - Map one value through the lookup table and return a color defined as a RGBA unsigned char tuple (4 bytes).
- `obj.GetColor (double v, double rgb[3])` - Map one value through the lookup table and return the color as an RGB array of doubles between 0 and 1.
- `double = obj.GetColor (double v)` - Map one value through the lookup table and return the alpha value (the opacity) as a double between 0 and 1.
- `double = obj.GetOpacity (double )` - Map one value through the lookup table and return the luminance 0.3*red + 0.59*green + 0.11*blue as a double between 0 and 1. Returns the luminance value for the specified scalar value.
- `double = obj.GetLuminance (double x)` - Specify an additional opacity (alpha) value to blend with. Values != 1 modify the resulting color consistent with the requested form of the output. This is typically used by an actor in order to blend its opacity.
- `obj.SetAlpha (double alpha)` - Specify an additional opacity (alpha) value to blend with. Values != 1 modify the resulting color consistent with the requested form of the output. This is typically used by an actor in order to blend its opacity.
- `double = obj.GetAlpha ()` - Specify an additional opacity (alpha) value to blend with. Values != 1 modify the resulting color consistent with the requested form of the output. This is typically used by an actor in order to blend its opacity.
- `vtkUnsignedCharArray = obj.MapScalars (vtkDataArray scalars, int colorMode, int component)` - An internal method maps a data array into a 4-component, unsigned char RGBA array. The color mode determines the behavior of mapping. If VTK_COLOR_MODE_DEFAULT is set, then unsigned char data arrays are treated as colors (and converted to RGBA if necessary); otherwise, the data is mapped through this instance of ScalarsToColors. The offset is used for data arrays with more than one component; it indicates which component to use to do the blending. When the component argument is -1, then the this object uses its own selected technique to change a vector into a scalar to map.
- `obj.SetVectorMode (int )` - Change mode that maps vectors by magnitude vs. component.
- `int = obj.GetVectorMode ()` - Change mode that maps vectors by magnitude vs. component.

- `obj.SetVectorModeToMagnitude ()` - Change mode that maps vectors by magnitude vs. component.
- `obj.SetVectorModeToComponent ()` - Change mode that maps vectors by magnitude vs. component.
- `obj.SetVectorComponent (int )` - If the mapper does not select which component of a vector to map to colors, you can specify it here.
- `int = obj.GetVectorComponent ()` - If the mapper does not select which component of a vector to map to colors, you can specify it here.
- `obj.MapScalarsThroughTable (vtkDataArray scalars, string output, int outputFormat)` - Map a set of scalars through the lookup table in a single operation. The output format can be set to VTK_RGBA (4 components), VTK_RGB (3 components), VTK_LUMINANCE (1 component, greyscale), or VTK_LUMINANCE_ALPHA (2 components) If not supplied, the output format defaults to RGBA.
- `obj.MapScalarsThroughTable (vtkDataArray scalars, string output)` - An internal method typically not used in applications.
- `vtkUnsignedCharArray = obj.ConvertUnsignedCharToRGBA (vtkUnsignedCharArray colors, int numComp, int` - An internal method used to convert a color array to RGBA. The method instantiates a vtkUnsignedCharArray and returns it. The user is responsible for managing the memory.
- `int = obj.UsingLogScale ()` - This should return 1 is the subclass is using log scale for mapping scalars to colors. Default implementation returns 0.

30.128 vtkServerSocket

30.128.1 Usage

To create an instance of class vtkServerSocket, simply invoke its constructor as follows

```
obj = vtkServerSocket
```

30.128.2 Methods

The class vtkServerSocket has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkServerSocket class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkServerSocket = obj.NewInstance ()`
- `vtkServerSocket = obj.SafeDownCast (vtkObject o)`
- `int = obj.CreateServer (int port)` - Creates a server socket at a given port and binds to it. Returns -1 on error. 0 on success.
- `vtkClientSocket = obj.WaitForConnection (long msec)` - Waits for a connection. When a connection is received a new vtkClientSocket object is created and returned. Returns NULL on timeout.
- `int = obj.GetServerPort ()` - Returns the port on which the server is running.

30.129 vtkShortArray

30.129.1 Usage

vtkShortArray is an array of values of type short. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkShortArray, simply invoke its constructor as follows

```
obj = vtkShortArray
```

30.129.2 Methods

The class vtkShortArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkShortArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkShortArray = obj.NewInstance ()`
- `vtkShortArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, short tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, short tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, short tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (short tuple)` - Get the data at a particular index.
- `short = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, short value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, short f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (short f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (short array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (short array, vtkIdType size, int save, int deleteMethod)`

30.130 vtkSignedCharArray

30.130.1 Usage

vtkSignedCharArray is an array of values of type signed char. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkSignedCharArray, simply invoke its constructor as follows

```
obj = vtkSignedCharArray
```

30.130.2 Methods

The class vtkSignedCharArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSignedCharArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSignedCharArray = obj.NewInstance ()`
- `vtkSignedCharArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `signed = obj.char GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, signed char value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, signed char f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (signed char f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `signed = obj.string WritePointer (vtkIdType id, vtkIdType number)` - Get the address of a particular data index. Performs no checks to verify that the memory has been allocated etc.
- `signed = obj.string GetPointer (vtkIdType id)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.

30.131 vtkSocket

30.131.1 Usage

This abstract class encapsulates a BSD socket. It provides an API for basic socket operations.

To create an instance of class vtkSocket, simply invoke its constructor as follows

```
obj = vtkSocket
```

30.131.2 Methods

The class vtkSocket has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSocket class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSocket = obj.NewInstance ()`
- `vtkSocket = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetConnected ()` - Close the socket.
- `obj.CloseSocket ()` - These methods send data over the socket. Returns 1 on success, 0 on error and raises vtkCommand::ErrorEvent.

30.132 vtkSocketCollection

30.132.1 Usage

Apart from being vtkCollection subclass for sockets, this class provides means to wait for activity on all the sockets in the collection simultaneously.

To create an instance of class vtkSocketCollection, simply invoke its constructor as follows

```
obj = vtkSocketCollection
```

30.132.2 Methods

The class vtkSocketCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSocketCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSocketCollection = obj.NewInstance ()`
- `vtkSocketCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkSocket soc)`
- `int = obj.SelectSockets (long msec)` - Select all Connected sockets in the collection. If msec is specified, it timesout after msec milliseconds on inactivity. Returns 0 on timeout, -1 on error; 1 is a socket was selected. The selected socket can be retrieved by GetLastSelectedSocket().
- `vtkSocket = obj.GetLastSelectedSocket ()` - Overridden to unset SelectedSocket.
- `obj.ReplaceItem (int i, vtkObject )` - Overridden to unset SelectedSocket.
- `obj.RemoveItem (int i)` - Overridden to unset SelectedSocket.
- `obj.RemoveItem (vtkObject )` - Overridden to unset SelectedSocket.
- `obj.RemoveAllItems ()` - Overridden to unset SelectedSocket.

30.133 vtkSphericalTransform

30.133.1 Usage

vtkSphericalTransform will convert (r,phi,theta) coordinates to (x,y,z) coordinates and back again. The angles are given in radians. By default, it converts spherical coordinates to rectangular, but GetInverse() returns a transform that will do the opposite. The equation that is used is x = r*sin(phi)*cos(theta), y = r*sin(phi)*sin(theta), z = r*cos(phi).

To create an instance of class vtkSphericalTransform, simply invoke its constructor as follows

```
obj = vtkSphericalTransform
```

30.133.2 Methods

The class vtkSphericalTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphericalTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSphericalTransform = obj.NewInstance ()`
- `vtkSphericalTransform = obj.SafeDownCast (vtkObject o)`
- `vtkAbstractTransform = obj.MakeTransform ()` - Make another transform of the same type.

30.134 vtkStringArray

30.134.1 Usage

Points and cells may sometimes have associated data that are stored as strings, e.g. many information visualization projects. This class provides a reasonably clean way to store and access those.

To create an instance of class vtkStringArray, simply invoke its constructor as follows

```
obj = vtkStringArray
```

30.134.2 Methods

The class vtkStringArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStringArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStringArray = obj.NewInstance ()`
- `vtkStringArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()`
- `int = obj.IsNumeric ()` - Release storage and reset array to initial state.
- `obj.Initialize ()` - Release storage and reset array to initial state.

- `int = obj.GetDataTypeSize ()` - Return the size of the data type. WARNING: This may not mean what you expect with strings. It will return sizeof(vtkstd::string) and not take into account the data included in any particular string.
- `obj.Squeeze ()` - Resize the array while conserving the data.
- `int = obj.Resize (vtkIdType numTuples)` - Resize the array while conserving the data.
- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.
- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at ith location in this array. Note that memory allocation is performed as necessary to hold the data.
- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at the end in this array. Note that memory allocation is performed as necessary to hold the data. Returns the location at which the data was inserted.
- `obj.InterpolateTuple (vtkIdType i, vtkIdList ptIndices, vtkAbstractArray source, double weights)` - Set the ith tuple in this array as the interpolated tuple value, given the ptIndices in the source array and associated interpolation weights. This method assumes that the two arrays are of the same type and strcuture.
- `obj.InterpolateTuple (vtkIdType i, vtkIdType id1, vtkAbstractArray source1, vtkIdType id2, vtkAbstr`
- `obj.GetTuples (vtkIdList ptIds, vtkAbstractArray output)` - Given a list of indices, return an array of values. You must insure that the output array has been previously allocated with enough space to hold the data and that the types match sufficiently to allow conversion (if necessary).
- `obj.GetTuples (vtkIdType p1, vtkIdType p2, vtkAbstractArray output)` - Get the values for the range of indices specified (i.e., p1-¿p2 inclusive). You must insure that the output array has been previously allocated with enough space to hold the data and that the type of the output array is compatible with the type of this array.
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate memory for this array. Delete old storage only if necessary. Note that ext is no longer used.
- `vtkStdString = obj.\&GetValue (vtkIdType id)` - Get the data at a particular index.
- `obj.SetValue (vtkIdType id, string value)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetNumberOfTuples (vtkIdType number)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `vtkIdType = obj.GetNumberOfValues ()`
- `int = obj.GetNumberOfElementComponents ()`
- `int = obj.GetElementComponentSize ()` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, string val)` - Insert data at a specified position in the array.

- `vtkIdType = obj.InsertNextValue (string f)` - Insert data at the end of the array. Return its location in the array.
- `obj.DeepCopy (vtkAbstractArray aa)` - Deep copy of another string array. Will complain and change nothing if the array passed in is not a vtkStringArray.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this data array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.

  This function takes into account the size of the contents of the strings as well as the string containers themselves.
- `vtkArrayIterator = obj.NewIterator ()` - Returns a vtkArrayIteratorTemplate¡vtkStdString¿.
- `vtkIdType = obj.GetDataSize ()` - Returns the size of the data in DataTypeSize units. Thus, the number of bytes for the data can be computed by GetDataSize() * GetDataTypeSize(). The size computation includes the string termination character for each string.
- `vtkIdType = obj.LookupValue (string value)`
- `obj.LookupValue (string value, vtkIdList ids)`
- `obj.DataChanged ()` - Tell the array explicitly that the data has changed. This is only necessary to call when you modify the array contents without using the array's API (i.e. you retrieve a pointer to the data and modify the array contents). You need to call this so that the fast lookup will know to rebuild itself. Otherwise, the lookup functions will give incorrect results.
- `obj.DataElementChanged (vtkIdType id)` - Tell the array explicitly that a single data element has changed. Like DataChanged(), then is only necessary when you modify the array contents without using the array's API.
- `obj.ClearLookup ()` - Delete the associated fast lookup data structure on this array, if it exists. The lookup will be rebuilt on the next call to a lookup function.

30.135 vtkStructuredData

30.135.1 Usage

vtkStructuredData is an abstract class that specifies an interface for topologically regular data. Regular data is data that can be accessed in rectangular fashion using an i-j-k index. A finite difference grid, a volume, or a pixmap are all considered regular.

To create an instance of class vtkStructuredData, simply invoke its constructor as follows

```
obj = vtkStructuredData
```

30.135.2 Methods

The class vtkStructuredData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredData = obj.NewInstance ()`
- `vtkStructuredData = obj.SafeDownCast (vtkObject o)`

30.136 vtkStructuredVisibilityConstraint

30.136.1 Usage

vtkStructuredVisibilityConstraint is a general class to manage a list of points/cell marked as invalid or invisible. Currently, it does this by maintaining an unsigned char array associated with points/cells. To conserve memory, this array is allocated only when it is needed (when Blank() is called the first time). Make sure to call Initialize() with the right dimensions before calling any methods that set/get visibility.

To create an instance of class vtkStructuredVisibilityConstraint, simply invoke its constructor as follows

```
obj = vtkStructuredVisibilityConstraint
```

30.136.2 Methods

The class vtkStructuredVisibilityConstraint has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredVisibilityConstraint class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredVisibilityConstraint = obj.NewInstance ()`
- `vtkStructuredVisibilityConstraint = obj.SafeDownCast (vtkObject o)`
- `char = obj.IsVisible (vtkIdType id)` - Returns 1 is the point/cell is visible, 0 otherwise.
- `obj.Blank (vtkIdType id)` - Sets the visibility flag of the given point/cell off. The first time blank is called, a new visibility array is created if it doesn't exist.
- `obj.UnBlank (vtkIdType id)` - Sets the visibility flag of the given point/cell on.
- `int = obj. GetDimensions ()` - Get the dimensions used to initialize the object.
- `obj.Initialize (int dims[3])` - Set the dimensions and set the Initialized flag to 1. Once an object is initialized, it's dimensions can not be changed anymore.
- `obj.SetVisibilityById (vtkUnsignedCharArray vis)` - Set/Get the array used to store the visibility flags.
- `vtkUnsignedCharArray = obj.GetVisibilityById ()` - Set/Get the array used to store the visibility flags.
- `obj.ShallowCopy (vtkStructuredVisibilityConstraint src)` - Copies the dimensions, the visibility array pointer and the initialized flag.
- `obj.DeepCopy (vtkStructuredVisibilityConstraint src)` - Copies the dimensions, the visibility array and the initialized flag.
- `char = obj.IsConstrained ()`

30.137 vtkTableExtentTranslator

30.137.1 Usage

vtkTableExtentTranslator provides a vtkExtentTranslator that is programmed with a specific extent corresponding to each piece number. Readers can provide this to an application to allow the pipeline to execute using the same piece breakdown that is provided in the input file.

To create an instance of class vtkTableExtentTranslator, simply invoke its constructor as follows

```
obj = vtkTableExtentTranslator
```

30.137.2 Methods

The class vtkTableExtentTranslator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableExtentTranslator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableExtentTranslator = obj.NewInstance ()`
- `vtkTableExtentTranslator = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPieces (int pieces)`
- `obj.SetNumberOfPiecesInTable (int pieces)` - Set the real number of pieces in the extent table.
- `int = obj.GetNumberOfPiecesInTable ()` - Set the real number of pieces in the extent table.
- `int = obj.PieceToExtent ()` - Called to translate the current piece into an extent. This is not thread safe.
- `int = obj.PieceToExtentByPoints ()` - Not supported by this subclass of vtkExtentTranslator.
- `int = obj.PieceToExtentThreadSafe (int piece, int numPieces, int ghostLevel, int wholeExtent, int r` - Not supported by this subclass of vtkExtentTranslator.
- `obj.SetExtentForPiece (int piece, int extent)` - Set the extent to be used for a piece. This sets the extent table entry for the piece.
- `obj.GetExtentForPiece (int piece, int extent)` - Get the extent table entry for the given piece. This is only for code that is setting up the table. Extent translation should always be done through the PieceToExtent method.
- `obj.SetMaximumGhostLevel (int )` - Set the maximum ghost level that can be requested. This can be used by a reader to make sure an extent request does not go outside the boundaries of the piece's file.
- `int = obj.GetMaximumGhostLevel ()` - Set the maximum ghost level that can be requested. This can be used by a reader to make sure an extent request does not go outside the boundaries of the piece's file.
- `obj.SetPieceAvailable (int piece, int available)` - Get/Set whether the given piece is available. Requesting a piece that is not available will produce errors in the pipeline.
- `int = obj.GetPieceAvailable (int piece)` - Get/Set whether the given piece is available. Requesting a piece that is not available will produce errors in the pipeline.

30.138 vtkTensor

30.138.1 Usage

vtkTensor is a floating point representation of an nxn tensor. vtkTensor provides methods for assignment and reference of tensor components. It does it in such a way as to minimize data copying.

To create an instance of class vtkTensor, simply invoke its constructor as follows

```
obj = vtkTensor
```

30.138.2 Methods

The class vtkTensor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTensor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTensor = obj.NewInstance ()`
- `vtkTensor = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Initialize tensor components to 0.0.
- `double = obj.GetComponent (int i, int j)` - Get the tensor component (i,j).
- `obj.SetComponent (int i, int j, double v)` - Set the value of the tensor component (i,j).
- `obj.AddComponent (int i, int j, double v)` - Add to the value of the tensor component at location (i,j).
- `obj.DeepCopy (vtkTensor t)` - Deep copy of one tensor to another tensor.

30.139 vtkThreadMessager

30.139.1 Usage

vtkMultithreader is a class that provides support for messaging between threads multithreaded using pthreads or Windows messaging.

To create an instance of class vtkThreadMessager, simply invoke its constructor as follows

```
obj = vtkThreadMessager
```

30.139.2 Methods

The class vtkThreadMessager has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThreadMessager class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThreadMessager = obj.NewInstance ()`
- `vtkThreadMessager = obj.SafeDownCast (vtkObject o)`
- `obj.WaitForMessage ()` - Wait (block, non-busy) until another thread sends a message.
- `obj.SendWakeMessage ()` - Send a message to all threads who are waiting via WaitForMessage().
- `obj.EnableWaitForReceiver ()` - pthreads only. If the wait is enabled, the thread who is to call WaitForMessage() will block until a receiver thread is ready to receive.
- `obj.DisableWaitForReceiver ()` - pthreads only. If the wait is enabled, the thread who is to call WaitForMessage() will block until a receiver thread is ready to receive.
- `obj.WaitForReceiver ()` - pthreads only. If wait is enable, this will block until one thread is ready to receive a message.
- `obj.SendMessage ()` - @deprecated Replaced by vtkThreadMessager::SendWakeMessage() as of VTK 5.0.

30.140 vtkTimePointUtility

30.140.1 Usage

vtkTimePointUtility is provides methods to perform common time operations.

To create an instance of class vtkTimePointUtility, simply invoke its constructor as follows

```
obj = vtkTimePointUtility
```

30.140.2 Methods

The class vtkTimePointUtility has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTimePointUtility class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTimePointUtility = obj.NewInstance ()`
- `vtkTimePointUtility = obj.SafeDownCast (vtkObject o)`

30.141 vtkTimerLog

30.141.1 Usage

vtkTimerLog contains walltime and cputime measurements associated with a given event. These results can be later analyzed when "dumping out" the table.

In addition, vtkTimerLog allows the user to simply get the current time, and to start/stop a simple timer separate from the timing table logging.

To create an instance of class vtkTimerLog, simply invoke its constructor as follows

```
obj = vtkTimerLog
```

30.141.2 Methods

The class vtkTimerLog has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTimerLog class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTimerLog = obj.NewInstance ()`
- `vtkTimerLog = obj.SafeDownCast (vtkObject o)`
- `obj.StartTimer ()` - Set the StartTime to the current time. Used with GetElapsedTime().
- `obj.StopTimer ()` - Sets EndTime to the current time. Used with GetElapsedTime().
- `double = obj.GetElapsedTime ()` - Returns the difference between StartTime and EndTime as a doubleing point value indicating the elapsed time in seconds.

30.142 vtkTransform

30.142.1 Usage

A vtkTransform can be used to describe the full range of linear (also known as affine) coordinate transformations in three dimensions, which are internally represented as a 4x4 homogeneous transformation matrix. When you create a new vtkTransform, it is always initialized to the identity transformation. ¡P¿The SetInput() method allows you to set another transform, instead of the identity transform, to be the base transformation. There is a pipeline mechanism to ensure that when the input is modified, the current transformation will be updated accordingly. This pipeline mechanism is also supported by the Concatenate() method. ¡P¿Most of the methods for manipulating this transformation, e.g. Translate, Rotate, and Concatenate, can operate in either PreMultiply (the default) or PostMultiply mode. In PreMultiply mode, the translation, concatenation, etc. will occur before any transformations which are represented by the current matrix. In PostMultiply mode, the additional transformation will occur after any transformations represented by the current matrix. ¡P¿This class performs all of its operations in a right handed coordinate system with right handed rotations. Some other graphics libraries use left handed coordinate systems and rotations.

To create an instance of class vtkTransform, simply invoke its constructor as follows

```
obj = vtkTransform
```

30.142.2 Methods

The class vtkTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransform = obj.NewInstance ()`
- `vtkTransform = obj.SafeDownCast (vtkObject o)`
- `obj.Identity ()` - Set the transformation to the identity transformation. If the transform has an Input, then the transformation will be reset so that it is the same as the Input.
- `obj.Inverse ()` - Invert the transformation. This will also set a flag so that the transformation will use the inverse of its Input, if an Input has been set.
- `obj.Translate (double x, double y, double z)` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Translate (double x[3])` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Translate (float x[3])` - Create a translation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.RotateWXYZ (double angle, double x, double y, double z)` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateWXYZ (double angle, double axis[3])` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.

- `obj.RotateWXYZ (double angle, float axis[3])` - Create a rotation matrix and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is in degrees, and (x,y,z) specifies the axis that the rotation will be performed around.
- `obj.RotateX (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.RotateY (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.RotateZ (double angle)` - Create a rotation matrix about the X, Y, or Z axis and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics. The angle is expressed in degrees.
- `obj.Scale (double x, double y, double z)` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Scale (double s[3])` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Scale (float s[3])` - Create a scale matrix (i.e. set the diagonal elements to x, y, z) and concatenate it with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.SetMatrix (vtkMatrix4x4 matrix)` - Set the current matrix directly. This actually calls Identity(), followed by Concatenate(matrix).
- `obj.SetMatrix (double elements[16])` - Set the current matrix directly. This actually calls Identity(), followed by Concatenate(matrix).
- `obj.Concatenate (vtkMatrix4x4 matrix)` - Concatenates the matrix with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (double elements[16])` - Concatenates the matrix with the current transformation according to PreMultiply or PostMultiply semantics.
- `obj.Concatenate (vtkLinearTransform transform)` - Concatenate the specified transform with the current transformation according to PreMultiply or PostMultiply semantics. The concatenation is pipelined, meaning that if any of the transformations are changed, even after Concatenate() is called, those changes will be reflected when you call TransformPoint().
- `obj.PreMultiply ()` - Sets the internal state of the transform to PreMultiply. All subsequent operations will occur before those already represented in the current transformation. In homogeneous matrix notation, M = M*A where M is the current transformation matrix and A is the applied matrix. The default is PreMultiply.
- `obj.PostMultiply ()` - Sets the internal state of the transform to PostMultiply. All subsequent operations will occur after those already represented in the current transformation. In homogeneous matrix notation, M = A*M where M is the current transformation matrix and A is the applied matrix. The default is PreMultiply.
- `int = obj.GetNumberOfConcatenatedTransforms ()` - Get the total number of transformations that are linked into this one via Concatenate() operations or via SetInput().
- `vtkLinearTransform = obj.GetConcatenatedTransform (int i)` - Get the x, y, z orientation angles from the transformation matrix as an array of three floating point values.

- `obj.GetOrientation (double orient[3])` - Get the x, y, z orientation angles from the transformation matrix as an array of three floating point values.
- `obj.GetOrientation (float orient[3])` - Get the x, y, z orientation angles from the transformation matrix as an array of three floating point values.
- `double = obj.GetOrientation ()` - Get the x, y, z orientation angles from the transformation matrix as an array of three floating point values.
- `obj.GetOrientationWXYZ (double wxyz[4])` - Return the wxyz angle+axis representing the current orientation. The angle is in degrees and the axis is a unit vector.
- `obj.GetOrientationWXYZ (float wxyz[4])` - Return the wxyz angle+axis representing the current orientation. The angle is in degrees and the axis is a unit vector.
- `double = obj.GetOrientationWXYZ ()` - Return the wxyz angle+axis representing the current orientation. The angle is in degrees and the axis is a unit vector.
- `obj.GetPosition (double pos[3])` - Return the position from the current transformation matrix as an array of three floating point numbers. This is simply returning the translation component of the 4x4 matrix.
- `obj.GetPosition (float pos[3])` - Return the position from the current transformation matrix as an array of three floating point numbers. This is simply returning the translation component of the 4x4 matrix.
- `double = obj.GetPosition ()` - Return the position from the current transformation matrix as an array of three floating point numbers. This is simply returning the translation component of the 4x4 matrix.
- `obj.GetScale (double scale[3])` - Return the scale factors of the current transformation matrix as an array of three float numbers. These scale factors are not necessarily about the x, y, and z axes unless unless the scale transformation was applied before any rotations.
- `obj.GetScale (float scale[3])` - Return the scale factors of the current transformation matrix as an array of three float numbers. These scale factors are not necessarily about the x, y, and z axes unless unless the scale transformation was applied before any rotations.
- `double = obj.GetScale ()` - Return the scale factors of the current transformation matrix as an array of three float numbers. These scale factors are not necessarily about the x, y, and z axes unless unless the scale transformation was applied before any rotations.
- `obj.GetInverse (vtkMatrix4x4 inverse)` - Return a matrix which is the inverse of the current transformation matrix.
- `obj.GetTranspose (vtkMatrix4x4 transpose)` - Return a matrix which is the transpose of the current transformation matrix. This is equivalent to the inverse if and only if the transformation is a pure rotation with no translation or scale.
- `obj.SetInput (vtkLinearTransform input)` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.
- `vtkLinearTransform = obj.GetInput ()` - Set the input for this transformation. This will be used as the base transformation if it is set. This method allows you to build a transform pipeline: if the input is modified, then this transformation will automatically update accordingly. Note that the InverseFlag, controlled via Inverse(), determines whether this transformation will use the Input or the inverse of the Input.

- `int = obj.GetInverseFlag ()` - Get the inverse flag of the transformation. This controls whether it is the Input or the inverse of the Input that is used as the base transformation. The InverseFlag is flipped every time Inverse() is called. The InverseFlag is off when a transform is first created.
- `obj.Push ()` - Pushes the current transformation onto the transformation stack.
- `obj.Pop ()` - Deletes the transformation on the top of the stack and sets the top to the next transformation on the stack.
- `int = obj.CircuitCheck (vtkAbstractTransform transform)` - Check for self-reference. Will return true if concatenating with the specified transform, setting it to be our inverse, or setting it to be our input will create a circular reference. CircuitCheck is automatically called by SetInput(), SetInverse(), and Concatenate(vtkXTransform *). Avoid using this function, it is experimental.
- `vtkAbstractTransform = obj.GetInverse ()` - Make a new transform of the same type.
- `vtkAbstractTransform = obj.MakeTransform ()` - Make a new transform of the same type.
- `long = obj.GetMTime ()` - Override GetMTime to account for input and concatenation.
- `obj.MultiplyPoint (float in[4], float out[4])` - Use this method only if you wish to compute the transformation in homogeneous (x,y,z,w) coordinates, otherwise use TransformPoint(). This method calls this-¿GetMatrix()-¿MultiplyPoint().
- `obj.MultiplyPoint (double in[4], double out[4])` - Use this method only if you wish to compute the transformation in homogeneous (x,y,z,w) coordinates, otherwise use TransformPoint(). This method calls this-¿GetMatrix()-¿MultiplyPoint().

30.143 vtkTransform2D

30.143.1 Usage

A vtkTransform2D can be used to describe the full range of linear (also known as affine) coordinate transformations in two dimensions, which are internally represented as a 3x3 homogeneous transformation matrix. When you create a new vtkTransform2D, it is always initialized to the identity transformation.

This class performs all of its operations in a right handed coordinate system with right handed rotations. Some other graphics libraries use left handed coordinate systems and rotations.

To create an instance of class vtkTransform2D, simply invoke its constructor as follows

```
obj = vtkTransform2D
```

30.143.2 Methods

The class vtkTransform2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransform2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransform2D = obj.NewInstance ()`
- `vtkTransform2D = obj.SafeDownCast (vtkObject o)`
- `obj.Identity ()` - Set the transformation to the identity transformation.
- `obj.Inverse ()` - Invert the transformation.

- `obj.Translate (double x, double y)` - Create a translation matrix and concatenate it with the current transformation.
- `obj.Translate (double x[2])` - Create a translation matrix and concatenate it with the current transformation.
- `obj.Translate (float x[2])` - Create a rotation matrix and concatenate it with the current transformation. The angle is in degrees.
- `obj.Rotate (double angle)` - Create a rotation matrix and concatenate it with the current transformation. The angle is in degrees.
- `obj.Scale (double x, double y)` - Create a scale matrix (i.e. set the diagonal elements to x, y) and concatenate it with the current transformation.
- `obj.Scale (double s[2])` - Create a scale matrix (i.e. set the diagonal elements to x, y) and concatenate it with the current transformation.
- `obj.Scale (float s[2])` - Set the current matrix directly.
- `obj.SetMatrix (vtkMatrix3x3 matrix)` - Set the current matrix directly.
- `obj.SetMatrix (double elements[9])` - Set the current matrix directly.
- `vtkMatrix3x3 = obj.GetMatrix ()` - Get the underlying 3x3 matrix.
- `obj.GetMatrix (vtkMatrix3x3 matrix)` - Get the underlying 3x3 matrix.
- `obj.GetPosition (double pos[2])` - Return the position from the current transformation matrix as an array of two floating point numbers. This is simply returning the translation component of the 3x3 matrix.
- `obj.GetPosition (float pos[2])` - Return a matrix which is the inverse of the current transformation matrix.
- `obj.GetInverse (vtkMatrix3x3 inverse)` - Return a matrix which is the inverse of the current transformation matrix.
- `obj.GetTranspose (vtkMatrix3x3 transpose)` - Return a matrix which is the transpose of the current transformation matrix. This is equivalent to the inverse if and only if the transformation is a pure rotation with no translation or scale.
- `long = obj.GetMTime ()` - Override GetMTime to account for input and concatenation.
- `obj.TransformPoints (float inPts, float outPts, int n)` - Apply the transformation to a series of points, and append the results to outPts. Where n is the number of points, and the float pointers are of length 2*n.
- `obj.TransformPoints (double inPts, double outPts, int n)` - Apply the transformation to a series of points, and append the results to outPts. Where n is the number of points, and the float pointers are of length 2*n.
- `obj.TransformPoints (vtkPoints2D inPts, vtkPoints2D outPts)` - Apply the transformation to a series of points, and append the results to outPts.
- `obj.InverseTransformPoints (float inPts, float outPts, int n)` - Apply the transformation to a series of points, and append the results to outPts. Where n is the number of points, and the float pointers are of length 2*n.
- `obj.InverseTransformPoints (double inPts, double outPts, int n)` - Apply the transformation to a series of points, and append the results to outPts. Where n is the number of points, and the float pointers are of length 2*n.

- `obj.InverseTransformPoints (vtkPoints2D inPts, vtkPoints2D outPts)` - Apply the transformation to a series of points, and append the results to outPts.
- `obj.MultiplyPoint (float in[3], float out[3])` - Use this method only if you wish to compute the transformation in homogeneous (x,y,w) coordinates, otherwise use TransformPoint(). This method calls this-¿GetMatrix()-¿MultiplyPoint().
- `obj.MultiplyPoint (double in[3], double out[3])` - Use this method only if you wish to compute the transformation in homogeneous (x,y,w) coordinates, otherwise use TransformPoint(). This method calls this-¿GetMatrix()-¿MultiplyPoint().

30.144 vtkTransformCollection

30.144.1 Usage

vtkTransformCollection is an object that creates and manipulates lists of objects of type vtkTransform.

To create an instance of class vtkTransformCollection, simply invoke its constructor as follows

```
obj = vtkTransformCollection
```

30.144.2 Methods

The class vtkTransformCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTransformCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTransformCollection = obj.NewInstance ()`
- `vtkTransformCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkTransform )` - Add a Transform to the list.
- `vtkTransform = obj.GetNextItem ()` - Get the next Transform in the list. Return NULL when the end of the list is reached.

30.145 vtkTypeFloat32Array

30.145.1 Usage

vtkTypeFloat32Array is an array of values of type vtkTypeFloat32. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeFloat32Array, simply invoke its constructor as follows

```
obj = vtkTypeFloat32Array
```

30.145.2 Methods

The class vtkTypeFloat32Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeFloat32Array class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkTypeFloat32Array = obj.NewInstance ()`
- `vtkTypeFloat32Array = obj.SafeDownCast (vtkObject o)`

30.146 vtkTypeFloat64Array

30.146.1 Usage

vtkTypeFloat64Array is an array of values of type vtkTypeFloat64. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeFloat64Array, simply invoke its constructor as follows

```
obj = vtkTypeFloat64Array
```

30.146.2 Methods

The class vtkTypeFloat64Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeFloat64Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeFloat64Array = obj.NewInstance ()`
- `vtkTypeFloat64Array = obj.SafeDownCast (vtkObject o)`

30.147 vtkTypeInt16Array

30.147.1 Usage

vtkTypeInt16Array is an array of values of type vtkTypeInt16. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeInt16Array, simply invoke its constructor as follows

```
obj = vtkTypeInt16Array
```

30.147.2 Methods

The class vtkTypeInt16Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeInt16Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeInt16Array = obj.NewInstance ()`
- `vtkTypeInt16Array = obj.SafeDownCast (vtkObject o)`

30.148 vtkTypeInt32Array

30.148.1 Usage

vtkTypeInt32Array is an array of values of type vtkTypeInt32. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeInt32Array, simply invoke its constructor as follows

```
obj = vtkTypeInt32Array
```

30.148.2 Methods

The class vtkTypeInt32Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeInt32Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeInt32Array = obj.NewInstance ()`
- `vtkTypeInt32Array = obj.SafeDownCast (vtkObject o)`

30.149 vtkTypeInt64Array

30.149.1 Usage

vtkTypeInt64Array is an array of values of type vtkTypeInt64. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeInt64Array, simply invoke its constructor as follows

```
obj = vtkTypeInt64Array
```

30.149.2 Methods

The class vtkTypeInt64Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeInt64Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeInt64Array = obj.NewInstance ()`
- `vtkTypeInt64Array = obj.SafeDownCast (vtkObject o)`

30.150 vtkTypeInt8Array

30.150.1 Usage

vtkTypeInt8Array is an array of values of type vtkTypeInt8. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeInt8Array, simply invoke its constructor as follows

```
obj = vtkTypeInt8Array
```

30.150.2 Methods

The class vtkTypeInt8Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeInt8Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeInt8Array = obj.NewInstance ()`
- `vtkTypeInt8Array = obj.SafeDownCast (vtkObject o)`

30.151 vtkTypeUInt16Array

30.151.1 Usage

vtkTypeUInt16Array is an array of values of type vtkTypeUInt16. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeUInt16Array, simply invoke its constructor as follows

```
obj = vtkTypeUInt16Array
```

30.151.2 Methods

The class vtkTypeUInt16Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeUInt16Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeUInt16Array = obj.NewInstance ()`
- `vtkTypeUInt16Array = obj.SafeDownCast (vtkObject o)`

30.152 vtkTypeUInt32Array

30.152.1 Usage

vtkTypeUInt32Array is an array of values of type vtkTypeUInt32. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeUInt32Array, simply invoke its constructor as follows

```
obj = vtkTypeUInt32Array
```

30.152.2 Methods

The class vtkTypeUInt32Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeUInt32Array class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkTypeUInt32Array = obj.NewInstance ()`
- `vtkTypeUInt32Array = obj.SafeDownCast (vtkObject o)`

30.153 vtkTypeUInt64Array

30.153.1 Usage

vtkTypeUInt64Array is an array of values of type vtkTypeUInt64. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeUInt64Array, simply invoke its constructor as follows

```
obj = vtkTypeUInt64Array
```

30.153.2 Methods

The class vtkTypeUInt64Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeUInt64Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeUInt64Array = obj.NewInstance ()`
- `vtkTypeUInt64Array = obj.SafeDownCast (vtkObject o)`

30.154 vtkTypeUInt8Array

30.154.1 Usage

vtkTypeUInt8Array is an array of values of type vtkTypeUInt8. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkTypeUInt8Array, simply invoke its constructor as follows

```
obj = vtkTypeUInt8Array
```

30.154.2 Methods

The class vtkTypeUInt8Array has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTypeUInt8Array class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTypeUInt8Array = obj.NewInstance ()`
- `vtkTypeUInt8Array = obj.SafeDownCast (vtkObject o)`

30.155 vtkUnicodeStringArray

30.155.1 Usage

.SECTION Thanks Developed by Timothy M. Shead (tshead@sandia.gov) at Sandia National Laboratories.
To create an instance of class vtkUnicodeStringArray, simply invoke its constructor as follows

```
obj = vtkUnicodeStringArray
```

30.155.2 Methods

The class vtkUnicodeStringArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnicodeStringArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnicodeStringArray = obj.NewInstance ()`
- `vtkUnicodeStringArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)`
- `obj.Initialize ()`
- `int = obj.GetDataType ()`
- `int = obj.GetDataTypeSize ()`
- `int = obj.GetElementComponentSize ()`
- `obj.SetNumberOfTuples (vtkIdType number)`
- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)`
- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)`
- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkAbstractArray source)`
- `obj.DeepCopy (vtkAbstractArray da)`
- `obj.InterpolateTuple (vtkIdType i, vtkIdList ptIndices, vtkAbstractArray source, double weights)`
- `obj.InterpolateTuple (vtkIdType i, vtkIdType id1, vtkAbstractArray source1, vtkIdType id2, vtkAbstr`
- `obj.Squeeze ()`
- `int = obj.Resize (vtkIdType numTuples)`
- `long = obj.GetActualMemorySize ()`
- `int = obj.IsNumeric ()`
- `vtkArrayIterator = obj.NewIterator ()`
- `obj.DataChanged ()`
- `obj.ClearLookup ()`
- `obj.InsertNextUTF8Value (string )`
- `obj.SetUTF8Value (vtkIdType i, string )`
- `string = obj.GetUTF8Value (vtkIdType i)`

30.156 vtkUnsignedCharArray

30.156.1 Usage

vtkUnsignedCharArray is an array of values of type unsigned char. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkUnsignedCharArray, simply invoke its constructor as follows

```
obj = vtkUnsignedCharArray
```

30.156.2 Methods

The class vtkUnsignedCharArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnsignedCharArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnsignedCharArray = obj.NewInstance ()`
- `vtkUnsignedCharArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, string tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, string tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, string tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (string tuple)` - Get the data at a particular index.
- `char = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, char value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, char f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (char f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (string array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (string array, vtkIdType size, int save, int deleteMethod)`

30.157 vtkUnsignedIntArray

30.157.1 Usage

vtkUnsignedIntArray is an array of values of type unsigned int. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkUnsignedIntArray, simply invoke its constructor as follows

```
obj = vtkUnsignedIntArray
```

30.157.2 Methods

The class vtkUnsignedIntArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnsignedIntArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnsignedIntArray = obj.NewInstance ()`
- `vtkUnsignedIntArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, int tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, int tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, int tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (int tuple)` - Get the data at a particular index.
- `int = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, int value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, int f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (int f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (int array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (int array, vtkIdType size, int save, int deleteMethod)`

30.158 vtkUnsignedLongArray

30.158.1 Usage

vtkUnsignedLongArray is an array of values of type unsigned long. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkUnsignedLongArray, simply invoke its constructor as follows

```
obj = vtkUnsignedLongArray
```

30.158.2 Methods

The class vtkUnsignedLongArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnsignedLongArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnsignedLongArray = obj.NewInstance ()`
- `vtkUnsignedLongArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, long tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, long tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, long tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (long tuple)` - Get the data at a particular index.
- `long = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, long value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, long f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (long f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (long array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (long array, vtkIdType size, int save, int deleteMethod)`

30.159 vtkUnsignedLongLongArray

30.159.1 Usage

vtkUnsignedLongLongArray is an array of values of type unsigned long long. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkUnsignedLongLongArray, simply invoke its constructor as follows

```
obj = vtkUnsignedLongLongArray
```

30.159.2 Methods

The class vtkUnsignedLongLongArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnsignedLongLongArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnsignedLongLongArray = obj.NewInstance ()`
- `vtkUnsignedLongLongArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `long = obj.long GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, long long value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, long long f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (long long f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `long = obj.long WritePointer (vtkIdType id, vtkIdType number)` - Get the address of a particular data index. Performs no checks to verify that the memory has been allocated etc.
- `long = obj.long GetPointer (vtkIdType id)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.

30.160 vtkUnsignedShortArray

30.160.1 Usage

vtkUnsignedShortArray is an array of values of type unsigned short. It provides methods for insertion and retrieval of values and will automatically resize itself to hold new data.

To create an instance of class vtkUnsignedShortArray, simply invoke its constructor as follows

```
obj = vtkUnsignedShortArray
```

30.160.2 Methods

The class vtkUnsignedShortArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnsignedShortArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnsignedShortArray = obj.NewInstance ()`
- `vtkUnsignedShortArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataType ()` - Copy the tuple value into a user-provided array.
- `obj.GetTupleValue (vtkIdType i, short tuple)` - Set the tuple value at the ith location in the array.
- `obj.SetTupleValue (vtkIdType i, short tuple)` - Insert (memory allocation performed) the tuple into the ith location in the array.
- `obj.InsertTupleValue (vtkIdType i, short tuple)` - Insert (memory allocation performed) the tuple onto the end of the array.
- `vtkIdType = obj.InsertNextTupleValue (short tuple)` - Get the data at a particular index.
- `short = obj.GetValue (vtkIdType id)` - Set the data at a particular index. Does not do range checking. Make sure you use the method SetNumberOfValues() before inserting data.
- `obj.SetValue (vtkIdType id, short value)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `obj.SetNumberOfValues (vtkIdType number)` - Insert data at a specified position in the array.
- `obj.InsertValue (vtkIdType id, short f)` - Insert data at the end of the array. Return its location in the array.
- `vtkIdType = obj.InsertNextValue (short f)` - Get the address of a particular data index. Make sure data is allocated for the number of items requested. Set MaxId according to the number of data values requested.
- `obj.SetArray (short array, vtkIdType size, int save)` - This method lets the user specify data to be held by the array. The array argument is a pointer to the data. size is the size of the array supplied by the user. Set save to 1 to keep the class from deleting the array when it cleans up or reallocates memory. The class uses the actual array provided; it does not copy the data from the suppled array.
- `obj.SetArray (short array, vtkIdType size, int save, int deleteMethod)`

30.161 vtkVariantArray

30.161.1 Usage

.SECTION Thanks Thanks to Patricia Crossno, Ken Moreland, Andrew Wilson and Brian Wylie from Sandia National Laboratories for their help in developing this class.

To create an instance of class vtkVariantArray, simply invoke its constructor as follows

```
obj = vtkVariantArray
```

30.161.2 Methods

The class vtkVariantArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVariantArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVariantArray = obj.NewInstance ()`
- `vtkVariantArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate memory for this array. Delete old storage only if necessary. Note that ext is no longer used.
- `obj.Initialize ()` - Release storage and reset array to initial state.
- `int = obj.GetDataType ()` - Return the underlying data type. An integer indicating data type is returned as specified in vtkSetGet.h.
- `int = obj.GetDataTypeSize ()` - Return the size of the underlying data type. For a bit, 1 is returned. For string 0 is returned. Arrays with variable length components return 0.
- `int = obj.GetElementComponentSize ()` - Return the size, in bytes, of the lowest-level element of an array. For vtkDataArray and subclasses this is the size of the data type. For vtkStringArray, this is sizeof(vtkStdString::value_type), which winds up being sizeof(char).
- `obj.SetNumberOfTuples (vtkIdType number)` - Set the number of tuples (a component group) in the array. Note that this may allocate space depending on the number of components.
- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Set the tuple at the ith location using the jth tuple in the source array. This method assumes that the two arrays have the same type and structure. Note that range checking and memory allocation is not performed; use in conjunction with SetNumberOfTuples() to allocate space.
- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at ith location in this array. Note that memory allocation is performed as necessary to hold the data.
- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkAbstractArray source)` - Insert the jth tuple in the source array, at the end in this array. Note that memory allocation is performed as necessary to hold the data. Returns the location at which the data was inserted.
- `obj.DeepCopy (vtkAbstractArray da)` - Deep copy of data. Implementation left to subclasses, which should support as many type conversions as possible given the data type.
- `obj.InterpolateTuple (vtkIdType i, vtkIdList ptIndices, vtkAbstractArray source, double weights)` - Set the ith tuple in this array as the interpolated tuple value, given the ptIndices in the source array and associated interpolation weights. This method assumes that the two arrays are of the same type and strcuture.
- `obj.InterpolateTuple (vtkIdType i, vtkIdType id1, vtkAbstractArray source1, vtkIdType id2, vtkAbstr`
- `obj.Squeeze ()` - Resize object to just fit data requirement. Reclaims extra memory.
- `int = obj.Resize (vtkIdType numTuples)` - Resize the array while conserving the data. Returns 1 if resizing succeeded and 0 otherwise.

- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this data array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `int = obj.IsNumeric ()` - Since each item can be of a different type, we say that a variant array is not numeric.
- `vtkArrayIterator = obj.NewIterator ()` - Subclasses must override this method and provide the right kind of templated vtkArrayIteratorTemplate.
- `obj.SetNumberOfValues (vtkIdType number)` - Specify the number of values for this object to hold. Does an allocation as well as setting the MaxId ivar. Used in conjunction with SetValue() method for fast insertion.
- `vtkIdType = obj.GetNumberOfValues ()` - Tell the array explicitly that the data has changed. This is only necessary to call when you modify the array contents without using the array's API (i.e. you retrieve a pointer to the data and modify the array contents). You need to call this so that the fast lookup will know to rebuild itself. Otherwise, the lookup functions will give incorrect results.
- `obj.DataChanged ()` - Tell the array explicitly that the data has changed. This is only necessary to call when you modify the array contents without using the array's API (i.e. you retrieve a pointer to the data and modify the array contents). You need to call this so that the fast lookup will know to rebuild itself. Otherwise, the lookup functions will give incorrect results.
- `obj.DataElementChanged (vtkIdType id)` - Tell the array explicitly that a single data element has changed. Like DataChanged(), then is only necessary when you modify the array contents without using the array's API.
- `obj.ClearLookup ()` - Delete the associated fast lookup data structure on this array, if it exists. The lookup will be rebuilt on the next call to a lookup function.
- `~vtkVariantArray = obj.()` - This destructor is public to work around a bug in version 1.36.0 of the Boost.Serialization library.

30.162 vtkVersion

30.162.1 Usage

Holds methods for defining/determining the current vtk version (major, minor, build).

To create an instance of class vtkVersion, simply invoke its constructor as follows

```
obj = vtkVersion
```

30.162.2 Methods

The class vtkVersion has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVersion class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVersion = obj.NewInstance ()`
- `vtkVersion = obj.SafeDownCast (vtkObject o)`

30.163 vtkVoidArray

30.163.1 Usage

vtkVoidArray is an array of pointers to void. It provides methods for insertion and retrieval of these pointers values, and will automatically resize itself to hold new data.

To create an instance of class vtkVoidArray, simply invoke its constructor as follows

```
obj = vtkVoidArray
```

30.163.2 Methods

The class vtkVoidArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVoidArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVoidArray = obj.NewInstance ()`
- `vtkVoidArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate memory for this array. Delete old storage only if necessary. Note that the parameter ext is no longer used.
- `obj.Initialize ()` - Release storage and reset array to initial state.
- `int = obj.GetDataType ()` - Return the size of the data contained in the array.
- `int = obj.GetDataTypeSize ()` - Set the number of void* pointers held in the array.
- `obj.SetNumberOfPointers (vtkIdType number)` - Get the number of void* pointers held in the array.
- `vtkIdType = obj.GetNumberOfPointers ()` - Get the void* pointer at the ith location.
- `obj.Reset ()` - Resize the array to just fit the inserted memory. Reclaims extra memory.
- `obj.Squeeze ()` - Get the address of a particular data index. Performs no checks to verify that the memory has been allocated etc.
- `obj.DeepCopy (vtkVoidArray va)` - Deep copy of another void array.

30.164 vtkWarpTransform

30.164.1 Usage

vtkWarpTransform provides a generic interface for nonlinear warp transformations.

To create an instance of class vtkWarpTransform, simply invoke its constructor as follows

```
obj = vtkWarpTransform
```

30.164.2 Methods

The class vtkWarpTransform has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWarpTransform class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWarpTransform = obj.NewInstance ()`
- `vtkWarpTransform = obj.SafeDownCast (vtkObject o)`
- `obj.Inverse ()` - Invert the transformation. Warp transformations are usually inverted using an iterative technique such as Newton's method. The inverse transform is usually around five or six times as computationally expensive as the forward transform.
- `int = obj.GetInverseFlag ()` - Get the inverse flag of the transformation. This flag is set to zero when the transformation is first created, and is flipped each time Inverse() is called.
- `obj.SetInverseTolerance (double )` - Set the tolerance for inverse transformation. The default is 0.001.
- `double = obj.GetInverseTolerance ()` - Set the tolerance for inverse transformation. The default is 0.001.
- `obj.SetInverseIterations (int )` - Set the maximum number of iterations for the inverse transformation. The default is 500, but usually only 2 to 5 iterations are used. The inversion method is fairly robust, and it should converge for nearly all smooth transformations that do not fold back on themselves.
- `int = obj.GetInverseIterations ()` - Set the maximum number of iterations for the inverse transformation. The default is 500, but usually only 2 to 5 iterations are used. The inversion method is fairly robust, and it should converge for nearly all smooth transformations that do not fold back on themselves.
- `obj.InternalTransformPoint (float in[3], float out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.InternalTransformPoint (double in[3], double out[3])` - This will calculate the transformation without calling Update. Meant for use only within other VTK classes.
- `obj.TemplateTransformPoint (float in[3], float out[3])` - Do not use these methods. They exists only as a work-around for internal templated functions (I really didn't want to make the Forward/Inverse methods public, is there a decent work around for this sort of thing?)
- `obj.TemplateTransformPoint (double in[3], double out[3])` - Do not use these methods. They exists only as a work-around for internal templated functions (I really didn't want to make the Forward/Inverse methods public, is there a decent work around for this sort of thing?)
- `obj.TemplateTransformInverse (float in[3], float out[3])` - Do not use these methods. They exists only as a work-around for internal templated functions (I really didn't want to make the Forward/Inverse methods public, is there a decent work around for this sort of thing?)
- `obj.TemplateTransformInverse (double in[3], double out[3])` - Do not use these methods. They exists only as a work-around for internal templated functions (I really didn't want to make the Forward/Inverse methods public, is there a decent work around for this sort of thing?)

30.165 vtkWindow

30.165.1 Usage

vtkWindow is an abstract object to specify the behavior of a rendering window. It contains vtkViewports.

To create an instance of class vtkWindow, simply invoke its constructor as follows

```
obj = vtkWindow
```

30.165.2 Methods

The class vtkWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWindow class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWindow = obj.NewInstance ()`
- `vtkWindow = obj.SafeDownCast (vtkObject o)`
- `obj.SetWindowInfo (string )` - These are window system independent methods that are used to help interface vtkWindow to native windowing systems.
- `obj.SetParentInfo (string )` - These are window system independent methods that are used to help interface vtkWindow to native windowing systems.
- `int = obj.GetPosition ()` - Set/Get the position in screen coordinates of the rendering window.
- `obj.SetPosition (int , int )` - Set/Get the position in screen coordinates of the rendering window.
- `obj.SetPosition (int a[2])` - Set/Get the position in screen coordinates of the rendering window.
- `int = obj.GetSize ()` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetSize (int , int )` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetSize (int a[2])` - Set/Get the size of the window in screen coordinates in pixels.
- `obj.SetMapped (int )` - Keep track of whether the rendering window has been mapped to screen.
- `int = obj.GetMapped ()` - Keep track of whether the rendering window has been mapped to screen.
- `obj.MappedOn ()` - Keep track of whether the rendering window has been mapped to screen.
- `obj.MappedOff ()` - Keep track of whether the rendering window has been mapped to screen.
- `obj.SetErase (int )` - Turn on/off erasing the screen between images. This allows multiple exposure sequences if turned on. You will need to turn double buffering off or make use of the SwapBuffers methods to prevent you from swapping buffers between exposures.
- `int = obj.GetErase ()` - Turn on/off erasing the screen between images. This allows multiple exposure sequences if turned on. You will need to turn double buffering off or make use of the SwapBuffers methods to prevent you from swapping buffers between exposures.
- `obj.EraseOn ()` - Turn on/off erasing the screen between images. This allows multiple exposure sequences if turned on. You will need to turn double buffering off or make use of the SwapBuffers methods to prevent you from swapping buffers between exposures.

- `obj.EraseOff ()` - Turn on/off erasing the screen between images. This allows multiple exposure sequences if turned on. You will need to turn double buffering off or make use of the SwapBuffers methods to prevent you from swapping buffers between exposures.
- `obj.SetDoubleBuffer (int )` - Keep track of whether double buffering is on or off
- `int = obj.GetDoubleBuffer ()` - Keep track of whether double buffering is on or off
- `obj.DoubleBufferOn ()` - Keep track of whether double buffering is on or off
- `obj.DoubleBufferOff ()` - Keep track of whether double buffering is on or off
- `string = obj.GetWindowName ()` - Get name of rendering window
- `obj.SetWindowName (string )` - Get name of rendering window
- `obj.Render ()` - Ask each viewport owned by this Window to render its image and synchronize this process.
- `int = obj.GetPixelData (int x, int y, int x2, int y2, int front, vtkUnsignedCharArray data)` - Get the pixel data of an image, transmitted as RGBRGBRGB. The front argument indicates if the front buffer should be used or the back buffer. It is the caller's responsibility to delete the resulting array. It is very important to realize that the memory in this array is organized from the bottom of the window to the top. The origin of the screen is in the lower left corner. The y axis increases as you go up the screen. So the storage of pixels is from left to right and from bottom to top. (x,y) is any corner of the rectangle. (x2,y2) is its opposite corner on the diagonal.
- `int = obj.GetDPI ()` - Return a best estimate to the dots per inch of the display device being rendered (or printed).
- `obj.SetDPI (int )` - Return a best estimate to the dots per inch of the display device being rendered (or printed).
- `int = obj.GetDPIMinValue ()` - Return a best estimate to the dots per inch of the display device being rendered (or printed).
- `int = obj.GetDPIMaxValue ()` - Return a best estimate to the dots per inch of the display device being rendered (or printed).
- `obj.SetOffScreenRendering (int )` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `int = obj.GetOffScreenRendering ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.OffScreenRenderingOn ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.OffScreenRenderingOff ()` - Create a window in memory instead of on the screen. This may not be supported for every type of window and on some windows you may need to invoke this prior to the first render.
- `obj.MakeCurrent ()` - Make the window current. May be overridden in subclasses to do for example a glXMakeCurrent or a wglMakeCurrent.

- `obj.SetTileScale (int , int )` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

- `obj.SetTileScale (int a[2])` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

- `int = obj. GetTileScale ()` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

- `obj.SetTileScale (int s)` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

- `obj.SetTileViewport (double , double , double , double )` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

- `obj.SetTileViewport (double a[4])` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

- `double = obj. GetTileViewport ()` - These methods are used by vtkWindowToImageFilter to tell a VTK window to simulate a larger window by tiling. For 3D geometry these methods have no impact. It is just in handling annotation that this information must be available to the mappers and the coordinate calculations.

30.166 vtkWindowLevelLookupTable

30.166.1 Usage

vtkWindowLevelLookupTable is an object that is used by mapper objects to map scalar values into rgba (red-green-blue-alpha transparency) color specification, or rgba into scalar values. The color table can be created by direct insertion of color values, or by specifying a window and level. Window / Level is used in medical imaging to specify a linear greyscale ramp. The Level is the center of the ramp. The Window is the width of the ramp.

To create an instance of class vtkWindowLevelLookupTable, simply invoke its constructor as follows

```
obj = vtkWindowLevelLookupTable
```

30.166.2 Methods

The class vtkWindowLevelLookupTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWindowLevelLookupTable class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkWindowLevelLookupTable = obj.NewInstance ()`
- `vtkWindowLevelLookupTable = obj.SafeDownCast (vtkObject o)`
- `obj.Build ()` - Generate lookup table as a linear ramp between MinimumTableValue and MaximumTableValue.
- `obj.SetWindow (double window)` - Set the window for the lookup table. The window is the difference between TableRange[0] and TableRange[1].
- `double = obj.GetWindow ()` - Set the window for the lookup table. The window is the difference between TableRange[0] and TableRange[1].
- `obj.SetLevel (double level)` - Set the Level for the lookup table. The level is the average of TableRange[0] and TableRange[1].
- `double = obj.GetLevel ()` - Set the Level for the lookup table. The level is the average of TableRange[0] and TableRange[1].
- `obj.SetInverseVideo (int iv)` - Set inverse video on or off. You can achieve the same effect by switching the MinimumTableValue and the MaximumTableValue.
- `int = obj.GetInverseVideo ()` - Set inverse video on or off. You can achieve the same effect by switching the MinimumTableValue and the MaximumTableValue.
- `obj.InverseVideoOn ()` - Set inverse video on or off. You can achieve the same effect by switching the MinimumTableValue and the MaximumTableValue.
- `obj.InverseVideoOff ()` - Set inverse video on or off. You can achieve the same effect by switching the MinimumTableValue and the MaximumTableValue.
- `obj.SetMinimumTableValue (double , double , double , double )` - Set the minimum table value. All lookup table entries below the start of the ramp will be set to this color. After you change this value, you must re-build the lookup table.
- `obj.SetMinimumTableValue (double a[4])` - Set the minimum table value. All lookup table entries below the start of the ramp will be set to this color. After you change this value, you must re-build the lookup table.
- `double = obj. GetMinimumTableValue ()` - Set the minimum table value. All lookup table entries below the start of the ramp will be set to this color. After you change this value, you must re-build the lookup table.
- `obj.SetMaximumTableValue (double , double , double , double )` - Set the maximum table value. All lookup table entries above the end of the ramp will be set to this color. After you change this value, you must re-build the lookup table.
- `obj.SetMaximumTableValue (double a[4])` - Set the maximum table value. All lookup table entries above the end of the ramp will be set to this color. After you change this value, you must re-build the lookup table.
- `double = obj. GetMaximumTableValue ()` - Set the maximum table value. All lookup table entries above the end of the ramp will be set to this color. After you change this value, you must re-build the lookup table.
- `obj.SetMinimumColor (int r, int g, int b, int a)` - @deprecated For backwards compatibility: specify the color using integers in the range [0,255].

- `obj.SetMinimumColor (char rgba[4])` - @deprecated For backwards compatibility: specify the color using integers in the range [0,255].
- `obj.GetMinimumColor (char rgba[4])` - @deprecated For backwards compatibility: specify the color using integers in the range [0,255].
- `obj.SetMaximumColor (int r, int g, int b, int a)` - @deprecated For backwards compatibility: specify the color using integers in the range [0,255].
- `obj.SetMaximumColor (char rgba[4])` - @deprecated For backwards compatibility: specify the color using integers in the range [0,255].
- `obj.GetMaximumColor (char rgba[4])` - @deprecated For backwards compatibility: specify the color using integers in the range [0,255].

30.167 vtkXMLDataElement

30.167.1 Usage

vtkXMLDataElement is used by vtkXMLDataParser to represent an XML element. It provides methods to access the element's attributes and nested elements in a convenient manner. This allows easy traversal of an input XML file by vtkXMLReader and its subclasses.

To create an instance of class vtkXMLDataElement, simply invoke its constructor as follows

```
obj = vtkXMLDataElement
```

30.167.2 Methods

The class vtkXMLDataElement has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLDataElement class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkXMLDataElement = obj.NewInstance ()`
- `vtkXMLDataElement = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetName ()` - Set/Get the name of the element. This is its XML tag.
- `obj.SetName (string \_arg)` - Set/Get the name of the element. This is its XML tag.
- `string = obj.GetId ()` - Set/Get the value of the id attribute of the element, if any.
- `obj.SetId (string )` - Set/Get the value of the id attribute of the element, if any.
- `string = obj.GetAttribute (string name)` - Get the attribute with the given name. If it doesn't exist, returns 0.
- `obj.SetAttribute (string name, string value)` - Set the attribute with the given name and value. If it doesn't exist, adds it.
- `obj.SetCharacterData (string c, int length)` - Set/Get the character data between XML start/end tags.
- `string = obj.GetCharacterData ()` - Set/Get the character data between XML start/end tags.

- `obj.SetIntAttribute (string name, int value)` - Set the attribute with the given name. We can not use the same GetScalarAttribute() construct since the compiler will not be able to resolve between SetAttribute(..., int) and SetAttribute(..., unsigned long).
- `obj.SetFloatAttribute (string name, float value)` - Set the attribute with the given name. We can not use the same GetScalarAttribute() construct since the compiler will not be able to resolve between SetAttribute(..., int) and SetAttribute(..., unsigned long).
- `obj.SetDoubleAttribute (string name, double value)` - Set the attribute with the given name. We can not use the same GetScalarAttribute() construct since the compiler will not be able to resolve between SetAttribute(..., int) and SetAttribute(..., unsigned long).
- `obj.SetUnsignedLongAttribute (string name, long value)` - Set the attribute with the given name. We can not use the same GetScalarAttribute() construct since the compiler will not be able to resolve between SetAttribute(..., int) and SetAttribute(..., unsigned long).
- `int = obj.GetVectorAttribute (string name, int length, int value)` - Get the attribute with the given name and converted to a scalar value. Returns length of vector read.
- `int = obj.GetVectorAttribute (string name, int length, float value)` - Get the attribute with the given name and converted to a scalar value. Returns length of vector read.
- `int = obj.GetVectorAttribute (string name, int length, double value)` - Get the attribute with the given name and converted to a scalar value. Returns length of vector read.
- `int = obj.GetVectorAttribute (string name, int length, long value)` - Get the attribute with the given name and converted to a scalar value. Returns length of vector read.
- `obj.SetVectorAttribute (string name, int length, int value)` - Set the attribute with the given name.
- `obj.SetVectorAttribute (string name, int length, float value)` - Set the attribute with the given name.
- `obj.SetVectorAttribute (string name, int length, double value)` - Set the attribute with the given name.
- `obj.SetVectorAttribute (string name, int length, long value)` - Set the attribute with the given name.
- `int = obj.GetNumberOfAttributes ()` - Get the number of attributes.
- `string = obj.GetAttributeName (int idx)` - Get the n-th attribute name. Returns 0 if there is no such attribute.
- `string = obj.GetAttributeValue (int idx)` - Get the n-th attribute value. Returns 0 if there is no such attribute.
- `obj.RemoveAttribute (string name)` - Remove one or all attributes.
- `obj.RemoveAllAttributes ()` - Remove one or all attributes.
- `vtkXMLDataElement = obj.GetParent ()` - Set/Get the parent of this element.
- `obj.SetParent (vtkXMLDataElement parent)` - Set/Get the parent of this element.
- `vtkXMLDataElement = obj.GetRoot ()` - Get root of the XML tree this element is part of.
- `int = obj.GetNumberOfNestedElements ()` - Get the number of elements nested in this one.
- `vtkXMLDataElement = obj.GetNestedElement (int index)` - Get the element nested in this one at the given index.

- `obj.AddNestedElement (vtkXMLDataElement element)` - Add nested element
- `obj.RemoveNestedElement (vtkXMLDataElement )` - Remove nested element.
- `obj.RemoveAllNestedElements ()` - Remove all nested elements.
- `vtkXMLDataElement = obj.FindNestedElement (string id)` - Find the first nested element with the given id, given name, or given name and id. WARNING: the search is only performed on the children, not the grand-children.
- `vtkXMLDataElement = obj.FindNestedElementWithName (string name)` - Find the first nested element with the given id, given name, or given name and id. WARNING: the search is only performed on the children, not the grand-children.
- `vtkXMLDataElement = obj.FindNestedElementWithNameAndId (string name, string id)` - Find the first nested element with the given id, given name, or given name and id. WARNING: the search is only performed on the children, not the grand-children.
- `vtkXMLDataElement = obj.FindNestedElementWithNameAndAttribute (string name, string att\_name, strin` - Find the first nested element with the given id, given name, or given name and id. WARNING: the search is only performed on the children, not the grand-children.
- `vtkXMLDataElement = obj.LookupElementWithName (string name)` - Find the first nested element with given name. WARNING: the search is performed on the whole XML tree.
- `vtkXMLDataElement = obj.LookupElement (string id)` - Lookup the element with the given id, starting at this scope.
- `long = obj.GetXMLByteIndex ()` - Set/Get the offset from the beginning of the XML document to this element.
- `obj.SetXMLByteIndex (long )` - Set/Get the offset from the beginning of the XML document to this element.
- `int = obj.IsEqualTo (vtkXMLDataElement elem)` - Check if the instance has the same name, attributes, character data and nested elements contents than the given element (this method is applied recursively on the nested elements, and they must be stored in the same order). Warning: Id, Parent, XMLByteIndex are ignored.
- `obj.DeepCopy (vtkXMLDataElement elem)` - Copy this element from another of the same type (elem), recursively. Old attributes and nested elements are removed, new ones are created given the contents of 'elem'. Warning: Parent is ignored.
- `obj.SetAttributeEncoding (int )` - Get/Set the internal character encoding of the attributes. Default type is VTK_ENCODING_UTF_8. Note that a vtkXMLDataParser has its own AttributesEncoding ivar. If this ivar is set to something other than VTK_ENCODING_NONE, it will be used to set the attribute encoding of each vtkXMLDataElement created by this vtkXMLDataParser.
- `int = obj.GetAttributeEncodingMinValue ()` - Get/Set the internal character encoding of the attributes. Default type is VTK_ENCODING_UTF_8. Note that a vtkXMLDataParser has its own AttributesEncoding ivar. If this ivar is set to something other than VTK_ENCODING_NONE, it will be used to set the attribute encoding of each vtkXMLDataElement created by this vtkXMLDataParser.
- `int = obj.GetAttributeEncodingMaxValue ()` - Get/Set the internal character encoding of the attributes. Default type is VTK_ENCODING_UTF_8. Note that a vtkXMLDataParser has its own AttributesEncoding ivar. If this ivar is set to something other than VTK_ENCODING_NONE, it will be used to set the attribute encoding of each vtkXMLDataElement created by this vtkXMLDataParser.

- `int = obj.GetAttributeEncoding ()` - Get/Set the internal character encoding of the attributes. Default type is VTK_ENCODING_UTF_8. Note that a vtkXMLDataParser has its own AttributesEncoding ivar. If this ivar is set to something other than VTK_ENCODING_NONE, it will be used to set the attribute encoding of each vtkXMLDataElement created by this vtkXMLDataParser.

- `obj.PrintXML (string fname)` - Prints element tree as XML.

- `int = obj.GetCharacterDataWidth ()` - Get/Set the width (in number of fields) that character data (that between open and closing tags ie. ¡X¿ ... ¡/X¿) is printed. If the width is less than one the tag's character data is printed all on one line. If it is greater than one the character data is streamed insterting line feeds every width number of fields. See PrintXML.

- `obj.SetCharacterDataWidth (int )` - Get/Set the width (in number of fields) that character data (that between open and closing tags ie. ¡X¿ ... ¡/X¿) is printed. If the width is less than one the tag's character data is printed all on one line. If it is greater than one the character data is streamed insterting line feeds every width number of fields. See PrintXML.

30.168 vtkXMLFileOutputWindow

30.168.1 Usage

Writes debug/warning/error output to an XML file. Uses prefined XML tags for each text display method. The text is processed to replace XML markup characters.

DisplayText - ¡Text¿
DisplayErrorText - ¡Error¿
DisplayWarningText - ¡Warning¿
DisplayGenericWarningText - ¡GenericWarning¿
DisplayDebugText - ¡Debug¿

The method DisplayTag outputs the text unprocessed. To use this class, instantiate it and then call SetInstance(this).

To create an instance of class vtkXMLFileOutputWindow, simply invoke its constructor as follows

```
obj = vtkXMLFileOutputWindow
```

30.168.2 Methods

The class vtkXMLFileOutputWindow has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkXMLFileOutputWindow class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkXMLFileOutputWindow = obj.NewInstance ()`

- `vtkXMLFileOutputWindow = obj.SafeDownCast (vtkObject o)`

- `obj.DisplayText (string )` - Put the text into the log file. The text is processed to replace &, ¡, ¿ with &, &lt, and &gt. Each display method outputs a different XML tag.

- `obj.DisplayErrorText (string )` - Put the text into the log file. The text is processed to replace &, ¡, ¿ with &, &lt, and &gt. Each display method outputs a different XML tag.

- `obj.DisplayWarningText (string )` - Put the text into the log file. The text is processed to replace &, ¡, ¿ with &, &lt, and &gt. Each display method outputs a different XML tag.

- `obj.DisplayGenericWarningText (string )` - Put the text into the log file. The text is processed to replace &, ¡, ¿ with &amp, &lt, and &gt. Each display method outputs a different XML tag.
- `obj.DisplayDebugText (string )` - Put the text into the log file. The text is processed to replace &, ¡, ¿ with &amp, &lt, and &gt. Each display method outputs a different XML tag.
- `obj.DisplayTag (string )` - Put the text into the log file without processing it.

Chapter 31

Visualization Toolkit Filtering Classes

31.1 vtkAbstractCellLocator

31.1.1 Usage

vtkAbstractCellLocator is a spatial search object to quickly locate cells in 3D. vtkAbstractCellLocator supplies a basic interface which concrete subclasses should implement.

.SECTION Warning When deriving a class from vtkAbstractCellLocator, one should include the 'hidden' member functions by the following construct in the derived class

```
//BTX
 using vtkAbstractCellLocator::IntersectWithLine;
 using vtkAbstractCellLocator::FindClosestPoint;
 using vtkAbstractCellLocator::FindClosestPointWithinRadius;
//ETX
```

To create an instance of class vtkAbstractCellLocator, simply invoke its constructor as follows

```
obj = vtkAbstractCellLocator
```

31.1.2 Methods

The class vtkAbstractCellLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractCellLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractCellLocator = obj.NewInstance ()`
- `vtkAbstractCellLocator = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfCellsPerNode (int )` - Specify the preferred/maximum number of cells in each node/bucket. Default 32. Locators generally operate by subdividing space into smaller regions until the number of cells in each region (or node) reaches the desired level.
- `int = obj.GetNumberOfCellsPerNodeMinValue ()` - Specify the preferred/maximum number of cells in each node/bucket. Default 32. Locators generally operate by subdividing space into smaller regions until the number of cells in each region (or node) reaches the desired level.

- `int = obj.GetNumberOfCellsPerNodeMaxValue ()` - Specify the preferred/maximum number of cells in each node/bucket. Default 32. Locators generally operate by subdividing space into smaller regions until the number of cells in each region (or node) reaches the desired level.
- `int = obj.GetNumberOfCellsPerNode ()` - Specify the preferred/maximum number of cells in each node/bucket. Default 32. Locators generally operate by subdividing space into smaller regions until the number of cells in each region (or node) reaches the desired level.
- `obj.SetCacheCellBounds (int )` - Boolean controls whether the bounds of each cell are computed only once and then saved. Should be 10 to 20calling any of the Intersect/Find routines and the extra memory won't cause disk caching (24 extra bytes per cell are required to save the bounds).
- `int = obj.GetCacheCellBounds ()` - Boolean controls whether the bounds of each cell are computed only once and then saved. Should be 10 to 20calling any of the Intersect/Find routines and the extra memory won't cause disk caching (24 extra bytes per cell are required to save the bounds).
- `obj.CacheCellBoundsOn ()` - Boolean controls whether the bounds of each cell are computed only once and then saved. Should be 10 to 20calling any of the Intersect/Find routines and the extra memory won't cause disk caching (24 extra bytes per cell are required to save the bounds).
- `obj.CacheCellBoundsOff ()` - Boolean controls whether the bounds of each cell are computed only once and then saved. Should be 10 to 20calling any of the Intersect/Find routines and the extra memory won't cause disk caching (24 extra bytes per cell are required to save the bounds).
- `obj.SetRetainCellLists (int )` - Boolean controls whether to maintain list of cells in each node. not applicable to all implementations, but if the locator is being used as a geometry simplification technique, there is no need to keep them.
- `int = obj.GetRetainCellLists ()` - Boolean controls whether to maintain list of cells in each node. not applicable to all implementations, but if the locator is being used as a geometry simplification technique, there is no need to keep them.
- `obj.RetainCellListsOn ()` - Boolean controls whether to maintain list of cells in each node. not applicable to all implementations, but if the locator is being used as a geometry simplification technique, there is no need to keep them.
- `obj.RetainCellListsOff ()` - Boolean controls whether to maintain list of cells in each node. not applicable to all implementations, but if the locator is being used as a geometry simplification technique, there is no need to keep them.
- `obj.SetLazyEvaluation (int )` - Most Locators build their search structures during BuildLocator but some may delay construction until it is actually needed. If LazyEvaluation is supported, this turns on/off the feature. if not supported, it is ignored.
- `int = obj.GetLazyEvaluation ()` - Most Locators build their search structures during BuildLocator but some may delay construction until it is actually needed. If LazyEvaluation is supported, this turns on/off the feature. if not supported, it is ignored.
- `obj.LazyEvaluationOn ()` - Most Locators build their search structures during BuildLocator but some may delay construction until it is actually needed. If LazyEvaluation is supported, this turns on/off the feature. if not supported, it is ignored.
- `obj.LazyEvaluationOff ()` - Most Locators build their search structures during BuildLocator but some may delay construction until it is actually needed. If LazyEvaluation is supported, this turns on/off the feature. if not supported, it is ignored.
- `obj.SetUseExistingSearchStructure (int )` - Some locators support querying a new dataset without rebuilding the search structure (typically this may occur when a dataset changes due to a time update, but is actually the same topology) Turning on this flag enables some locators to skip the rebuilding phase

- `int = obj.GetUseExistingSearchStructure ()` - Some locators support querying a new dataset without rebuilding the search structure (typically this may occur when a dataset changes due to a time update, but is actually the same topology) Turning on this flag enables some locators to skip the rebuilding phase
- `obj.UseExistingSearchStructureOn ()` - Some locators support querying a new dataset without rebuilding the search structure (typically this may occur when a dataset changes due to a time update, but is actually the same topology) Turning on this flag enables some locators to skip the rebuilding phase
- `obj.UseExistingSearchStructureOff ()` - Some locators support querying a new dataset without rebuilding the search structure (typically this may occur when a dataset changes due to a time update, but is actually the same topology) Turning on this flag enables some locators to skip the rebuilding phase
- `int = obj.IntersectWithLine (double p1[3], double p2[3], vtkPoints points, vtkIdList cellIds)` - Take the passed line segment and intersect it with the data set. This method assumes that the data set is a vtkPolyData that describes a closed surface, and the intersection points that are returned in 'points' alternate between entrance points and exit points. The return value of the function is 0 if no intersections were found, -1 if point 'a0' lies inside the closed surface, or +1 if point 'a0' lies outside the closed surface. Either 'points' or 'cellIds' can be set to NULL if you don't want to receive that information. This method is currently only implemented in vtkOBBTree
- `obj.FindCellsWithinBounds (double bbox, vtkIdList cells)` - Return a list of unique cell ids inside of a given bounding box. The user must provide the vtkIdList to populate. This method returns data only after the locator has been built.
- `obj.FindCellsAlongLine (double p1[3], double p2[3], double tolerance, vtkIdList cells)` - Given a finite line defined by the two points (p1,p2), return the list of unique cell ids in the buckets containing the line. It is possible that an empty cell list is returned. The user must provide the vtkIdList to populate. This method returns data only after the locator has been built.
- `vtkIdType = obj.FindCell (double x[3])` - Returns the Id of the cell containing the point, returns -1 if no cell found. This interface uses a tolerance of zero
- `vtkIdType = obj.FindCell (double x[3], double tol2, vtkGenericCell GenCell, double pcoords[3], doub` - Find the cell containing a given point. returns -1 if no cell found the cell parameters are copied into the supplied variables, a cell must be provided to store the information.
- `bool = obj.InsideCellBounds (double x[3], vtkIdType cell\_ID)` - Quickly test if a point is inside the bounds of a particular cell. Some locators cache cell bounds and this function can make use of fast access to the data.

31.2 vtkAbstractInterpolatedVelocityField

31.2.1 Usage

vtkAbstractInterpolatedVelocityField acts as a continuous velocity field by performing cell interpolation on the underlying vtkDataSet. This is an abstract sub-class of vtkFunctionSet, NumberOfIndependentVariables = 4 (x,y,z,t) and NumberOfFunctions = 3 (u,v,w). With a brute-force scheme, every time an evaluation is performed, the target cell containing point (x,y,z) needs to be found by calling FindCell(), via either vtkDataSet or vtkAbstractCelllocator's sub-classes (vtkCellLocator & vtkModifiedBSPTree). As it incurs a large cost, one (for vtkCellLocatorInterpolatedVelocityField via vtkAbstractCellLocator) or two (for vtkInterpolatedVelocityField via vtkDataSet that involves vtkPointLocator in addressing vtkPointSet) levels of cell caching may be exploited to increase the performance.

For vtkInterpolatedVelocityField, level #0 begins with intra-cell caching. Specifically if the previous cell is valid and the next point is still in it (i.e., vtkCell::EvaluatePosition() returns 1, coupled with

newly created parametric coordinates & weights), the function values can be interpolated and only vtkCell::EvaluatePosition() is invoked. If this fails, then level #1 follows by inter-cell search for the target cell that contains the next point. By an inter-cell search, the previous cell provides an important clue or serves as an immediate neighbor to aid in locating the target cell via vtkPointSet:: FindCell(). If this still fails, a global cell location / search is invoked via vtkPointSet::FindCell(). Here regardless of either inter-cell or global search, vtkPointLocator is in fact employed (for datasets of type vtkPointSet only, note vtkImageData and vtkRectilinearGrid are able to provide rapid and robust cell location due to the simple mesh topology) as a crucial tool underlying the cell locator. However, the use of vtkPointLocator makes vtkInterpolatedVelocityField non-robust in cell location for vtkPointSet.

For vtkCellLocatorInterpolatedVelocityField, the only caching (level #0) works by intra-cell trial. In case of failure, a global search for the target cell is invoked via vtkAbstractCellLocator::FindCell() and the actual work is done by either vtkCellLocator or vtkModifiedBSPTree (for datasets of type vtkPointSet only, while vtkImageData and vtkRectilinearGrid themselves are able to provide fast robust cell location). Without the involvement of vtkPointLocator, robust cell location is achieved for vtkPointSet.

To create an instance of class vtkAbstractInterpolatedVelocityField, simply invoke its constructor as follows

```
obj = vtkAbstractInterpolatedVelocityField
```

31.2.2 Methods

The class vtkAbstractInterpolatedVelocityField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractInterpolatedVelocityField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractInterpolatedVelocityField = obj.NewInstance ()`
- `vtkAbstractInterpolatedVelocityField = obj.SafeDownCast (vtkObject o)`
- `obj.SetCaching (bool )` - Set/Get the caching flag. If this flag is turned ON, there are two levels of caching for derived concrete class vtkInterpolatedVelocityField and one level of caching for derived concrete class vtkCellLocatorInterpolatedVelocityField. Otherwise a global cell location is always invoked for evaluating the function values at any point.
- `bool = obj.GetCaching ()` - Set/Get the caching flag. If this flag is turned ON, there are two levels of caching for derived concrete class vtkInterpolatedVelocityField and one level of caching for derived concrete class vtkCellLocatorInterpolatedVelocityField. Otherwise a global cell location is always invoked for evaluating the function values at any point.
- `int = obj.GetCacheHit ()` - Get the caching statistics. CacheHit refers to the number of level #0 cache hits while CacheMiss is the number of level #0 cache misses.
- `int = obj.GetCacheMiss ()` - Get the caching statistics. CacheHit refers to the number of level #0 cache hits while CacheMiss is the number of level #0 cache misses.
- `int = obj.GetLastDataSetIndex ()` - Get the most recently visited dataset and it id. The dataset is used for a guess regarding where the next point will be, without searching through all datasets. When setting the last dataset, care is needed as no reference counting or checks are performed. This feature is intended for custom interpolators only that cache datasets independently.
- `vtkDataSet = obj.GetLastDataSet ()` - Get the most recently visited dataset and it id. The dataset is used for a guess regarding where the next point will be, without searching through all datasets. When setting the last dataset, care is needed as no reference counting or checks are performed. This feature is intended for custom interpolators only that cache datasets independently.

- `vtkIdType = obj.GetLastCellId ()` - Get/Set the id of the cell cached from last evaluation.
- `obj.SetLastCellId (vtkIdType c)` - Set the id of the most recently visited cell of a dataset.
- `obj.SetLastCellId (vtkIdType c, int dataindex)` - Set the id of the most recently visited cell of a dataset.
- `string = obj.GetVectorsSelection ()` - Get/Set the name of a spcified vector array. By default it is NULL, with the active vector array for use.
- `obj.SelectVectors (string fieldName)` - Set/Get the flag indicating vector post-normalization (following vector interpolation). Vector post-normalization is required to avoid the 'curve-overshooting' problem (caused by high velocity magnitude) that occurs when Cell-Length is used as the step size unit (particularly the Minimum step size unit). Furthermore, it is required by RK45 to achieve, as expected, high numerical accuracy (or high smoothness of flow lines) through adaptive step sizing. Note this operation is performed (when NormalizeVector TRUE) right after vector interpolation such that the differing amount of contribution of each node (of a cell) to the resulting direction of the interpolated vector, due to the possibly significantly-differing velocity magnitude values at the nodes (which is the case with large cells), can be reflected as is. Also note that this flag needs to be turned to FALSE after vtkInitialValueProblemSolver:: ComputeNextStep() as subsequent operations, e.g., vorticity computation, may need non-normalized vectors.
- `obj.SetNormalizeVector (bool )` - Set/Get the flag indicating vector post-normalization (following vector interpolation). Vector post-normalization is required to avoid the 'curve-overshooting' problem (caused by high velocity magnitude) that occurs when Cell-Length is used as the step size unit (particularly the Minimum step size unit). Furthermore, it is required by RK45 to achieve, as expected, high numerical accuracy (or high smoothness of flow lines) through adaptive step sizing. Note this operation is performed (when NormalizeVector TRUE) right after vector interpolation such that the differing amount of contribution of each node (of a cell) to the resulting direction of the interpolated vector, due to the possibly significantly-differing velocity magnitude values at the nodes (which is the case with large cells), can be reflected as is. Also note that this flag needs to be turned to FALSE after vtkInitialValueProblemSolver:: ComputeNextStep() as subsequent operations, e.g., vorticity computation, may need non-normalized vectors.
- `bool = obj.GetNormalizeVector ()` - Set/Get the flag indicating vector post-normalization (following vector interpolation). Vector post-normalization is required to avoid the 'curve-overshooting' problem (caused by high velocity magnitude) that occurs when Cell-Length is used as the step size unit (particularly the Minimum step size unit). Furthermore, it is required by RK45 to achieve, as expected, high numerical accuracy (or high smoothness of flow lines) through adaptive step sizing. Note this operation is performed (when NormalizeVector TRUE) right after vector interpolation such that the differing amount of contribution of each node (of a cell) to the resulting direction of the interpolated vector, due to the possibly significantly-differing velocity magnitude values at the nodes (which is the case with large cells), can be reflected as is. Also note that this flag needs to be turned to FALSE after vtkInitialValueProblemSolver:: ComputeNextStep() as subsequent operations, e.g., vorticity computation, may need non-normalized vectors.
- `obj.CopyParameters (vtkAbstractInterpolatedVelocityField from)` - Add a dataset for implicit velocity function evaluation. If more than one dataset is added, the evaluation point is searched in all until a match is found. THIS FUNCTION DOES NOT CHANGE THE REFERENCE COUNT OF dataset FOR THREAD SAFETY REASONS.
- `obj.AddDataSet (vtkDataSet dataset)` - Add a dataset for implicit velocity function evaluation. If more than one dataset is added, the evaluation point is searched in all until a match is found. THIS FUNCTION DOES NOT CHANGE THE REFERENCE COUNT OF dataset FOR THREAD SAFETY REASONS.
- `int = obj.FunctionValues (double x, double f)` - Evaluate the velocity field f at point (x, y, z).

- `obj.ClearLastCellId ()` - Get the interpolation weights cached from last evaluation. Return 1 if the cached cell is valid and 0 otherwise.
- `int = obj.GetLastWeights (double w)` - Get the interpolation weights cached from last evaluation. Return 1 if the cached cell is valid and 0 otherwise.
- `int = obj.GetLastLocalCoordinates (double pcoords[3])` - Get the interpolation weights cached from last evaluation. Return 1 if the cached cell is valid and 0 otherwise.

31.3 vtkAbstractMapper

31.3.1 Usage

vtkAbstractMapper is an abstract class to specify interface between data and graphics primitives or software rendering techniques. Subclasses of vtkAbstractMapper can be used for rendering 2D data, geometry, or volumetric data.

To create an instance of class vtkAbstractMapper, simply invoke its constructor as follows

```
obj = vtkAbstractMapper
```

31.3.2 Methods

The class vtkAbstractMapper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractMapper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractMapper = obj.NewInstance ()`
- `vtkAbstractMapper = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Override Modifiedtime as we have added Clipping planes
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this mapper. The parameter window could be used to determine which graphic resources to release.
- `double = obj.GetTimeToDraw ()` - Get the time required to draw the geometry last time it was rendered
- `obj.AddClippingPlane (vtkPlane plane)` - Specify clipping planes to be applied when the data is mapped (at most 6 clipping planes can be specified).
- `obj.RemoveClippingPlane (vtkPlane plane)` - Specify clipping planes to be applied when the data is mapped (at most 6 clipping planes can be specified).
- `obj.RemoveAllClippingPlanes ()` - Specify clipping planes to be applied when the data is mapped (at most 6 clipping planes can be specified).
- `obj.SetClippingPlanes (vtkPlaneCollection )` - Get/Set the vtkPlaneCollection which specifies the clipping planes.
- `vtkPlaneCollection = obj.GetClippingPlanes ()` - Get/Set the vtkPlaneCollection which specifies the clipping planes.
- `obj.SetClippingPlanes (vtkPlanes planes)` - An alternative way to set clipping planes: use up to six planes found in the supplied instance of the implicit function vtkPlanes.
- `obj.ShallowCopy (vtkAbstractMapper m)` - Make a shallow copy of this mapper.

31.4 vtkAbstractPointLocator

31.4.1 Usage

vtkAbstractPointLocator is an abstract spatial search object to quickly locate points in 3D. vtkAbstractPointLocator works by dividing a specified region of space into "rectangular" buckets, and then keeping a list of points that lie in each bucket. Typical operation involves giving a position in 3D and finding the closest point. The points are provided from the specified dataset input.

To create an instance of class vtkAbstractPointLocator, simply invoke its constructor as follows

```
obj = vtkAbstractPointLocator
```

31.4.2 Methods

The class vtkAbstractPointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAbstractPointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAbstractPointLocator = obj.NewInstance ()`
- `vtkAbstractPointLocator = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.FindClosestPoint (double x[3])` - Given a position x, return the id of the point closest to it. Alternative method requires separate x-y-z values. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `vtkIdType = obj.FindClosestPoint (double x, double y, double z)` - Given a position x, return the id of the point closest to it. Alternative method requires separate x-y-z values. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindClosestNPoints (int N, double x[3], vtkIdList result)` - Find the closest N points to a position. This returns the closest N points to a position. A faster method could be created that returned N close points to a position, but necessarily the exact N closest. The returned points are sorted from closest to farthest. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindClosestNPoints (int N, double x, double y, double z, vtkIdList result)` - Find the closest N points to a position. This returns the closest N points to a position. A faster method could be created that returned N close points to a position, but necessarily the exact N closest. The returned points are sorted from closest to farthest. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindPointsWithinRadius (double R, double x[3], vtkIdList result)` - Find all points within a specified radius R of position x. The result is not sorted in any specific manner. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindPointsWithinRadius (double R, double x, double y, double z, vtkIdList result)` - Find all points within a specified radius R of position x. The result is not sorted in any specific manner. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.GetBounds (double )` - Provide an accessor to the bounds.
- `obj.FreeSearchStructure ()` - See vtkLocator interface documentation. These methods are not thread safe.

- `obj.BuildLocator ()` - See vtkLocator interface documentation. These methods are not thread safe.
- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - See vtkLocator interface documentation. These methods are not thread safe.

31.5 vtkActor2D

31.5.1 Usage

vtkActor2D is similar to vtkActor, but it is made to be used with two dimensional images and annotation. vtkActor2D has a position but does not use a transformation matrix like vtkActor (see the superclass vtkProp for information on positioning vtkActor2D). vtkActor2D has a reference to a vtkMapper2D object which does the rendering.

To create an instance of class vtkActor2D, simply invoke its constructor as follows

```
obj = vtkActor2D
```

31.5.2 Methods

The class vtkActor2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkActor2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkActor2D = obj.NewInstance ()`
- `vtkActor2D = obj.SafeDownCast (vtkObject o)`
- `int = obj.RenderOverlay (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderOpaqueGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport viewport)` - Support the standard render methods.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.SetMapper (vtkMapper2D mapper)` - Set/Get the vtkMapper2D which defines the data to be drawn.
- `vtkMapper2D = obj.GetMapper ()` - Set/Get the vtkMapper2D which defines the data to be drawn.
- `obj.SetLayerNumber (int )` - Set/Get the layer number in the overlay planes into which to render.
- `int = obj.GetLayerNumber ()` - Set/Get the layer number in the overlay planes into which to render.
- `vtkProperty2D = obj.GetProperty ()` - Returns this actor's vtkProperty2D. Creates a property if one doesn't already exist.
- `obj.SetProperty (vtkProperty2D )` - Set this vtkProp's vtkProperty2D.
- `vtkCoordinate = obj.GetPositionCoordinate ()` - Get the PositionCoordinate instance of vtkCoordinate. This is used for for complicated or relative positioning. The position variable controls the lower left corner of the Actor2D

- `obj.SetPosition (double, double)` - Get the PositionCoordinate instance of vtkCoordinate. This is used for for complicated or relative positioning. The position variable controls the lower left corner of the Actor2D
- `obj.SetPosition (double a[2])` - Get the PositionCoordinate instance of vtkCoordinate. This is used for for complicated or relative positioning. The position variable controls the lower left corner of the Actor2D
- `double = obj.GetPosition ()` - Get the PositionCoordinate instance of vtkCoordinate. This is used for for complicated or relative positioning. The position variable controls the lower left corner of the Actor2D
- `obj.SetDisplayPosition (int , int )` - Set the Prop2D's position in display coordinates.
- `vtkCoordinate = obj.GetPosition2Coordinate ()` - Access the Position2 instance variable. This variable controls the upper right corner of the Actor2D. It is by default relative to Position and in normalized viewport coordinates. Some 2D actor subclasses ignore the position2 variable
- `obj.SetPosition2 (double, double)` - Access the Position2 instance variable. This variable controls the upper right corner of the Actor2D. It is by default relative to Position and in normalized viewport coordinates. Some 2D actor subclasses ignore the position2 variable
- `obj.SetPosition2 (double a[2])` - Access the Position2 instance variable. This variable controls the upper right corner of the Actor2D. It is by default relative to Position and in normalized viewport coordinates. Some 2D actor subclasses ignore the position2 variable
- `double = obj.GetPosition2 ()` - Access the Position2 instance variable. This variable controls the upper right corner of the Actor2D. It is by default relative to Position and in normalized viewport coordinates. Some 2D actor subclasses ignore the position2 variable
- `obj.SetWidth (double w)` - Set/Get the height and width of the Actor2D. The value is expressed as a fraction of the viewport. This really is just another way of setting the Position2 instance variable.
- `double = obj.GetWidth ()` - Set/Get the height and width of the Actor2D. The value is expressed as a fraction of the viewport. This really is just another way of setting the Position2 instance variable.
- `obj.SetHeight (double h)` - Set/Get the height and width of the Actor2D. The value is expressed as a fraction of the viewport. This really is just another way of setting the Position2 instance variable.
- `double = obj.GetHeight ()` - Set/Get the height and width of the Actor2D. The value is expressed as a fraction of the viewport. This really is just another way of setting the Position2 instance variable.
- `long = obj.GetMTime ()` - Return this objects MTime.
- `obj.GetActors2D (vtkPropCollection pc)` - For some exporters and other other operations we must be able to collect all the actors or volumes. These methods are used in that process.
- `obj.ShallowCopy (vtkProp prop)` - Shallow copy of this vtkActor2D. Overloads the virtual vtkProp method.
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `vtkCoordinate = obj.GetActualPositionCoordinate (void )` - Return the actual vtkCoordinate reference that the mapper should use to position the actor. This is used internally by the mappers and should be overridden in specialized subclasses and otherwise ignored.
- `vtkCoordinate = obj.GetActualPosition2Coordinate (void )`

31.6 vtkActor2DCollection

31.6.1 Usage

vtkActor2DCollection is a subclass of vtkCollection. vtkActor2DCollection maintains a collection of vtkActor2D objects that is sorted by layer number, with lower layer numbers at the start of the list. This allows the vtkActor2D objects to be rendered in the correct order.

To create an instance of class vtkActor2DCollection, simply invoke its constructor as follows

```
obj = vtkActor2DCollection
```

31.6.2 Methods

The class vtkActor2DCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkActor2DCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkActor2DCollection = obj.NewInstance ()`
- `vtkActor2DCollection = obj.SafeDownCast (vtkObject o)`
- `obj.Sort ()` - Sorts the vtkActor2DCollection by layer number. Smaller layer numbers are first. Layer numbers can be any integer value.
- `obj.AddItem (vtkActor2D a)` - Add an actor to the list. The new actor is inserted in the list according to it's layer number.
- `int = obj.IsItemPresent (vtkActor2D a)` - Standard Collection methods
- `vtkActor2D = obj.GetNextActor2D ()` - Standard Collection methods
- `vtkActor2D = obj.GetLastActor2D ()` - Standard Collection methods
- `vtkActor2D = obj.GetNextItem ()` - Access routines that are provided for compatibility with previous version of VTK. Please use the GetNextActor2D(), GetLastActor2D() variants where possible.
- `vtkActor2D = obj.GetLastItem ()` - Access routines that are provided for compatibility with previous version of VTK. Please use the GetNextActor2D(), GetLastActor2D() variants where possible.
- `obj.RenderOverlay (vtkViewport viewport)` - Sort and then render the collection of 2D actors.

31.7 vtkAdjacentVertexIterator

31.7.1 Usage

vtkAdjacentVertexIterator iterates through all vertices adjacent to a vertex, i.e. the vertices which may be reached by traversing an out edge of the source vertex. Use graph-¿GetAdjacentVertices(v, it) to initialize the iterator.

To create an instance of class vtkAdjacentVertexIterator, simply invoke its constructor as follows

```
obj = vtkAdjacentVertexIterator
```

31.7.2 Methods

The class vtkAdjacentVertexIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAdjacentVertexIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAdjacentVertexIterator = obj.NewInstance ()`
- `vtkAdjacentVertexIterator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkGraph g, vtkIdType v)` - Initialize the iterator with a graph and vertex.
- `vtkGraph = obj.GetGraph ()` - Get the graph and vertex associated with this iterator.
- `vtkIdType = obj.GetVertex ()` - Get the graph and vertex associated with this iterator.
- `vtkIdType = obj.Next ()` - Whether this iterator has more edges.
- `bool = obj.HasNext ()`

31.8 vtkAlgorithm

31.8.1 Usage

vtkAlgorithm is the superclass for all sources, filters, and sinks in VTK. It defines a generalized interface for executing data processing algorithms. Pipeline connections are associated with input and output ports that are independent of the type of data passing through the connections.

Instances may be used independently or within pipelines with a variety of architectures and update mechanisms. Pipelines are controlled by instances of vtkExecutive. Every vtkAlgorithm instance has an associated vtkExecutive when it is used in a pipeline. The executive is responsible for data flow.

To create an instance of class vtkAlgorithm, simply invoke its constructor as follows

```
obj = vtkAlgorithm
```

31.8.2 Methods

The class vtkAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAlgorithm = obj.NewInstance ()`
- `vtkAlgorithm = obj.SafeDownCast (vtkObject o)`
- `int = obj.HasExecutive ()` - Check whether this algorithm has an assigned executive. This will NOT create a default executive.
- `vtkExecutive = obj.GetExecutive ()` - Get this algorithm's executive. If it has none, a default executive will be created.

- `obj.SetExecutive (vtkExecutive executive)` - Set this algorithm's executive. This algorithm is removed from any executive to which it has previously been assigned and then assigned to the given executive.
- `int = obj.ModifyRequest (vtkInformation request, int when)` - This method gives the algorithm a chance to modify the contents of a request before or after (specified in the when argument) it is forwarded. The default implementation is empty. Returns 1 on success, 0 on failure. When can be either vtkExecutive::BeforeForward or vtkExecutive::AfterForward.
- `vtkInformation = obj.GetInputPortInformation (int port)` - Get the information object associated with an input port. There is one input port per kind of input to the algorithm. Each input port tells executives what kind of data and downstream requests this algorithm can handle for that input.
- `vtkInformation = obj.GetOutputPortInformation (int port)` - Get the information object associated with an output port. There is one output port per output from the algorithm. Each output port tells executives what kind of upstream requests this algorithm can handle for that output.
- `vtkInformation = obj.GetInformation ()` - Set/Get the information object associated with this algorithm.
- `obj.SetInformation (vtkInformation )` - Set/Get the information object associated with this algorithm.
- `int = obj.GetNumberOfInputPorts ()` - Get the number of input ports used by the algorithm.
- `int = obj.GetNumberOfOutputPorts ()` - Get the number of output ports provided by the algorithm.
- `obj.Register (vtkObjectBase o)` - Participate in garbage collection.
- `obj.UnRegister (vtkObjectBase o)` - Participate in garbage collection.
- `obj.SetAbortExecute (int )` - Set/Get the AbortExecute flag for the process object. Process objects may handle premature termination of execution in different ways.
- `int = obj.GetAbortExecute ()` - Set/Get the AbortExecute flag for the process object. Process objects may handle premature termination of execution in different ways.
- `obj.AbortExecuteOn ()` - Set/Get the AbortExecute flag for the process object. Process objects may handle premature termination of execution in different ways.
- `obj.AbortExecuteOff ()` - Set/Get the AbortExecute flag for the process object. Process objects may handle premature termination of execution in different ways.
- `obj.SetProgress (double )` - Set/Get the execution progress of a process object.
- `double = obj.GetProgressMinValue ()` - Set/Get the execution progress of a process object.
- `double = obj.GetProgressMaxValue ()` - Set/Get the execution progress of a process object.
- `double = obj.GetProgress ()` - Set/Get the execution progress of a process object.
- `obj.UpdateProgress (double amount)` - Update the progress of the process object. If a ProgressMethod exists, executes it. Then set the Progress ivar to amount. The parameter amount should range between (0,1).
- `obj.SetProgressText (string ptext)` - Set the current text message associated with the progress state. This may be used by a calling process/GUI. Note: Because SetProgressText() is called from inside RequestData() it does not modify the algorithm object. Algorithms are not allowed to modify themselves from inside RequestData().

- `string = obj.GetProgressText ()` - Set the current text message associated with the progress state. This may be used by a calling process/GUI. Note: Because SetProgressText() is called from inside RequestData() it does not modify the algorithm object. Algorithms are not allowed to modify themselves from inside RequestData().

- `long = obj.GetErrorCode ()` - The error code contains a possible error that occured while reading or writing the file.

- `obj.SetInputArrayToProcess (int idx, int port, int connection, int fieldAssociation, string name)` - Set the input data arrays that this algorithm will process. Specifically the idx array that this algorithm will process (starting from 0) is the array on port, connection with the specified association and name or attribute type (such as SCALARS). The fieldAssociation refers to which field in the data object the array is stored. See vtkDataObject::FieldAssociations for detail.

- `obj.SetInputArrayToProcess (int idx, int port, int connection, int fieldAssociation, int fieldAttri` - Set the input data arrays that this algorithm will process. Specifically the idx array that this algorithm will process (starting from 0) is the array on port, connection with the specified association and name or attribute type (such as SCALARS). The fieldAssociation refers to which field in the data object the array is stored. See vtkDataObject::FieldAssociations for detail.

- `obj.SetInputArrayToProcess (int idx, vtkInformation info)` - Set the input data arrays that this algorithm will process. Specifically the idx array that this algorithm will process (starting from 0) is the array on port, connection with the specified association and name or attribute type (such as SCALARS). The fieldAssociation refers to which field in the data object the array is stored. See vtkDataObject::FieldAssociations for detail.

- `obj.SetInputArrayToProcess (int idx, int port, int connection, string fieldAssociation, string attr` - String based versions of SetInputArrayToProcess(). Because fieldAssociation and fieldAttributeType are enums, they cannot be easily accessed from scripting language. These methods provides an easy and safe way of passing association and attribute type information. Field association is one of the following: @verbatim vtkDataObject::FIELD_ASSOCIATION_POINTS vtkDataObject::FIELD_ASSOCIATION_CELLS vtkDataObject::FIELD_ASSOCIATION_NONE vtkDataObject::FIELD_ASSOCIATION_POINTS_THEN_CELLS @endverbatim Attribute type is one of the following: @verbatim vtkDataSetAttributes::SCALARS vtkDataSetAttributes::VECTORS vtkDataSetAttributes::NORMALS vtkDataSetAttributes::TCOORDS vtkDataSetAttributes::TENSORS @endverbatim If the last argument is not an attribute type, it is assumed to be an array name.

- `vtkInformation = obj.GetInputArrayInformation (int idx)` - Get the info object for the specified input array to this algorithm

- `obj.RemoveAllInputs ()` - Remove all the input data.

- `vtkDataObject = obj.GetOutputDataObject (int port)` - Get the data object that will contain the algorithm output for the given port.

- `vtkDataObject = obj.GetInputDataObject (int port, int connection)` - Get the data object that will contain the algorithm input for the given port and given connection.

- `obj.SetInputConnection (int port, vtkAlgorithmOutput input)` - Set the connection for the given input port index. Each input port of a filter has a specific purpose. A port may have zero or more connections and the required number is specified by each filter. Setting the connection with this method removes all other connections from the port. To add more than one connection use AddInputConnection().

  The input for the connection is the output port of another filter, which is obtained with GetOutputPort(). Typical usage is

  filter2-¿SetInputConnection(0, filter1-¿GetOutputPort(0)).

- `obj.SetInputConnection (vtkAlgorithmOutput input)` - Set the connection for the given input port index. Each input port of a filter has a specific purpose. A port may have zero or more connections and the required number is specified by each filter. Setting the connection with this method removes all other connections from the port. To add more than one connection use AddInputConnection().

  The input for the connection is the output port of another filter, which is obtained with GetOutputPort(). Typical usage is

  filter2-¿SetInputConnection(0, filter1-¿GetOutputPort(0)).

- `obj.AddInputConnection (int port, vtkAlgorithmOutput input)` - Add a connection to the given input port index. See SetInputConnection() for details on input connections. This method is the complement to RemoveInputConnection() in that it adds only the connection specified without affecting other connections. Typical usage is

  filter2-¿AddInputConnection(0, filter1-¿GetOutputPort(0)).

- `obj.AddInputConnection (vtkAlgorithmOutput input)` - Add a connection to the given input port index. See SetInputConnection() for details on input connections. This method is the complement to RemoveInputConnection() in that it adds only the connection specified without affecting other connections. Typical usage is

  filter2-¿AddInputConnection(0, filter1-¿GetOutputPort(0)).

- `obj.RemoveInputConnection (int port, vtkAlgorithmOutput input)` - Remove a connection from the given input port index. See SetInputConnection() for details on input connection. This method is the complement to AddInputConnection() in that it removes only the connection specified without affecting other connections. Typical usage is

  filter2-¿RemoveInputConnection(0, filter1-¿GetOutputPort(0)).

- `vtkAlgorithmOutput = obj.GetOutputPort (int index)` - Get a proxy object corresponding to the given output port of this algorithm. The proxy object can be passed to another algorithm's SetInputConnection(), AddInputConnection(), and RemoveInputConnection() methods to modify pipeline connectivity.

- `vtkAlgorithmOutput = obj.GetOutputPort ()` - Get the number of inputs currently connected to a port.

- `int = obj.GetNumberOfInputConnections (int port)` - Get the number of inputs currently connected to a port.

- `int = obj.GetTotalNumberOfInputConnections ()` - Get the total number of inputs for this algorithm

- `vtkAlgorithmOutput = obj.GetInputConnection (int port, int index)` - Get the algorithm output port connected to an input port.

- `obj.Update ()` - Bring this algorithm's outputs up-to-date.

- `obj.UpdateInformation ()` - Backward compatibility method to invoke UpdateInformation on executive.

- `obj.UpdateWholeExtent ()` - Bring this algorithm's outputs up-to-date.

- `obj.SetReleaseDataFlag (int )` - Turn release data flag on or off for all output ports.

- `int = obj.GetReleaseDataFlag ()` - Turn release data flag on or off for all output ports.

- `obj.ReleaseDataFlagOn ()` - Turn release data flag on or off for all output ports.

- `obj.ReleaseDataFlagOff ()` - Turn release data flag on or off for all output ports.

- `int = obj.UpdateExtentIsEmpty (vtkDataObject output)` - This detects when the UpdateExtent will generate no data This condition is satisfied when the UpdateExtent has zero volume (0,-1,...) or the UpdateNumberOfPieces is 0. The source uses this call to determine whether to call Execute.
- `int = obj.UpdateExtentIsEmpty (vtkInformation pinfo, int extentType)` - This detects when the UpdateExtent will generate no data This condition is satisfied when the UpdateExtent has zero volume (0,-1,...) or the UpdateNumberOfPieces is 0. The source uses this call to determine whether to call Execute.
- `double = obj.ComputePriority ()` - Returns the priority of the piece described by the current update extent. The priority is a number between 0.0 and 1.0 with 0 meaning skippable (REQUEST_DATA not needed) and 1.0 meaning important.

31.9 vtkAlgorithmOutput

31.9.1 Usage

vtkAlgorithmOutput is a proxy object returned by the GetOutputPort method of vtkAlgorithm. It may be passed to the SetInputConnection, AddInputConnection, or RemoveInputConnection methods of another vtkAlgorithm to establish a connection between an output and input port. The connection is not stored in the proxy object: it is simply a convenience for creating or removing connections.

To create an instance of class vtkAlgorithmOutput, simply invoke its constructor as follows

```
obj = vtkAlgorithmOutput
```

31.9.2 Methods

The class vtkAlgorithmOutput has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAlgorithmOutput class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAlgorithmOutput = obj.NewInstance ()`
- `vtkAlgorithmOutput = obj.SafeDownCast (vtkObject o)`
- `obj.SetIndex (int index)`
- `int = obj.GetIndex ()`
- `vtkAlgorithm = obj.GetProducer ()`
- `obj.SetProducer (vtkAlgorithm producer)`

31.10 vtkAnnotation

31.10.1 Usage

vtkAnnotation is a collection of annotation properties along with an associated selection indicating the portion of data the annotation refers to.

.SECTION Thanks Timothy M. Shead (tshead@sandia.gov) at Sandia National Laboratories contributed code to this class.

To create an instance of class vtkAnnotation, simply invoke its constructor as follows

```
obj = vtkAnnotation
```

31.10.2 Methods

The class vtkAnnotation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnnotation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnnotation = obj.NewInstance ()`
- `vtkAnnotation = obj.SafeDownCast (vtkObject o)`
- `vtkSelection = obj.GetSelection ()` - The selection to which this set of annotations will apply.
- `obj.SetSelection (vtkSelection selection)` - The selection to which this set of annotations will apply.
- `obj.Initialize ()` - Initialize the annotation to an empty state.
- `obj.ShallowCopy (vtkDataObject other)` - Make this annotation have the same properties and have the same selection of another annotation.
- `obj.DeepCopy (vtkDataObject other)` - Make this annotation have the same properties and have a copy of the selection of another annotation.
- `long = obj.GetMTime ()` - Get the modified time of this object.

31.11 vtkAnnotationLayers

31.11.1 Usage

vtkAnnotationLayers stores a vector of annotation layers. Each layer may contain any number of vtkAnnotation objects. The ordering of the layers introduces a prioritization of annotations. Annotations in higher layers may obscure annotations in lower layers.

To create an instance of class vtkAnnotationLayers, simply invoke its constructor as follows

```
obj = vtkAnnotationLayers
```

31.11.2 Methods

The class vtkAnnotationLayers has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnnotationLayers class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnnotationLayers = obj.NewInstance ()`
- `vtkAnnotationLayers = obj.SafeDownCast (vtkObject o)`
- `obj.SetCurrentAnnotation (vtkAnnotation ann)` - The current annotation associated with this annotation link.
- `vtkAnnotation = obj.GetCurrentAnnotation ()` - The current annotation associated with this annotation link.

- `obj.SetCurrentSelection (vtkSelection sel)` - The current selection associated with this annotation link. This is simply the selection contained in the current annotation.
- `vtkSelection = obj.GetCurrentSelection ()` - The current selection associated with this annotation link. This is simply the selection contained in the current annotation.
- `int = obj.GetNumberOfAnnotations ()` - The number of annotations in a specific layer.
- `vtkAnnotation = obj.GetAnnotation (int idx)` - Retrieve an annotation from a layer.
- `obj.AddAnnotation (vtkAnnotation ann)` - Add an annotation to a layer.
- `obj.RemoveAnnotation (vtkAnnotation ann)` - Remove an annotation from a layer.
- `obj.Initialize ()` - Initialize the data structure to an empty state.
- `obj.ShallowCopy (vtkDataObject other)` - Copy data from another data object into this one which references the same member annotations.
- `obj.DeepCopy (vtkDataObject other)` - Copy data from another data object into this one, performing a deep copy of member annotations.
- `long = obj.GetMTime ()` - The modified time for this object.

31.12 vtkAnnotationLayersAlgorithm

31.12.1 Usage

vtkAnnotationLayersAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be vtkAnnotationLayers. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation. For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

To create an instance of class vtkAnnotationLayersAlgorithm, simply invoke its constructor as follows

```
obj = vtkAnnotationLayersAlgorithm
```

31.12.2 Methods

The class vtkAnnotationLayersAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAnnotationLayersAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkAnnotationLayersAlgorithm = obj.NewInstance ()`
- `vtkAnnotationLayersAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkAnnotationLayers = obj.GetOutput ()` - Get the output data object for a port on this algorithm.

- `vtkAnnotationLayers = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.13 vtkArrayData

31.13.1 Usage

Because vtkArray cannot be stored as attributes of data objects (yet), a "carrier" object is needed to pass vtkArray through the pipeline. vtkArrayData acts as a container of zero-to-many vtkArray instances, which can be retrieved via a zero-based index. Note that a collection of arrays stored in vtkArrayData may-or-may-not have related types, dimensions, or extents.

To create an instance of class vtkArrayData, simply invoke its constructor as follows

```
obj = vtkArrayData
```

31.13.2 Methods

The class vtkArrayData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayData = obj.NewInstance ()`
- `vtkArrayData = obj.SafeDownCast (vtkObject o)`
- `obj.AddArray (vtkArray )` - Adds a vtkArray to the collection
- `obj.ClearArrays ()` - Clears the contents of the collection
- `vtkIdType = obj.GetNumberOfArrays ()` - Returns the number of vtkArray instances in the collection
- `vtkArray = obj.GetArray (vtkIdType index)` - Returns the n-th vtkArray in the collection
- `vtkArray = obj.GetArrayByName (string name)` - Returns the array having called name from the collection
- `int = obj.GetDataObjectType ()`
- `obj.ShallowCopy (vtkDataObject other)`
- `obj.DeepCopy (vtkDataObject other)`

31.14 vtkArrayDataAlgorithm

31.14.1 Usage

vtkArrayDataAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be vtkArrayData. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation. For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

To create an instance of class vtkArrayDataAlgorithm, simply invoke its constructor as follows

```
obj = vtkArrayDataAlgorithm
```

31.14.2 Methods

The class vtkArrayDataAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkArrayDataAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkArrayDataAlgorithm = obj.NewInstance ()`
- `vtkArrayDataAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkArrayData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkArrayData = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.15 vtkAttributesErrorMetric

31.15.1 Usage

It is a concrete error metric, based on an attribute criterium: the variation of the active attribute/component value from a linear ramp

To create an instance of class vtkAttributesErrorMetric, simply invoke its constructor as follows

```
obj = vtkAttributesErrorMetric
```

31.15.2 Methods

The class vtkAttributesErrorMetric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkAttributesErrorMetric class.

- `string = obj.GetClassName ()` - Standard VTK type and error macros.
- `int = obj.IsA (string name)` - Standard VTK type and error macros.
- `vtkAttributesErrorMetric = obj.NewInstance ()` - Standard VTK type and error macros.
- `vtkAttributesErrorMetric = obj.SafeDownCast (vtkObject o)` - Standard VTK type and error macros.
- `double = obj.GetAbsoluteAttributeTolerance ()` - Absolute tolerance of the active scalar (attribute+component). Subdivision is required if the square distance between the real attribute at the mid point on the edge and the interpolated attribute is greater than AbsoluteAttributeTolerance. This is the attribute accuracy. 0.01 will give better result than 0.1.
- `obj.SetAbsoluteAttributeTolerance (double value)` - Set the absolute attribute accuracy to 'value'. See GetAbsoluteAttributeTolerance() for details. It is particularly useful when some concrete implementation of vtkGenericAttribute does not support GetRange() request, called internally in SetAttributeTolerance(). It may happen when the implementation support higher order attributes but cannot compute the range.
- `double = obj.GetAttributeTolerance ()` - Relative tolerance of the active scalar (attribute+component). Subdivision is required if the square distance between the real attribute at the mid point on the edge and the interpolated attribute is greater than AttributeTolerance. This is the attribute accuracy. 0.01 will give better result than 0.1.
- `obj.SetAttributeTolerance (double value)` - Set the relative attribute accuracy to 'value'. See GetAttributeTolerance() for details.
- `int = obj.RequiresEdgeSubdivision (double leftPoint, double midPoint, double rightPoint, double alp` - Does the edge need to be subdivided according to the distance between the value of the active attribute/component at the midpoint and the mean value between the endpoints? The edge is defined by its 'leftPoint' and its 'rightPoint'. 'leftPoint', 'midPoint' and 'rightPoint' have to be initialized before calling RequiresEdgeSubdivision(). Their format is global coordinates, parametric coordinates and point centered attributes: xyx rst abc de... 'alpha' is the normalized abscissa of the midpoint along the edge. (close to 0 means close to the left point, close to 1 means close to the right point)

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `double = obj.GetError (double leftPoint, double midPoint, double rightPoint, double alpha)` - Return the error at the mid-point. The type of error depends on the state of the concrete error metric. For instance, it can return an absolute or relative error metric. See RequiresEdgeSubdivision() for a description of the arguments.

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6

31.16 vtkBiQuadraticQuad

31.16.1 Usage

vtkQuadraticQuad is a concrete implementation of vtkNonLinearCell to represent a two-dimensional, 9-node isoparametric parabolic quadrilateral element with a Centerpoint. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node for each of the four

edges of the cell and a center node at the surface. The ordering of the eight points defining the cell are point ids (0-3,4-8) where ids 0-3 define the four corner vertices of the quad; ids 4-7 define the midedge nodes (0,1), (1,2), (2,3), (3,0) and 8 define the face center node.

To create an instance of class vtkBiQuadraticQuad, simply invoke its constructor as follows

```
obj = vtkBiQuadraticQuad
```

31.16.2 Methods

The class vtkBiQuadraticQuad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBiQuadraticQuad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBiQuadraticQuad = obj.NewInstance ()`
- `vtkBiQuadraticQuad = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )`
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this biquadratic quad using scalar value provided. Like contouring, except that it cuts the twi quads to produce linear triangles.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the pyramid in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[9])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[18])`

31.17 vtkBiQuadraticQuadraticHexahedron

31.17.1 Usage

vtkBiQuadraticQuadraticHexahedron is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 24-node isoparametric biquadratic hexahedron. The interpolation is the standard finite element, biquadratic-quadratic isoparametric shape function. The cell includes mid-edge and center-face nodes. The ordering of the 24 points defining the cell is point ids (0-7,8-19, 20-23) where point ids 0-7 are the eight corner vertices of the cube; followed by twelve midedge nodes (8-19), nodes 20-23 are the center-face nodes. Note that these midedge nodes correspond lie on the edges defined by (0,1), (1,2), (2,3), (3,0), (4,5), (5,6), (6,7), (7,4), (0,4), (1,5), (2,6), (3,7). The center face nodes lieing in quad 22-(0,1,5,4), 21-(1,2,6,5), 23-(2,3,7,6) and 22-(3,0,4,7)

 0-- 8--1
```

To create an instance of class vtkBiQuadraticQuadraticHexahedron, simply invoke its constructor as follows

```
obj = vtkBiQuadraticQuadraticHexahedron
```

31.17.2 Methods

The class vtkBiQuadraticQuadraticHexahedron has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBiQuadraticQuadraticHexahedron class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBiQuadraticQuadraticHexahedron = obj.NewInstance ()`
- `vtkBiQuadraticQuadraticHexahedron = obj.SafeDownCast (vtkObject o)`

- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this biquadratic hexahedron using scalar value provided. Like contouring, except that it cuts the hex to produce linear tetrahedron.
- `obj.InterpolateFunctions (double pcoords[3], double weights[24])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[72])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.18 vtkBiQuadraticQuadraticWedge

31.18.1 Usage

vtkBiQuadraticQuadraticWedge is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 18-node isoparametric biquadratic wedge. The interpolation is the standard finite element, biquadratic-quadratic isoparametric shape function plus the linear functions. The cell includes a mid-edge node. The ordering of the 18 points defining the cell is point ids (0-5,6-15, 16-18) where point ids 0-5 are the six corner vertices of the wedge; followed by nine midedge nodes (6-15) and 3 center-face nodes. Note that these midedge nodes correspond lie on the edges defined by (0,1), (1,2), (2,0), (3,4), (4,5), (5,3), (0,3), (1,4), (2,5), and the center-face nodes are lieing in quads 16-(0,1,4,3), 17-(1,2,5,4) and (2,0,3,5).

To create an instance of class vtkBiQuadraticQuadraticWedge, simply invoke its constructor as follows

```
obj = vtkBiQuadraticQuadraticWedge
```

31.18.2 Methods

The class vtkBiQuadraticQuadraticWedge has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBiQuadraticQuadraticWedge class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkBiQuadraticQuadraticWedge = obj.NewInstance ()`
- `vtkBiQuadraticQuadraticWedge = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic Wedge using scalar value provided. Like contouring, except that it cuts the hex to produce linear tetrahedron.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic wedge in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[15])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[45])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.19 vtkBiQuadraticTriangle

31.19.1 Usage

vtkBiQuadraticTriangle is a concrete implementation of vtkNonLinearCell to represent a two-dimensional, 7-node, isoparametric parabolic triangle. The interpolation is the standard finite element, bi-quadratic isoparametric shape function. The cell includes three mid-edge nodes besides the three triangle vertices and a center node. The ordering of the three points defining the cell is point ids (0-2,3-6) where id #3 is the midedge node between points (0,1); id #4 is the midedge node between points (1,2); and id #5 is the midedge node between points (2,0). id #6 is the center node of the cell.

To create an instance of class vtkBiQuadraticTriangle, simply invoke its constructor as follows

```
obj = vtkBiQuadraticTriangle
```

31.19.2 Methods

The class vtkBiQuadraticTriangle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBiQuadraticTriangle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBiQuadraticTriangle = obj.NewInstance ()`
- `vtkBiQuadraticTriangle = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )`
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic triangle using scalar value provided. Like contouring, except that it cuts the triangle to produce linear triangles.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic triangle in parametric coordinates.
- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned.
- `obj.InterpolateFunctions (double pcoords[3], double weights[7])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[14])`

31.20 vtkBSPCuts

31.20.1 Usage

This class converts between the vtkKdTree representation of a tree of vtkKdNodes (used by vtkDistributed-DataFilter) and a compact array representation that might be provided by a graph partitioning library like Zoltan. Such a representation could be used in message passing.

To create an instance of class vtkBSPCuts, simply invoke its constructor as follows

```
obj = vtkBSPCuts
```

31.20.2 Methods

The class vtkBSPCuts has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBSPCuts class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBSPCuts = obj.NewInstance ()`
- `vtkBSPCuts = obj.SafeDownCast (vtkObject o)`
- `obj.CreateCuts (double bounds, int ncuts, int dim, double coord, int lower, int upper, double lower`
- `obj.CreateCuts (vtkKdNode kd)`
- `vtkKdNode = obj.GetKdNodeTree ()`
- `int = obj.GetNumberOfCuts ()`
- `int = obj.GetArrays (int len, int dim, double coord, int lower, int upper, double lowerDataCoord, d`
- `int = obj.Equals (vtkBSPCuts other, double tolerance)` - Compare these cuts with those of the other tree. Returns true if the two trees are the same.
- `obj.PrintTree ()`
- `obj.PrintArrays ()`

31.21 vtkBSPIntersections

31.21.1 Usage

Given an axis aligned binary spatial partitioning described by a vtkBSPCuts object, perform intersection queries on various geometric entities with regions of the spatial partitioning.

To create an instance of class vtkBSPIntersections, simply invoke its constructor as follows

```
obj = vtkBSPIntersections
```

31.21.2 Methods

The class vtkBSPIntersections has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkBSPIntersections class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkBSPIntersections = obj.NewInstance ()`
- `vtkBSPIntersections = obj.SafeDownCast (vtkObject o)`
- `obj.SetCuts (vtkBSPCuts cuts)`
- `vtkBSPCuts = obj.GetCuts ()`
- `int = obj.GetBounds (double bounds)`
- `int = obj.GetNumberOfRegions ()`
- `int = obj.GetRegionBounds (int regionID, double bounds[6])`
- `int = obj.GetRegionDataBounds (int regionID, double bounds[6])`
- `int = obj.IntersectsBox (int regionId, double x)` - Determine whether a region of the spatial decomposition intersects an axis aligned box.
- `int = obj.IntersectsBox (int regionId, double xmin, double xmax, double ymin, double ymax, double z` - Determine whether a region of the spatial decomposition intersects an axis aligned box.
- `int = obj.IntersectsBox (int ids, int len, double x)` - Compute a list of the Ids of all regions that intersect the specified axis aligned box. Returns: the number of ids in the list.
- `int = obj.IntersectsBox (int ids, int len, double x0, double x1, double y0, double y1, double z0, d` - Compute a list of the Ids of all regions that intersect the specified axis aligned box. Returns: the number of ids in the list.
- `int = obj.IntersectsSphere2 (int regionId, double x, double y, double z, double rSquared)` - Determine whether a region of the spatial decomposition intersects a sphere, given the center of the sphere and the square of it's radius.
- `int = obj.IntersectsSphere2 (int ids, int len, double x, double y, double z, double rSquared)` - Compute a list of the Ids of all regions that intersect the specified sphere. The sphere is given by it's center and the square of it's radius. Returns: the number of ids in the list.
- `int = obj.IntersectsCell (int regionId, vtkCell cell, int cellRegion)` - Determine whether a region of the spatial decomposition intersects the given cell. If you already know the region that the cell centroid lies in, provide that as the last argument to make the computation quicker.
- `int = obj.IntersectsCell (int ids, int len, vtkCell cell, int cellRegion)` - Compute a list of the Ids of all regions that intersect the given cell. If you alrady know the region that the cell centroid lies in, provide that as the last argument to make the computation quicker. Returns the number of regions the cell intersects.
- `int = obj.GetComputeIntersectionsUsingDataBounds ()`
- `obj.SetComputeIntersectionsUsingDataBounds (int c)`
- `obj.ComputeIntersectionsUsingDataBoundsOn ()`
- `obj.ComputeIntersectionsUsingDataBoundsOff ()`

31.22 vtkCachedStreamingDemandDrivenPipeline

31.22.1 Usage

vtkCachedStreamingDemandDrivenPipeline

To create an instance of class vtkCachedStreamingDemandDrivenPipeline, simply invoke its constructor as follows

```
obj = vtkCachedStreamingDemandDrivenPipeline
```

31.22.2 Methods

The class vtkCachedStreamingDemandDrivenPipeline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCachedStreamingDemandDrivenPipeline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCachedStreamingDemandDrivenPipeline = obj.NewInstance ()`
- `vtkCachedStreamingDemandDrivenPipeline = obj.SafeDownCast (vtkObject o)`
- `int = obj.Update ()` - Bring the algorithm's outputs up-to-date.
- `int = obj.Update (int port)` - Bring the algorithm's outputs up-to-date.
- `obj.SetCacheSize (int size)` - This is the maximum number of images that can be retained in memory. it defaults to 10.
- `int = obj.GetCacheSize ()` - This is the maximum number of images that can be retained in memory. it defaults to 10.

31.23 vtkCardinalSpline

31.23.1 Usage

vtkCardinalSpline is a concrete implementation of vtkSpline using a Cardinal basis.

To create an instance of class vtkCardinalSpline, simply invoke its constructor as follows

```
obj = vtkCardinalSpline
```

31.23.2 Methods

The class vtkCardinalSpline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCardinalSpline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCardinalSpline = obj.NewInstance ()`
- `vtkCardinalSpline = obj.SafeDownCast (vtkObject o)`
- `obj.Compute ()`
- `double = obj.Evaluate (double t)` - Evaluate a 1D cardinal spline.
- `obj.DeepCopy (vtkSpline s)` - Deep copy of cardinal spline data.

31.24 vtkCastToConcrete

31.24.1 Usage

vtkCastToConcrete is a filter that works around type-checking limitations in the filter classes. Some filters generate abstract types on output, and cannot be connected to the input of filters requiring a concrete input type. For example, vtkElevationFilter generates vtkDataSet for output, and cannot be connected to vtkDecimate, because vtkDecimate requires vtkPolyData as input. This is true even though (in this example) the input to vtkElevationFilter is of type vtkPolyData, and you know the output of vtkElevationFilter is the same type as its input.

vtkCastToConcrete performs run-time checking to insure that output type is of the right type. An error message will result if you try to cast an input type improperly. Otherwise, the filter performs the appropriate cast and returns the data.

To create an instance of class vtkCastToConcrete, simply invoke its constructor as follows

```
obj = vtkCastToConcrete
```

31.24.2 Methods

The class vtkCastToConcrete has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCastToConcrete class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCastToConcrete = obj.NewInstance ()`
- `vtkCastToConcrete = obj.SafeDownCast (vtkObject o)`

31.25 vtkCell

31.25.1 Usage

vtkCell is an abstract class that specifies the interfaces for data cells. Data cells are simple topological elements like points, lines, polygons, and tetrahedra of which visualization datasets are composed. In some cases visualization datasets may explicitly represent cells (e.g., vtkPolyData, vtkUnstructuredGrid), and in some cases, the datasets are implicitly composed of cells (e.g., vtkStructuredPoints).

To create an instance of class vtkCell, simply invoke its constructor as follows

```
obj = vtkCell
```

31.25.2 Methods

The class vtkCell has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCell class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCell = obj.NewInstance ()`
- `vtkCell = obj.SafeDownCast (vtkObject o)`

- `obj.ShallowCopy (vtkCell c)` - Copy this cell by reference counting the internal data structures. This is safe if you want a "read-only" copy. If you modify the cell you might wish to use DeepCopy().
- `obj.DeepCopy (vtkCell c)` - Copy this cell by completely copying internal data structures. This is slower but safer than ShallowCopy().
- `int = obj.GetCellType ()` - Return the type of cell.
- `int = obj.GetCellDimension ()` - Return the topological dimensional of the cell (0,1,2, or 3).
- `int = obj.IsLinear ()` - Some cells require initialization prior to access. For example, they may have to triangulate themselves or set up internal data structures.
- `int = obj.RequiresInitialization ()` - Some cells require initialization prior to access. For example, they may have to triangulate themselves or set up internal data structures.
- `obj.Initialize ()` - Explicit cells require additional representational information beyond the usual cell type and connectivity list information. Most cells in VTK are implicit cells.
- `int = obj.IsExplicitCell ()` - Get the point coordinates for the cell.
- `vtkPoints = obj.GetPoints ()` - Return the number of points in the cell.
- `vtkIdType = obj.GetNumberOfPoints ()` - Return the number of edges in the cell.
- `int = obj.GetNumberOfEdges ()` - Return the number of edges in the cell.
- `int = obj.GetNumberOfFaces ()` - Return the number of faces in the cell.
- `vtkIdList = obj.GetPointIds ()` - For cell point i, return the actual point id.
- `vtkIdType = obj.GetPointId (int ptId)` - Return the edge cell from the edgeId of the cell.
- `vtkCell = obj.GetEdge (int edgeId)` - Return the edge cell from the edgeId of the cell.
- `vtkCell = obj.GetFace (int faceId)` - Return the face cell from the faceId of the cell.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - Given parametric coordinates of a point, return the closest cell boundary, and whether the point is inside or outside of the cell. The cell boundary is defined by a list of points (pts) that specify a face (3D cell), edge (2D cell), or vertex (1D cell). If the return value of the method is != 0, then the point is inside the cell.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - Generate contouring primitives. The scalar list cellScalars are scalar values at each cell point. The point locator is essentially a points list that merges points as they are inserted (i.e., prevents duplicates). Contouring primitives can be vertices, lines, or polygons. It is possible to interpolate point data along the edge by providing input and output point data - if outPd is NULL, then no interpolation is performed. Also, if the output cell data is non-NULL, the cell data from the contoured cell is passed to the generated contouring primitives. (Note: the CopyAllocate() method must be invoked on both the output cell and point data. The cellId refers to the cell from which the cell data is copied.)
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Cut (or clip) the cell based on the input cellScalars and the specified value. The output of the clip operation will be one or more cells of the same topological dimension as the original cell. The flag insideOut controls what part of the cell is considered inside - normally cell points whose scalar value is greater than "value" are considered inside. If insideOut is on, this is reversed. Also, if the output cell data is non-NULL, the cell data from the clipped cell is passed to the generated contouring primitives. (Note: the CopyAllocate() method must be invoked on both the output cell and point data. The cellId refers to the cell from which the cell data is copied.)

- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - Generate simplices of proper dimension. If cell is 3D, tetrahedron are generated; if 2D triangles; if 1D lines; if 0D points. The form of the output is a sequence of points, each n+1 points (where n is topological cell dimension) defining a simplex. The index is a parameter that controls which triangulation to use (if more than one is possible). If numerical degeneracy encountered, 0 is returned, otherwise 1 is returned. This method does not insert new points: all the points that define the simplices are the points that define the cell.

- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - Compute derivatives given cell subId and parametric coordinates. The values array is a series of data value(s) at the cell points. There is a one-to-one correspondence between cell point and data value(s). Dim is the number of data values per cell point. Derivs are derivatives in the x-y-z coordinate directions for each data value. Thus, if computing derivatives for a scalar function in a hexahedron, dim=1, 8 values are supplied, and 3 deriv values are returned (i.e., derivatives in x-y-z directions). On the other hand, if computing derivatives of velocity (vx,vy,vz) dim=3, 24 values are supplied ((vx,vy,vz)1, (vx,vy,vz)2, ...()8), and 9 deriv values are returned ((d(vx)/dx),(d(vx)/dy),(d(vx)/dz), (d(vy)/dx),(d(vy)/dy), (d(vy)/dz), (d(vz)/dx),(d(vz)/dy),(d(vz)/dz)).

- `obj.GetBounds (double bounds[6])` - Compute cell bounding box (xmin,xmax,ymin,ymax,zmin,zmax). Copy result into user provided array.

- `double = obj.GetBounds ()` - Compute cell bounding box (xmin,xmax,ymin,ymax,zmin,zmax). Return pointer to array of six double values.

- `double = obj.GetLength2 ()` - Compute Length squared of cell (i.e., bounding box diagonal squared).

- `int = obj.GetParametricCenter (double pcoords[3])` - Return center of the cell in parametric coordinates. Note that the parametric center is not always located at (0.5,0.5,0.5). The return value is the subId that the center is in (if a composite cell). If you want the center in x-y-z space, invoke the EvaluateLocation() method.

- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned. This is used during picking to get the correct cell picked. (The tolerance will occasionally allow cells to be picked who are not really intersected "inside" the cell.)

- `int = obj.IsPrimaryCell ()` - Return a contiguous array of parametric coordinates of the points defining this cell. In other words, (px,py,pz, px,py,pz, etc..) The coordinates are ordered consistent with the definition of the point ordering for the cell. This method returns a non-NULL pointer when the cell is a primary type (i.e., IsPrimaryCell() is true). Note that 3D parametric coordinates are returned no matter what the topological dimension of the cell.

- `obj.InterpolateFunctions (double pcoords[3], double weights[3])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives) No-ops at this level. Typically overridden in subclasses.

- `obj.InterpolateDerivs (double pcoords[3], double derivs[3])`

31.26 vtkCell3D

31.26.1 Usage

vtkCell3D is an abstract class that extends the interfaces for 3D data cells, and implements methods needed to satisfy the vtkCell API. The 3D cells include hexehedra, tetrahedra, wedge, pyramid, and voxel.

To create an instance of class vtkCell3D, simply invoke its constructor as follows

```
obj = vtkCell3D
```

31.26.2 Methods

The class vtkCell3D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCell3D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCell3D = obj.NewInstance ()`
- `vtkCell3D = obj.SafeDownCast (vtkObject o)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Cut (or clip) the cell based on the input cellScalars and the specified value. The output of the clip operation will be one or more cells of the same topological dimension as the original cell. The flag insideOut controls what part of the cell is considered inside - normally cell points whose scalar value is greater than "value" are considered inside. If insideOut is on, this is reversed. Also, if the output cell data is non-NULL, the cell data from the clipped cell is passed to the generated contouring primitives. (Note: the CopyAllocate() method must be invoked on both the output cell and point data. The cellId refers to the cell from which the cell data is copied.) (Satisfies vtkCell API.)
- `int = obj.GetCellDimension ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate tetrahedra during clipping.
- `obj.SetMergeTolerance (double )` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate tetrahedra during clipping.
- `double = obj.GetMergeToleranceMinValue ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate tetrahedra during clipping.
- `double = obj.GetMergeToleranceMaxValue ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate tetrahedra during clipping.
- `double = obj.GetMergeTolerance ()` - Set the tolerance for merging clip intersection points that are near the vertices of cells. This tolerance is used to prevent the generation of degenerate tetrahedra during clipping.

31.27 vtkCellArray

31.27.1 Usage

vtkCellArray is a supporting object that explicitly represents cell connectivity. The cell array structure is a raw integer list of the form: (n,id1,id2,...,idn, n,id1,id2,...,idn, ...) where n is the number of points in the cell, and id is a zero-offset index into an associated point list.

Advantages of this data structure are its compactness, simplicity, and easy interface to external data. However, it is totally inadequate for random access. This functionality (when necessary) is accomplished by using the vtkCellTypes and vtkCellLinks objects to extend the definition of the data structure.

To create an instance of class vtkCellArray, simply invoke its constructor as follows

```
obj = vtkCellArray
```

31.27.2 Methods

The class vtkCellArray has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellArray class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellArray = obj.NewInstance ()`
- `vtkCellArray = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (vtkIdType sz, int ext)` - Free any memory and reset to an empty state.
- `obj.Initialize ()` - Free any memory and reset to an empty state.
- `vtkIdType = obj.GetNumberOfCells ()` - Get the number of cells in the array.
- `obj.SetNumberOfCells (vtkIdType )` - Set the number of cells in the array. DO NOT do any kind of allocation, advanced use only.
- `vtkIdType = obj.EstimateSize (vtkIdType numCells, int maxPtsPerCell)` - A cell traversal methods that is more efficient than vtkDataSet traversal methods. InitTraversal() initializes the traversal of the list of cells.
- `obj.InitTraversal ()` - A cell traversal methods that is more efficient than vtkDataSet traversal methods. InitTraversal() initializes the traversal of the list of cells.
- `vtkIdType = obj.GetSize ()` - Get the total number of entries (i.e., data values) in the connectivity array. This may be much less than the allocated size (i.e., return value from GetSize().)
- `vtkIdType = obj.GetNumberOfConnectivityEntries ()` - Internal method used to retrieve a cell given an offset into the internal array.
- `vtkIdType = obj.InsertNextCell (vtkCell cell)` - Insert a cell object. Return the cell id of the cell.
- `vtkIdType = obj.InsertNextCell (vtkIdList pts)` - Create a cell by specifying a list of point ids. Return the cell id of the cell.
- `vtkIdType = obj.InsertNextCell (int npts)` - Create cells by specifying count, and then adding points one at a time using method InsertCellPoint(). If you don't know the count initially, use the method UpdateCellCount() to complete the cell. Return the cell id of the cell.
- `obj.InsertCellPoint (vtkIdType id)` - Used in conjunction with InsertNextCell(int npts) to add another point to the list of cells.
- `obj.UpdateCellCount (int npts)` - Used in conjunction with InsertNextCell(int npts) and InsertCellPoint() to update the number of points defining the cell.
- `vtkIdType = obj.GetInsertLocation (int npts)` - Computes the current insertion location within the internal array. Used in conjunction with GetCell(int loc,...).
- `vtkIdType = obj.GetTraversalLocation ()` - Get/Set the current traversal location.
- `obj.SetTraversalLocation (vtkIdType loc)` - Computes the current traversal location within the internal array. Used in conjunction with GetCell(int loc,...).

- `vtkIdType = obj.GetTraversalLocation (vtkIdType npts)` - Special method inverts ordering of current cell. Must be called carefully or the cell topology may be corrupted.
- `obj.ReverseCell (vtkIdType loc)` - Special method inverts ordering of current cell. Must be called carefully or the cell topology may be corrupted.
- `int = obj.GetMaxCellSize ()` - Returns the size of the largest cell. The size is the number of points defining the cell.
- `vtkIdType = obj.GetPointer ()` - Get pointer to data array for purpose of direct writes of data. Size is the total storage consumed by the cell array. ncells is the number of cells represented in the array.
- `vtkIdType = obj.WritePointer (vtkIdType ncells, vtkIdType size)` - Get pointer to data array for purpose of direct writes of data. Size is the total storage consumed by the cell array. ncells is the number of cells represented in the array.
- `obj.SetCells (vtkIdType ncells, vtkIdTypeArray cells)` - Define multiple cells by providing a connectivity list. The list is in the form (npts,p0,p1,...p(npts-1), repeated for each cell). Be careful using this method because it discards the old cells, and anything referring these cells becomes invalid (for example, if BuildCells() has been called see vtkPolyData). The traversal location is reset to the beginning of the list; the insertion location is set to the end of the list.
- `obj.DeepCopy (vtkCellArray ca)` - Perform a deep copy (no reference counting) of the given cell array.
- `vtkIdTypeArray = obj.GetData ()` - Reuse list. Reset to initial condition.
- `obj.Reset ()` - Reuse list. Reset to initial condition.
- `obj.Squeeze ()` - Return the memory in kilobytes consumed by this cell array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this cell array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.

31.28 vtkCellData

31.28.1 Usage

vtkCellData is a class that is used to represent and manipulate cell attribute data (e.g., scalars, vectors, normals, texture coordinates, etc.) Special methods are provided to work with filter objects, such as passing data through filter, copying data from one cell to another, and interpolating data given cell interpolation weights.

To create an instance of class vtkCellData, simply invoke its constructor as follows

```
obj = vtkCellData
```

31.28.2 Methods

The class vtkCellData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellData = obj.NewInstance ()`
- `vtkCellData = obj.SafeDownCast (vtkObject o)`

31.29 vtkCellLinks

31.29.1 Usage

vtkCellLinks is a supplemental object to vtkCellArray and vtkCellTypes, enabling access from points to the cells using the points. vtkCellLinks is a list of Links, each link represents a dynamic list of cell id's using the point. The information provided by this object can be used to determine neighbors and construct other local topological information.

To create an instance of class vtkCellLinks, simply invoke its constructor as follows

```
obj = vtkCellLinks
```

31.29.2 Methods

The class vtkCellLinks has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellLinks class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellLinks = obj.NewInstance ()`
- `vtkCellLinks = obj.SafeDownCast (vtkObject o)`
- `obj.Allocate (vtkIdType numLinks, vtkIdType ext)` - Allocate the specified number of links (i.e., number of points) that will be built.
- `short = obj.GetNcells (vtkIdType ptId)` - Get the number of cells using the point specified by ptId.
- `obj.BuildLinks (vtkDataSet data)` - Build the link list array.
- `obj.BuildLinks (vtkDataSet data, vtkCellArray Connectivity)` - Build the link list array.
- `vtkIdType = obj.GetCells (vtkIdType ptId)` - Return a list of cell ids using the point.
- `vtkIdType = obj.InsertNextPoint (int numLinks)` - Insert a new point into the cell-links data structure. The size parameter is the initial size of the list.
- `obj.InsertNextCellReference (vtkIdType ptId, vtkIdType cellId)` - Insert a cell id into the list of cells (at the end) using the cell id provided. (Make sure to extend the link list (if necessary) using the method ResizeCellList().)
- `obj.DeletePoint (vtkIdType ptId)` - Delete point (and storage) by destroying links to using cells.
- `obj.RemoveCellReference (vtkIdType cellId, vtkIdType ptId)` - Delete the reference to the cell (cellId) from the point (ptId). This removes the reference to the cellId from the cell list, but does not resize the list (recover memory with ResizeCellList(), if necessary).

- `obj.AddCellReference (vtkIdType cellId, vtkIdType ptId)` - Add the reference to the cell (cellId) from the point (ptId). This adds a reference to the cellId from the cell list, but does not resize the list (extend memory with ResizeCellList(), if necessary).
- `obj.ResizeCellList (vtkIdType ptId, int size)` - Change the length of a point's link list (i.e., list of cells using a point) by the size specified.
- `obj.Squeeze ()` - Reclaim any unused memory.
- `obj.Reset ()` - Reset to a state of no entries without freeing the memory.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this cell links array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `obj.DeepCopy (vtkCellLinks src)` - Standard DeepCopy method. Since this object contains no reference to other objects, there is no ShallowCopy.

31.30 vtkCellLocator

31.30.1 Usage

vtkCellLocator is a spatial search object to quickly locate cells in 3D. vtkCellLocator uses a uniform-level octree subdivision, where each octant (an octant is also referred to as a bucket) carries an indication of whether it is empty or not, and each leaf octant carries a list of the cells inside of it. (An octant is not empty if it has one or more cells inside of it.) Typical operations are intersection with a line to return candidate cells, or intersection with another vtkCellLocator to return candidate cells.

To create an instance of class vtkCellLocator, simply invoke its constructor as follows

```
obj = vtkCellLocator
```

31.30.2 Methods

The class vtkCellLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellLocator = obj.NewInstance ()`
- `vtkCellLocator = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfCellsPerBucket (int N)` - Specify the average number of cells in each octant.
- `int = obj.GetNumberOfCellsPerBucket ()` - reimplemented from vtkAbstractCellLocator to support bad compilers
- `int = obj.IntersectWithLine (double a0[3], double a1[3], vtkPoints points, vtkIdList cellIds)` - Return intersection point (if any) AND the cell which was intersected by the finite line. The cell is returned as a cell id and as a generic cell. For other IntersectWithLine signatures, see vtkAbstractCellLocator
- `vtkIdList = obj.GetCells (int bucket)` - Get the cells in a particular bucket.

- `int = obj.GetNumberOfBuckets (void )` - Return number of buckets available. Insure that the locator has been built before attempting to access buckets (octants).

- `vtkIdType = obj.FindCell (double x[3])` - Find the cell containing a given point. returns -1 if no cell found the cell parameters are copied into the supplied variables, a cell must be provided to store the information.

- `vtkIdType = obj.FindCell (double x[3], double tol2, vtkGenericCell GenCell, double pcoords[3], doub` - Find the cell containing a given point. returns -1 if no cell found the cell parameters are copied into the supplied variables, a cell must be provided to store the information.

- `obj.FindCellsWithinBounds (double bbox, vtkIdList cells)` - Return a list of unique cell ids inside of a given bounding box. The user must provide the vtkIdList to populate. This method returns data only after the locator has been built.

- `obj.FindCellsAlongLine (double p1[3], double p2[3], double tolerance, vtkIdList cells)` - Given a finite line defined by the two points (p1,p2), return the list of unique cell ids in the buckets containing the line. It is possible that an empty cell list is returned. The user must provide the vtkIdList to populate. This method returns data only after the locator has been built.

- `obj.FreeSearchStructure ()` - Satisfy vtkLocator abstract interface.

- `obj.BuildLocator ()` - Satisfy vtkLocator abstract interface.

- `obj.BuildLocatorIfNeeded ()` - Satisfy vtkLocator abstract interface.

- `obj.ForceBuildLocator ()` - Satisfy vtkLocator abstract interface.

- `obj.BuildLocatorInternal ()` - Satisfy vtkLocator abstract interface.

- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - Satisfy vtkLocator abstract interface.

31.31 vtkCellLocatorInterpolatedVelocityField

31.31.1 Usage

vtkCellLocatorInterpolatedVelocityField acts as a continuous velocity field via cell interpolation on a vtkDataSet, NumberOfIndependentVariables = 4 (x,y,z,t) and NumberOfFunctions = 3 (u,v,w). As a concrete sub-class of vtkAbstractInterpolatedVelocityField, it adopts vtkAbstractCellLocator's sub-classes, e.g., vtkCellLocator and vtkModifiedBSPTree, without the use of vtkPointLocator (employed by vtkDataSet/vtkPointSet::FindCell() in vtkInterpolatedVelocityField). vtkCellLocatorInterpolatedVelocityField adopts one level of cell caching. Specifically, if the next point is still within the previous cell, cell location is then simply skipped and vtkCell::EvaluatePosition() is called to obtain the new parametric coordinates and weights that are used to interpolate the velocity function values across the vertices of this cell. Otherwise a global cell (the target containing the next point) location is instead directly invoked, without exploiting the clue that vtkInterpolatedVelocityField makes use of from the previous cell (an immediate neighbor). Although ignoring the neighbor cell may incur a relatively high computational cost, vtkCellLocatorInterpolatedVelocityField is more robust in locating the target cell than its sibling class vtkInterpolatedVelocityField.

To create an instance of class vtkCellLocatorInterpolatedVelocityField, simply invoke its constructor as follows

```
obj = vtkCellLocatorInterpolatedVelocityField
```

31.31.2 Methods

The class vtkCellLocatorInterpolatedVelocityField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellLocatorInterpolatedVelocityField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCellLocatorInterpolatedVelocityField = obj.NewInstance ()`
- `vtkCellLocatorInterpolatedVelocityField = obj.SafeDownCast (vtkObject o)`
- `vtkAbstractCellLocator = obj.GetLastCellLocator ()` - Get the cell locator attached to the most recently visited dataset.
- `vtkAbstractCellLocator = obj.GetCellLocatorPrototype ()` - Get the prototype of the cell locator that is used for interpolating the velocity field during integration.
- `obj.SetCellLocatorPrototype (vtkAbstractCellLocator prototype)` - Set a prototype of the cell locator that is used for interpolating the velocity field during integration.
- `obj.CopyParameters (vtkAbstractInterpolatedVelocityField from)` - Import parameters. Subclasses can add more after chaining.
- `obj.AddDataSet (vtkDataSet dataset)` - Add a dataset coupled with a cell locator (of type vtkAbstractCellLocator) for vector function evaluation. Note the use of a vtkAbstractCellLocator enables robust cell location. If more than one dataset is added, the evaluation point is searched in all until a match is found. THIS FUNCTION DOES NOT CHANGE THE REFERENCE COUNT OF dataset FOR THREAD SAFETY REASONS.
- `int = obj.FunctionValues (double x, double f)` - Evaluate the velocity field f at point (x, y, z).
- `obj.SetLastCellId (vtkIdType c, int dataindex)` - Set the cell id cached by the last evaluation within a specified dataset.
- `obj.SetLastCellId (vtkIdType c)`

31.32 vtkCellTypes

31.32.1 Usage

This class is a supplemental object to vtkCellArray to allow random access into cells as well as representing cell type information. The "location" field is the location in the vtkCellArray list in terms of an integer offset. An integer offset was used instead of a pointer for easy storage and inter-process communication. The type information is defined in the file vtkCellType.h.

To create an instance of class vtkCellTypes, simply invoke its constructor as follows

```
obj = vtkCellTypes
```

31.32.2 Methods

The class vtkCellTypes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCellTypes class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkCellTypes = obj.NewInstance ()`
- `vtkCellTypes = obj.SafeDownCast (vtkObject o)`
- `int = obj.Allocate (int sz, int ext)` - Allocate memory for this array. Delete old storage only if necessary.
- `obj.InsertCell (int id, char type, int loc)` - Add a cell at specified id.
- `int = obj.InsertNextCell (char type, int loc)` - Add a cell to the object in the next available slot.
- `obj.SetCellTypes (int ncells, vtkUnsignedCharArray cellTypes, vtkIntArray cellLocations)` - Specify a group of cell types.
- `int = obj.GetCellLocation (int cellId)` - Return the location of the cell in the associated vtkCellArray.
- `obj.DeleteCell (vtkIdType cellId)` - Delete cell by setting to NULL cell type.
- `int = obj.GetNumberOfTypes ()` - Return the number of types in the list.
- `int = obj.IsType (char type)` - Return 1 if type specified is contained in list; 0 otherwise.
- `int = obj.InsertNextType (char type)` - Add the type specified to the end of the list. Range checking is performed.
- `char = obj.GetCellType (int cellId)` - Return the type of cell.
- `obj.Squeeze ()` - Reclaim any extra memory.
- `obj.Reset ()` - Initialize object without releasing memory.
- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this cell type array. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object. The information returned is valid only after the pipeline has been updated.
- `obj.DeepCopy (vtkCellTypes src)` - Standard DeepCopy method. Since this object contains no reference to other objects, there is no ShallowCopy.

31.33 vtkColorTransferFunction

31.33.1 Usage

vtkColorTransferFunction is a color mapping in RGB or HSV space that uses piecewise hermite functions to allow interpolation that can be piecewise constant, piecewise linear, or somewhere in-between (a modified piecewise hermite function that squishes the function according to a sharpness parameter). The function also allows for the specification of the midpoint (the place where the function reaches the average of the two bounding nodes) as a normalize distance between nodes. See the description of class vtkPiecewiseFunction for an explanation of midpoint and sharpness.

To create an instance of class vtkColorTransferFunction, simply invoke its constructor as follows

```
obj = vtkColorTransferFunction
```

31.33.2 Methods

The class vtkColorTransferFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkColorTransferFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkColorTransferFunction = obj.NewInstance ()`
- `vtkColorTransferFunction = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkColorTransferFunction f)`
- `obj.ShallowCopy (vtkColorTransferFunction f)`
- `int = obj.GetSize ()` - How many points are there defining this function?
- `int = obj.AddRGBPoint (double x, double r, double g, double b)` - Add/Remove a point to/from the function defined in RGB or HSV Return the index of the point (0 based), or -1 on error. See the description of class vtkPiecewiseFunction for an explanation of midpoint and sharpness.
- `int = obj.AddRGBPoint (double x, double r, double g, double b, double midpoint, double sharpness)` - Add/Remove a point to/from the function defined in RGB or HSV Return the index of the point (0 based), or -1 on error. See the description of class vtkPiecewiseFunction for an explanation of midpoint and sharpness.
- `int = obj.AddHSVPoint (double x, double h, double s, double v)` - Add/Remove a point to/from the function defined in RGB or HSV Return the index of the point (0 based), or -1 on error. See the description of class vtkPiecewiseFunction for an explanation of midpoint and sharpness.
- `int = obj.AddHSVPoint (double x, double h, double s, double v, double midpoint, double sharpness)` - Add/Remove a point to/from the function defined in RGB or HSV Return the index of the point (0 based), or -1 on error. See the description of class vtkPiecewiseFunction for an explanation of midpoint and sharpness.
- `int = obj.RemovePoint (double x)` - Add/Remove a point to/from the function defined in RGB or HSV Return the index of the point (0 based), or -1 on error. See the description of class vtkPiecewiseFunction for an explanation of midpoint and sharpness.
- `obj.AddRGBSegment (double x1, double r1, double g1, double b1, double x2, double r2, double g2, dou` - Add two points to the function and remove all the points between them
- `obj.AddHSVSegment (double x1, double h1, double s1, double v1, double x2, double h2, double s2, dou` - Add two points to the function and remove all the points between them
- `obj.RemoveAllPoints ()` - Remove all points
- `double = obj.GetColor (double x)` - Returns an RGB color for the specified scalar value
- `obj.GetColor (double x, double rgb[3])` - Returns an RGB color for the specified scalar value
- `double = obj.GetRedValue (double x)` - Get the color components individually.
- `double = obj.GetGreenValue (double x)` - Get the color components individually.
- `double = obj.GetBlueValue (double x)` - Get the color components individually.

- `int = obj.GetNodeValue (int index, double val[6])` - For the node specified by index, set/get the location (X), R, G, and B values, midpoint, and sharpness values at the node.
- `int = obj.SetNodeValue (int index, double val[6])` - For the node specified by index, set/get the location (X), R, G, and B values, midpoint, and sharpness values at the node.
- `double = obj. GetRange ()` - Returns min and max position of all function points.
- `int = obj.AdjustRange (double range[2])` - Remove all points out of the new range, and make sure there is a point at each end of that range. Return 1 on success, 0 otherwise.
- `obj.GetTable (double x1, double x2, int n, double table)` - Fills in a table of n function values between x1 and x2
- `obj.GetTable (double x1, double x2, int n, float table)` - Fills in a table of n function values between x1 and x2
- `obj.BuildFunctionFromTable (double x1, double x2, int size, double table)` - Construct a color transfer function from a table. Function range is is set to [x1, x2], each function size is set to size, and function points are regularly spaced between x1 and x2. Parameter "table" is assumed to be a block of memory of size [3*size]
- `obj.SetClamping (int )` - Sets and gets the clamping value for this transfer function.
- `int = obj.GetClampingMinValue ()` - Sets and gets the clamping value for this transfer function.
- `int = obj.GetClampingMaxValue ()` - Sets and gets the clamping value for this transfer function.
- `int = obj.GetClamping ()` - Sets and gets the clamping value for this transfer function.
- `obj.ClampingOn ()` - Sets and gets the clamping value for this transfer function.
- `obj.ClampingOff ()` - Sets and gets the clamping value for this transfer function.
- `obj.SetColorSpace (int )` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.
- `int = obj.GetColorSpaceMinValue ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.
- `int = obj.GetColorSpaceMaxValue ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.
- `obj.SetColorSpaceToRGB ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.SetColorSpaceToHSV ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.SetColorSpaceToLab ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.SetColorSpaceToDiverging ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `int = obj.GetColorSpace ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.SetHSVWrap (int )` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `int = obj.GetHSVWrap ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.HSVWrapOn ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.HSVWrapOff ()` - Set/Get the color space used for interpolation: RGB, HSV, CIELAB, or Diverging. In HSV mode, if HSVWrap is on, it will take the shortest path in Hue (going back through 0 if that is the shortest way around the hue circle) whereas if HSVWrap is off it will not go through 0 (in order the match the current functionality of vtkLookupTable). Diverging is a special mode where colors will pass through white when interpolating between two saturated colors.

- `obj.SetScale (int )` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, and the range contains zero, the color mapping will be linear.

- `obj.SetScaleToLinear ()` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, and the range contains zero, the color mapping will be linear.

- `obj.SetScaleToLog10 ()` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, and the range contains zero, the color mapping will be linear.

- `int = obj.GetScale ()` - Set the type of scale to use, linear or logarithmic. The default is linear. If the scale is logarithmic, and the range contains zero, the color mapping will be linear.
- `obj.FillFromDataPointer (int , double )` - Returns a list of all nodes Fills from a pointer to data stored in a similar list of nodes.
- `obj.SetAllowDuplicateScalars (int )` - Toggle whether to allow duplicate scalar values in the color transfer function (off by default).
- `int = obj.GetAllowDuplicateScalars ()` - Toggle whether to allow duplicate scalar values in the color transfer function (off by default).
- `obj.AllowDuplicateScalarsOn ()` - Toggle whether to allow duplicate scalar values in the color transfer function (off by default).
- `obj.AllowDuplicateScalarsOff ()` - Toggle whether to allow duplicate scalar values in the color transfer function (off by default).

31.34 vtkCompositeDataIterator

31.34.1 Usage

vtkCompositeDataIterator provides an interface for accessing datasets in a collection (vtkCompositeDataIterator).

To create an instance of class vtkCompositeDataIterator, simply invoke its constructor as follows

```
obj = vtkCompositeDataIterator
```

31.34.2 Methods

The class vtkCompositeDataIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeDataIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeDataIterator = obj.NewInstance ()`
- `vtkCompositeDataIterator = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataSet (vtkCompositeDataSet ds)` - Set the composite dataset this iterator is iterating over. Must be set before traversal begins.
- `vtkCompositeDataSet = obj.GetDataSet ()` - Set the composite dataset this iterator is iterating over. Must be set before traversal begins.
- `obj.InitTraversal ()` - Begin iterating over the composite dataset structure.
- `obj.InitReverseTraversal ()` - Begin iterating over the composite dataset structure in reverse order.
- `obj.GoToFirstItem ()` - Move the iterator to the beginning of the collection.
- `obj.GoToNextItem ()` - Move the iterator to the next item in the collection.
- `int = obj.IsDoneWithTraversal ()` - Test whether the iterator is finished with the traversal. Returns 1 for yes, and 0 for no. It is safe to call any of the GetCurrent...() methods only when IsDoneWithTraversal() returns 0.

- `vtkDataObject = obj.GetCurrentDataObject ()` - Returns the current item. Valid only when IsDoneWithTraversal() returns 0.
- `vtkInformation = obj.GetCurrentMetaData ()` - Returns the meta-data associated with the current item. This will allocate a new vtkInformation object is none is already present. Use HasCurrentMetaData to avoid unnecessary creation of vtkInformation objects.
- `int = obj.HasCurrentMetaData ()` - Returns if the a meta-data information object is present for the current item. Return 1 on success, 0 otherwise.
- `obj.SetVisitOnlyLeaves (int )` - If VisitOnlyLeaves is true, the iterator will only visit nodes (sub-datasets) that are not composite. If it encounters a composite data set, it will automatically traverse that composite dataset until it finds non-composite datasets. With this options, it is possible to visit all non-composite datasets in tree of composite datasets (composite of composite of composite for example :-)) If VisitOnlyLeaves is false, GetCurrentDataObject() may return vtkCompositeDataSet. By default, VisitOnlyLeaves is 1.
- `int = obj.GetVisitOnlyLeaves ()` - If VisitOnlyLeaves is true, the iterator will only visit nodes (sub-datasets) that are not composite. If it encounters a composite data set, it will automatically traverse that composite dataset until it finds non-composite datasets. With this options, it is possible to visit all non-composite datasets in tree of composite datasets (composite of composite of composite for example :-)) If VisitOnlyLeaves is false, GetCurrentDataObject() may return vtkCompositeDataSet. By default, VisitOnlyLeaves is 1.
- `obj.VisitOnlyLeavesOn ()` - If VisitOnlyLeaves is true, the iterator will only visit nodes (sub-datasets) that are not composite. If it encounters a composite data set, it will automatically traverse that composite dataset until it finds non-composite datasets. With this options, it is possible to visit all non-composite datasets in tree of composite datasets (composite of composite of composite for example :-)) If VisitOnlyLeaves is false, GetCurrentDataObject() may return vtkCompositeDataSet. By default, VisitOnlyLeaves is 1.
- `obj.VisitOnlyLeavesOff ()` - If VisitOnlyLeaves is true, the iterator will only visit nodes (sub-datasets) that are not composite. If it encounters a composite data set, it will automatically traverse that composite dataset until it finds non-composite datasets. With this options, it is possible to visit all non-composite datasets in tree of composite datasets (composite of composite of composite for example :-)) If VisitOnlyLeaves is false, GetCurrentDataObject() may return vtkCompositeDataSet. By default, VisitOnlyLeaves is 1.
- `obj.SetTraverseSubTree (int )` - If TraverseSubTree is set to true, the iterator will visit the entire tree structure, otherwise it only visits the first level children. Set to 1 by default.
- `int = obj.GetTraverseSubTree ()` - If TraverseSubTree is set to true, the iterator will visit the entire tree structure, otherwise it only visits the first level children. Set to 1 by default.
- `obj.TraverseSubTreeOn ()` - If TraverseSubTree is set to true, the iterator will visit the entire tree structure, otherwise it only visits the first level children. Set to 1 by default.
- `obj.TraverseSubTreeOff ()` - If TraverseSubTree is set to true, the iterator will visit the entire tree structure, otherwise it only visits the first level children. Set to 1 by default.
- `obj.SetSkipEmptyNodes (int )` - If SkipEmptyNodes is true, then NULL datasets will be skipped. Default is true.
- `int = obj.GetSkipEmptyNodes ()` - If SkipEmptyNodes is true, then NULL datasets will be skipped. Default is true.
- `obj.SkipEmptyNodesOn ()` - If SkipEmptyNodes is true, then NULL datasets will be skipped. Default is true.

- `obj.SkipEmptyNodesOff ()` - If SkipEmptyNodes is true, then NULL datasets will be skipped. Default is true.
- `int = obj.GetCurrentFlatIndex ()` - Flat index is an index obtained by traversing the tree in pre-order. This can be used to uniquely identify nodes in the tree. Not valid if IsDoneWithTraversal() returns true.
- `int = obj.GetReverse ()` - Returns if the iteration is in reverse order.

31.35 vtkCompositeDataPipeline

31.35.1 Usage

vtkCompositeDataPipeline is an executive that supports the processing of composite dataset. It supports algorithms that are aware of composite dataset as well as those that are not. Type checking is performed at run time. Algorithms that are not composite dataset-aware have to support all dataset types contained in the composite dataset. The pipeline execution can be summarized as follows:

* REQUEST_INFORMATION: The producers have to provide information about the contents of the composite dataset in this pass. Sources that can produce more than one piece (note that a piece is different than a block; each piece consistes of 0 or more blocks) should set MAXIMUM_NUMBER_OF_PIECES to -1.

* REQUEST_UPDATE_EXTENT: This pass is identical to the one implemented in vtkStreamingDemandDrivenPipeline

* REQUEST_DATA: This is where the algorithms execute. If the vtkCompositeDataPipeline is assigned to a simple filter, it will invoke the vtkStreamingDemandDrivenPipeline passes in a loop, passing a different block each time and will collect the results in a composite dataset. .SECTION See also vtkCompositeDataSet

To create an instance of class vtkCompositeDataPipeline, simply invoke its constructor as follows

```
obj = vtkCompositeDataPipeline
```

31.35.2 Methods

The class vtkCompositeDataPipeline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeDataPipeline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeDataPipeline = obj.NewInstance ()`
- `vtkCompositeDataPipeline = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetCompositeOutputData (int port)` - Returns the data object stored with the DATA_OBJECT() in the output port

31.36 vtkCompositeDataSet

31.36.1 Usage

vtkCompositeDataSet is an abstract class that represents a collection of datasets (including other composite datasets). It provides an interface to access the datasets through iterators. vtkCompositeDataSet provides methods that are used by subclasses to store the datasets. vtkCompositeDataSet provides the datastructure for a full tree representation. Subclasses provide the semantics for it and control how this tree is built.

To create an instance of class vtkCompositeDataSet, simply invoke its constructor as follows

```
obj = vtkCompositeDataSet
```

31.36.2 Methods

The class vtkCompositeDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeDataSet = obj.NewInstance ()`
- `vtkCompositeDataSet = obj.SafeDownCast (vtkObject o)`
- `vtkCompositeDataIterator = obj.NewIterator ()` - Return a new iterator (the iterator has to be deleted by user).
- `int = obj.GetDataObjectType ()` - Get the port currently producing this object.
- `vtkAlgorithmOutput = obj.GetProducerPort ()` - Get the port currently producing this object.
- `obj.CopyStructure (vtkCompositeDataSet input)` - Copies the tree structure from the input. All pointers to non-composite data objects are intialized to NULL. This also shallow copies the meta data associated with all the nodes.
- `obj.SetDataSet (vtkCompositeDataIterator iter, vtkDataObject dataObj)` - Sets the data set at the location pointed by the iterator. The iterator does not need to be iterating over this dataset itself. It can be any composite datasite with similar structure (achieved by using CopyStructure).
- `vtkDataObject = obj.GetDataSet (vtkCompositeDataIterator iter)` - Returns the dataset located at the positiong pointed by the iterator. The iterator does not need to be iterating over this dataset itself. It can be an iterator for composite dataset with similar structure (achieved by using CopyStructure).
- `vtkInformation = obj.GetMetaData (vtkCompositeDataIterator iter)` - Returns the meta-data associated with the position pointed by the iterator. This will create a new vtkInformation object if none already exists. Use HasMetaData to avoid creating the vtkInformation object unnecessarily. The iterator does not need to be iterating over this dataset itself. It can be an iterator for composite dataset with similar structure (achieved by using CopyStructure).
- `int = obj.HasMetaData (vtkCompositeDataIterator iter)` - Returns if any meta-data associated with the position pointed by the iterator. The iterator does not need to be iterating over this dataset itself. It can be an iterator for composite dataset with similar structure (achieved by using CopyStructure).
- `obj.Initialize ()` - Restore data object to initial state,
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `vtkIdType = obj.GetNumberOfPoints ()` - Returns the total number of points of all blocks. This will iterate over all blocks and call GetNumberOfPoints() so it might be expansive.

31.37 vtkCompositeDataSetAlgorithm

31.37.1 Usage

Algorithms that take any type of data object (including composite dataset) and produce a vtkCompositeDataSet in the output can subclass from this class.

To create an instance of class vtkCompositeDataSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkCompositeDataSetAlgorithm
```

31.37.2 Methods

The class vtkCompositeDataSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompositeDataSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCompositeDataSetAlgorithm = obj.NewInstance ()`
- `vtkCompositeDataSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkCompositeDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkCompositeDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.38 vtkCone

31.38.1 Usage

vtkCone computes the implicit function and function gradient for a cone. vtkCone is a concrete implementation of vtkImplicitFunction. The cone vertex is located at the origin with axis of rotation coincident with x-axis. (Use the superclass' vtkImplicitFunction transformation matrix if necessary to reposition.) The angle specifies the angle between the axis of rotation and the side of the cone.

To create an instance of class vtkCone, simply invoke its constructor as follows

```
obj = vtkCone
```

31.38.2 Methods

The class vtkCone has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCone class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCone = obj.NewInstance ()`
- `vtkCone = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double g[3])`
- `obj.SetAngle (double )` - Set/Get the cone angle (expressed in degrees).
- `double = obj.GetAngleMinValue ()` - Set/Get the cone angle (expressed in degrees).
- `double = obj.GetAngleMaxValue ()` - Set/Get the cone angle (expressed in degrees).
- `double = obj.GetAngle ()` - Set/Get the cone angle (expressed in degrees).

31.39 vtkConvexPointSet

31.39.1 Usage

vtkConvexPointSet is a concrete implementation that represents a 3D cell defined by a convex set of points. An example of such a cell is an octant (from an octree). vtkConvexPointSet uses the ordered triangulations approach (vtkOrderedTriangulator) to create triangulations guaranteed to be compatible across shared faces. This allows a general approach to processing complex, convex cell types.

To create an instance of class vtkConvexPointSet, simply invoke its constructor as follows

```
obj = vtkConvexPointSet
```

31.39.2 Methods

The class vtkConvexPointSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkConvexPointSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkConvexPointSet = obj.NewInstance ()`
- `vtkConvexPointSet = obj.SafeDownCast (vtkObject o)`
- `int = obj.HasFixedTopology ()` - See vtkCell3D API for description of these methods.
- `int = obj.GetCellType ()` - This cell requires that it be initialized prior to access.
- `int = obj.RequiresInitialization ()` - This cell requires that it be initialized prior to access.
- `obj.Initialize ()` - This cell requires that it be initialized prior to access.

- `int = obj.GetNumberOfEdges ()` - A convex point set has no explicit cell edge or faces; however implicitly (after triangulation) it does. Currently the method GetNumberOfEdges() always returns 0 while the GetNumberOfFaces() returns the number of boundary triangles of the triangulation of the convex point set. The method GetNumberOfFaces() triggers a triangulation of the convex point set; repeated calls to GetFace() then return the boundary faces. (Note: GetNumberOfEdges() currently returns 0 because it is a rarely used method and hard to implement. It can be changed in the future.

- `vtkCell = obj.GetEdge (int )` - A convex point set has no explicit cell edge or faces; however implicitly (after triangulation) it does. Currently the method GetNumberOfEdges() always returns 0 while the GetNumberOfFaces() returns the number of boundary triangles of the triangulation of the convex point set. The method GetNumberOfFaces() triggers a triangulation of the convex point set; repeated calls to GetFace() then return the boundary faces. (Note: GetNumberOfEdges() currently returns 0 because it is a rarely used method and hard to implement. It can be changed in the future.

- `int = obj.GetNumberOfFaces ()` - A convex point set has no explicit cell edge or faces; however implicitly (after triangulation) it does. Currently the method GetNumberOfEdges() always returns 0 while the GetNumberOfFaces() returns the number of boundary triangles of the triangulation of the convex point set. The method GetNumberOfFaces() triggers a triangulation of the convex point set; repeated calls to GetFace() then return the boundary faces. (Note: GetNumberOfEdges() currently returns 0 because it is a rarely used method and hard to implement. It can be changed in the future.

- `vtkCell = obj.GetFace (int faceId)` - A convex point set has no explicit cell edge or faces; however implicitly (after triangulation) it does. Currently the method GetNumberOfEdges() always returns 0 while the GetNumberOfFaces() returns the number of boundary triangles of the triangulation of the convex point set. The method GetNumberOfFaces() triggers a triangulation of the convex point set; repeated calls to GetFace() then return the boundary faces. (Note: GetNumberOfEdges() currently returns 0 because it is a rarely used method and hard to implement. It can be changed in the future.

- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - Satisfy the vtkCell API. This method contours by triangulating the cell and then contouring the resulting tetrahedra.

- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Satisfy the vtkCell API. This method contours by triangulating the cell and then adding clip-edge intersection points into the triangulation; extracting the clipped region.

- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - Triangulate using methods of vtkOrderedTriangulator.

- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - Computes derivatives by triangulating and from subId and pcoords, evaluating derivatives on the resulting tetrahedron.

- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - Returns the set of points forming a face of the triangulation of these points that are on the boundary of the cell that are closest parametrically to the point specified.

- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the cell in parametric coordinates.

- `int = obj.IsPrimaryCell ()` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

- `obj.InterpolateFunctions (double pcoords[3], double sf)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

31.40 vtkCoordinate

31.40.1 Usage

vtkCoordinate represents position in a variety of coordinate systems, and converts position to other coordinate systems. It also supports relative positioning, so you can create a cascade of vtkCoordinate objects (no loops please!) that refer to each other. The typical usage of this object is to set the coordinate system in which to represent a position (e.g., SetCoordinateSystemToNormalizedDisplay()), set the value of the coordinate (e.g., SetValue()), and then invoke the appropriate method to convert to another coordinate system (e.g., GetComputedWorldValue()).

The coordinate systems in vtk are as follows: ¡PRE¿ DISPLAY - x-y pixel values in window NORMALIZED DISPLAY - x-y (0,1) normalized values VIEWPORT - x-y pixel values in viewport NORMALIZED VIEWPORT - x-y (0,1) normalized value in viewport VIEW - x-y-z (-1,1) values in camera coordinates. (z is depth) WORLD - x-y-z global coordinate values USERDEFINED - x-y-z in User defined space ¡/PRE¿

If you cascade vtkCoordinate objects, you refer to another vtkCoordinate object which in turn can refer to others, and so on. This allows you to create composite groups of things like vtkActor2D that are positioned relative to one another. Note that in cascaded sequences, each vtkCoordinate object may be specified in different coordinate systems!

To create an instance of class vtkCoordinate, simply invoke its constructor as follows

```
obj = vtkCoordinate
```

31.40.2 Methods

The class vtkCoordinate has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCoordinate class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCoordinate = obj.NewInstance ()`
- `vtkCoordinate = obj.SafeDownCast (vtkObject o)`
- `obj.SetCoordinateSystem (int )` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.
- `int = obj.GetCoordinateSystem ()` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.
- `obj.SetCoordinateSystemToDisplay ()` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.
- `obj.SetCoordinateSystemToNormalizedDisplay ()` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.
- `obj.SetCoordinateSystemToViewport ()` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.
- `obj.SetCoordinateSystemToNormalizedViewport ()` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.

- `obj.SetCoordinateSystemToView ()` - Set/get the coordinate system which this coordinate is defined in. The options are Display, Normalized Display, Viewport, Normalized Viewport, View, and World.

- `obj.SetCoordinateSystemToWorld ()`

- `string = obj.GetCoordinateSystemAsString ()`

- `obj.SetValue (double , double , double )` - Set/get the value of this coordinate. This can be thought of as the position of this coordinate in its coordinate system.

- `obj.SetValue (double a[3])` - Set/get the value of this coordinate. This can be thought of as the position of this coordinate in its coordinate system.

- `double = obj. GetValue ()` - Set/get the value of this coordinate. This can be thought of as the position of this coordinate in its coordinate system.

- `obj.SetValue (double a, double b)` - If this coordinate is relative to another coordinate, then specify that coordinate as the ReferenceCoordinate. If this is NULL the coordinate is assumed to be absolute.

- `obj.SetReferenceCoordinate (vtkCoordinate )` - If this coordinate is relative to another coordinate, then specify that coordinate as the ReferenceCoordinate. If this is NULL the coordinate is assumed to be absolute.

- `vtkCoordinate = obj.GetReferenceCoordinate ()` - If this coordinate is relative to another coordinate, then specify that coordinate as the ReferenceCoordinate. If this is NULL the coordinate is assumed to be absolute.

- `obj.SetViewport (vtkViewport viewport)` - If you want this coordinate to be relative to a specific vtkViewport (vtkRenderer) then you can specify that here. NOTE: this is a raw pointer, not a weak pointer not a reference counted object to avoid reference cycle loop between rendering classes and filter classes.

- `vtkViewport = obj.GetViewport ()` - If you want this coordinate to be relative to a specific vtkViewport (vtkRenderer) then you can specify that here. NOTE: this is a raw pointer, not a weak pointer not a reference counted object to avoid reference cycle loop between rendering classes and filter classes.

- `double = obj.GetComputedWorldValue (vtkViewport )` - Return the computed value in a specified coordinate system.

- `int = obj.GetComputedViewportValue (vtkViewport )` - Return the computed value in a specified coordinate system.

- `int = obj.GetComputedDisplayValue (vtkViewport )` - Return the computed value in a specified coordinate system.

- `int = obj.GetComputedLocalDisplayValue (vtkViewport )` - Return the computed value in a specified coordinate system.

- `double = obj.GetComputedDoubleViewportValue (vtkViewport )`

- `double = obj.GetComputedDoubleDisplayValue (vtkViewport )`

31.41 vtkCubicLine

31.41.1 Usage

vtkCubicLine is a concrete implementation of vtkNonLinearCell to represent a 1D Cubic line. The Cubic Line is the 4 nodes isoparametric parabolic line . The interpolation is the standard finite element, cubic isoparametric shape function. The cell includes two mid-edge nodes. The ordering of the four points defining the cell is point ids (0,1,2,3) where id #2 and #3 are the mid-edge nodes. Please note that the parametric coordinates lie between -1 and 1 in accordance with most standard documentations. .SECTION Thanks ¡verbatim¿ This file has been developed by Oxalya - www.oxalya.com Copyright (c) EDF - www.edf.fr ¡/verbatim¿

To create an instance of class vtkCubicLine, simply invoke its constructor as follows

```
obj = vtkCubicLine
```

31.41.2 Methods

The class vtkCubicLine has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCubicLine class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCubicLine = obj.NewInstance ()`
- `vtkCubicLine = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this line using scalar value provided. Like contouring, except that it cuts the line to produce other lines.

- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the triangle in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[4])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[4])`

31.42 vtkCylinder

31.42.1 Usage

vtkCylinder computes the implicit function and function gradient for a cylinder. vtkCylinder is a concrete implementation of vtkImplicitFunction. Cylinder is centered at Center and axes of rotation is along the y-axis. (Use the superclass' vtkImplicitFunction transformation matrix if necessary to reposition.)

To create an instance of class vtkCylinder, simply invoke its constructor as follows

```
obj = vtkCylinder
```

31.42.2 Methods

The class vtkCylinder has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCylinder class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkCylinder = obj.NewInstance ()`
- `vtkCylinder = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double g[3])`
- `obj.SetRadius (double )` - Set/Get cylinder radius.
- `double = obj.GetRadius ()` - Set/Get cylinder radius.
- `obj.SetCenter (double , double , double )` - Set/Get cylinder center
- `obj.SetCenter (double  a[3])` - Set/Get cylinder center
- `double = obj. GetCenter ()` - Set/Get cylinder center

31.43 vtkDataObject

31.43.1 Usage

vtkDataObject is an general representation of visualization data. It serves to encapsulate instance variables and methods for visualization network execution, as well as representing data consisting of a field (i.e., just an unstructured pile of data). This is to be compared with a vtkDataSet, which is data with geometric and/or topological structure.

vtkDataObjects are used to represent arbitrary repositories of data via the vtkFieldData instance variable. These data must be eventually mapped into a concrete subclass of vtkDataSet before they can actually be displayed.

To create an instance of class vtkDataObject, simply invoke its constructor as follows

```
obj = vtkDataObject
```

31.43.2 Methods

The class vtkDataObject has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObject class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObject = obj.NewInstance ()`
- `vtkDataObject = obj.SafeDownCast (vtkObject o)`
- `vtkSource = obj.GetSource ()` - Set/Get the source object creating this data object.
- `obj.SetSource (vtkSource s)` - Set/Get the source object creating this data object.
- `vtkInformation = obj.GetInformation ()` - Set/Get the information object associated with this data object.
- `obj.SetInformation (vtkInformation )` - Set/Get the information object associated with this data object.
- `vtkInformation = obj.GetPipelineInformation ()` - Get/Set the pipeline information object that owns this data object.
- `obj.SetPipelineInformation (vtkInformation )` - Get/Set the pipeline information object that owns this data object.
- `vtkAlgorithmOutput = obj.GetProducerPort ()` - Get the port currently producing this object.
- `long = obj.GetMTime ()` - Data objects are composite objects and need to check each part for MTime. The information object also needs to be considered.
- `obj.Initialize ()` - Restore data object to initial state,
- `obj.ReleaseData ()` - Release data back to system to conserve memory resource. Used during visualization network execution. Releasing this data does not make down-stream data invalid, so it does not modify the MTime of this data object.
- `int = obj.ShouldIReleaseData ()` - Return flag indicating whether data should be released after use by a filter.
- `int = obj.GetDataReleased ()` - Get the flag indicating the data has been released.
- `obj.SetReleaseDataFlag (int )` - Turn on/off flag to control whether this object's data is released after being used by a filter.
- `int = obj.GetReleaseDataFlag ()` - Turn on/off flag to control whether this object's data is released after being used by a filter.
- `obj.ReleaseDataFlagOn ()` - Turn on/off flag to control whether this object's data is released after being used by a filter.
- `obj.ReleaseDataFlagOff ()` - Turn on/off flag to control whether this object's data is released after being used by a filter.

- `obj.GlobalReleaseDataFlagOn ()` - Turn on/off flag to control whether every object releases its data after being used by a filter.
- `obj.GlobalReleaseDataFlagOff ()` - Turn on/off flag to control whether every object releases its data after being used by a filter.
- `obj.SetFieldData (vtkFieldData )` - Assign or retrieve a general field data to this data object.
- `vtkFieldData = obj.GetFieldData ()` - Assign or retrieve a general field data to this data object.
- `obj.Register (vtkObjectBase o)`
- `obj.UnRegister (vtkObjectBase o)`
- `obj.Update ()` - Provides opportunity for the data object to insure internal consistency before access. Also causes owning source/filter (if any) to update itself. The Update() method is composed of UpdateInformation(), PropagateUpdateExtent(), TriggerAsynchronousUpdate(), and UpdateData().
- `obj.UpdateInformation ()` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. Update all the "easy to update" information about the object such as the extent which will be used to control the update. This propagates all the way up then back down the pipeline. As a by-product the PipelineMTime is updated.
- `obj.PropagateUpdateExtent ()` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. The update extent for this object is propagated up the pipeline. This propagation may early terminate based on the PipelineMTime.
- `obj.TriggerAsynchronousUpdate ()` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. Propagate back up the pipeline for ports and trigger the update on the other side of the port to allow for asynchronous parallel processing in the pipeline. This propagation may early terminate based on the PipelineMTime.
- `obj.UpdateData ()` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. Propagate the update back up the pipeline, and perform the actual work of updating on the way down. When the propagate arrives at a port, block and wait for the asynchronous update to finish on the other side. This propagation may early terminate based on the PipelineMTime.
- `long = obj.GetEstimatedMemorySize ()` - Get the estimated size of this data object itself. Should be called after UpdateInformation() and PropagateUpdateExtent() have both been called. Should be overridden in a subclass - otherwise the default is to assume that this data object requires no memory. The size is returned in kilobytes.
- `obj.SetUpdateExtent (int piece, int numPieces, int ghostLevel)` - A generic way of specifying an update extent. Subclasses must decide what a piece is. When the NumberOfPieces is zero, then no data is requested, and the source will not execute.
- `obj.SetUpdateExtent (int piece, int numPieces)` - Set the update extent for data objects that use 3D extents. Using this method on data objects that set extents as pieces (such as vtkPolyData or vtkUnstructuredGrid) has no real effect. Don't use the set macro to set the update extent since we don't want this object to be modified just due to a change in update extent. When the volume of the extent is zero (0, -1,..), then no data is requested, and the source will not execute.
- `obj.SetUpdateExtent (int x0, int x1, int y0, int y1, int z0, int z1)` - Set the update extent for data objects that use 3D extents. Using this method on data objects that set extents as pieces (such as vtkPolyData or vtkUnstructuredGrid) has no real effect. Don't use the set macro to set the update extent since we don't want this object to be modified just due to a change in update extent.

When the volume of the extent is zero (0, -1,..), then no data is requested, and the source will not execute.

- `obj.SetUpdateExtent (int extent[6])` - Set the update extent for data objects that use 3D extents. Using this method on data objects that set extents as pieces (such as vtkPolyData or vtkUnstructuredGrid) has no real effect. Don't use the set macro to set the update extent since we don't want this object to be modified just due to a change in update extent. When the volume of the extent is zero (0, -1,..), then no data is requested, and the source will not execute.

- `int = obj.GetUpdateExtent ()` - Set the update extent for data objects that use 3D extents. Using this method on data objects that set extents as pieces (such as vtkPolyData or vtkUnstructuredGrid) has no real effect. Don't use the set macro to set the update extent since we don't want this object to be modified just due to a change in update extent. When the volume of the extent is zero (0, -1,..), then no data is requested, and the source will not execute.

- `obj.GetUpdateExtent (int extent[6])` - Set the update extent for data objects that use 3D extents. Using this method on data objects that set extents as pieces (such as vtkPolyData or vtkUnstructuredGrid) has no real effect. Don't use the set macro to set the update extent since we don't want this object to be modified just due to a change in update extent. When the volume of the extent is zero (0, -1,..), then no data is requested, and the source will not execute.

- `int = obj.GetDataObjectType ()` - Used by Threaded ports to determine if they should initiate an asynchronous update (still in development).

- `long = obj.GetUpdateTime ()` - Used by Threaded ports to determine if they should initiate an asynchronous update (still in development).

- `obj.SetUpdateExtentToWholeExtent ()` - If the whole input extent is required to generate the requested output extent, this method can be called to set the input update extent to the whole input extent. This method assumes that the whole extent is known (that UpdateInformation has been called)

- `long = obj.GetPipelineMTime ()` - Get the cumulative modified time of everything upstream. Does not include the MTime of this object.

- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value).

- `obj.CopyInformation (vtkDataObject data)` - Copy the generic information (WholeExtent ...)

- `obj.CopyTypeSpecificInformation (vtkDataObject data)` - By default, there is no type specific information

- `obj.SetUpdatePiece (int piece)` - Set / Get the update piece and the update number of pieces. Similar to update extent in 3D.

- `obj.SetUpdateNumberOfPieces (int num)` - Set / Get the update piece and the update number of pieces. Similar to update extent in 3D.

- `int = obj.GetUpdatePiece ()` - Set / Get the update piece and the update number of pieces. Similar to update extent in 3D.

- `int = obj.GetUpdateNumberOfPieces ()` - Set / Get the update piece and the update number of pieces. Similar to update extent in 3D.

- `obj.SetUpdateGhostLevel (int level)` - Set / Get the update ghost level and the update number of ghost levels. Similar to update extent in 3D.

- `int = obj.GetUpdateGhostLevel ()` - Set / Get the update ghost level and the update number of ghost levels. Similar to update extent in 3D.
- `obj.SetRequestExactExtent (int flag)` - This request flag indicates whether the requester can handle more data than requested. Right now it is used in vtkImageData. Image filters can return more data than requested. The the consumer cannot handle this (i.e. DataSetToDataSetFitler) the image will crop itself. This functionality used to be in ImageToStructuredPoints.
- `int = obj.GetRequestExactExtent ()` - This request flag indicates whether the requester can handle more data than requested. Right now it is used in vtkImageData. Image filters can return more data than requested. The the consumer cannot handle this (i.e. DataSetToDataSetFitler) the image will crop itself. This functionality used to be in ImageToStructuredPoints.
- `obj.RequestExactExtentOn ()` - This request flag indicates whether the requester can handle more data than requested. Right now it is used in vtkImageData. Image filters can return more data than requested. The the consumer cannot handle this (i.e. DataSetToDataSetFitler) the image will crop itself. This functionality used to be in ImageToStructuredPoints.
- `obj.RequestExactExtentOff ()` - This request flag indicates whether the requester can handle more data than requested. Right now it is used in vtkImageData. Image filters can return more data than requested. The the consumer cannot handle this (i.e. DataSetToDataSetFitler) the image will crop itself. This functionality used to be in ImageToStructuredPoints.
- `obj.SetWholeExtent (int x0, int x1, int y0, int y1, int z0, int z1)` - Set/Get the whole extent of this data object. The whole extent is meta data for structured data sets. It gets set by the source during the update information call.
- `obj.SetWholeExtent (int extent[6])` - Set/Get the whole extent of this data object. The whole extent is meta data for structured data sets. It gets set by the source during the update information call.
- `int = obj.GetWholeExtent ()` - Set/Get the whole extent of this data object. The whole extent is meta data for structured data sets. It gets set by the source during the update information call.
- `obj.GetWholeExtent (int extent[6])` - Set/Get the whole extent of this data object. The whole extent is meta data for structured data sets. It gets set by the source during the update information call.
- `obj.SetWholeBoundingBox (double x0, double x1, double y0, double y1, double z0, double z1)` - Set/Get the whole bounding box of this data object. The whole whole bounding box is meta data for data sets It gets set by the source during the update information call.
- `obj.SetWholeBoundingBox (double bb[6])` - Set/Get the whole bounding box of this data object. The whole whole bounding box is meta data for data sets It gets set by the source during the update information call.
- `double = obj.GetWholeBoundingBox ()` - Set/Get the whole bounding box of this data object. The whole whole bounding box is meta data for data sets It gets set by the source during the update information call.
- `obj.GetWholeBoundingBox (double extent[6])` - Set/Get the whole bounding box of this data object. The whole whole bounding box is meta data for data sets It gets set by the source during the update information call.
- `obj.SetMaximumNumberOfPieces (int )` - Set/Get the maximum number of pieces that can be requested. The maximum number of pieces is meta data for unstructured data sets. It gets set by the source during the update information call. A value of -1 indicates that there is no maximum. A value of

- `int = obj.GetMaximumNumberOfPieces ()` - Set/Get the maximum number of pieces that can be requested. The maximum number of pieces is meta data for unstructured data sets. It gets set by the source during the update information call. A value of -1 indicates that there is no maximum. A value of

- `obj.CopyInformationToPipeline (vtkInformation request, vtkInformation input, vtkInformation output,` - Copy information about this data object to the output information from its own Information for the given request. If the second argument is not NULL then it is the pipeline information object for the input to this data object's producer. If forceCopy is true, information is copied even if it exists in the output.

- `obj.CopyInformationToPipeline (vtkInformation request, vtkInformation input)` - Copy information about this data object from the PipelineInformation to its own Information for the given request.

- `obj.CopyInformationFromPipeline (vtkInformation request)` - Copy information about this data object from the PipelineInformation to its own Information for the given request.

- `obj.DataHasBeenGenerated ()` - This method is called by the source when it executes to generate data. It is sort of the opposite of ReleaseData. It sets the DataReleased flag to 0, and sets a new UpdateTime.

- `obj.PrepareForNewData ()` - make the output data ready for new data to be inserted. For most objects we just call Initialize. But for vtkImageData we leave the old data in case the memory can be reused.

- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy. These copy the data, but not any of the pipeline connections.

- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy. These copy the data, but not any of the pipeline connections.

- `obj.SetExtentTranslator (vtkExtentTranslator translator)` - An object that will translate pieces into structured extents.

- `vtkExtentTranslator = obj.GetExtentTranslator ()` - An object that will translate pieces into structured extents.

- `int = obj.GetExtentType ()` - The ExtentType will be left as VTK_PIECES_EXTENT for data objects such as vtkPolyData and vtkUnstructuredGrid. The ExtentType will be changed to VTK_3D_EXTENT for data objects with 3D structure such as vtkImageData (and its subclass vtkStructuredPoints), vtkRectilinearGrid, and vtkStructuredGrid. The default is the have an extent in pieces, with only one piece (no streaming possible).

- `obj.Crop ()` - This method crops the data object (if necesary) so that the extent matches the update extent.

- `vtkDataSetAttributes = obj.GetAttributes (int type)` - Returns the attributes of the data object of the specified attribute type. The type may be: ¡ul¿ ¡li¿POINT - Defined in vtkDataSet subclasses. ¡li¿CELL - Defined in vtkDataSet subclasses. ¡li¿VERTEX - Defined in vtkGraph subclasses. ¡li¿EDGE - Defined in vtkGraph subclasses. ¡li¿ROW - Defined in vtkTable. ¡/ul¿ The other attribute type, FIELD, will return NULL since field data is stored as a vtkFieldData instance, not a vtkDataSetAttributes instance. To retrieve field data, use GetAttributesAsFieldData.

- `vtkFieldData = obj.GetAttributesAsFieldData (int type)` - Returns the attributes of the data object as a vtkFieldData. This returns non-null values in all the same cases as GetAttributes, in addition to the case of FIELD, which will return the field data for any vtkDataObject subclass.

- `int = obj.GetAttributeTypeForArray (vtkAbstractArray arr)` - Retrieves the attribute type that an array came from. This is useful for obtaining which attribute type a input array to an algorithm came from (retrieved from GetInputAbstractArrayToProcesss).
- `vtkIdType = obj.GetNumberOfElements (int type)` - Get the number of elements for a specific attribute type (POINT, CELL, etc.).

31.44 vtkDataObjectAlgorithm

31.44.1 Usage

To create an instance of class vtkDataObjectAlgorithm, simply invoke its constructor as follows

```
obj = vtkDataObjectAlgorithm
```

31.44.2 Methods

The class vtkDataObjectAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectAlgorithm = obj.NewInstance ()`
- `vtkDataObjectAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.45 vtkDataObjectCollection

31.45.1 Usage

vtkDataObjectCollection is an object that creates and manipulates lists of data objects. See also vtkCollection and subclasses.

To create an instance of class vtkDataObjectCollection, simply invoke its constructor as follows

```
obj = vtkDataObjectCollection
```

31.45.2 Methods

The class vtkDataObjectCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectCollection = obj.NewInstance ()`
- `vtkDataObjectCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkDataObject ds)` - Get the next data object in the list.
- `vtkDataObject = obj.GetNextItem ()` - Get the ith data object in the list.
- `vtkDataObject = obj.GetItem (int i)`

31.46 vtkDataObjectSource

31.46.1 Usage

vtkDataObjectSource is an abstract object that specifies behavior and interface of field source objects. Field source objects are source objects that create vtkFieldData (field data) on output.

Concrete subclasses of vtkDataObjectSource must define Update() and Execute() methods. The public method Update() invokes network execution and will bring the network up-to-date. The protected Execute() method actually does the work of data creation/generation. The difference between the two methods is that Update() implements input consistency checks and modified time comparisons and then invokes the Execute() which is an implementation of a particular algorithm.

vtkDataObjectSource provides a mechanism for invoking the methods StartMethod() and EndMethod() before and after object execution (via Execute()). These are convenience methods you can use for any purpose (e.g., debugging info, highlighting/notifying user interface, etc.) These methods accept a single void* pointer that can be used to send data to the methods. It is also possible to specify a function to delete the argument via StartMethodArgDelete and EndMethodArgDelete.

Another method, ProgressMethod() can be specified. Some filters invoke this method periodically during their execution. The use is similar to that of StartMethod() and EndMethod().

An important feature of subclasses of vtkDataObjectSource is that it is possible to control the memory-management model (i.e., retain output versus delete output data). If enabled the ReleaseDataFlag enables the deletion of the output data once the downstream process object finishes processing the data (please see text).

To create an instance of class vtkDataObjectSource, simply invoke its constructor as follows

```
obj = vtkDataObjectSource
```

31.46.2 Methods

The class vtkDataObjectSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectSource = obj.NewInstance ()`
- `vtkDataObjectSource = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetOutput ()` - Get the output field of this source.
- `vtkDataObject = obj.GetOutput (int idx)`
- `obj.SetOutput (vtkDataObject )`

31.47 vtkDataObjectTypes

31.47.1 Usage

vtkDataObjectTypes is a helper class that supports conversion between integer types defined in vtkType.h and string names as well as creation of data objects from either integer or string types. This class has to be updated every time a new data type is added to VTK.

To create an instance of class vtkDataObjectTypes, simply invoke its constructor as follows

```
obj = vtkDataObjectTypes
```

31.47.2 Methods

The class vtkDataObjectTypes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataObjectTypes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataObjectTypes = obj.NewInstance ()`
- `vtkDataObjectTypes = obj.SafeDownCast (vtkObject o)`

31.48 vtkDataSet

31.48.1 Usage

vtkDataSet is an abstract class that specifies an interface for dataset objects. vtkDataSet also provides methods to provide informations about the data, such as center, bounding box, and representative length.

In vtk a dataset consists of a structure (geometry and topology) and attribute data. The structure is defined implicitly or explicitly as a collection of cells. The geometry of the structure is contained in point coordinates plus the cell interpolation functions. The topology of the dataset structure is defined by cell types and how the cells share their defining points.

Attribute data in vtk is either point data (data at points) or cell data (data at cells). Typically filters operate on point data, but some may operate on cell data, both cell and point data, either one, or none.

To create an instance of class vtkDataSet, simply invoke its constructor as follows

```
obj = vtkDataSet
```

31.48.2 Methods

The class vtkDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSet = obj.NewInstance ()`
- `vtkDataSet = obj.SafeDownCast (vtkObject o)`
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an object. Note that the invoking object and the object pointed to by the parameter ds must be of the same type. THIS METHOD IS NOT THREAD SAFE.
- `obj.CopyAttributes (vtkDataSet ds)` - Copy the attributes associated with the specified dataset to this instance of vtkDataSet. THIS METHOD IS NOT THREAD SAFE.
- `vtkIdType = obj.GetNumberOfPoints ()` - Determine the number of points composing the dataset. THIS METHOD IS THREAD SAFE
- `vtkIdType = obj.GetNumberOfCells ()` - Determine the number of cells composing the dataset. THIS METHOD IS THREAD SAFE
- `double = obj.GetPoint (vtkIdType ptId)` - Get point coordinates with ptId such that: 0 ¡= ptId ¡ NumberOfPoints. THIS METHOD IS NOT THREAD SAFE.
- `obj.GetPoint (vtkIdType id, double x[3])` - Copy point coordinates into user provided array x[3] for specified point id. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Get cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. THIS METHOD IS NOT THREAD SAFE.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Get cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. This is a thread-safe alternative to the previous GetCell() method. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `obj.GetCellBounds (vtkIdType cellId, double bounds[6])` - Get the bounds of the cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. A subclass may be able to determine the bounds of cell without using an expensive GetCell() method. A default implementation is provided that actually uses a GetCell() call. This is to ensure the method is available to all datasets. Subclasses should override this method to provide an efficient implementation. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `int = obj.GetCellType (vtkIdType cellId)` - Get type of cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `obj.GetCellTypes (vtkCellTypes types)` - Get a list of types of cells in a dataset. The list consists of an array of types (not necessarily in any order), with a single entry per type. For example a dataset 5 triangles, 3 lines, and 100 hexahedra would result a list of three entries, corresponding to the types VTK_TRIANGLE, VTK_LINE, and VTK_HEXAHEDRON. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Topological inquiry to get points defining cell. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Topological inquiry to get cells using point. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `obj.GetCellNeighbors (vtkIdType cellId, vtkIdList ptIds, vtkIdList cellIds)` - Topological inquiry to get all cells using list of points exclusive of cell specified (e.g., cellId). Note that the list consists of only cells that use ALL the points provided. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `vtkIdType = obj.FindPoint (double x, double y, double z)` - Locate the closest point to the global coordinate x. Return the point id. If point id ¡ 0; then no point found. (This may arise when point is outside of dataset.) THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `vtkIdType = obj.FindPoint (double x[3])` - Locate the closest point to the global coordinate x. Return the point id. If point id ¡ 0; then no point found. (This may arise when point is outside of dataset.) THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `long = obj.GetMTime ()` - Datasets are composite objects and need to check each part for MTime THIS METHOD IS THREAD SAFE

- `vtkCellData = obj.GetCellData ()` - Return a pointer to this dataset's cell data. THIS METHOD IS THREAD SAFE

- `vtkPointData = obj.GetPointData ()` - Return a pointer to this dataset's point data. THIS METHOD IS THREAD SAFE

- `obj.Squeeze ()` - Reclaim any extra memory used to store data. THIS METHOD IS NOT THREAD SAFE.

- `obj.ComputeBounds ()` - Compute the data bounding box from data points. THIS METHOD IS NOT THREAD SAFE.

- `double = obj.GetBounds ()` - Return a pointer to the geometry bounding box in the form (xmin,xmax, ymin,ymax, zmin,zmax). THIS METHOD IS NOT THREAD SAFE.

- `obj.GetBounds (double bounds[6])` - Return a pointer to the geometry bounding box in the form (xmin,xmax, ymin,ymax, zmin,zmax). THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `double = obj.GetCenter ()` - Get the center of the bounding box. THIS METHOD IS NOT THREAD SAFE.

- `obj.GetCenter (double center[3])` - Get the center of the bounding box. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `double = obj.GetLength ()` - Return the length of the diagonal of the bounding box. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `obj.Initialize ()` - Restore data object to initial state, THIS METHOD IS NOT THREAD SAFE.

- `obj.GetScalarRange (double range[2])` - Convenience method to get the range of the scalar data (if there is any scalar data). Returns the (min/max) range of combined point and cell data. If there are no point or cell scalars the method will return (0,1). Note: Update needs to be called to create the scalars. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED

- `double = obj.GetScalarRange ()` - Convenience method to get the range of the scalar data (if there is any scalar data). THIS METHOD IS NOT THREAD SAFE.

- `int = obj.GetMaxCellSize ()` - Convenience method returns largest cell size in dataset. This is generally used to allocate memory for supporting data structures. THIS METHOD IS THREAD SAFE

- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.

- `int = obj.GetDataObjectType ()` - Shallow and Deep copy.

- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.

- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.

- `int = obj.CheckAttributes ()` - This method checks to see if the cell and point attributes match the geometry. Many filters will crash if the number of tupples in an array is less than the number of points/cells. This method returns 1 if there is a mismatch, and 0 if everything is ok. It prints an error if an array is too short, and a warning if an array is too long.

- `obj.GenerateGhostLevelArray ()` - Normally called by pipeline executives or algoritgms only. This method computes the ghost arrays for a given dataset.

- `vtkFieldData = obj.GetAttributesAsFieldData (int type)` - Returns the attributes of the data object as a vtkFieldData. This returns non-null values in all the same cases as GetAttributes, in addition to the case of FIELD, which will return the field data for any vtkDataObject subclass.

- `vtkIdType = obj.GetNumberOfElements (int type)` - Get the number of elements for a specific attribute type (POINT, CELL, etc.).

31.49 vtkDataSetAlgorithm

31.49.1 Usage

vtkDataSetAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. Ther are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this classes contstructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be DataSet. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into seperate functions such as RequestDataObject RequestData and RequestInformation. The default implementation of RequestDataObject will create an output data of the same type as the input.

To create an instance of class vtkDataSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkDataSetAlgorithm
```

31.49.2 Methods

The class vtkDataSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetAlgorithm = obj.NewInstance ()`
- `vtkDataSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()` - Get the input data object. This method is not recommended for use, but lots of old style filters use it.
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as vtkPolyData.
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output as vtkStructuredPoints.
- `vtkImageData = obj.GetImageDataOutput ()` - Get the output as vtkStructuredPoints.
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as vtkStructuredGrid.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as vtkUnstructuredGrid.
- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output as vtkRectilinearGrid.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (vtkDataSet )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataSet )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (vtkDataSet )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataSet )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.50 vtkDataSetAttributes

31.50.1 Usage

vtkDataSetAttributes is a class that is used to represent and manipulate attribute data (e.g., scalars, vectors, normals, texture coordinates, tensors, global ids, pedigree ids, and field data).

This adds to vtkFieldData the ability to pick one of the arrays from the field as the currently active array for each attribute type. In other words, you pick one array to be called "THE" Scalars, and then filters down the pipeline will treat that array specially. For example vtkContourFilter will contour "THE" Scalar array unless a different array is asked for.

Additionally vtkDataSetAttributes provides methods that filters call to pass data through, copy data into, and interpolate from Fields. PassData passes entire arrays from the source to the destination. Copy passes through some subset of the tuples from the source to the destination. Interpolate interpolates from the chosen tuple(s) in the source data, using the provided weights, to produce new tuples in the destination. Each attribute type has pass, copy and interpolate "copy" flags that can be set in the destination to choose which attribute arrays will be transfered from the source to the destination.

Finally this class provides a mechanism to determine which attributes a group of sources have in common, and to copy tuples from a source into the destination, for only those attributes that are held by all.

To create an instance of class vtkDataSetAttributes, simply invoke its constructor as follows

```
obj = vtkDataSetAttributes
```

31.50.2 Methods

The class vtkDataSetAttributes has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetAttributes class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetAttributes = obj.NewInstance ()`
- `vtkDataSetAttributes = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Initialize all of the object's data to NULL Also, clear the copy flags.
- `obj.Update ()` - Deep copy of data (i.e., create new data arrays and copy from input data). Ignores the copy flags but preserves them in the output.

- `obj.DeepCopy (vtkFieldData pd)` - Deep copy of data (i.e., create new data arrays and copy from input data). Ignores the copy flags but preserves them in the output.
- `obj.ShallowCopy (vtkFieldData pd)` - Shallow copy of data (i.e., use reference counting). Ignores the copy flags but preserves them in the output.
- `int = obj.SetScalars (vtkDataArray da)` - Set/Get the scalar data.
- `int = obj.SetActiveScalars (string name)` - Set/Get the scalar data.
- `vtkDataArray = obj.GetScalars ()` - Set/Get the scalar data.
- `int = obj.SetVectors (vtkDataArray da)` - Set/Get the vector data.
- `int = obj.SetActiveVectors (string name)` - Set/Get the vector data.
- `vtkDataArray = obj.GetVectors ()` - Set/Get the vector data.
- `int = obj.SetNormals (vtkDataArray da)` - Set/get the normal data.
- `int = obj.SetActiveNormals (string name)` - Set/get the normal data.
- `vtkDataArray = obj.GetNormals ()` - Set/get the normal data.
- `int = obj.SetTCoords (vtkDataArray da)` - Set/Get the texture coordinate data.
- `int = obj.SetActiveTCoords (string name)` - Set/Get the texture coordinate data.
- `vtkDataArray = obj.GetTCoords ()` - Set/Get the texture coordinate data.
- `int = obj.SetTensors (vtkDataArray da)` - Set/Get the tensor data.
- `int = obj.SetActiveTensors (string name)` - Set/Get the tensor data.
- `vtkDataArray = obj.GetTensors ()` - Set/Get the tensor data.
- `int = obj.SetGlobalIds (vtkDataArray da)` - Set/Get the global id data.
- `int = obj.SetActiveGlobalIds (string name)` - Set/Get the global id data.
- `vtkDataArray = obj.GetGlobalIds ()` - Set/Get the global id data.
- `int = obj.SetPedigreeIds (vtkAbstractArray da)` - Set/Get the pedigree id data.
- `int = obj.SetActivePedigreeIds (string name)` - Set/Get the pedigree id data.
- `vtkAbstractArray = obj.GetPedigreeIds ()` - Set/Get the pedigree id data.
- `vtkDataArray = obj.GetScalars (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.
- `vtkDataArray = obj.GetVectors (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.
- `vtkDataArray = obj.GetNormals (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.
- `vtkDataArray = obj.GetTCoords (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.

- `vtkDataArray = obj.GetTensors (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.

- `vtkDataArray = obj.GetGlobalIds (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.

- `vtkAbstractArray = obj.GetPedigreeIds (string name)` - This will first look for an array with the correct name. If one exists, it is returned. Otherwise, the name argument is ignored, and the active attribute is returned.

- `int = obj.SetActiveAttribute (string name, int attributeType)` - Make the array with the given name the active attribute. Attribute types are: vtkDataSetAttributes::SCALARS = 0 vtkDataSetAttributes::VECTORS = 1 vtkDataSetAttributes::NORMALS = 2 vtkDataSetAttributes::TCOORDS = 3 vtkDataSetAttributes::TENSORS = 4 vtkDataSetAttributes::GLOBALIDS = 5 vtkDataSetAttributes::PEDIGREEIDS = 6 Returns the index of the array if succesful, -1 if the array is not in the list of arrays.

- `int = obj.SetActiveAttribute (int index, int attributeType)` - Make the array with the given index the active attribute.

- `obj.GetAttributeIndices (int indexArray)` - Get the field data array indices corresponding to scalars, vectors, tensors, etc.

- `int = obj.IsArrayAnAttribute (int idx)` - Determine whether a data array of index idx is considered a data set attribute (i.e., scalar, vector, tensor, etc). Return less-than zero if it is, otherwise an index 0¡=idx¡NUM_ATTRIBUTES to indicate which attribute.

- `vtkDataArray = obj.GetAttribute (int attributeType)` - Return an attribute given the attribute type (see vtkDataSetAttributes::AttributeTypes). Some attributes (such as PEDIGREEIDS) may not be vtkDataArray subclass, so in that case use GetAbstractAttribute().

- `vtkAbstractArray = obj.GetAbstractAttribute (int attributeType)` - Return an attribute given the attribute type (see vtkDataSetAttributes::AttributeTypes). This is the same as GetAttribute(), except that the returned array is a vtkAbstractArray instead of vtkDataArray. Some attributes (such as PEDIGREEIDS) may not be vtkDataArray subclass.

- `obj.RemoveArray (string name)` - Remove an array (with the given name) from the list of arrays.

- `obj.SetCopyAttribute (int index, int value, int ctypeALLCOPY)` - Specify whether to copy the data attribute referred to by index. ctype selects from the AttributeCopyOperations. If ctype is set to ALLCOPY, then COPYTUPLE, INTERPOLATE, and PASSDATA are set to value. If value is 0, copying is disallowed. otherwise it is allowed.

- `obj.SetCopyScalars (int i, int ctypeALLCOPY)` - Turn on/off the copying of scalar data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyScalars (int ctypeALLCOPY)` - Turn on/off the copying of scalar data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyScalarsOn ()` - Turn on/off the copying of scalar data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyScalarsOff ()` - Turn on/off the copying of scalar data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.SetCopyVectors (int i, int ctypeALLCOPY)` - Turn on/off the copying of vector data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyVectors (int ctypeALLCOPY)` - Turn on/off the copying of vector data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyVectorsOn ()` - Turn on/off the copying of vector data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyVectorsOff ()` - Turn on/off the copying of vector data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.SetCopyNormals (int i, int ctypeALLCOPY)` - Turn on/off the copying of normals data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyNormals (int ctypeALLCOPY)` - Turn on/off the copying of normals data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyNormalsOn ()` - Turn on/off the copying of normals data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyNormalsOff ()` - Turn on/off the copying of normals data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.SetCopyTCoords (int i, int ctypeALLCOPY)` - Turn on/off the copying of texture coordinates data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyTCoords (int ctypeALLCOPY)` - Turn on/off the copying of texture coordinates data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyTCoordsOn ()` - Turn on/off the copying of texture coordinates data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyTCoordsOff ()` - Turn on/off the copying of texture coordinates data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.SetCopyTensors (int i, int ctypeALLCOPY)` - Turn on/off the copying of tensor data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyTensors (int ctypeALLCOPY)` - Turn on/off the copying of tensor data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyTensorsOn ()` - Turn on/off the copying of tensor data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyTensorsOff ()` - Turn on/off the copying of tensor data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.SetCopyGlobalIds (int i, int ctypeALLCOPY)` - Turn on/off the copying of global id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyGlobalIds (int ctypeALLCOPY)` - Turn on/off the copying of global id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyGlobalIdsOn ()` - Turn on/off the copying of global id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyGlobalIdsOff ()` - Turn on/off the copying of global id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.SetCopyPedigreeIds (int i, int ctypeALLCOPY)` - Turn on/off the copying of pedigree id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `int = obj.GetCopyPedigreeIds (int ctypeALLCOPY)` - Turn on/off the copying of pedigree id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyPedigreeIdsOn ()` - Turn on/off the copying of pedigree id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyPedigreeIdsOff ()` - Turn on/off the copying of pedigree id data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyAllOn (int ctypeALLCOPY)` - Turn on copying of all data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.CopyAllOff (int ctypeALLCOPY)` - Turn off copying of all data. ctype is one of the AttributeCopyOperations, and controls copy, interpolate and passdata behavior. For set, ctype=ALLCOPY means set all three flags to the same value. For get, ctype=ALLCOPY returns true only if all three flags are true.

  During copying, interpolation and passdata, the following rules are followed for each array: 1. If the copy/interpolate/pass flag for an attribute is set (on or off), it is applied. This overrides rules 2 and 3. 2. If the copy flag for an array is set (on or off), it is applied This overrides rule 3. 3. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array

- `obj.PassData (vtkFieldData fd)` - Pass entire arrays of input data through to output. Obey the "copy" flags. When passing a field, the following copying rules are followed: 1) Check if a field is an attribute, if yes and if there is a PASSDATA copy flag for that attribute (on or off), obey the flag for that attribute, ignore (2) and (3), 2) if there is a copy field for that field (on or off), obey the flag, ignore (3) 3) obey CopyAllOn/Off

- `obj.CopyAllocate (vtkDataSetAttributes pd, vtkIdType sze, vtkIdType ext)` - Allocates point data for point-by-point (or cell-by-cell) copy operation. If sze=0, then use the input DataSetAttributes to create (i.e., find initial size of) new objects; otherwise use the sze variable. Note that pd HAS to be the vtkDataSetAttributes object which will later be used with CopyData. If this is not the case, consider using the alternative forms of CopyAllocate and CopyData. ext is no longer used. If shallowCopyArrays is true, input arrays are copied to the output instead of new ones being allocated.

- `obj.CopyAllocate (vtkDataSetAttributes pd, vtkIdType sze, vtkIdType ext, int shallowCopyArrays)` - Allocates point data for point-by-point (or cell-by-cell) copy operation. If sze=0, then use the input DataSetAttributes to create (i.e., find initial size of) new objects; otherwise use the sze variable. Note that pd HAS to be the vtkDataSetAttributes object which will later be used with CopyData. If this is not the case, consider using the alternative forms of CopyAllocate and CopyData. ext is no longer used. If shallowCopyArrays is true, input arrays are copied to the output instead of new ones being allocated.

- `obj.CopyStructuredData (vtkDataSetAttributes inDsa, int inExt, int outExt)` - This method is used to copy data arrays in images. You should call "CopyAllocate" before calling this method.

- `obj.CopyData (vtkDataSetAttributes fromPd, vtkIdType fromId, vtkIdType toId)` - Copy the attribute data from one id to another. Make sure CopyAllocate() has been invoked before using this method. When copying a field, the following copying rules are followed: 1) Check if a field is an attribute, if yes and if there is a COPYTUPLE copy flag for that attribute (on or off), obey the flag for that attribute, ignore (2) and (3), 2) if there is a copy field for that field (on or off), obey the flag, ignore (3) 3) obey CopyAllOn/Off

- `obj.CopyTuple (vtkAbstractArray fromData, vtkAbstractArray toData, vtkIdType fromId, vtkIdType toId` - Copy a tuple of data from one data array to another. This method assumes that the fromData and toData objects are of the same type, and have the same number of components. This is true if you invoke CopyAllocate() or InterpolateAllocate().

- `obj.InterpolateAllocate (vtkDataSetAttributes pd, vtkIdType sze, vtkIdType ext)` - Initialize point interpolation method. Note that pd HAS to be the vtkDataSetAttributes object which will later be used with InterpolatePoint or InterpolateEdge. ext is no longer used. If shallowCopyArrays is true, input arrays are copied to the output instead of new ones being allocated.

- `obj.InterpolateAllocate (vtkDataSetAttributes pd, vtkIdType sze, vtkIdType ext, int shallowCopyArra` - Initialize point interpolation method. Note that pd HAS to be the vtkDataSetAttributes object which will later be used with InterpolatePoint or InterpolateEdge. ext is no longer used. If shallowCopyArrays is true, input arrays are copied to the output instead of new ones being allocated.

- `obj.InterpolatePoint (vtkDataSetAttributes fromPd, vtkIdType toId, vtkIdList ids, double weights)` - Interpolate data set attributes from other data set attributes given cell or point ids and associated interpolation weights. If the INTERPOLATION copy flag is set to 0 for an array, interpolation is prevented. If the flag is set to 1, weighted interpolation occurs. If the flag is set to 2, nearest neighbor interpolation is used.

- `obj.InterpolateEdge (vtkDataSetAttributes fromPd, vtkIdType toId, vtkIdType p1, vtkIdType p2, doubl` - Interpolate data from the two points p1,p2 (forming an edge) and an interpolation factor, t, along the edge. The weight ranges from (0,1), with t=0 located at p1. Make sure that the method InterpolateAllocate() has been invoked before using this method. If the INTERPOLATION copy flag is set to 0 for an array, interpolation is prevented. If the flag is set to 1, weighted interpolation occurs. If the flag is set to 2, nearest neighbor interpolation is used.

- `obj.InterpolateTime (vtkDataSetAttributes from1, vtkDataSetAttributes from2, vtkIdType id, double t` - Interpolate data from the same id (point or cell) at different points in time (parameter t). Two input data set attributes objects are input. The parameter t lies between (0¡=t¡=1). IMPORTANT: it is assumed that the number of attributes and number of components is the same for both from1 and from2, and the type of data for from1 and from2 are the same. Make sure that the method InterpolateAllocate() has been invoked before using this method. If the INTERPOLATION copy flag is set to 0 for an array, interpolation is prevented. If the flag is set to 1, weighted interpolation occurs. If the flag is set to 2, nearest neighbor interpolation is used.

31.51 vtkDataSetCollection

31.51.1 Usage

vtkDataSetCollection is an object that creates and manipulates lists of datasets. See also vtkCollection and subclasses.

To create an instance of class vtkDataSetCollection, simply invoke its constructor as follows

```
obj = vtkDataSetCollection
```

31.51.2 Methods

The class vtkDataSetCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetCollection = obj.NewInstance ()`
- `vtkDataSetCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkDataSet ds)` - Get the next dataset in the list.
- `vtkDataSet = obj.GetNextItem ()` - Get the next dataset in the list.
- `vtkDataSet = obj.GetNextDataSet ()` - Get the next dataset in the list.
- `vtkDataSet = obj.GetItem (int i)` - Get the ith dataset in the list.
- `vtkDataSet = obj.GetDataSet (int i)` - Get the ith dataset in the list.

31.52 vtkDataSetSource

31.52.1 Usage

vtkDataSetSource is an abstract class whose subclasses generate datasets.

To create an instance of class vtkDataSetSource, simply invoke its constructor as follows

```
obj = vtkDataSetSource
```

31.52.2 Methods

The class vtkDataSetSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetSource = obj.NewInstance ()`
- `vtkDataSetSource = obj.SafeDownCast (vtkObject o)`
- `vtkDataSet = obj.GetOutput ()` - Get the output of this source.
- `vtkDataSet = obj.GetOutput (int idx)` - Get the output of this source.
- `obj.SetOutput (vtkDataSet )`

31.53 vtkDataSetToDataSetFilter

31.53.1 Usage

vtkDataSetToDataSetFilter is an abstract filter class. Subclasses of vtkDataSetToDataSetFilter take a dataset as input and create a dataset as output. The form of the input geometry is not changed in these filters, only the point attributes (e.g. scalars, vectors, etc.).

This is an abstract filter type. What that means is that the output of the filter is an abstract type (i.e., vtkDataSet), no matter what the input of the filter is. This can cause problems connecting together filters due to the change in dataset type. (For example, in a series of filters processing vtkPolyData, when a vtkDataSetToDataSetFilter or subclass is introduced into the pipeline, if the filter downstream of it takes vtkPolyData as input, the pipeline connection cannot be made.) To get around this problem, use one of the convenience methods to return a concrete type (e.g., vtkGetPolyDataOutput(), GetStructuredPointsOutput(), etc.).

To create an instance of class vtkDataSetToDataSetFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToDataSetFilter
```

31.53.2 Methods

The class vtkDataSetToDataSetFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToDataSetFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToDataSetFilter = obj.NewInstance ()`
- `vtkDataSetToDataSetFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Specify the input data or filter.
- `vtkDataSet = obj.GetOutput ()` - Get the output of this filter. If output is NULL then input hasn't been set which is necessary for abstract objects.
- `vtkDataSet = obj.GetOutput (int idx)` - Get the output of this filter. If output is NULL then input hasn't been set which is necessary for abstract objects.
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as vtkPolyData.
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output as vtkStructuredPoints.
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as vtkStructuredGrid.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as vtkUnstructuredGrid.
- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output as vtkRectilinearGrid.
- `vtkDataSet = obj.GetInput ()` - Get the input data or filter.
- `obj.ComputeInputUpdateExtents (vtkDataObject output)` - By default copy the output update extent to the input

31.54 vtkDataSetToImageFilter

31.54.1 Usage

vtkDataSetToImageFilter is an abstract filter class whose subclasses take as input any dataset and generate image data on output.

To create an instance of class vtkDataSetToImageFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToImageFilter
```

31.54.2 Methods

The class vtkDataSetToImageFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToImageFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToImageFilter = obj.NewInstance ()`
- `vtkDataSetToImageFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Set / get the input data or filter.
- `vtkDataSet = obj.GetInput ()` - Set / get the input data or filter.

31.55 vtkDataSetToPolyDataFilter

31.55.1 Usage

vtkDataSetToPolyDataFilter is an abstract filter class whose subclasses take as input any dataset and generate polygonal data on output.

To create an instance of class vtkDataSetToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToPolyDataFilter
```

31.55.2 Methods

The class vtkDataSetToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToPolyDataFilter = obj.NewInstance ()`
- `vtkDataSetToPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Set / get the input data or filter.
- `vtkDataSet = obj.GetInput ()` - Set / get the input data or filter.
- `obj.ComputeInputUpdateExtents (vtkDataObject output)` - Do not let images return more than requested.

31.56 vtkDataSetToStructuredGridFilter

31.56.1 Usage

vtkDataSetToStructuredGridFilter is an abstract filter class whose subclasses take as input any dataset and generate a structured grid on output.

To create an instance of class vtkDataSetToStructuredGridFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToStructuredGridFilter
```

31.56.2 Methods

The class vtkDataSetToStructuredGridFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToStructuredGridFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToStructuredGridFilter = obj.NewInstance ()`
- `vtkDataSetToStructuredGridFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Set / get the input data or filter.
- `vtkDataSet = obj.GetInput ()` - Set / get the input data or filter.

31.57 vtkDataSetToStructuredPointsFilter

31.57.1 Usage

vtkDataSetToStructuredPointsFilter is an abstract filter class whose subclasses take as input any dataset and generate structured points data on output.

To create an instance of class vtkDataSetToStructuredPointsFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToStructuredPointsFilter
```

31.57.2 Methods

The class vtkDataSetToStructuredPointsFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToStructuredPointsFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToStructuredPointsFilter = obj.NewInstance ()`
- `vtkDataSetToStructuredPointsFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Set / get the input data or filter.
- `vtkDataSet = obj.GetInput ()` - Set / get the input data or filter.

31.58 vtkDataSetToUnstructuredGridFilter

31.58.1 Usage

vtkDataSetToUnstructuredGridFilter is an abstract filter class whose subclasses take as input any dataset and generate an unstructured grid on output.

To create an instance of class vtkDataSetToUnstructuredGridFilter, simply invoke its constructor as follows

```
obj = vtkDataSetToUnstructuredGridFilter
```

31.58.2 Methods

The class vtkDataSetToUnstructuredGridFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDataSetToUnstructuredGridFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDataSetToUnstructuredGridFilter = obj.NewInstance ()`
- `vtkDataSetToUnstructuredGridFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkDataSet input)` - Set / get the input data or filter.
- `vtkDataSet = obj.GetInput ()` - Set / get the input data or filter.

31.59 vtkDemandDrivenPipeline

31.59.1 Usage

vtkDemandDrivenPipeline is an executive that will execute an algorithm only when its outputs are out-of-date with respect to its inputs.

To create an instance of class vtkDemandDrivenPipeline, simply invoke its constructor as follows

```
obj = vtkDemandDrivenPipeline
```

31.59.2 Methods

The class vtkDemandDrivenPipeline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDemandDrivenPipeline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDemandDrivenPipeline = obj.NewInstance ()`
- `vtkDemandDrivenPipeline = obj.SafeDownCast (vtkObject o)`
- `int = obj.Update ()` - Bring the algorithm's outputs up-to-date. Returns 1 for success and 0 for failure.
- `int = obj.Update (int port)` - Bring the algorithm's outputs up-to-date. Returns 1 for success and 0 for failure.

- `long = obj.GetPipelineMTime ()` - Get the PipelineMTime for this exective.
- `int = obj.SetReleaseDataFlag (int port, int n)` - Set whether the given output port releases data when it is consumed. Returns 1 if the the value changes and 0 otherwise.
- `int = obj.GetReleaseDataFlag (int port)` - Get whether the given output port releases data when it is consumed.
- `int = obj.UpdatePipelineMTime ()` - Bring the PipelineMTime up to date.
- `int = obj.UpdateDataObject ()` - Bring the output data object's existence up to date. This does not actually produce data, but does create the data object that will store data produced during the UpdateData step.
- `int = obj.UpdateInformation ()` - Bring the output information up to date.
- `int = obj.UpdateData (int outputPort)` - Bring the output data up to date. This should be called only when information is up to date. Use the Update method if it is not known that the information is up to date.

31.60 vtkDirectedAcyclicGraph

31.60.1 Usage

vtkDirectedAcyclicGraph is a connected directed graph with no cycles. A tree is a type of directed graph, so works with all graph algorithms.

vtkDirectedAcyclicGraph is a read-only data structure. To construct a tree, create an instance of vtkMutableDirectedGraph. Add vertices and edges with AddVertex() and AddEdge(). You may alternately start by adding a single vertex as the root then call graph-¿AddChild(parent) which adds a new vertex and connects the parent to the child. The tree MUST have all edges in the proper direction, from parent to child. After building the tree, call tree-¿CheckedShallowCopy(graph) to copy the structure into a vtkDirectedAcyclicGraph. This method will return false if the graph is an invalid tree.

vtkDirectedAcyclicGraph provides some convenience methods for obtaining the parent and children of a vertex, for finding the root, and determining if a vertex is a leaf (a vertex with no children).

To create an instance of class vtkDirectedAcyclicGraph, simply invoke its constructor as follows

```
obj = vtkDirectedAcyclicGraph
```

31.60.2 Methods

The class vtkDirectedAcyclicGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDirectedAcyclicGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDirectedAcyclicGraph = obj.NewInstance ()`
- `vtkDirectedAcyclicGraph = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()`

31.61 vtkDirectedGraph

31.61.1 Usage

vtkDirectedGraph is a collection of vertices along with a collection of directed edges (edges that have a source and target). ShallowCopy() and DeepCopy() (and CheckedShallowCopy(), CheckedDeepCopy()) accept instances of vtkTree and vtkMutableDirectedGraph.

vtkDirectedGraph is read-only. To create an undirected graph, use an instance of vtkMutableDirectedGraph, then you may set the structure to a vtkDirectedGraph using ShallowCopy().

To create an instance of class vtkDirectedGraph, simply invoke its constructor as follows

```
obj = vtkDirectedGraph
```

31.61.2 Methods

The class vtkDirectedGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDirectedGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDirectedGraph = obj.NewInstance ()`
- `vtkDirectedGraph = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()`

31.62 vtkDirectedGraphAlgorithm

31.62.1 Usage

vtkDirectedGraphAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline edgehitecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be Graph. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation. For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

.SECTION Thanks Thanks to Patricia Crossno, Ken Moreland, Andrew Wilson and Brian Wylie from Sandia National Laboratories for their help in developing this class.

To create an instance of class vtkDirectedGraphAlgorithm, simply invoke its constructor as follows

```
obj = vtkDirectedGraphAlgorithm
```

31.62.2 Methods

The class vtkDirectedGraphAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDirectedGraphAlgorithm class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkDirectedGraphAlgorithm = obj.NewInstance ()`
- `vtkDirectedGraphAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkDirectedGraph = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkDirectedGraph = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.63 vtkDiscretizableColorTransferFunction

31.63.1 Usage

This is a cross between a vtkColorTransferFunction and a vtkLookupTable selectively combiniting the functionality of both. NOTE: One must call Build() after making any changes to the points in the ColorTransferFunction to ensure that the discrete and non-discrete version match up.

To create an instance of class vtkDiscretizableColorTransferFunction, simply invoke its constructor as follows

```
obj = vtkDiscretizableColorTransferFunction
```

31.63.2 Methods

The class vtkDiscretizableColorTransferFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDiscretizableColorTransferFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDiscretizableColorTransferFunction = obj.NewInstance ()`
- `vtkDiscretizableColorTransferFunction = obj.SafeDownCast (vtkObject o)`
- `obj.Build ()` - Generate discretized lookup table, if applicable. This method must be called after changes to the ColorTransferFunction otherwise the discretized version will be inconsitent with the non-discretized one.
- `obj.SetDiscretize (int )` - Set if the values are to mapped after discretization. The number of discrete values is set by using SetNumberOfValues(). Not set by default, i.e. color value is determined by interpolating at the scalar value.

- `int = obj.GetDiscretize ()` - Set if the values are to mapped after discretization. The number of discrete values is set by using SetNumberOfValues(). Not set by default, i.e. color value is determined by interpolating at the scalar value.
- `obj.DiscretizeOn ()` - Set if the values are to mapped after discretization. The number of discrete values is set by using SetNumberOfValues(). Not set by default, i.e. color value is determined by interpolating at the scalar value.
- `obj.DiscretizeOff ()` - Set if the values are to mapped after discretization. The number of discrete values is set by using SetNumberOfValues(). Not set by default, i.e. color value is determined by interpolating at the scalar value.
- `obj.SetUseLogScale (int useLogScale)` - Get/Set if log scale must be used while mapping scalars to colors. The default is 0.
- `int = obj.GetUseLogScale ()` - Get/Set if log scale must be used while mapping scalars to colors. The default is 0.
- `obj.SetNumberOfValues (vtkIdType number)` - Set the number of values i.e. colors to be generated in the discrete lookup table. This has no effect if Discretize is off. The default is 256.
- `vtkIdType = obj.GetNumberOfValues ()` - Set the number of values i.e. colors to be generated in the discrete lookup table. This has no effect if Discretize is off. The default is 256.
- `obj.GetColor (double v, double rgb[3])` - Map one value through the lookup table and return the color as an RGB array of doubles between 0 and 1.
- `vtkUnsignedCharArray = obj.MapScalars (vtkDataArray scalars, int colorMode, int component)` - An internal method maps a data array into a 4-component, unsigned char RGBA array. The color mode determines the behavior of mapping. If VTK_COLOR_MODE_DEFAULT is set, then unsigned char data arrays are treated as colors (and converted to RGBA if necessary); otherwise, the data is mapped through this instance of ScalarsToColors. The offset is used for data arrays with more than one component; it indicates which component to use to do the blending. When the component argument is -1, then the this object uses its own selected technique to change a vector into a scalar to map.
- `obj.SetAlpha (double alpha)` - Specify an additional opacity (alpha) value to blend with. Values != 1 modify the resulting color consistent with the requested form of the output. This is typically used by an actor in order to blend its opacity. Overridden to pass the alpha to the internal vtkLookupTable.
- `int = obj.UsingLogScale ()`

31.64 vtkDistributedGraphHelper

31.64.1 Usage

A distributed graph helper can be attached to an empty vtkGraph object to turn the vtkGraph into a distributed graph, whose vertices and edges are distributed across several different processors. vtkDistributedGraphHelper is an abstract class. Use a subclass of vtkDistributedGraphHelper, such as vtkPBGLDistributedGraphHelper, to build distributed graphs.

The distributed graph helper provides facilities used by vtkGraph to communicate with other processors that store other parts of the same distributed graph. The only user-level functionality provided by vtkDistributedGraphHelper involves this communication among processors and the ability to map between "distributed" vertex and edge IDs and their component parts (processor and local index). For example, the Synchronize() method provides a barrier that allows all processors to catch up to the same point in the code before any processor can leave that Synchronize() call. For example, one would call Synchronize() after adding many edges to a distributed graph, so that all processors can handle the addition of inter-processor edges and continue, after the Synchronize() call, with a consistent view of the distributed graph. For more information about manipulating (distributed) graphs, see the vtkGraph documentation.

To create an instance of class vtkDistributedGraphHelper, simply invoke its constructor as follows

```
obj = vtkDistributedGraphHelper
```

31.64.2 Methods

The class vtkDistributedGraphHelper has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkDistributedGraphHelper class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkDistributedGraphHelper = obj.NewInstance ()`
- `vtkDistributedGraphHelper = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetVertexOwner (vtkIdType v) const` - Returns owner of vertex v, by extracting top ceil(log2 P) bits of v.
- `vtkIdType = obj.GetVertexIndex (vtkIdType v) const` - Returns local index of vertex v, by masking off top ceil(log2 P) bits of v.
- `vtkIdType = obj.GetEdgeOwner (vtkIdType e\_id) const` - Returns owner of edge with ID e_id, by extracting top ceil(log2 P) bits of e_id.
- `vtkIdType = obj.GetEdgeIndex (vtkIdType e\_id) const` - Returns local index of edge with ID e_id, by masking off top ceil(log2 P) bits of e_id.
- `vtkIdType = obj.MakeDistributedId (int owner, vtkIdType local)` - Builds a distributed ID consisting of the given owner and the local ID.
- `obj.Synchronize ()` - Synchronizes all of the processors involved in this distributed graph, so that all processors have a consistent view of the distributed graph for the computation that follows. This routine should be invoked after adding new edges into the distributed graph, so that other processors will see those edges (or their corresponding back-edges).
- `vtkDistributedGraphHelper = obj.Clone ()` - Clones the distributed graph helper, returning another distributed graph helper of the same kind that can be used in another vtkGraph.

31.65 vtkEdgeListIterator

31.65.1 Usage

vtkEdgeListIterator iterates through all the edges in a graph, by traversing the adjacency list for each vertex. You may instantiate this class directly and call SetGraph() to traverse a certain graph. You may also call the graph's GetEdges() method to set up the iterator for a certain graph.

Note that this class does NOT guarantee that the edges will be processed in order of their ids (i.e. it will not necessarily return edge 0, then edge 1, etc.).

To create an instance of class vtkEdgeListIterator, simply invoke its constructor as follows

```
obj = vtkEdgeListIterator
```

31.65.2 Methods

The class vtkEdgeListIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEdgeListIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEdgeListIterator = obj.NewInstance ()`
- `vtkEdgeListIterator = obj.SafeDownCast (vtkObject o)`
- `vtkGraph = obj.GetGraph ()`
- `obj.SetGraph (vtkGraph graph)`
- `vtkGraphEdge = obj.NextGraphEdge ()` - Just like Next(), but returns heavy-weight vtkGraphEdge object instead of the vtkEdgeType struct, for use with wrappers. The graph edge is owned by this iterator, and changes after each call to NextGraphEdge().
- `bool = obj.HasNext ()` - Whether this iterator has more edges.

31.66 vtkEmptyCell

31.66.1 Usage

vtkEmptyCell is a concrete implementation of vtkCell. It is used during processing to represented a deleted element.

To create an instance of class vtkEmptyCell, simply invoke its constructor as follows

```
obj = vtkEmptyCell
```

31.66.2 Methods

The class vtkEmptyCell has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkEmptyCell class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkEmptyCell = obj.NewInstance ()`
- `vtkEmptyCell = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.

- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.InterpolateFunctions (double pcoords[3], double weights)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

31.67 vtkExecutive

31.67.1 Usage

vtkExecutive is the superclass for all pipeline executives in VTK. A VTK executive is responsible for controlling one instance of vtkAlgorithm. A pipeline consists of one or more executives that control data flow. Every reader, source, writer, or data processing algorithm in the pipeline is implemented in an instance of vtkAlgorithm.

To create an instance of class vtkExecutive, simply invoke its constructor as follows

```
obj = vtkExecutive
```

31.67.2 Methods

The class vtkExecutive has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExecutive class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExecutive = obj.NewInstance ()`
- `vtkExecutive = obj.SafeDownCast (vtkObject o)`
- `vtkAlgorithm = obj.GetAlgorithm ()` - Get the algorithm to which this executive has been assigned.
- `int = obj.Update ()` - Bring the algorithm's outputs up-to-date. Returns 1 for success and 0 for failure.
- `int = obj.Update (int port)` - Bring the algorithm's outputs up-to-date. Returns 1 for success and 0 for failure.
- `int = obj.GetNumberOfInputPorts ()` - Get the number of input/output ports for the algorithm associated with this executive. Returns 0 if no algorithm is set.
- `int = obj.GetNumberOfOutputPorts ()` - Get the number of input/output ports for the algorithm associated with this executive. Returns 0 if no algorithm is set.

- `int = obj.GetNumberOfInputConnections (int port)` - Get the number of input connections on the given port.
- `vtkInformation = obj.GetOutputInformation (int port)` - Get the pipeline information object for the given output port.
- `vtkInformationVector = obj.GetOutputInformation ()` - Get the pipeline information object for all output ports.
- `vtkInformation = obj.GetInputInformation (int port, int connection)` - Get the pipeline information for the given input connection.
- `vtkInformationVector = obj.GetInputInformation (int port)` - Get the pipeline information vectors for the given input port.
- `vtkExecutive = obj.GetInputExecutive (int port, int connection)` - Get the executive managing the given input connection.
- `vtkDataObject = obj.GetOutputData (int port)` - Get/Set the data object for an output port of the algorithm.
- `obj.SetOutputData (int port, vtkDataObject , vtkInformation info)` - Get/Set the data object for an output port of the algorithm.
- `obj.SetOutputData (int port, vtkDataObject )` - Get/Set the data object for an output port of the algorithm.
- `vtkDataObject = obj.GetInputData (int port, int connection)` - Get the data object for an input port of the algorithm.
- `vtkAlgorithmOutput = obj.GetProducerPort (vtkDataObject )` - Get the output port that produces the given data object.
- `obj.SetSharedOutputInformation (vtkInformationVector outInfoVec)` - Set a pointer to an outside instance of input or output information vectors. No references are held to the given vectors, and setting this does not change the executive object modification time. This is a preliminary interface to use in implementing filters with internal pipelines, and may change without notice when a future interface is created.
- `obj.Register (vtkObjectBase o)` - Participate in garbage collection.
- `obj.UnRegister (vtkObjectBase o)` - Participate in garbage collection.

31.68 vtkExecutiveCollection

31.68.1 Usage

vtkExecutiveCollection is an object that creates and manipulates lists of objects that are (inherited from) vtkExecutives.

To create an instance of class vtkExecutiveCollection, simply invoke its constructor as follows

```
obj = vtkExecutiveCollection
```

31.68.2 Methods

The class vtkExecutiveCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExecutiveCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExecutiveCollection = obj.NewInstance ()`
- `vtkExecutiveCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkExecutive exec)` - Get the next executive in the list.
- `vtkExecutive = obj.GetNextItem ()`

31.69 vtkExplicitCell

31.69.1 Usage

vtkExplicitCell is an abstract superclass for cells that cannot be represented implicitly. An implicit representation requires only a cell type and connectivity list (e.g., triangle). Explicit cells require information beyond this; e.g., a NURBS surface or cells that require explicit face/edge descriptions. Most cells in VTK are implicitly represented.

To create an instance of class vtkExplicitCell, simply invoke its constructor as follows

```
obj = vtkExplicitCell
```

31.69.2 Methods

The class vtkExplicitCell has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkExplicitCell class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkExplicitCell = obj.NewInstance ()`
- `vtkExplicitCell = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsExplicitCell ()` - Set/Get the cell id. This is necessary for explicit cells because they often need to keep extra information (typically contained in the cell data of a point set). This information might be things like knot points/weights, boundaries, etc.
- `obj.SetCellId (vtkIdType )` - Set/Get the cell id. This is necessary for explicit cells because they often need to keep extra information (typically contained in the cell data of a point set). This information might be things like knot points/weights, boundaries, etc.
- `vtkIdType = obj.GetCellId ()` - Set/Get the cell id. This is necessary for explicit cells because they often need to keep extra information (typically contained in the cell data of a point set). This information might be things like knot points/weights, boundaries, etc.

- `obj.SetDataSet (vtkDataSet )` - Set/Get the mesh that owns this cell. This is necessary for explicit cells because they often need to keep extra information (typically contained in the cell data of a point set). This information might be things like knot points/weights, boundaries, etc.
- `vtkDataSet = obj.GetDataSet ()` - Set/Get the mesh that owns this cell. This is necessary for explicit cells because they often need to keep extra information (typically contained in the cell data of a point set). This information might be things like knot points/weights, boundaries, etc.

31.70 vtkFieldData

31.70.1 Usage

vtkFieldData represents and manipulates fields of data. The model of a field is a m x n matrix of data values, where m is the number of tuples, and n is the number of components. (A tuple is a row of n components in the matrix.) The field is assumed to be composed of a set of one or more data arrays, where the data in the arrays are of different types (e.g., int, double, char, etc.), and there may be variable numbers of components in each array. Note that each data array is assumed to be "m" in length (i.e., number of tuples), which typically corresponds to the number of points or cells in a dataset. Also, each data array must have a character-string name. (This is used to manipulate data.)

There are two ways of manipulating and interfacing to fields. You can do it generically by manipulating components/tuples via a double-type data exchange, or you can do it by grabbing the arrays and manipulating them directly. The former is simpler but performs type conversion, which is bad if your data has non-castable types like (void) pointers, or you lose information as a result of the cast. The, more efficient method means managing each array in the field. Using this method you can create faster, more efficient algorithms that do not lose information.

To create an instance of class vtkFieldData, simply invoke its constructor as follows

```
obj = vtkFieldData
```

31.70.2 Methods

The class vtkFieldData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkFieldData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkFieldData = obj.NewInstance ()`
- `vtkFieldData = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Release all data but do not delete object. Also, clear the copy flags.
- `int = obj.Allocate (vtkIdType sz, vtkIdType ext)` - Allocate data for each array. Note that ext is no longer used.
- `obj.CopyStructure (vtkFieldData )` - Copy data array structure from a given field. The same arrays will exist with the same types, but will contain nothing in the copy.
- `obj.AllocateArrays (int num)` - AllocateOfArrays actually sets the number of vtkAbstractArray pointers in the vtkFieldData object, not the number of used pointers (arrays). Adding more arrays will cause the object to dynamically adjust the number of pointers if it needs to extend. Although AllocateArrays can be used if the number of arrays which will be added is known, it can be omitted with a small computation cost.

- `int = obj.GetNumberOfArrays ()` - Add an array to the array list. If an array with the same name already exists - then the added array will replace it.
- `int = obj.AddArray (vtkAbstractArray array)` - Add an array to the array list. If an array with the same name already exists - then the added array will replace it.
- `obj.RemoveArray (string name)` - Return the ith array in the field. A NULL is returned if the index i is out of range. A NULL is returned if the array at the given index is not a vtkDataArray.
- `vtkDataArray = obj.GetArray (int i)` - Return the ith array in the field. A NULL is returned if the index i is out of range. A NULL is returned if the array at the given index is not a vtkDataArray.
- `vtkDataArray = obj.GetArray (string arrayName)` - Returns the ith array in the field. Unlike GetArray(), this method returns a vtkAbstractArray. A NULL is returned only if the index i is out of range.
- `vtkAbstractArray = obj.GetAbstractArray (int i)` - Returns the ith array in the field. Unlike GetArray(), this method returns a vtkAbstractArray. A NULL is returned only if the index i is out of range.
- `vtkAbstractArray = obj.GetAbstractArray (string arrayName)` - Return 1 if an array with the given name could be found. 0 otherwise.
- `int = obj.HasArray (string name)` - Get the name of ith array. Note that this is equivalent to: GetAbstractArray(i)-¿GetName() if ith array pointer is not NULL
- `string = obj.GetArrayName (int i)` - Pass entire arrays of input data through to output. Obey the "copy" flags.
- `obj.PassData (vtkFieldData fd)` - Pass entire arrays of input data through to output. Obey the "copy" flags.
- `obj.CopyFieldOn (string name)` - Turn on/off the copying of the field specified by name. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array
- `obj.CopyFieldOff (string name)` - Turn on copying of all data. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array
- `obj.CopyAllOn (int unused)` - Turn on copying of all data. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array
- `obj.CopyAllOff (int unused)` - Turn off copying of all data. During the copying/passing, the following rules are followed for each array: 1. If the copy flag for an array is set (on or off), it is applied This overrides rule 2. 2. If CopyAllOn is set, copy the array. If CopyAllOff is set, do not copy the array
- `obj.DeepCopy (vtkFieldData da)` - Copy a field by creating new data arrays (i.e., duplicate storage).
- `obj.ShallowCopy (vtkFieldData da)` - Copy a field by reference counting the data arrays.
- `obj.Squeeze ()` - Squeezes each data array in the field (Squeeze() reclaims unused memory.)
- `obj.Reset ()` - Resets each data array in the field (Reset() does not release memory but it makes the arrays look like they are empty.)

- `long = obj.GetActualMemorySize ()` - Return the memory in kilobytes consumed by this field data. Used to support streaming and reading/writing data. The value returned is guaranteed to be greater than or equal to the memory required to actually represent the data represented by this object.
- `long = obj.GetMTime ()` - Check object's components for modified times.
- `obj.GetField (vtkIdList ptId, vtkFieldData f)` - Get a field from a list of ids. Supplied field f should have same types and number of data arrays as this one (i.e., like CopyStructure() creates). This method should not be used if the instance is from a subclass of vtkFieldData (vtkPointData or vtkCellData). This is because in those cases, the attribute data is stored with the other fields and will cause the method to behave in an unexpected way.
- `int = obj.GetNumberOfComponents ()` - Get the number of components in the field. This is determined by adding up the components in each non-NULL array. This method should not be used if the instance is from a subclass of vtkFieldData (vtkPointData or vtkCellData). This is because in those cases, the attribute data is stored with the other fields and will cause the method to behave in an unexpected way.
- `vtkIdType = obj.GetNumberOfTuples ()` - Get the number of tuples in the field. Note: some fields have arrays with different numbers of tuples; this method returns the number of tuples in the first array. Mixed-length arrays may have to be treated specially. This method should not be used if the instance is from a subclass of vtkFieldData (vtkPointData or vtkCellData). This is because in those cases, the attribute data is stored with the other fields and will cause the method to behave in an unexpected way.
- `obj.SetNumberOfTuples (vtkIdType number)` - Set the number of tuples for each data array in the field. This method should not be used if the instance is from a subclass of vtkFieldData (vtkPointData or vtkCellData). This is because in those cases, the attribute data is stored with the other fields and will cause the method to behave in an unexpected way.
- `obj.SetTuple (vtkIdType i, vtkIdType j, vtkFieldData source)` - Set the jth tuple in source field data at the ith location. Set operations mean that no range checking is performed, so they're faster.
- `obj.InsertTuple (vtkIdType i, vtkIdType j, vtkFieldData source)` - Insert the jth tuple in source field data at the ith location. Range checking is performed and memory allocates as necessary.
- `vtkIdType = obj.InsertNextTuple (vtkIdType j, vtkFieldData source)` - Insert the jth tuple in source field data at the end of the tuple matrix. Range checking is performed and memory is allocated as necessary.
- `obj.GetTuple (vtkIdType i, double tuple)` - Copy the ith tuple value into a user provided tuple array. Make sure that you've allocated enough space for the copy. @deprecated as of VTK 5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.
- `obj.SetTuple (vtkIdType i, double tuple)` - Set the tuple value at the ith location. Set operations mean that no range checking is performed, so they're faster. @deprecated as of VTK 5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.
- `obj.InsertTuple (vtkIdType i, double tuple)` - Insert the tuple value at the ith location. Range checking is performed and memory allocates as necessary. @deprecated as of VTK 5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.
- `vtkIdType = obj.InsertNextTuple (double tuple)` - Insert the tuple value at the end of the tuple matrix. Range checking is performed and memory is allocated as necessary. @deprecated as of VTK

5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.

- `double = obj.GetComponent (vtkIdType i, int j)` - Get the component value at the ith tuple (or row) and jth component (or column). @deprecated as of VTK 5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.
- `obj.SetComponent (vtkIdType i, int j, double c)` - Set the component value at the ith tuple (or row) and jth component (or column). Range checking is not performed, so set the object up properly before invoking. @deprecated as of VTK 5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.
- `obj.InsertComponent (vtkIdType i, int j, double c)` - Insert the component value at the ith tuple (or row) and jth component (or column). Range checking is performed and memory allocated as necessary o hold data. @deprecated as of VTK 5.2. Using this method for FieldData having arrays that are not subclasses of vtkDataArray may yield unexpected results.

31.71 vtkGenericAdaptorCell

31.71.1 Usage

In VTK, spatial-temporal data is defined in terms of a dataset which is composed of cells. The cells are topological entities over which an interpolation field is applied. Cells are defined in terms of a topology (e.g., vertices, lines, triangles, polygons, tetrahedra, etc.), points that instantiate the geometry of the cells, and interpolation fields (in the general case one interpolation field is for geometry, the other is for attribute data associated with the cell).

Currently most algorithms in VTK use vtkCell and vtkDataSet, which make assumptions about the nature of datasets, cells, and attributes. In particular, this abstraction assumes that cell interpolation functions are linear, or products of linear functions. Further, VTK implements most of the interpolation functions. This implementation starts breaking down as the complexity of the interpolation (or basis) functions increases.

vtkGenericAdaptorCell addresses these issues by providing more general abstraction for cells. It also adopts modern C++ practices including using iterators. The vtkGenericAdaptorCell is designed to fit within the adaptor framework; meaning that it is meant to adapt VTK to external simulation systems (see the GenericFiltering/README.html).

Please note that most cells are defined in terms of other cells (the boundary cells). They are also defined in terms of points, which are not the same as vertices (vertices are a 0-D cell; points represent a position in space).

Another important concept is the notion of DOFNodes. These concept supports cell types with complex interpolation functions. For example, higher-order p-method finite elements may have different functions on each of their topological features (edges, faces, region). The coefficients of these polynomial functions are associated with DOFNodes. (There is a single DOFNode for each topological feature.) Note that from this perspective, points are used to establish the topological form of the cell; mid-side nodes and such are considered DOFNodes.

To create an instance of class vtkGenericAdaptorCell, simply invoke its constructor as follows

```
obj = vtkGenericAdaptorCell
```

31.71.2 Methods

The class vtkGenericAdaptorCell has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericAdaptorCell class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkGenericAdaptorCell = obj.NewInstance ()`
- `vtkGenericAdaptorCell = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.GetId ()` - Unique identification number of the cell over the whole data set. This unique key may not be contiguous.
- `int = obj.IsInDataSet ()` - Does 'this' a cell of a dataset? (otherwise, it is a boundary cell)
- `int = obj.GetType ()` - Return the type of the current cell.
  (result==VTK_HIGHER_ORDER_TRIANGLE)—— (result==VTK_HIGHER_ORDER_TETRAHEDRON)
- `int = obj.GetDimension ()` - Return the topological dimension of the current cell.
- `int = obj.GetGeometryOrder ()` - Return the interpolation order of the geometry.
- `int = obj.IsGeometryLinear ()` - Does the cell have a non-linear interpolation for the geometry?
- `int = obj.GetAttributeOrder (vtkGenericAttribute a)` - Return the interpolation order of attribute 'a' on the cell (may differ by cell).
- `int = obj.GetHighestOrderAttribute (vtkGenericAttributeCollection ac)` - Return the index of the first point centered attribute with the highest order in 'ac'.
- `int = obj.IsAttributeLinear (vtkGenericAttribute a)` - Does the attribute 'a' have a non-linear interpolation?
- `int = obj.IsPrimary ()` - Is the cell primary (i.e. not composite) ?
- `int = obj.GetNumberOfPoints ()` - Return the number of corner points that compose the cell.
- `int = obj.GetNumberOfBoundaries (int dim)` - Return the number of boundaries of dimension 'dim' (or all dimensions greater than 0 and less than GetDimension() if -1) of the cell. When dim is -1, the number of vertices is not included in the count because vertices are a special case: a vertex will have at most a single field value associated with it; DOF nodes may have an arbitrary number of field values associated with them.
- `int = obj.GetNumberOfDOFNodes ()` - Accumulated number of DOF nodes of the current cell. A DOF node is a component of cell with a given topological dimension. e.g.: a triangle has 4 DOF: 1 face and 3 edges. An hexahedron has 19 DOF: 1 region, 6 faces, and 12 edges.

  The number of vertices is not included in the count because vertices are a special case: a vertex will have at most a single field value associated with it; DOF nodes may have an arbitrary number of field values associated with them.
- `obj.GetPointIterator (vtkGenericPointIterator it)` - Return the points of cell into 'it'.
- `vtkGenericCellIterator = obj.NewCellIterator ()` - Create an empty cell iterator. The user is responsible for deleting it.
- `obj.GetBoundaryIterator (vtkGenericCellIterator boundaries, int dim)` - Return the 'boundaries' cells of dimension 'dim' (or all dimensions less than GetDimension() if -1) that are part of the boundary of the cell.
- `int = obj.CountNeighbors (vtkGenericAdaptorCell boundary)` - Number of cells (dimension¿boundary-¿GetDimension()) of the dataset that share the boundary 'boundary' of 'this'. 'this' IS NOT INCLUDED.
- `obj.CountEdgeNeighbors (int sharing)` - Number of cells (dimension¿boundary-¿GetDimension()) of the dataset that share the boundary 'boundary' of 'this'. 'this' IS NOT INCLUDED.

- `obj.GetNeighbors (vtkGenericAdaptorCell boundary, vtkGenericCellIterator neighbors)` - Put into 'neighbors' the cells (dimension¿boundary-¿GetDimension()) of the dataset that share the boundary 'boundary' with this cell. 'this' IS NOT INCLUDED.

- `obj.EvaluateLocation (int subId, double pcoords[3], double x[3])` - Determine the global coordinates 'x' from sub-cell 'subId' and parametric coordinates 'pcoords' in the cell.

  &&(pcoords[1]¡=1)&&(0¡=pcoords[2])&&(pcoords[2]¡=1)

- `obj.InterpolateTuple (vtkGenericAttribute a, double pcoords[3], double val)` - Interpolate the attribute 'a' at local position 'pcoords' of the cell into 'val'.

  pcoords[1]¡=1 && pcoords[2]¿=0 && pcoords[2]¡=1

- `obj.InterpolateTuple (vtkGenericAttributeCollection c, double pcoords[3], double val)` - Interpolate the whole collection of attributes 'c' at local position 'pcoords' of the cell into 'val'. Only point centered attributes are taken into account.

  pcoords[1]¡=1 && pcoords[2]¿=0 && pcoords[2]¡=1

- `obj.Contour (vtkContourValues values, vtkImplicitFunction f, vtkGenericAttributeCollection attribut` - Generate a contour (contouring primitives) for each 'values' or with respect to an implicit function 'f'. Contouring is performed on the scalar attribute ('attributes-¿GetActiveAttribute()' 'attributes-¿GetActiveComponent()'). Contouring interpolates the 'attributes-¿GetNumberOfattributesToInterpolate()' attributes 'attributes-¿GetAttributesToInterpolate()'. The 'locator', 'verts', 'lines', 'polys', 'outPd' and 'outCd' are cumulative data arrays over cell iterations: they store the result of each call to Contour(): - 'locator' is a points list that merges points as they are inserted (i.e., prevents duplicates). - 'verts' is an array of generated vertices - 'lines' is an array of generated lines - 'polys' is an array of generated polygons - 'outPd' is an array of interpolated point data along the edge (if not-NULL) - 'outCd' is an array of copied cell data of the current cell (if not-NULL) 'internalPd', 'secondaryPd' and 'secondaryCd' are initialized by the filter that call it from 'attributes'. - 'internalPd' stores the result of the tessellation pass: the higher-order cell is tessellated into linear sub-cells. - 'secondaryPd' and 'secondaryCd' are used internally as inputs to the Contour() method on linear sub-cells. Note: the CopyAllocate() method must be invoked on both 'outPd' and 'outCd', from 'secondaryPd' and 'secondaryCd'.

  NOTE: 'vtkGenericAttributeCollection *attributes' will be replaced by a 'vtkInformation'.

- `obj.Clip (double value, vtkImplicitFunction f, vtkGenericAttributeCollection attributes, vtkGeneric` - Cut (or clip) the current cell with respect to the contour defined by the 'value' or the implicit function 'f' of the scalar attribute ('attributes-¿GetActiveAttribute()','attributes-¿GetActiveComponent()'). If 'f' exists, 'value' is not used. The output is the part of the current cell which is inside the contour. The output is a set of zero, one or more cells of the same topological dimension as the current cell. Normally, cell points whose scalar value is greater than "value" are considered inside. If 'insideOut' is on, this is reversed. Clipping interpolates the 'attributes-¿GetNumberOfattributesToInterpolate()' attributes 'attributes-¿GetAttributesToInterpolate()'. 'locator', 'connectivity', 'outPd' and 'outCd' are cumulative data arrays over cell iterations: they store the result of each call to Clip(): - 'locator' is a points list that merges points as they are inserted (i.e., prevents duplicates). - 'connectivity' is an array of generated cells - 'outPd' is an array of interpolated point data along the edge (if not-NULL) - 'outCd' is an array of copied cell data of the current cell (if not-NULL) 'internalPd', 'secondaryPd' and 'secondaryCd' are initialized by the filter that call it from 'attributes'. - 'internalPd' stores the result of the tessellation pass: the higher-order cell is tessellated into linear sub-cells. - 'secondaryPd' and 'secondaryCd' are used internally as inputs to the Clip() method on linear sub-cells. Note: the CopyAllocate() method must be invoked on both 'outPd' and 'outCd', from 'secondaryPd' and 'secondaryCd'.

  NOTE: 'vtkGenericAttributeCollection *attributes' will be replaced by a 'vtkInformation'.

- `obj.Derivatives (int subId, double pcoords[3], vtkGenericAttribute attribute, double derivs)` - Compute derivatives 'derivs' of the attribute 'attribute' (from its values at the corner points of the

cell) given sub-cell 'subId' (0 means primary cell) and parametric coordinates 'pcoords'. Derivatives are in the x-y-z coordinate directions for each data value.

&&(pcoords[1]¡=1)&&(0¡=pcoords[2])

- `obj.GetBounds (double bounds[6])` - Compute the bounding box of the current cell in 'bounds' in global coordinates. THREAD SAFE

- `double = obj.GetLength2 ()` - Return the bounding box diagonal squared of the current cell.

- `int = obj.GetParametricCenter (double pcoords[3])` - Get the center of the current cell (in parametric coordinates) and place it in 'pcoords'. If the current cell is a composite, the return value is the sub-cell id that the center is in. (result¿=0) && (IsPrimary() implies result==0)

- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate 'pcoords' to the current cell. If inside the cell, a distance of zero is returned. This is used during picking to get the correct cell picked. (The tolerance will occasionally allow cells to be picked who are not really intersected "inside" the cell.)

- `obj.Tessellate (vtkGenericAttributeCollection attributes, vtkGenericCellTessellator tess, vtkPoints` - Tessellate the cell if it is not linear or if at least one attribute of 'attributes' is not linear. The output are linear cells of the same dimension than the cell. If the cell is linear and all attributes are linear, the output is just a copy of the current cell. 'points', 'cellArray', 'pd' and 'cd' are cumulative output data arrays over cell iterations: they store the result of each call to Tessellate(). 'internalPd' is initialized by the calling filter and stores the result of the tessellation. If it is not null, 'types' is filled with the types of the linear cells. 'types' is null when it is called from vtkGenericGeometryFilter and not null when it is called from vtkGenericDatasetTessellator.

- `int = obj.IsFaceOnBoundary (vtkIdType faceId)` - Is the face 'faceId' of the current cell on the exterior boundary of the dataset?

- `int = obj.IsOnBoundary ()` - Is the cell on the exterior boundary of the dataset?

- `obj.TriangulateFace (vtkGenericAttributeCollection attributes, vtkGenericCellTessellator tess, int` - Tessellate face 'index' of the cell. See Tessellate() for further explanations.

- `int = obj.GetNumberOfVerticesOnFace (int faceId)` - Return the number of vertices defining face 'faceId'.

31.72 vtkGenericAttribute

31.72.1 Usage

vtkGenericAttribute is an abstract class that defines an API for attribute data. Attribute data is data associated with the topology or geometry of a dataset (i.e., points, cells, etc.). vtkGenericAttribute is part of the adaptor framework (see GenericFiltering/README.html).

vtkGenericAttribute provides a more general interface to attribute data than its counterpart vtkDataArray (which assumes a linear, contiguous array). It adopts an iterator interface, and allows attributes to be associated with points, edges, faces, or edges.

To create an instance of class vtkGenericAttribute, simply invoke its constructor as follows

```
obj = vtkGenericAttribute
```

31.72.2 Methods

The class vtkGenericAttribute has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericAttribute class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericAttribute = obj.NewInstance ()`
- `vtkGenericAttribute = obj.SafeDownCast (vtkObject o)`
- `string = obj.GetName ()` - Name of the attribute. (e.g. "velocity")
- `int = obj.GetNumberOfComponents ()` - Dimension of the attribute. (1 for scalar, 3 for velocity)
- `int = obj.GetCentering ()` - Is the attribute centered either on points, cells or boundaries?
- `int = obj.GetType ()` - Type of the attribute: scalar, vector, normal, texture coordinate, tensor
  ——(result==vtkDataSetAttributes::VECTORS) ——(result==vtkDataSetAttributes::NORMALS) ——(result==vtkDataSetAttributes::TCOORDS) ——(result==vtkDataSetAttributes::TENSORS)
- `int = obj.GetComponentType ()` - Type of the components of the attribute: int, float, double
  ——(result==VTK_UNSIGNED_CHAR) ——(result==VTK_SHORT) ——(result==VTK_UNSIGNED_SHORT)——
  ——(result==VTK_UNSIGNED_INT) ——(result==VTK_LONG) ——(result==VTK_UNSIGNED_LONG)
  ——(result==VTK_FLOAT) ——(result==VTK_DOUBLE) ——(result==VTK_ID_TYPE)
- `vtkIdType = obj.GetSize ()` - Number of tuples.
- `long = obj.GetActualMemorySize ()` - Size in kilobytes taken by the attribute.
- `obj.GetRange (int component, double range[2])` - Range of the attribute component 'component'. If 'component'==-1, it returns the range of the magnitude (euclidean norm). THREAD SAFE
- `double = obj.GetMaxNorm ()` - Return the maximum euclidean norm for the tuples.
- `obj.GetTuple (vtkGenericAdaptorCell c, double tuple)` - Put attribute at all points of cell 'c' in 'tuple'.
- `obj.GetTuple (vtkGenericCellIterator c, double tuple)` - Put attribute at all points of cell 'c' in 'tuple'.
- `obj.GetTuple (vtkGenericPointIterator p, double tuple)` - Put the value of the attribute at position 'p' into 'tuple'.
- `obj.GetComponent (int i, vtkGenericCellIterator c, double values)` - Put component 'i' of the attribute at all points of cell 'c' in 'values'.
- `double = obj.GetComponent (int i, vtkGenericPointIterator p)` - Value of the component 'i' of the attribute at position 'p'.
- `obj.DeepCopy (vtkGenericAttribute other)` - Recursive duplication of 'other' in 'this'.
- `obj.ShallowCopy (vtkGenericAttribute other)` - Update 'this' using fields of 'other'.

31.73 vtkGenericAttributeCollection

31.73.1 Usage

vtkGenericAttributeCollection is a class that collects attributes (represented by vtkGenericAttribute).

To create an instance of class vtkGenericAttributeCollection, simply invoke its constructor as follows

```
obj = vtkGenericAttributeCollection
```

31.73.2 Methods

The class vtkGenericAttributeCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericAttributeCollection class.

- `string = obj.GetClassName ()` - Standard type definition and print methods for a VTK class.
- `int = obj.IsA (string name)` - Standard type definition and print methods for a VTK class.
- `vtkGenericAttributeCollection = obj.NewInstance ()` - Standard type definition and print methods for a VTK class.
- `vtkGenericAttributeCollection = obj.SafeDownCast (vtkObject o)` - Standard type definition and print methods for a VTK class.
- `int = obj.GetNumberOfAttributes ()` - Return the number of attributes (e.g., instances of vtkGenericAttribute) in the collection.
- `int = obj.GetNumberOfComponents ()` - Return the number of components. This is the sum of all components found in all attributes.
- `int = obj.GetNumberOfPointCenteredComponents ()` - Return the number of components. This is the sum of all components found in all point centered attributes.
- `int = obj.GetMaxNumberOfComponents ()` - Maximum number of components encountered among all attributes.
- `long = obj.GetActualMemorySize ()` - Actual size of the data in kilobytes; only valid after the pipeline has updated. It is guaranteed to be greater than or equal to the memory required to represent the data.
- `int = obj.IsEmpty ()` - Indicate whether the collection contains any attributes.
- `vtkGenericAttribute = obj.GetAttribute (int i)` - Return a pointer to the ith instance of vtkGenericAttribute.
- `int = obj.FindAttribute (string name)` - Return the index of the attribute named 'name'. Return the non-negative index if found. Return -1 otherwise.
- `int = obj.GetAttributeIndex (int i)` - Return the index of the first component of attribute 'i' in an array of format attrib0comp0 attrib0comp1 ... attrib4comp0 ...
- `obj.InsertNextAttribute (vtkGenericAttribute a)` - Add the attribute 'a' to the end of the collection.
- `obj.InsertAttribute (int i, vtkGenericAttribute a)` - Replace the attribute at index 'i' by 'a'.
- `obj.RemoveAttribute (int i)` - Remove the attribute at 'i'.
- `obj.Reset ()` - Remove all attributes.

- `obj.DeepCopy (vtkGenericAttributeCollection other)` - Copy, without reference counting, the other attribute array.
- `obj.ShallowCopy (vtkGenericAttributeCollection other)` - Copy, via reference counting, the other attribute array.
- `long = obj.GetMTime ()` - vtkAttributeCollection is a composite object and needs to check each member of its collection for modified time.
- `int = obj.GetActiveAttribute ()` - Index of the attribute to be processed (not necessarily scalar).
- `int = obj.GetActiveComponent ()` - Component of the active attribute to be processed. -1 means module.

  result¡GetAttribute(GetActiveAttribute())-¿GetNumberOfComponents()
- `obj.SetActiveAttribute (int attribute, int component)` - Set the scalar attribute to be processed. -1 means module.

  component¡GetAttribute(attribute)-¿GetNumberOfComponents()

  GetActiveComponent()==component
- `int = obj.GetNumberOfAttributesToInterpolate ()` - Number of attributes to interpolate.
- `int = obj.HasAttribute (int size, int attributes, int attribute)`
- `obj.SetAttributesToInterpolate (int size, int attributes)` - Set the attributes to interpolate.

  !HasAttributes(size,attributes,GetActiveAttribute())

  (GetAttributesToInterpolate()==attributes)
- `obj.SetAttributesToInterpolateToAll ()` - Set the attributes to interpolate.

  !HasAttributes(size,attributes,GetActiveAttribute())

  (GetAttributesToInterpolate()==attributes)

31.74 vtkGenericCell

31.74.1 Usage

vtkGenericCell is a class that provides access to concrete types of cells. It's main purpose is to allow thread-safe access to cells, supporting the vtkDataSet::GetCell(vtkGenericCell *) method. vtkGenericCell acts like any type of cell, it just dereferences an internal representation. The SetCellType() methods use #define constants; these are defined in the file vtkCellType.h.

To create an instance of class vtkGenericCell, simply invoke its constructor as follows

```
obj = vtkGenericCell
```

31.74.2 Methods

The class vtkGenericCell has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericCell class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkGenericCell = obj.NewInstance ()`
- `vtkGenericCell = obj.SafeDownCast (vtkObject o)`
- `obj.ShallowCopy (vtkCell c)` - See the vtkCell API for descriptions of these methods.
- `obj.DeepCopy (vtkCell c)` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.IsLinear ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.RequiresInitialization ()` - See the vtkCell API for descriptions of these methods.
- `obj.Initialize ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetParametricCenter (double pcoords[3])` - See the vtkCell API for descriptions of these methods.
- `int = obj.IsPrimaryCell ()` - See the vtkCell API for descriptions of these methods.
- `obj.InterpolateFunctions (double pcoords[3], double weights)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.SetCellType (int cellType)` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToEmptyCell ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.

- `obj.SetCellTypeToVertex ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToPolyVertex ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToLine ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToPolyLine ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToTriangle ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToTriangleStrip ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToPolygon ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToPixel ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuad ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToTetra ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToVoxel ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToHexahedron ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.

- `obj.SetCellTypeToWedge ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToPyramid ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToPentagonalPrism ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToHexagonalPrism ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToConvexPointSet ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticEdge ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToCubicLine ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticTriangle ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToBiQuadraticTriangle ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCel *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticQuad ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticTetra ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticHexahedron ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCel *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.

- `obj.SetCellTypeToQuadraticWedge ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticPyramid ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticLinearQuad ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCel *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToBiQuadraticQuad ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericCell *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToQuadraticLinearWedge ()` - This method is used to support the vtkDataSet::GetCell(vtkGenericC *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToBiQuadraticQuadraticWedge ()` - This method is used to support the vtkDataSet::GetCell(vtkGen *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToTriQuadraticHexahedron ()` - This method is used to support the vtkDataSet::GetCell(vtkGeneric *) method. It allows vtkGenericCell to act like any cell type by dereferencing an internal instance of a concrete cell type. When you set the cell type, you are resetting a pointer to an internal cell which is then used for computation.
- `obj.SetCellTypeToBiQuadraticQuadraticHexahedron ()` - Instantiate a new vtkCell based on it's cell type value

31.75 vtkGenericCellIterator

31.75.1 Usage

This class (and subclasses) are used to iterate over cells. Use it only in conjunction with vtkGenericDataSet (i.e., the adaptor framework).

Typical use is:

```
vtkGenericDataSet *dataset;
vtkGenericCellIterator *it = dataset->NewCellIterator(2);
for (it->Begin(); !it->IsAtEnd(); it->Next());
  {
  spec=it->GetCell();
  }
```

To create an instance of class vtkGenericCellIterator, simply invoke its constructor as follows

```
obj = vtkGenericCellIterator
```

31.75.2 Methods

The class vtkGenericCellIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericCellIterator class.

- `string = obj.GetClassName ()` - Standard VTK construction and type macros.
- `int = obj.IsA (string name)` - Standard VTK construction and type macros.
- `vtkGenericCellIterator = obj.NewInstance ()` - Standard VTK construction and type macros.
- `vtkGenericCellIterator = obj.SafeDownCast (vtkObject o)` - Standard VTK construction and type macros.
- `obj.Begin ()` - Move iterator to first position if any (loop initialization).
- `int = obj.IsAtEnd ()` - Is the iterator at the end of traversal?
- `vtkGenericAdaptorCell = obj.NewCell ()` - Create an empty cell. The user is responsible for deleting it.
- `obj.GetCell (vtkGenericAdaptorCell c)` - Get the cell at current position. The cell should be instantiated with the NewCell() method.

  THREAD SAFE
- `vtkGenericAdaptorCell = obj.GetCell ()` - Get the cell at the current traversal position. NOT THREAD SAFE
- `obj.Next ()` - Move the iterator to the next position in the list.

31.76 vtkGenericCellTessellator

31.76.1 Usage

vtkGenericCellTessellator is a helper class to perform adaptive tessellation of particular cell topologies. The major purpose for this class is to transform higher-order cell types (e.g., higher-order finite elements) into linear cells that can then be easily visualized by VTK. This class works in conjunction with the vtkGenericDataSet and vtkGenericAdaptorCell classes.

This algorithm is based on edge subdivision. An error metric along each edge is evaluated, and if the error is greater than some tolerance, the edge is subdivided (as well as all connected 2D and 3D cells). The process repeats until the error metric is satisfied.

A significant issue addressed by this algorithm is to insure face compatibility across neigboring cells. That is, diagonals due to face triangulation must match to insure that the mesh is compatible. The algorithm employs a precomputed table to accelerate the tessellation process. The table was generated with the help of vtkOrderedTriangulator; the basic idea is that the choice of diagonal is made by considering the relative value of the point ids.

To create an instance of class vtkGenericCellTessellator, simply invoke its constructor as follows

```
obj = vtkGenericCellTessellator
```

31.76.2 Methods

The class vtkGenericCellTessellator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericCellTessellator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericCellTessellator = obj.NewInstance ()`
- `vtkGenericCellTessellator = obj.SafeDownCast (vtkObject o)`
- `obj.TessellateFace (vtkGenericAdaptorCell cell, vtkGenericAttributeCollection att, vtkIdType index,` - Tessellate a face of a 3D 'cell'. The face is specified by the index value. The result is a set of smaller linear triangles in 'cellArray' with 'points' and point data 'internalPd'.
- `obj.Tessellate (vtkGenericAdaptorCell cell, vtkGenericAttributeCollection att, vtkDoubleArray point` - Tessellate a 3D 'cell'. The result is a set of smaller linear tetrahedra in 'cellArray' with 'points' and point data 'internalPd'.
- `obj.Triangulate (vtkGenericAdaptorCell cell, vtkGenericAttributeCollection att, vtkDoubleArray poir` - Triangulate a 2D 'cell'. The result is a set of smaller linear triangles in 'cellArray' with 'points' and point data 'internalPd'.
- `obj.SetErrorMetrics (vtkCollection someErrorMetrics)` - Specify the list of error metrics used to decide if an edge has to be splitted or not. It is a collection of vtkGenericSubdivisionErrorMetric-s.
- `vtkCollection = obj.GetErrorMetrics ()` - Specify the list of error metrics used to decide if an edge has to be splitted or not. It is a collection of vtkGenericSubdivisionErrorMetric-s.
- `obj.Initialize (vtkGenericDataSet ds)` - Initialize the tessellator with a data set 'ds'.
- `obj.InitErrorMetrics (vtkGenericDataSet ds)` - Init the error metric with the dataset. Should be called in each filter before any tessellation of any cell.
- `int = obj.GetMeasurement ()` - If true, measure the quality of the fixed subdivision.
- `obj.SetMeasurement (int )` - If true, measure the quality of the fixed subdivision.
- `obj.GetMaxErrors (double errors)` - Get the maximum error measured after the fixed subdivision.

31.77 vtkGenericDataSet

31.77.1 Usage

In VTK, spatial-temporal data is defined in terms of a dataset. The dataset consists of geometry (e.g., points), topology (e.g., cells), and attributes (e.g., scalars, vectors, etc.) vtkGenericDataSet is an abstract class defining this abstraction.

Since vtkGenericDataSet provides a general interface to manipulate data, algorithms that process it tend to be slower than those specialized for a particular data type. For this reason, there are concrete, non-abstract subclasses that represent and provide access to data more efficiently. Note that filters to process this dataset type are currently found in the VTK/GenericFiltering/ subdirectory.

Unlike the vtkDataSet class, vtkGenericDataSet provides a more flexible interface including support for iterators. vtkGenericDataSet is also designed to interface VTK to external simulation packages without the penalty of copying memory (see VTK/GenericFiltering/README.html) for more information. Thus vtkGenericDataSet plays a central role in the adaptor framework.

Please note that this class introduces the concepts of "boundary cells". This refers to the boundaries of a cell (e.g., face of a tetrahedron) which may in turn be represented as a cell. Boundary cells are derivative topological features of cells, and are therefore never explicitly represented in the dataset. Often in visualization algorithms, looping over boundaries (edges or faces) is employed, while the actual dataset cells may not traversed. Thus there are methods to loop over these boundary cells.

Finally, as a point of clarification, points are not the same as vertices. Vertices refer to points, and points specify a position is space. Vertices are a type of 0-D cell. Also, the concept of a DOFNode, which

is where coefficients for higher-order cells are kept, is a new concept introduced by the adaptor framework (see vtkGenericAdaptorCell for more information).

To create an instance of class vtkGenericDataSet, simply invoke its constructor as follows

```
obj = vtkGenericDataSet
```

31.77.2 Methods

The class vtkGenericDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericDataSet class.

- `string = obj.GetClassName ()` - Standard VTK type and print macros.
- `int = obj.IsA (string name)` - Standard VTK type and print macros.
- `vtkGenericDataSet = obj.NewInstance ()` - Standard VTK type and print macros.
- `vtkGenericDataSet = obj.SafeDownCast (vtkObject o)` - Standard VTK type and print macros.
- `vtkIdType = obj.GetNumberOfPoints ()` - Return the number of points composing the dataset. See NewPointIterator() for more details.
- `vtkIdType = obj.GetNumberOfCells (int dim)` - Return the number of cells that explicitly define the dataset. See NewCellIterator() for more details.
- `int = obj.GetCellDimension ()` - Return -1 if the dataset is explicitly defined by cells of varying dimensions or if there are no cells. If the dataset is explicitly defined by cells of a unique dimension, return this dimension.
- `obj.GetCellTypes (vtkCellTypes types)` - Get a list of types of cells in a dataset. The list consists of an array of types (not necessarily in any order), with a single entry per type. For example a dataset 5 triangles, 3 lines, and 100 hexahedra would result a list of three entries, corresponding to the types VTK_TRIANGLE, VTK_LINE, and VTK_HEXAHEDRON. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `vtkGenericCellIterator = obj.NewCellIterator (int dim)` - Return an iterator to traverse cells of dimension 'dim' (or all dimensions if -1) that explicitly define the dataset. For instance, it will return only tetrahedra if the mesh is defined by tetrahedra. If the mesh is composed of two parts, one with tetrahedra and another part with triangles, it will return both, but will not return the boundary edges and vertices of these cells. The user is responsible for deleting the iterator.
- `vtkGenericCellIterator = obj.NewBoundaryIterator (int dim, int exteriorOnly)` - Return an iterator to traverse cell boundaries of dimension 'dim' (or all dimensions if -1) of the dataset. If 'exteriorOnly' is true, only the exterior cell boundaries of the dataset will be returned, otherwise it will return exterior and interior cell boundaries. The user is responsible for deleting the iterator.
- `vtkGenericPointIterator = obj.NewPointIterator ()` - Return an iterator to traverse the points composing the dataset; they can be points that define a cell (corner points) or isolated points. The user is responsible for deleting the iterator.
- `obj.FindPoint (double x[3], vtkGenericPointIterator p)` - Locate the closest point 'p' to position 'x' (global coordinates).
- `long = obj.GetMTime ()` - Datasets are composite objects and need to check each part for their modified time.
- `obj.ComputeBounds ()` - Compute the geometry bounding box.

- `obj.GetBounds (double bounds[6])` - Return the geometry bounding box in global coordinates in the form (xmin,xmax, ymin,ymax, zmin,zmax) in the 'bounds' array.
- `obj.GetCenter (double center[3])` - Get the center of the bounding box in global coordinates.
- `double = obj.GetLength ()` - Return the length of the diagonal of the bounding box.
- `vtkGenericAttributeCollection = obj.GetAttributes ()` - Get the collection of attributes associated with this dataset.
- `vtkDataSetAttributes = obj.GetAttributes (int type)` - Set/Get a cell tessellator if cells must be tessellated during processing.
- `obj.SetTessellator (vtkGenericCellTessellator tessellator)` - Set/Get a cell tessellator if cells must be tessellated during processing.
- `vtkGenericCellTessellator = obj.GetTessellator ()` - Set/Get a cell tessellator if cells must be tessellated during processing.
- `long = obj.GetActualMemorySize ()` - Actual size of the data in kilobytes; only valid after the pipeline has updated. It is guaranteed to be greater than or equal to the memory required to represent the data.
- `int = obj.GetDataObjectType ()` - Return the type of data object.
- `vtkIdType = obj.GetEstimatedSize ()` - Estimated size needed after tessellation (or special operation)

31.78 vtkGenericDataSetAlgorithm

31.78.1 Usage

To create an instance of class vtkGenericDataSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkGenericDataSetAlgorithm
```

31.78.2 Methods

The class vtkGenericDataSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericDataSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericDataSetAlgorithm = obj.NewInstance ()`
- `vtkGenericDataSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkGenericDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkGenericDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`

- `vtkGenericDataSet = obj.GetGenericDataSetInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.79 vtkGenericEdgeTable

31.79.1 Usage

vtkGenericEdgeTable is used to indicate the existance of and hold information about edges. Similar to vtkEdgeTable, this class is more sophisticated in that it uses reference counting to keep track of when information about an edge should be deleted.

vtkGenericEdgeTable is a helper class used in the adaptor framework. It is used during the tessellation process to hold information about the error metric on each edge. This avoids recomputing the error metric each time the same edge is visited.

To create an instance of class vtkGenericEdgeTable, simply invoke its constructor as follows

```
obj = vtkGenericEdgeTable
```

31.79.2 Methods

The class vtkGenericEdgeTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericEdgeTable class.

- `string = obj.GetClassName ()` - Standard VTK type and print macros.
- `int = obj.IsA (string name)` - Standard VTK type and print macros.
- `vtkGenericEdgeTable = obj.NewInstance ()` - Standard VTK type and print macros.
- `vtkGenericEdgeTable = obj.SafeDownCast (vtkObject o)` - Standard VTK type and print macros.
- `obj.InsertEdge (vtkIdType e1, vtkIdType e2, vtkIdType cellId, int ref)` - Insert an edge but do not split it.
- `int = obj.RemoveEdge (vtkIdType e1, vtkIdType e2)` - Method to remove an edge from the table. The method returns the current reference count.
- `int = obj.IncrementEdgeReferenceCount (vtkIdType e1, vtkIdType e2, vtkIdType cellId)` - Method that increments the referencecount and returns it.

- `int = obj.CheckEdgeReferenceCount (vtkIdType e1, vtkIdType e2)` - Return the edge reference count.
- `obj.Initialize (vtkIdType start)` - To specify the starting point id. It will initialize LastPointId This is very sensitive the start point should be cautiously chosen
- `int = obj.GetNumberOfComponents ()` - Return the total number of components for the point-centered attributes.
- `obj.SetNumberOfComponents (int count)` - Set the total number of components for the point-centered attributes.
- `int = obj.CheckPoint (vtkIdType ptId)` - Check if a point is already in the point table.
- `int = obj.CheckPoint (vtkIdType ptId, double point[3], double scalar)` - Check for the existence of a point and return its coordinate value.
- `obj.InsertPoint (vtkIdType ptId, double point[3])` - Insert point associated with an edge.
- `obj.InsertPointAndScalar (vtkIdType ptId, double pt[3], double s)` - Insert point associated with an edge. re: sizeof(s)==GetNumberOfComponents()
- `obj.RemovePoint (vtkIdType ptId)` - Remove a point from the point table.
- `obj.IncrementPointReferenceCount (vtkIdType ptId)` - Increment the reference count for the indicated point.
- `obj.DumpTable ()` - For debugging purposes. It is particularly useful to dump the table and check that nothing is left after a complete iteration. LoadFactor should ideally be very low to be able to have a constant time access
- `obj.LoadFactor ()` - For debugging purposes. It is particularly useful to dump the table and check that nothing is left after a complete iteration. LoadFactor should ideally be very low to be able to have a constant time access

31.80 vtkGenericInterpolatedVelocityField

31.80.1 Usage

vtkGenericInterpolatedVelocityField acts as a continuous velocity field by performing cell interpolation on the underlying vtkDataSet. This is a concrete sub-class of vtkFunctionSet with NumberOfIndependentVariables = 4 (x,y,z,t) and NumberOfFunctions = 3 (u,v,w). Normally, every time an evaluation is performed, the cell which contains the point (x,y,z) has to be found by calling FindCell. This is a computationally expansive operation. In certain cases, the cell search can be avoided or shortened by providing a guess for the cell iterator. For example, in streamline integration, the next evaluation is usually in the same or a neighbour cell. For this reason, vtkGenericInterpolatedVelocityField stores the last cell iterator. If caching is turned on, it uses this iterator as the starting point.

To create an instance of class vtkGenericInterpolatedVelocityField, simply invoke its constructor as follows

```
obj = vtkGenericInterpolatedVelocityField
```

31.80.2 Methods

The class vtkGenericInterpolatedVelocityField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericInterpolatedVelocityField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGenericInterpolatedVelocityField = obj.NewInstance ()`
- `vtkGenericInterpolatedVelocityField = obj.SafeDownCast (vtkObject o)`
- `int = obj.FunctionValues (double x, double f)` - Evaluate the velocity field, f, at (x, y, z, t). For now, t is ignored.
- `obj.AddDataSet (vtkGenericDataSet dataset)` - Add a dataset used for the implicit function evaluation. If more than one dataset is added, the evaluation point is searched in all until a match is found. THIS FUNCTION DOES NOT CHANGE THE REFERENCE COUNT OF dataset FOR THREAD SAFETY REASONS.
- `obj.ClearLastCell ()` - Set the last cell id to -1 so that the next search does not start from the previous cell
- `vtkGenericAdaptorCell = obj.GetLastCell ()` - Return the cell cached from last evaluation.
- `int = obj.GetLastLocalCoordinates (double pcoords[3])` - Returns the interpolation weights cached from last evaluation if the cached cell is valid (returns 1). Otherwise, it does not change w and returns 0.
- `int = obj.GetCaching ()` - Turn caching on/off.
- `obj.SetCaching (int )` - Turn caching on/off.
- `obj.CachingOn ()` - Turn caching on/off.
- `obj.CachingOff ()` - Turn caching on/off.
- `int = obj.GetCacheHit ()` - Caching statistics.
- `int = obj.GetCacheMiss ()` - Caching statistics.
- `string = obj.GetVectorsSelection ()` - If you want to work with an arbitrary vector array, then set its name here. By default this in NULL and the filter will use the active vector array.
- `obj.SelectVectors (string fieldName)` - Returns the last dataset that was visited. Can be used as a first guess as to where the next point will be as well as to avoid searching through all datasets to get more information about the point.
- `vtkGenericDataSet = obj.GetLastDataSet ()` - Returns the last dataset that was visited. Can be used as a first guess as to where the next point will be as well as to avoid searching through all datasets to get more information about the point.
- `obj.CopyParameters (vtkGenericInterpolatedVelocityField from)` - Copy the user set parameters from source. This copies the Caching parameters. Sub-classes can add more after chaining.

31.81 vtkGenericPointIterator

31.81.1 Usage

This class (and subclasses) are used to iterate over points. Use it only in conjunction with vtkGenericDataSet (i.e., the adaptor framework).

Typical use is:

```
vtkGenericDataSet *dataset;
vtkGenericPointIterator *it = dataset->NewPointIterator();
for (it->Begin(); !it->IsAtEnd(); it->Next());
  {
  x=it->GetPosition();
  }
```

To create an instance of class vtkGenericPointIterator, simply invoke its constructor as follows

```
obj = vtkGenericPointIterator
```

31.81.2 Methods

The class vtkGenericPointIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericPointIterator class.

- `string = obj.GetClassName ()` - Standard VTK construction and type macros.
- `int = obj.IsA (string name)` - Standard VTK construction and type macros.
- `vtkGenericPointIterator = obj.NewInstance ()` - Standard VTK construction and type macros.
- `vtkGenericPointIterator = obj.SafeDownCast (vtkObject o)` - Standard VTK construction and type macros.
- `obj.Begin ()` - Move iterator to first position if any (loop initialization).
- `int = obj.IsAtEnd ()` - Is the iterator at the end of traversal?
- `obj.Next ()` - Move the iterator to the next position in the list.
- `obj.GetPosition (double x[3])` - Get the coordinates of the point at the current iterator position.
- `vtkIdType = obj.GetId ()` - Return the unique identifier for the point, could be non-contiguous.

31.82 vtkGenericSubdivisionErrorMetric

31.82.1 Usage

Objects of that class answer the following question during the cell subdivision: "does the edge need to be subdivided?" through RequiresEdgeSubdivision(). The answer depends on the criterium actually used in the subclass of this abstract class: a geometric-based error metric (variation of edge from a straight line), an attribute-based error metric (variation of the active attribute/component value from a linear ramp) , a view-depend error metric, ... Cell subdivision is performed in the context of the adaptor framework: higher-order, or complex cells, are automatically tessellated into simplices so that they can be processed with conventional visualization algorithms.

To create an instance of class vtkGenericSubdivisionErrorMetric, simply invoke its constructor as follows

```
obj = vtkGenericSubdivisionErrorMetric
```

31.82.2 Methods

The class vtkGenericSubdivisionErrorMetric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGenericSubdivisionErrorMetric class.

- `string = obj.GetClassName ()` - Standard VTK type and error macros.
- `int = obj.IsA (string name)` - Standard VTK type and error macros.
- `vtkGenericSubdivisionErrorMetric = obj.NewInstance ()` - Standard VTK type and error macros.
- `vtkGenericSubdivisionErrorMetric = obj.SafeDownCast (vtkObject o)` - Standard VTK type and error macros.
- `int = obj.RequiresEdgeSubdivision (double leftPoint, double midPoint, double rightPoint, double alp` - Does the edge need to be subdivided according to the implemented computation? The edge is defined by its 'leftPoint' and its 'rightPoint'. 'leftPoint', 'midPoint' and 'rightPoint' have to be initialized before calling RequiresEdgeSubdivision(). Their format is global coordinates, parametric coordinates and point centered attributes: xyx rst abc de... 'alpha' is the normalized abscissa of the midpoint along the edge. (close to 0 means close to the left point, close to 1 means close to the right point)

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `double = obj.GetError (double leftPoint, double midPoint, double rightPoint, double alpha)` - Return the error at the mid-point. The type of error depends on the state of the concrete error metric. For instance, it can return an absolute or relative error metric. See RequiresEdgeSubdivision() for a description of the arguments.

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `obj.SetGenericCell (vtkGenericAdaptorCell cell)` - The cell that the edge belongs to.
- `vtkGenericAdaptorCell = obj.GetGenericCell ()` - The cell that the edge belongs to.
- `obj.SetDataSet (vtkGenericDataSet ds)` - Set/Get the dataset to be tessellated.
- `vtkGenericDataSet = obj.GetDataSet ()` - Set/Get the dataset to be tessellated.

31.83 vtkGeometricErrorMetric

31.83.1 Usage

It is a concrete error metric, based on a geometric criterium: the variation of the edge from a straight line.
To create an instance of class vtkGeometricErrorMetric, simply invoke its constructor as follows

```
obj = vtkGeometricErrorMetric
```

31.83.2 Methods

The class vtkGeometricErrorMetric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeometricErrorMetric class.

- `string = obj.GetClassName ()` - Standard VTK type and error macros.
- `int = obj.IsA (string name)` - Standard VTK type and error macros.
- `vtkGeometricErrorMetric = obj.NewInstance ()` - Standard VTK type and error macros.

- `vtkGeometricErrorMetric = obj.SafeDownCast (vtkObject o)` - Standard VTK type and error macros.
- `double = obj.GetAbsoluteGeometricTolerance ()` - Return the squared absolute geometric accuracy. See SetAbsoluteGeometricTolerance() for details.
- `obj.SetAbsoluteGeometricTolerance (double value)` - Set the geometric accuracy with a squared absolute value. This is the geometric object-based accuracy. Subdivision will be required if the square distance between the real point and the straight line passing through the vertices of the edge is greater than 'value'. For instance 0.01 will give better result than 0.1.
- `obj.SetRelativeGeometricTolerance (double value, vtkGenericDataSet ds)` - Set the geometric accuracy with a value relative to the length of the bounding box of the dataset. Internally compute the absolute tolerance. For instance 0.01 will give better result than 0.1.
- `int = obj.RequiresEdgeSubdivision (double leftPoint, double midPoint, double rightPoint, double alp` - Does the edge need to be subdivided according to the distance between the line passing through its endpoints and the mid point? The edge is defined by its 'leftPoint' and its 'rightPoint'. 'leftPoint', 'midPoint' and 'rightPoint' have to be initialized before calling RequiresEdgeSubdivision(). Their format is global coordinates, parametric coordinates and point centered attributes: xyx rst abc de... 'alpha' is the normalized abscissa of the midpoint along the edge. (close to 0 means close to the left point, close to 1 means close to the right point)

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `double = obj.GetError (double leftPoint, double midPoint, double rightPoint, double alpha)` - Return the error at the mid-point. It will return an error relative to the bounding box size if GetRelative() is true, a square absolute error otherwise. See RequiresEdgeSubdivision() for a description of the arguments.

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `int = obj.GetRelative ()` - Return the type of output of GetError()

31.84 vtkGraph

31.84.1 Usage

vtkGraph is the abstract base class that provides all read-only API for graph data types. A graph consists of a collection of vertices and a collection of edges connecting pairs of vertices. The vtkDirectedGraph subclass represents a graph whose edges have inherent order from source vertex to target vertex, while vtkUndirectedGraph is a graph whose edges have no inherent ordering.

Graph vertices may be traversed in two ways. In the current implementation, all vertices are assigned consecutive ids starting at zero, so they may be traversed in a simple for loop from 0 to graph-¿GetNumberOfVertices() - 1. You may alternately create a vtkVertexListIterator and call graph-¿GetVertices(it). it-¿Next() will return the id of the next vertex, while it-¿HasNext() indicates whether there are more vertices in the graph. This is the preferred method, since in the future graphs may support filtering or subsetting where the vertex ids may not be contiguous.

Graph edges must be traversed through iterators. To traverse all edges in a graph, create an instance of vtkEdgeListIterator and call graph-¿GetEdges(it). it-¿Next() returns lightweight vtkEdgeType structures, which contain the public fields Id, Source and Target. Id is the identifier for the edge, which may be used to look up values in assiciated edge data arrays. Source and Target store the ids of the source and target vertices of the edge. Note that the edge list iterator DOES NOT necessarily iterate over edges in order of ascending id. To traverse edges from wrapper code (Python, Tcl, Java), use it-¿NextGraphEdge() instead of it-¿Next(). This will return a heavyweight, wrappable vtkGraphEdge object, which has the same fields as vtkEdgeType accessible through getter methods.

To traverse all edges outgoing from a vertex, create a vtkOutEdgeIterator and call graph-¿GetOutEdges(v, it). it-¿Next() returns a lightweight vtkOutEdgeType containing the fields Id and Target. The source of the edge is always the vertex that was passed as an argument to GetOutEdges(). Incoming edges may be similarly traversed with vtkInEdgeIterator, which returns vtkInEdgeType structures with Id and Source fields. Both vtkOutEdgeIterator and vtkInEdgeIterator also provide the wrapper functions NextGraphEdge() which return vtkGraphEdge objects.

An additional iterator, vtkAdjacentVertexIterator can traverse outgoing vertices directly, instead needing to parse through edges. Initialize the iterator by calling graph-¿GetAdjacentVertices(v, it).

vtkGraph has two instances of vtkDataSetAttributes for associated vertex and edge data. It also has a vtkPoints instance which may store x,y,z locations for each vertex. This is populated by filters such as vtkGraphLayout and vtkAssignCoordinates.

All graph types share the same implementation, so the structure of one may be shared among multiple graphs, even graphs of different types. Structures from vtkUndirectedGraph and vtkMutableUndirectedGraph may be shared directly. Structures from vtkDirectedGraph, vtkMutableDirectedGraph, and vtkTree may be shared directly with the exception that setting a structure to a tree requires that a "is a tree" test passes.

For graph types that are known to be compatible, calling ShallowCopy() or DeepCopy() will work as expected. When the outcome of a conversion is unknown (i.e. setting a graph to a tree), CheckedShallowCopy() and CheckedDeepCopy() exist which are identical to ShallowCopy() and DeepCopy(), except that instead of emitting an error for an incompatible structure, the function returns false. This allows you to programmatically check structure compatibility without causing error messages.

To construct a graph, use vtkMutableDirectedGraph or vtkMutableUndirectedGraph. You may then use CheckedShallowCopy to set the contents of a mutable graph type into one of the non-mutable types vtkDirectedGraph, vtkUndirectedGraph. To construct a tree, use vtkMutableDirectedGraph, with directed edges which point from the parent to the child, then use CheckedShallowCopy to set the structure to a vtkTree.

To create an instance of class vtkGraph, simply invoke its constructor as follows

```
obj = vtkGraph
```

31.84.2 Methods

The class vtkGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraph = obj.NewInstance ()`
- `vtkGraph = obj.SafeDownCast (vtkObject o)`
- `vtkDataSetAttributes = obj.GetVertexData ()` - Get the vertex or edge data.
- `vtkDataSetAttributes = obj.GetEdgeData ()` - Get the vertex or edge data.
- `int = obj.GetDataObjectType ()` - Initialize to an empty graph.
- `obj.Initialize ()` - Initialize to an empty graph.
- `obj.GetPoint (vtkIdType ptId, double x[3])` - These methods return the point (0,0,0) until the points structure is created, when it returns the actual point position. In a distributed graph, only the points for local vertices can be retrieved.
- `vtkPoints = obj.GetPoints ()` - Returns the points array for this graph. If points is not yet constructed, generates and returns a new points array filled with (0,0,0) coordinates. In a distributed graph, only the points for local vertices can be retrieved or modified.

- `obj.SetPoints (vtkPoints points)` - Returns the points array for this graph. If points is not yet constructed, generates and returns a new points array filled with (0,0,0) coordinates. In a distributed graph, only the points for local vertices can be retrieved or modified.
- `obj.ComputeBounds ()` - Compute the bounds of the graph. In a distributed graph, this computes the bounds around the local part of the graph.
- `obj.GetBounds (double bounds[6])` - Return a pointer to the geometry bounding box in the form (xmin,xmax, ymin,ymax, zmin,zmax). In a distributed graph, this computes the bounds around the local part of the graph.
- `long = obj.GetMTime ()` - The modified time of the graph.
- `obj.GetOutEdges (vtkIdType v, vtkOutEdgeIterator it)` - Initializes the out edge iterator to iterate over all outgoing edges of vertex v. For an undirected graph, returns all incident edges. In a distributed graph, the vertex v must be local to this processor.
- `vtkIdType = obj.GetDegree (vtkIdType v)` - The total of all incoming and outgoing vertices for vertex v. For undirected graphs, this is simply the number of edges incident to v. In a distributed graph, the vertex v must be local to this processor.
- `vtkIdType = obj.GetOutDegree (vtkIdType v)` - The number of outgoing edges from vertex v. For undirected graphs, returns the same as GetDegree(). In a distributed graph, the vertex v must be local to this processor.
- `obj.GetOutEdge (vtkIdType v, vtkIdType index, vtkGraphEdge e)` - Random-access method for retrieving outgoing edges from vertex v. The method fills the vtkGraphEdge instance with the id, source, and target of the edge. This method is provided for wrappers, GetOutEdge(vtkIdType, vtkIdType) is preferred.
- `obj.GetInEdges (vtkIdType v, vtkInEdgeIterator it)` - Initializes the in edge iterator to iterate over all incoming edges to vertex v. For an undirected graph, returns all incident edges. In a distributed graph, the vertex v must be local to this processor.
- `vtkIdType = obj.GetInDegree (vtkIdType v)` - The number of incoming edges to vertex v. For undirected graphs, returns the same as GetDegree(). In a distributed graph, the vertex v must be local to this processor.
- `obj.GetInEdge (vtkIdType v, vtkIdType index, vtkGraphEdge e)` - Random-access method for retrieving incoming edges to vertex v. The method fills the vtkGraphEdge instance with the id, source, and target of the edge. This method is provided for wrappers, GetInEdge(vtkIdType, vtkIdType) is preferred.
- `obj.GetAdjacentVertices (vtkIdType v, vtkAdjacentVertexIterator it)` - Initializes the adjacent vertex iterator to iterate over all outgoing vertices from vertex v. For an undirected graph, returns all adjacent vertices. In a distributed graph, the vertex v must be local to this processor.
- `obj.GetEdges (vtkEdgeListIterator it)` - Initializes the edge list iterator to iterate over all edges in the graph. Edges may not be traversed in order of increasing edge id. In a distributed graph, this returns edges that are stored locally.
- `vtkIdType = obj.GetNumberOfEdges ()` - The number of edges in the graph. In a distributed graph, this returns the number of edges stored locally.
- `obj.GetVertices (vtkVertexListIterator it)` - Initializes the vertex list iterator to iterate over all vertices in the graph. In a distributed graph, the iterator traverses all local vertices.
- `vtkIdType = obj.GetNumberOfVertices ()` - The number of vertices in the graph. In a distributed graph, returns the number of local vertices in the graph.

- `obj.SetDistributedGraphHelper (vtkDistributedGraphHelper helper)` - Sets the distributed graph helper of this graph, turning it into a distributed graph. This operation can only be executed on an empty graph.
- `vtkDistributedGraphHelper = obj.GetDistributedGraphHelper ()` - Retrieves the distributed graph helper for this graph
- `obj.ShallowCopy (vtkDataObject obj)` - Shallow copies the data object into this graph. If it is an incompatible graph, reports an error.
- `obj.DeepCopy (vtkDataObject obj)` - Deep copies the data object into this graph. If it is an incompatible graph, reports an error.
- `obj.CopyStructure (vtkGraph g)` - Does a shallow copy of the topological information, but not the associated attributes.
- `bool = obj.CheckedShallowCopy (vtkGraph g)` - Performs the same operation as ShallowCopy(), but instead of reporting an error for an incompatible graph, returns false.
- `bool = obj.CheckedDeepCopy (vtkGraph g)` - Performs the same operation as DeepCopy(), but instead of reporting an error for an incompatible graph, returns false.
- `obj.Squeeze ()`
- `obj.ReorderOutVertices (vtkIdType v, vtkIdTypeArray vertices)` - Reorder the outgoing vertices of a vertex. The vertex list must have the same elements as the current out edge list, just in a different order. This method does not change the topology of the graph. In a distributed graph, the vertex v must be local.
- `bool = obj.IsSameStructure (vtkGraph other)` - Returns true if both graphs point to the same adjacency structure. Can be used to test the copy-on-write feature of the graph.
- `vtkIdType = obj.GetSourceVertex (vtkIdType e)` - Retrieve the source and target vertices for an edge id. NOTE: The first time this is called, the graph will build a mapping array from edge id to source/target that is the same size as the number of edges in the graph. If you have access to a vtkOutEdgeType, vtkInEdgeType, vtkEdgeType, or vtkGraphEdge, you should directly use these structures to look up the source or target instead of this method.
- `vtkIdType = obj.GetTargetVertex (vtkIdType e)` - Retrieve the source and target vertices for an edge id. NOTE: The first time this is called, the graph will build a mapping array from edge id to source/target that is the same size as the number of edges in the graph. If you have access to a vtkOutEdgeType, vtkInEdgeType, vtkEdgeType, or vtkGraphEdge, you should directly use these structures to look up the source or target instead of this method.
- `vtkIdType = obj.GetNumberOfEdgePoints (vtkIdType e)` - Get the number of edge points associated with an edge.
- `double = obj.GetEdgePoint (vtkIdType e, vtkIdType i)` - Get the x,y,z location of a point along edge e.
- `obj.ClearEdgePoints (vtkIdType e)` - Clear all points associated with an edge.
- `obj.SetEdgePoint (vtkIdType e, vtkIdType i, double x[3])` - Set an x,y,z location of a point along an edge. This assumes there is already a point at location i, and simply overwrites it.
- `obj.SetEdgePoint (vtkIdType e, vtkIdType i, double x, double y, double z)` - Adds a point to the end of the list of edge points for a certain edge.
- `obj.AddEdgePoint (vtkIdType e, double x[3])` - Adds a point to the end of the list of edge points for a certain edge.

- `obj.AddEdgePoint (vtkIdType e, double x, double y, double z)` - Copy the internal edge point data from another graph into this graph. Both graphs must have the same number of edges.
- `obj.ShallowCopyEdgePoints (vtkGraph g)` - Copy the internal edge point data from another graph into this graph. Both graphs must have the same number of edges.
- `obj.DeepCopyEdgePoints (vtkGraph g)` - Copy the internal edge point data from another graph into this graph. Both graphs must have the same number of edges.
- `vtkGraphInternals = obj.GetGraphInternals (bool modifying)` - Returns the internal representation of the graph. If modifying is true, then the returned vtkGraphInternals object will be unique to this vtkGraph object.
- `obj.GetInducedEdges (vtkIdTypeArray verts, vtkIdTypeArray edges)` - Fills a list of edge indices with the edges contained in the induced subgraph formed by the vertices in the vertex list.
- `vtkFieldData = obj.GetAttributesAsFieldData (int type)` - Returns the attributes of the data object as a vtkFieldData. This returns non-null values in all the same cases as GetAttributes, in addition to the case of FIELD, which will return the field data for any vtkDataObject subclass.
- `vtkIdType = obj.GetNumberOfElements (int type)` - Get the number of elements for a specific attribute type (VERTEX, EDGE, etc.).
- `obj.Dump ()` - Dump the contents of the graph to standard output.

31.85 vtkGraphAlgorithm

31.85.1 Usage

vtkGraphAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be Graph. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation. For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

.SECTION Thanks Thanks to Patricia Crossno, Ken Moreland, Andrew Wilson and Brian Wylie from Sandia National Laboratories for their help in developing this class.

To create an instance of class vtkGraphAlgorithm, simply invoke its constructor as follows

```
obj = vtkGraphAlgorithm
```

31.85.2 Methods

The class vtkGraphAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphAlgorithm = obj.NewInstance ()`

- `vtkGraphAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkGraph = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkGraph = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.86 vtkGraphEdge

31.86.1 Usage

A heavy-weight (vtkObject subclass) graph edge object that may be used instead of the vtkEdgeType struct, for use with wrappers. The edge contains the source and target vertex ids, and the edge id.

To create an instance of class vtkGraphEdge, simply invoke its constructor as follows

```
obj = vtkGraphEdge
```

31.86.2 Methods

The class vtkGraphEdge has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGraphEdge class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGraphEdge = obj.NewInstance ()`
- `vtkGraphEdge = obj.SafeDownCast (vtkObject o)`
- `obj.SetSource (vtkIdType )` - The source of the edge.
- `vtkIdType = obj.GetSource ()` - The source of the edge.
- `obj.SetTarget (vtkIdType )` - The target of the edge.
- `vtkIdType = obj.GetTarget ()` - The target of the edge.
- `obj.SetId (vtkIdType )` - The id of the edge.
- `vtkIdType = obj.GetId ()` - The id of the edge.

31.87 vtkGraphInternals

31.87.1 Usage

This is the internal representation of vtkGraph, used only in rare cases where one must modify that representation.

To create an instance of class vtkGraphInternals, simply invoke its constructor as follows

```
obj = vtkGraphInternals
```

31.88 vtkHexagonalPrism

31.88.1 Usage

vtkHexagonalPrism is a concrete implementation of vtkCell to represent a linear 3D prism with hexagonal base. Such prism is defined by the twelve points (0-12) where (0,1,2,3,4,5) is the base of the prism which, using the right hand rule, forms a hexagon whose normal points is in the direction of the opposite face (6,7,8,9,10,11).

To create an instance of class vtkHexagonalPrism, simply invoke its constructor as follows

```
obj = vtkHexagonalPrism
```

31.88.2 Methods

The class vtkHexagonalPrism has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHexagonalPrism class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHexagonalPrism = obj.NewInstance ()`
- `vtkHexagonalPrism = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the wedge in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[12])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[36])` - Return the ids of the vertices defining edge/face (‘edgeId‘/‘faceId’). Ids are related to the cell, not to the dataset.

31.89 vtkHexahedron

31.89.1 Usage

vtkHexahedron is a concrete implementation of vtkCell to represent a linear, 3D rectangular hexahedron (e.g., "brick" topology). vtkHexahedron uses the standard isoparametric shape functions for a linear hexahedron. The hexahedron is defined by the eight points (0-7) where (0,1,2,3) is the base of the hexahedron which, using the right hand rule, forms a quadrilaterial whose normal points in the direction of the opposite face (4,5,6,7).

To create an instance of class vtkHexahedron, simply invoke its constructor as follows

```
obj = vtkHexahedron
```

31.89.2 Methods

The class vtkHexahedron has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHexahedron class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHexahedron = obj.NewInstance ()`
- `vtkHexahedron = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.InterpolateFunctions (double pcoords[3], double weights[8])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[24])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.90 vtkHierarchicalBoxDataIterator

31.90.1 Usage

To create an instance of class vtkHierarchicalBoxDataIterator, simply invoke its constructor as follows

```
obj = vtkHierarchicalBoxDataIterator
```

31.90.2 Methods

The class vtkHierarchicalBoxDataIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalBoxDataIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalBoxDataIterator = obj.NewInstance ()`
- `vtkHierarchicalBoxDataIterator = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCurrentLevel ()` - Returns the level for the current dataset.
- `int = obj.GetCurrentIndex ()` - Returns the dataset index for the current data object. Valid only if the current data is a leaf node i.e. no a composite dataset.

31.91 vtkHierarchicalBoxDataSet

31.91.1 Usage

vtkHierarchicalBoxDataSet is a concrete implementation of vtkCompositeDataSet. The dataset type is restricted to vtkUniformGrid. Each dataset has an associated vtkAMRBox that represents it's region (similar to extent) in space.

.SECTION Warning To compute the cellId of a cell within a vtkUniformGrid with AMRBox=box, you should not use vtkUniformGrid::ComputeCellId(x,y,z) but instead use the following pseudo code: for (int i=0; i¡3; i++) cellDims[i] = box.HiCorner[i] - box.LoCorner[i] + 1; vtkIdType cellId = (z-box.LoCorner[2])*cellDims[0]*cellDims[1] + (y-box.LoCorner[1])*cellDims[0] + (x-box.LoCorner[0]);

NOTE vtkAMRBox is used to compute cell visibility, therefor it should be dimensioned according to the visible region.

To create an instance of class vtkHierarchicalBoxDataSet, simply invoke its constructor as follows

```
obj = vtkHierarchicalBoxDataSet
```

31.91.2 Methods

The class vtkHierarchicalBoxDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalBoxDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalBoxDataSet = obj.NewInstance ()`
- `vtkHierarchicalBoxDataSet = obj.SafeDownCast (vtkObject o)`
- `vtkCompositeDataIterator = obj.NewIterator ()` - Return a new iterator (the iterator has to be deleted by user).
- `int = obj.GetDataObjectType ()` - Set the number of refinement levels. This call might cause allocation if the new number of levels is larger than the current one.
- `obj.SetNumberOfLevels (int numLevels)` - Set the number of refinement levels. This call might cause allocation if the new number of levels is larger than the current one.

- `int = obj.GetNumberOfLevels ()` - Returns the number of levels.
- `obj.SetNumberOfDataSets (int level, int numdatasets)` - Set the number of data set at a given level.
- `int = obj.GetNumberOfDataSets (int level)` - Returns the number of data sets available at any level.
- `obj.SetDataSet (vtkCompositeDataIterator iter, vtkDataObject dataObj)` - Set the dataset pointer for a given node. This will resize the number of levels and the number of datasets in the level to fit level, id requested.
- `obj.SetDataSet (int level, int id, int LoCorner[3], int HiCorner[3], vtkUniformGrid dataSet)` - Set the dataset pointer for a given node. This will resize the number of levels and the number of datasets in the level to fit level, id requested.
- `vtkInformation = obj.GetLevelMetaData (int level)` - Returns if meta-data exists for a given level.
- `int = obj.HasLevelMetaData (int level)` - Get meta-data associated with a dataset. This may allocate a new vtkInformation object if none is already present. Use HasMetaData to avoid unnecessary allocations.
- `vtkInformation = obj.GetMetaData (int level, int index)` - Get meta-data associated with a dataset. This may allocate a new vtkInformation object if none is already present. Use HasMetaData to avoid unnecessary allocations.
- `int = obj.HasMetaData (int level, int index)` - Returns if meta-data exists for a given dataset under a given level.
- `obj.SetRefinementRatio (int level, int refRatio)` - Sets the refinement of a given level. The spacing at level level+1 is defined as spacing(level+1) = spacing(level)/refRatio(level). Note that currently, this is not enforced by this class however some algorithms might not function properly if the spacing in the blocks (vtkUniformGrid) does not match the one described by the refinement ratio.
- `int = obj.GetRefinementRatio (int level)` - Returns the refinement of a given level.
- `int = obj.GetRefinementRatio (vtkCompositeDataIterator iter)` - Returns the refinement ratio for the position pointed by the iterator.
- `obj.GenerateVisibilityArrays ()` - Blank lower level cells if they are overlapped by higher level ones.
- `obj.GetScalarRange (double range[])` - Copy the cached scalar range into range.
- `vtkDataObject = obj.GetDataSet (vtkCompositeDataIterator iter)` - Unhiding superclass method.
- `vtkInformation = obj.GetMetaData (vtkCompositeDataIterator iter)` - Unhiding superclass method.
- `int = obj.HasMetaData (vtkCompositeDataIterator iter)` - Given the level and dataset index, returns the flat index provided level and dataset index are valid.
- `int = obj.GetFlatIndex (int level, int index)` - Given the level and dataset index, returns the flat index provided level and dataset index are valid.

31.92 vtkHierarchicalBoxDataSetAlgorithm

31.92.1 Usage

Algorithms that take any type of data object (including composite dataset) and produce a vtkHierarchicalBoxDataSet in the output can subclass from this class.

To create an instance of class vtkHierarchicalBoxDataSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkHierarchicalBoxDataSetAlgorithm
```

31.92.2 Methods

The class vtkHierarchicalBoxDataSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHierarchicalBoxDataSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHierarchicalBoxDataSetAlgorithm = obj.NewInstance ()`
- `vtkHierarchicalBoxDataSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkHierarchicalBoxDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkHierarchicalBoxDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.93 vtkHyperOctree

31.93.1 Usage

An hyperoctree is a dataset where each node has either exactly 2n̂ children or no child at all if the node is a leaf. 'n' is the dimension of the dataset (1 (binary tree), 2 (quadtree) or 3 (octree)). The class name comes from the following paper:

```
@ARTICLE{yau-srihari-1983,
 author={Mann-May Yau and Sargur N. Srihari},
 title={A Hierarchical Data Structure for Multidimensional Digital Images},
 journal={Communications of the ACM},
 month={July},
 year={1983},
```

```
volume={26},
number={7},
pages={504--515}
}
```

Each node is a cell. Attributes are associated with cells, not with points. The geometry is implicitly given by the size of the root node on each axis and position of the center and the orientation. (TODO: review center position and orientation). The geometry is then not limited to an hybercube but can have a rectangular shape. Attributes are associated with leaves. For LOD (Level-Of-Detail) purpose, attributes can be computed on none-leaf nodes by computing the average values from its children (which can be leaves or not).

By construction, an hyperoctree is efficient in memory usage when the geometry is sparse. The LOD feature allows to cull quickly part of the dataset.

A couple of filters can be applied on this dataset: contour, outline, geometry.

* 3D case (octree) for each node, each child index (from 0 to 7) is encoded in the following orientation. It is easy to access each child as a cell of a grid. Note also that the binary representation is relevant, each bit code a side: bit 0 encodes -x side (0) or +x side (1) bit 1 encodes -y side (0) or +y side (1) bit 2 encodes -z side (0) or +z side (2) - the -z side first - 0: -y -x sides - 1: -y +x sides - 2: +y -x sides - 3: +y +x sides

```
             +y
+-+-+        \^
|2|3|        |
+-+-+  O +z  +-> +x
|0|1|
+-+-+
```

- then the +z side, in counter-clockwise - 4: -y -x sides - 5: -y +x sides - 6: +y -x sides - 7: +y +x sides

```
             +y
+-+-+        \^
|6|7|        |
+-+-+  O +z  +-> +x
|4|5|
+-+-+
```

The cases with fewer dimensions are consistent with the octree case:

* Quadtree: in counter-clockwise - 0: -y -x edges - 1: -y +x edges - 2: +y -x edges - 3: +y +x edges

```
        +y
+-+-+   \^
|2|3|   |
+-+-+  O+-> +x
|0|1|
+-+-+
```

* Binary tree:

```
+0+1+  O+-> +x
```

To create an instance of class vtkHyperOctree, simply invoke its constructor as follows

```
obj = vtkHyperOctree
```

31.93.2 Methods

The class vtkHyperOctree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctree = obj.NewInstance ()`
- `vtkHyperOctree = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Return what type of dataset this is.
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an input rectilinear grid object.
- `int = obj.GetDimension ()` - Return the dimension of the tree (1D:binary tree(2 children), 2D:quadtree(4 children), 3D:octree (8 children))
- `obj.SetDimension (int dim)` - Set the dimension of the tree with 'dim'. See GetDimension() for details.
- `vtkIdType = obj.GetNumberOfCells ()` - Return the number of cells in the dual grid.
- `vtkIdType = obj.GetNumberOfLeaves ()` - Get the number of leaves in the tree.
- `vtkIdType = obj.GetNumberOfPoints ()` - Return the number of points in the dual grid.
- `vtkIdType = obj.GetMaxNumberOfPoints (int level)` - Return the number of points corresponding to an hyperoctree starting at level 'level' where all the leaves at at the last level. In this case, the hyperoctree is like a uniform grid. So this number is the number of points of the uniform grid.
- `vtkIdType = obj.GetMaxNumberOfPointsOnBoundary (int level)` - Return the number of points corresponding to the boundary of an hyperoctree starting at level 'level' where all the leaves at at the last level. In this case, the hyperoctree is like a uniform grid. So this number is the number of points of on the boundary of the uniform grid. For an octree, the boundary are the faces. For a quadtree, the boundary are the edges.
- `vtkIdType = obj.GetMaxNumberOfCellsOnBoundary (int level)` - Return the number of cells corresponding to the boundary of a cell of level 'level' where all the leaves at at the last level.
- `vtkIdType = obj.GetNumberOfLevels ()` - Return the number of levels.
- `obj.SetSize (double , double , double )` - Set the size on each axis.
- `obj.SetSize (double  a[3])` - Set the size on each axis.
- `double = obj. GetSize ()` - Return the size on each axis.
- `obj.SetOrigin (double , double , double )` - Set the origin (position of corner (0,0,0) of the root.
- `obj.SetOrigin (double  a[3])` - Set the origin (position of corner (0,0,0) of the root.
- `double = obj. GetOrigin ()` - Set the origin (position of corner (0,0,0) of the root. Return the origin (position of corner (0,0,0)) of the root.
- `vtkHyperOctreeCursor = obj.NewCellCursor ()` - Create a new cursor: an object that can traverse the cell of an hyperoctree.

- `obj.SubdivideLeaf (vtkHyperOctreeCursor leaf)` - Subdivide node pointed by cursor, only if its a leaf. At the end, cursor points on the node that used to be leaf.
- `obj.CollapseTerminalNode (vtkHyperOctreeCursor node)` - Collapse a node for which all children are leaves. At the end, cursor points on the leaf that used to be a node.
- `double = obj.GetPoint (vtkIdType ptId)` - Get point coordinates with ptId such that: 0 ¡= ptId ¡ NumberOfPoints. THIS METHOD IS NOT THREAD SAFE.
- `obj.GetPoint (vtkIdType id, double x[3])` - Copy point coordinates into user provided array x[3] for specified point id. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Get cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. THIS METHOD IS NOT THREAD SAFE.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Get cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. This is a thread-safe alternative to the previous GetCell() method. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `int = obj.GetCellType (vtkIdType cellId)` - Get type of cell with cellId such that: 0 ¡= cellId ¡ NumberOfCells. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Topological inquiry to get points defining cell. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Topological inquiry to get cells using point. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `obj.GetCellNeighbors (vtkIdType cellId, vtkIdList ptIds, vtkIdList cellIds)` - Topological inquiry to get all cells using list of points exclusive of cell specified (e.g., cellId). Note that the list consists of only cells that use ALL the points provided. THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `vtkIdType = obj.FindPoint (double x[3])`
- `obj.Initialize ()` - Restore data object to initial state, THIS METHOD IS NOT THREAD SAFE.
- `int = obj.GetMaxCellSize ()` - Convenience method returns largest cell size in dataset. This is generally used to allocate memory for supporting data structures. This is the number of points of a cell. THIS METHOD IS THREAD SAFE
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.GetPointsOnFace (vtkHyperOctreeCursor sibling, int face, int level, vtkHyperOctreePointsGrabber` - Get the points of node 'sibling' on its face 'face'.
- `obj.GetPointsOnParentFaces (int faces[3], int level, vtkHyperOctreeCursor cursor, vtkHyperOctreePoi` - Get the points of the parent node of 'cursor' on its faces 'faces' at level 'level' or deeper.
- `obj.GetPointsOnEdge (vtkHyperOctreeCursor sibling, int level, int axis, int k, int j, vtkHyperOctre` - Get the points of node 'sibling' on its edge 'axis','k','j'. If axis==0, the edge is X-aligned and k gives the z coordinate and j the y-coordinate. If axis==1, the edge is Y-aligned and k gives the x coordinate and j the z coordinate. If axis==2, the edge is Z-aligned and k gives the y coordinate and j the x coordinate.

- `obj.GetPointsOnParentEdge (vtkHyperOctreeCursor cursor, int level, int axis, int k, int j, vtkHyper`
  - Get the points of the parent node of 'cursor' on its edge 'axis','k','j' at level 'level' or deeper. If axis==0, the edge is X-aligned and k gives the z coordinate and j the y-coordinate. If axis==1, the edge is Y-aligned and k gives the x coordinate and j the z coordinate. If axis==2, the edge is Z-aligned and k gives the y coordinate and j the x coordinate.
- `obj.GetPointsOnEdge2D (vtkHyperOctreeCursor sibling, int edge, int level, vtkHyperOctreePointsGrabb`
  - Get the points of node 'sibling' on its edge 'edge'.
- `obj.GetPointsOnParentEdge2D (vtkHyperOctreeCursor cursor, int edge, int level, vtkHyperOctreePoints`
  - Get the points of the parent node of 'cursor' on its edge 'edge' at level 'level' or deeper. (edge=0 for -X, 1 for +X, 2 for -Y, 3 for +Y)
- `vtkDataSetAttributes = obj.GetLeafData ()` - A generic way to set the leaf data attributes. This can be either point data for dual or cell data for normal grid.
- `obj.SetDualGridFlag (int flag)` - Switch between returning leaves as cells, or the dual grid.
- `int = obj.GetDualGridFlag ()` - Switch between returning leaves as cells, or the dual grid.
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.

31.94 vtkHyperOctreeAlgorithm

31.94.1 Usage

To create an instance of class vtkHyperOctreeAlgorithm, simply invoke its constructor as follows

```
obj = vtkHyperOctreeAlgorithm
```

31.94.2 Methods

The class vtkHyperOctreeAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeAlgorithm = obj.NewInstance ()`
- `vtkHyperOctreeAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkHyperOctree = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkHyperOctree = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `vtkHyperOctree = obj.GetHyperOctreeInput (int port)`

- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm.

31.95 vtkHyperOctreeCursor

31.95.1 Usage

Objects that can traverse hyperoctree nodes. It is an abstract class. Cursors are created by the hyperoctree.
To create an instance of class vtkHyperOctreeCursor, simply invoke its constructor as follows

```
obj = vtkHyperOctreeCursor
```

31.95.2 Methods

The class vtkHyperOctreeCursor has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkHyperOctreeCursor class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkHyperOctreeCursor = obj.NewInstance ()`
- `vtkHyperOctreeCursor = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetLeafId ()` - Return the index of the current leaf in the data arrays.
- `int = obj.CurrentIsLeaf ()` - Is the node pointed by the cursor a leaf?
- `int = obj.CurrentIsRoot ()` - Is the node pointed by the cursor the root?
- `int = obj.GetCurrentLevel ()` - Return the level of the node pointed by the cursor.
- `int = obj.GetChildIndex ()` - Return the child number of the current node relative to its parent.
- `int = obj.CurrentIsTerminalNode ()`
- `obj.ToRoot ()` - Move the cursor the root node.
- `obj.ToParent ()` - Move the cursor to the parent of the current node.
- `obj.ToChild (int child)` - Move the cursor to child ‘child’ of the current node.
- `obj.ToSameNode (vtkHyperOctreeCursor other)` - Move the cursor to the same node pointed by ‘other’.
- `int = obj.IsEqual (vtkHyperOctreeCursor other)` - Is ‘this’ equal to ‘other’?
- `vtkHyperOctreeCursor = obj.Clone ()` - Create a copy of ‘this’.
- `int = obj.SameTree (vtkHyperOctreeCursor other)` - Are ‘this’ and ‘other’ pointing on the same hyperoctree?
- `int = obj.GetIndex (int d)` - Return the index in dimension ‘d’, as if the node was a cell of a uniform grid of 1¡¡GetCurrentLevel() cells in each dimension.

- `int = obj.GetNumberOfChildren ()` - Return the number of children for each node of the tree.
- `int = obj.GetDimension ()` - Return the dimension of the tree.
- `obj.MoveToNode (int indices, int level)` - Move to the node described by its indices in each dimension and at a given level. If there is actually a node or a leaf at this location, Found() returns true. Otherwise, Found() returns false and the cursor moves to the closest parent of the query. It can be the root in the worst case.
- `int = obj.Found ()`

31.96 vtkImageAlgorithm

31.96.1 Usage

vtkImageAlgorithm is a filter superclass that hides much of the pipeline complexity. It handles breaking the pipeline execution into smaller extents so that the vtkImageData limits are observed. It also provides support for multithreading. If you don't need any of this functionality, consider using vtkSimpleImageToImageFilter instead. .SECTION See also vtkSimpleImageToImageFilter

To create an instance of class vtkImageAlgorithm, simply invoke its constructor as follows

```
obj = vtkImageAlgorithm
```

31.96.2 Methods

The class vtkImageAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageAlgorithm = obj.NewInstance ()`
- `vtkImageAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkImageData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkImageData = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `vtkDataObject = obj.GetInput (int port)`
- `vtkDataObject = obj.GetInput ()`

- `vtkImageData = obj.GetImageDataInput (int port)`
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.97 vtkImageData

31.97.1 Usage

vtkImageData is a data object that is a concrete implementation of vtkDataSet. vtkImageData represents a geometric structure that is a topological and geometrical regular array of points. Examples include volumes (voxel data) and pixmaps.

To create an instance of class vtkImageData, simply invoke its constructor as follows

```
obj = vtkImageData
```

31.97.2 Methods

The class vtkImageData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageData = obj.NewInstance ()`
- `vtkImageData = obj.SafeDownCast (vtkObject o)`
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an input image data object.
- `int = obj.GetDataObjectType ()` - Return what type of dataset this is.
- `vtkIdType = obj.GetNumberOfCells ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.GetNumberOfPoints ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `double = obj.GetPoint (vtkIdType ptId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPoint (vtkIdType id, double x[3])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Standard vtkDataSet API methods. See vtkDataSet for more information.

- `obj.GetCellBounds (vtkIdType cellId, double bounds[6])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.FindPoint (double x, double y, double z)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.FindPoint (double x[3])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetCellType (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.ComputeBounds ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetMaxCellSize ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.Initialize ()` - Restore data object to initial state,
- `obj.SetDimensions (int i, int j, int k)` - Pass your way. This is for backward compatibility only. Use SetExtent() instead. Same as SetExtent(0, i-1, 0, j-1, 0, k-1)
- `obj.SetDimensions (int dims[3])` - Pass your way. This is for backward compatibility only. Use SetExtent() instead. Same as SetExtent(0, dims[0]-1, 0, dims[1]-1, 0, dims[2]-1)
- `int = obj.GetDimensions ()` - Get dimensions of this structured points dataset. It is the number of points on each axis. Dimensions are computed from Extents during this call.
- `obj.GetDimensions (int dims[3])` - Get dimensions of this structured points dataset. It is the number of points on each axis. Dimensions are computed from Extents during this call.
- `int = obj.ComputeStructuredCoordinates (double x[3], int ijk[3], double pcoords[3])` - Convenience function computes the structured coordinates for a point x[3]. The voxel is specified by the array ijk[3], and the parametric coordinates in the cell are specified with pcoords[3]. The function returns a 0 if the point x is outside of the volume, and a 1 if inside the volume.
- `obj.GetVoxelGradient (int i, int j, int k, vtkDataArray s, vtkDataArray g)` - Given structured coordinates (i,j,k) for a voxel cell, compute the eight gradient values for the voxel corners. The order in which the gradient vectors are arranged corresponds to the ordering of the voxel points. Gradient vector is computed by central differences (except on edges of volume where forward difference is used). The scalars s are the scalars from which the gradient is to be computed. This method will treat only 3D structured point datasets (i.e., volumes).
- `obj.GetPointGradient (int i, int j, int k, vtkDataArray s, double g[3])` - Given structured coordinates (i,j,k) for a point in a structured point dataset, compute the gradient vector from the scalar data at that point. The scalars s are the scalars from which the gradient is to be computed. This method will treat structured point datasets of any dimension.
- `int = obj.GetDataDimension ()` - Return the dimensionality of the data.
- `vtkIdType = obj.ComputePointId (int ijk[3])` - Given a location in structured coordinates (i-j-k), return the point id.
- `vtkIdType = obj.ComputeCellId (int ijk[3])` - Given a location in structured coordinates (i-j-k), return the cell id.

- `obj.SetAxisUpdateExtent (int axis, int min, int max)` - Set / Get the extent on just one axis
- `obj.UpdateInformation ()` - Override to copy information from pipeline information to data information for backward compatibility. See vtkDataObject::UpdateInformation for details.
- `obj.SetExtent (int extent[6])` - Set/Get the extent. On each axis, the extent is defined by the index of the first point and the index of the last point. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z). The dataset extent does not have to start at (0,0,0). (0,0,0) is just the extent of the origin. The first point (the one with Id=0) is at extent (Extent[0],Extent[2],Extent[4]). As for any dataset, a data array on point data starts at Id=0.
- `obj.SetExtent (int x1, int x2, int y1, int y2, int z1, int z2)` - Set/Get the extent. On each axis, the extent is defined by the index of the first point and the index of the last point. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z). The dataset extent does not have to start at (0,0,0). (0,0,0) is just the extent of the origin. The first point (the one with Id=0) is at extent (Extent[0],Extent[2],Extent[4]). As for any dataset, a data array on point data starts at Id=0.
- `int = obj. GetExtent ()` - Set/Get the extent. On each axis, the extent is defined by the index of the first point and the index of the last point. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z). The dataset extent does not have to start at (0,0,0). (0,0,0) is just the extent of the origin. The first point (the one with Id=0) is at extent (Extent[0],Extent[2],Extent[4]). As for any dataset, a data array on point data starts at Id=0.
- `long = obj.GetEstimatedMemorySize ()` - Get the estimated size of this data object itself. Should be called after UpdateInformation() and PropagateUpdateExtent() have both been called. This estimate should be fairly accurate since this is structured data.
- `double = obj.GetScalarTypeMin ()` - These returns the minimum and maximum values the ScalarType can hold without overflowing.
- `double = obj.GetScalarTypeMax ()` - These returns the minimum and maximum values the ScalarType can hold without overflowing.
- `int = obj.GetScalarSize ()` - Set the size of the scalar type in bytes.
- `vtkIdType = obj.GetIncrements ()` - Different ways to get the increments for moving around the data. GetIncrements() calls ComputeIncrements() to ensure the increments are up to date.
- `obj.GetIncrements (vtkIdType inc[3])` - Different ways to get the increments for moving around the data. GetIncrements() calls ComputeIncrements() to ensure the increments are up to date.
- `float = obj.GetScalarComponentAsFloat (int x, int y, int z, int component)` - For access to data from tcl
- `obj.SetScalarComponentFromFloat (int x, int y, int z, int component, float v)` - For access to data from tcl
- `double = obj.GetScalarComponentAsDouble (int x, int y, int z, int component)` - For access to data from tcl
- `obj.SetScalarComponentFromDouble (int x, int y, int z, int component, double v)` - For access to data from tcl
- `obj.AllocateScalars ()` - Allocate the vtkScalars object associated with this object.
- `obj.CopyAndCastFrom (vtkImageData inData, int extent[6])` - This method is passed a input and output region, and executes the filter algorithm to fill the output from the input. It just executes a switch statement to call the correct function for the regions data types.

- `obj.CopyAndCastFrom (vtkImageData inData, int x0, int x1, int y0, int y1, int z0, int z1)` - Reallocates and copies to set the Extent to the UpdateExtent. This is used internally when the exact extent is requested, and the source generated more than the update extent.

- `obj.Crop ()` - Reallocates and copies to set the Extent to the UpdateExtent. This is used internally when the exact extent is requested, and the source generated more than the update extent.

- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.

- `obj.SetSpacing (double , double , double )` - Set the spacing (width,height,length) of the cubical cells that compose the data set.

- `obj.SetSpacing (double  a[3])` - Set the spacing (width,height,length) of the cubical cells that compose the data set.

- `double = obj. GetSpacing ()` - Set the spacing (width,height,length) of the cubical cells that compose the data set.

- `obj.SetOrigin (double , double , double )` - Set/Get the origin of the dataset. The origin is the position in world coordinates of the point of extent (0,0,0). This point does not have to be part of the dataset, in other words, the dataset extent does not have to start at (0,0,0) and the origin can be outside of the dataset bounding box. The origin plus spacing determine the position in space of the points.

- `obj.SetOrigin (double  a[3])` - Set/Get the origin of the dataset. The origin is the position in world coordinates of the point of extent (0,0,0). This point does not have to be part of the dataset, in other words, the dataset extent does not have to start at (0,0,0) and the origin can be outside of the dataset bounding box. The origin plus spacing determine the position in space of the points.

- `double = obj. GetOrigin ()` - Set/Get the origin of the dataset. The origin is the position in world coordinates of the point of extent (0,0,0). This point does not have to be part of the dataset, in other words, the dataset extent does not have to start at (0,0,0) and the origin can be outside of the dataset bounding box. The origin plus spacing determine the position in space of the points.

- `obj.SetScalarTypeToFloat ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToDouble ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToInt ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToUnsignedInt ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToLong ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToUnsignedLong ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToShort ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToUnsignedShort ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToUnsignedChar ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToSignedChar ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarTypeToChar ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetScalarType (int )` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `int = obj.GetScalarType ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `string = obj.GetScalarTypeAsString ()` - Set/Get the data scalar type (i.e VTK_DOUBLE). Note that these methods are setting and getting the pipeline scalar type. i.e. they are setting the type that the image data will be once it has executed. Until the REQUEST_DATA pass the actual scalars may be of some other type. This is for backwards compatibility

- `obj.SetNumberOfScalarComponents (int n)` - Set/Get the number of scalar components for points. As with the SetScalarType method this is setting pipeline info.

- `int = obj.GetNumberOfScalarComponents ()` - Set/Get the number of scalar components for points. As with the SetScalarType method this is setting pipeline info.

- `obj.CopyTypeSpecificInformation (vtkDataObject image)`

- `obj.CopyInformationToPipeline (vtkInformation request, vtkInformation input, vtkInformation output,` - Override these to handle origin, spacing, scalar type, and scalar number of components. See vtkDataObject for details.
- `obj.CopyInformationFromPipeline (vtkInformation request)` - Override these to handle origin, spacing, scalar type, and scalar number of components. See vtkDataObject for details.
- `obj.PrepareForNewData ()` - make the output data ready for new data to be inserted. For most objects we just call Initialize. But for image data we leave the old data in case the memory can be reused.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.ComputeInternalExtent (int intExt, int tgtExt, int bnds)` - Given how many pixel are required on a side for bounrary conditions (in bnds), the target extent to traverse, compute the internal extent (the extent for this ImageData that does nto suffer from any boundary conditions) and place it in intExt
- `int = obj.GetExtentType ()` - The extent type is a 3D extent

31.98 vtkImageInPlaceFilter

31.98.1 Usage

vtkImageInPlaceFilter is a filter super class that operates directly on the input region. The data is copied if the requested region has different extent than the input region or some other object is referencing the input region.

To create an instance of class vtkImageInPlaceFilter, simply invoke its constructor as follows

```
obj = vtkImageInPlaceFilter
```

31.98.2 Methods

The class vtkImageInPlaceFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageInPlaceFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageInPlaceFilter = obj.NewInstance ()`
- `vtkImageInPlaceFilter = obj.SafeDownCast (vtkObject o)`

31.99 vtkImageMultipleInputFilter

31.99.1 Usage

vtkImageMultipleInputFilter is a super class for filters that have any number of inputs. Streaming is not available in this class yet.

To create an instance of class vtkImageMultipleInputFilter, simply invoke its constructor as follows

```
obj = vtkImageMultipleInputFilter
```

31.99.2 Methods

The class vtkImageMultipleInputFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMultipleInputFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMultipleInputFilter = obj.NewInstance ()`
- `vtkImageMultipleInputFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (int num, vtkImageData input)` - Set an Input of this filter.
- `obj.AddInput (vtkImageData input)` - Adds an input to the first null position in the input list. Expands the list memory if necessary
- `obj.RemoveInput (vtkImageData input)` - Adds an input to the first null position in the input list. Expands the list memory if necessary
- `vtkImageData = obj.GetInput (int num)` - Get one input to this filter.
- `vtkImageData = obj.GetInput ()` - Get one input to this filter.
- `obj.SetBypass (int )` - Turning bypass on will cause the filter to turn off and simply pass the data from the first input (input0) through. It is implemented for consistency with vtkImageToImageFilter.
- `int = obj.GetBypass ()` - Turning bypass on will cause the filter to turn off and simply pass the data from the first input (input0) through. It is implemented for consistency with vtkImageToImageFilter.
- `obj.BypassOn ()` - Turning bypass on will cause the filter to turn off and simply pass the data from the first input (input0) through. It is implemented for consistency with vtkImageToImageFilter.
- `obj.BypassOff ()` - Turning bypass on will cause the filter to turn off and simply pass the data from the first input (input0) through. It is implemented for consistency with vtkImageToImageFilter.
- `obj.SetNumberOfThreads (int )` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreadsMinValue ()` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreadsMaxValue ()` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreads ()` - Get/Set the number of threads to create when rendering
- `int = obj.SplitExtent (int splitExt[6], int startExt[6], int num, int total)` - Putting this here until I merge graphics and imaging streaming.

31.100 vtkImageMultipleInputOutputFilter

31.100.1 Usage

vtkImageMultipleInputOutputFilter is a super class for filters that have any number of inputs. Streaming is not available in this class yet.

To create an instance of class vtkImageMultipleInputOutputFilter, simply invoke its constructor as follows

```
obj = vtkImageMultipleInputOutputFilter
```

31.100.2 Methods

The class vtkImageMultipleInputOutputFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageMultipleInputOutputFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageMultipleInputOutputFilter = obj.NewInstance ()`
- `vtkImageMultipleInputOutputFilter = obj.SafeDownCast (vtkObject o)`
- `vtkImageData = obj.GetOutput (int num)` - Get one input to this filter.
- `vtkImageData = obj.GetOutput ()` - Get one input to this filter.

31.101 vtkImageSource

31.101.1 Usage

vtkImageSource is the superclass for all imaging sources and filters. The method Update(), called by the cache, is the major interface to the source.

To create an instance of class vtkImageSource, simply invoke its constructor as follows

```
obj = vtkImageSource
```

31.101.2 Methods

The class vtkImageSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageSource = obj.NewInstance ()`
- `vtkImageSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutput (vtkImageData output)` - Get the output of this source.
- `vtkImageData = obj.GetOutput ()` - Get the output of this source.
- `vtkImageData = obj.GetOutput (int idx)` - Get the output of this source.

31.102 vtkImageToImageFilter

31.102.1 Usage

vtkImageToImageFilter is a filter superclass that hides much of the pipeline complexity. It handles breaking the pipeline execution into smaller extents so that the vtkImageData limits are observed. It also provides support for multithreading. If you don't need any of this functionality, consider using vtkSimpleImageToImageFilter instead. .SECTION Warning This used to be the parent class for most imaging filter in VTK4.x,

now this role has been replaced by vtkImageAlgorithm. You should consider using vtkImageAlgorithm instead, when writing filter for VTK5 and above. This class was kept to ensure full backward compatibility. .SECTION See also vtkSimpleImageToImageFilter vtkImageSpatialFilter vtkImageAlgorithm

To create an instance of class vtkImageToImageFilter, simply invoke its constructor as follows

```
obj = vtkImageToImageFilter
```

31.102.2 Methods

The class vtkImageToImageFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageToImageFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageToImageFilter = obj.NewInstance ()`
- `vtkImageToImageFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData input)` - Set the Input of a filter.
- `vtkImageData = obj.GetInput ()` - Set the Input of a filter.
- `obj.SetBypass (int )` - Obsolete feature - do not use.
- `obj.BypassOn ()` - Obsolete feature - do not use.
- `obj.BypassOff ()` - Obsolete feature - do not use.
- `int = obj.GetBypass ()` - Obsolete feature - do not use.
- `obj.ThreadedExecute (vtkImageData inData, vtkImageData outData, int extent[6], int threadId)` - If the subclass does not define an Execute method, then the task will be broken up, multiple threads will be spawned, and each thread will call this method. It is public so that the thread functions can call this method.
- `obj.SetNumberOfThreads (int )` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreadsMinValue ()` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreadsMaxValue ()` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreads ()` - Get/Set the number of threads to create when rendering
- `obj.SetInputMemoryLimit (int )`
- `long = obj.GetInputMemoryLimit ()`
- `int = obj.SplitExtent (int splitExt[6], int startExt[6], int num, int total)` - Putting this here until I merge graphics and imaging streaming.

31.103 vtkImageToStructuredPoints

31.103.1 Usage

vtkImageToStructuredPoints changes an image cache format to a structured points dataset. It takes an Input plus an optional VectorInput. The VectorInput converts the RGB scalar components of the VectorInput to vector pointdata attributes. This filter will try to reference count the data but in some cases it must make a copy.

To create an instance of class vtkImageToStructuredPoints, simply invoke its constructor as follows

```
obj = vtkImageToStructuredPoints
```

31.103.2 Methods

The class vtkImageToStructuredPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageToStructuredPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageToStructuredPoints = obj.NewInstance ()`
- `vtkImageToStructuredPoints = obj.SafeDownCast (vtkObject o)`
- `obj.SetVectorInput (vtkImageData input)` - Set/Get the input object from the image pipeline.
- `vtkImageData = obj.GetVectorInput ()` - Set/Get the input object from the image pipeline.
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output of the filter.

31.104 vtkImageTwoInputFilter

31.104.1 Usage

vtkImageTwoInputFilter handles two inputs. It is just a subclass of vtkImageMultipleInputFilter with some methods that are specific to two inputs. Although the inputs are labeled input1 and input2, they are stored in an array indexed starting at 0.

To create an instance of class vtkImageTwoInputFilter, simply invoke its constructor as follows

```
obj = vtkImageTwoInputFilter
```

31.104.2 Methods

The class vtkImageTwoInputFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImageTwoInputFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImageTwoInputFilter = obj.NewInstance ()`
- `vtkImageTwoInputFilter = obj.SafeDownCast (vtkObject o)`

- `obj.SetInput1 (vtkImageData input)` - Set the Input1 of this filter. If a ScalarType has not been set, then the ScalarType of the input is used.
- `obj.SetInput2 (vtkImageData input)` - Set the Input2 of this filter. If a ScalarType has not been set, then the ScalarType of the input is used.
- `vtkImageData = obj.GetInput1 ()` - Get the inputs to this filter.
- `vtkImageData = obj.GetInput2 ()` - Get the inputs to this filter.

31.105 vtkImplicitBoolean

31.105.1 Usage

vtkImplicitBoolean is an implicit function consisting of boolean combinations of implicit functions. The class has a list of functions (FunctionList) that are combined according to a specified operator (VTK_UNION or VTK_INTERSECTION or VTK_DIFFERENCE). You can use nested combinations of vtkImplicitFunction's (and/or vtkImplicitBoolean) to create elaborate implicit functions. vtkImplicitBoolean is a concrete implementation of vtkImplicitFunction.

The operators work as follows. The VTK_UNION operator takes the minimum value of all implicit functions. The VTK_INTERSECTION operator takes the maximum value of all implicit functions. The VTK_DIFFERENCE operator subtracts the 2nd through last implicit functions from the first. The VTK_UNION_OF_MAGNI takes the minimum absolute value of the implicit functions.

To create an instance of class vtkImplicitBoolean, simply invoke its constructor as follows

```
obj = vtkImplicitBoolean
```

31.105.2 Methods

The class vtkImplicitBoolean has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitBoolean class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitBoolean = obj.NewInstance ()`
- `vtkImplicitBoolean = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])` - Evaluate boolean combinations of implicit function using current operator.
- `double = obj.EvaluateFunction (double x, double y, double z)` - Evaluate boolean combinations of implicit function using current operator.
- `obj.EvaluateGradient (double x[3], double g[3])` - Evaluate gradient of boolean combination.
- `long = obj.GetMTime ()` - Override modified time retrieval because of object dependencies.
- `obj.AddFunction (vtkImplicitFunction in)` - Add another implicit function to the list of functions.
- `obj.RemoveFunction (vtkImplicitFunction in)` - Remove a function from the list of implicit functions to boolean.
- `vtkImplicitFunctionCollection = obj.GetFunction ()` - Return the collection of implicit functions.

- `obj.SetOperationType (int )` - Specify the type of boolean operation.
- `int = obj.GetOperationTypeMinValue ()` - Specify the type of boolean operation.
- `int = obj.GetOperationTypeMaxValue ()` - Specify the type of boolean operation.
- `int = obj.GetOperationType ()` - Specify the type of boolean operation.
- `obj.SetOperationTypeToUnion ()` - Specify the type of boolean operation.
- `obj.SetOperationTypeToIntersection ()` - Specify the type of boolean operation.
- `obj.SetOperationTypeToDifference ()` - Specify the type of boolean operation.
- `obj.SetOperationTypeToUnionOfMagnitudes ()` - Specify the type of boolean operation.
- `string = obj.GetOperationTypeAsString ()` - Specify the type of boolean operation.

31.106 vtkImplicitDataSet

31.106.1 Usage

vtkImplicitDataSet treats any type of dataset as if it were an implicit function. This means it computes a function value and gradient. vtkImplicitDataSet is a concrete implementation of vtkImplicitFunction.

vtkImplicitDataSet computes the function (at the point x) by performing cell interpolation. That is, it finds the cell containing x, and then uses the cell's interpolation functions to compute an interpolated scalar value at x. (A similar approach is used to find the gradient, if requested.) Points outside of the dataset are assigned the value of the ivar OutValue, and the gradient value OutGradient.

To create an instance of class vtkImplicitDataSet, simply invoke its constructor as follows

```
obj = vtkImplicitDataSet
```

31.106.2 Methods

The class vtkImplicitDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitDataSet = obj.NewInstance ()`
- `vtkImplicitDataSet = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Return the MTime also considering the DataSet dependency.
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double n[3])`
- `obj.SetDataSet (vtkDataSet )` - Set / get the dataset used for the implicit function evaluation.
- `vtkDataSet = obj.GetDataSet ()` - Set / get the dataset used for the implicit function evaluation.
- `obj.SetOutValue (double )` - Set / get the function value to use for points outside of the dataset.

- `double = obj.GetOutValue ()` - Set / get the function value to use for points outside of the dataset.
- `obj.SetOutGradient (double , double , double )` - Set / get the function gradient to use for points outside of the dataset.
- `obj.SetOutGradient (double a[3])` - Set / get the function gradient to use for points outside of the dataset.
- `double = obj. GetOutGradient ()` - Set / get the function gradient to use for points outside of the dataset.

31.107 vtkImplicitHalo

31.107.1 Usage

vtkImplicitHalo evaluates to 1.0 for each position in the sphere of a given center and radius Radius*(1-FadeOut). It evaluates to 0.0 for each position out the sphere of a given Center and radius Radius. It fades out linearly from 1.0 to 0.0 for points in a radius from Radius*(1-FadeOut) to Radius. vtkImplicitHalo is a concrete implementation of vtkImplicitFunction. It is useful as an input to vtkSampleFunction to generate an 2D image of an halo. It is used this way by vtkShadowMapPass.

To create an instance of class vtkImplicitHalo, simply invoke its constructor as follows

```
obj = vtkImplicitHalo
```

31.107.2 Methods

The class vtkImplicitHalo has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitHalo class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitHalo = obj.NewInstance ()`
- `vtkImplicitHalo = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double g[3])`
- `obj.SetRadius (double )` - Radius of the sphere.
- `double = obj.GetRadius ()` - Radius of the sphere.
- `obj.SetCenter (double , double , double )` - Center of the sphere.
- `obj.SetCenter (double a[3])` - Center of the sphere.
- `double = obj. GetCenter ()` - Center of the sphere.
- `obj.SetFadeOut (double )` - FadeOut ratio. Valid values are between 0.0 and 1.0.
- `double = obj.GetFadeOut ()` - FadeOut ratio. Valid values are between 0.0 and 1.0.

31.108 vtkImplicitSelectionLoop

31.108.1 Usage

vtkImplicitSelectionLoop computes the implicit function value and function gradient for a irregular, cylinder-like object whose cross section is defined by a set of points forming a loop. The loop need not be convex nor its points coplanar. However, the loop must be non-self-intersecting when projected onto the plane defined by the accumulated cross product around the loop (i.e., the axis of the loop). (Alternatively, you can specify the normal to use.)

The following procedure is used to compute the implicit function value for a point x. Each point of the loop is first projected onto the plane defined by the loop normal. This forms a polygon. Then, to evaluate the implicit function value, inside/outside tests are used to determine if x is inside the polygon, and the distance to the loop boundary is computed (negative values are inside the loop).

One example application of this implicit function class is to draw a loop on the surface of a mesh, and use the loop to clip or extract cells from within the loop. Remember, the selection loop is "infinite" in length, you can use a plane (in boolean combination) to cap the extent of the selection loop. Another trick is to use a connectivity filter to extract the closest region to a given point (i.e., one of the points used to define the selection loop).

To create an instance of class vtkImplicitSelectionLoop, simply invoke its constructor as follows

```
obj = vtkImplicitSelectionLoop
```

31.108.2 Methods

The class vtkImplicitSelectionLoop has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitSelectionLoop class.

- `string = obj.GetClassName ()` - Standard VTK methods for printing and type information.
- `int = obj.IsA (string name)` - Standard VTK methods for printing and type information.
- `vtkImplicitSelectionLoop = obj.NewInstance ()` - Standard VTK methods for printing and type information.
- `vtkImplicitSelectionLoop = obj.SafeDownCast (vtkObject o)` - Standard VTK methods for printing and type information.
- `double = obj.EvaluateFunction (double x[3])` - Evaluate selection loop returning a signed distance.
- `double = obj.EvaluateFunction (double x, double y, double z)` - Evaluate selection loop returning a signed distance.
- `obj.EvaluateGradient (double x[3], double n[3])` - Evaluate selection loop returning the gradient.
- `obj.SetLoop (vtkPoints )` - Set/Get the array of point coordinates defining the loop. There must be at least three points used to define a loop.
- `vtkPoints = obj.GetLoop ()` - Set/Get the array of point coordinates defining the loop. There must be at least three points used to define a loop.
- `obj.SetAutomaticNormalGeneration (int )` - Turn on/off automatic normal generation. By default, the normal is computed from the accumulated cross product of the edges. You can also specify the normal to use.

- `int = obj.GetAutomaticNormalGeneration ()` - Turn on/off automatic normal generation. By default, the normal is computed from the accumulated cross product of the edges. You can also specify the normal to use.
- `obj.AutomaticNormalGenerationOn ()` - Turn on/off automatic normal generation. By default, the normal is computed from the accumulated cross product of the edges. You can also specify the normal to use.
- `obj.AutomaticNormalGenerationOff ()` - Turn on/off automatic normal generation. By default, the normal is computed from the accumulated cross product of the edges. You can also specify the normal to use.
- `obj.SetNormal (double , double , double )` - Set / get the normal used to determine whether a point is inside or outside the selection loop.
- `obj.SetNormal (double a[3])` - Set / get the normal used to determine whether a point is inside or outside the selection loop.
- `double = obj. GetNormal ()` - Set / get the normal used to determine whether a point is inside or outside the selection loop.
- `long = obj.GetMTime ()` - Overload GetMTime() because we depend on the Loop

31.109 vtkImplicitSum

31.109.1 Usage

vtkImplicitSum produces a linear combination of other implicit functions. The contribution of each function is weighted by a scalar coefficient. The NormalizeByWeight option normalizes the output so that the scalar weights add up to 1. Note that this function gives accurate sums and gradients only if the input functions are linear.

To create an instance of class vtkImplicitSum, simply invoke its constructor as follows

```
obj = vtkImplicitSum
```

31.109.2 Methods

The class vtkImplicitSum has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitSum class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitSum = obj.NewInstance ()`
- `vtkImplicitSum = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])` - Evaluate implicit function using current functions and weights.
- `double = obj.EvaluateFunction (double x, double y, double z)` - Evaluate implicit function using current functions and weights.
- `obj.EvaluateGradient (double x[3], double g[3])` - Evaluate gradient of the weighted sum of functions. Input functions should be linear.

- `long = obj.GetMTime ()` - Override modified time retrieval because of object dependencies.
- `obj.AddFunction (vtkImplicitFunction in, double weight)` - Add another implicit function to the list of functions, along with a weighting factor.
- `obj.AddFunction (vtkImplicitFunction in)` - Remove all functions from the list.
- `obj.RemoveAllFunctions ()` - Remove all functions from the list.
- `obj.SetFunctionWeight (vtkImplicitFunction f, double weight)` - Set the weight (coefficient) of the given function to be weight.
- `obj.SetNormalizeByWeight (int )` - When calculating the function and gradient values of the composite function, setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the gradient vector. By default, NormalizeByWeight is off.
- `int = obj.GetNormalizeByWeight ()` - When calculating the function and gradient values of the composite function, setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the gradient vector. By default, NormalizeByWeight is off.
- `obj.NormalizeByWeightOn ()` - When calculating the function and gradient values of the composite function, setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the gradient vector. By default, NormalizeByWeight is off.
- `obj.NormalizeByWeightOff ()` - When calculating the function and gradient values of the composite function, setting NormalizeByWeight on will divide the final result by the total weight of the component functions. This process does not otherwise normalize the gradient vector. By default, NormalizeByWeight is off.

31.110 vtkImplicitVolume

31.110.1 Usage

vtkImplicitVolume treats a volume (e.g., structured point dataset) as if it were an implicit function. This means it computes a function value and gradient. vtkImplicitVolume is a concrete implementation of vtkImplicitFunction.

vtkImplicitDataSet computes the function (at the point x) by performing cell interpolation. That is, it finds the cell containing x, and then uses the cell's interpolation functions to compute an interpolated scalar value at x. (A similar approach is used to find the gradient, if requested.) Points outside of the dataset are assigned the value of the ivar OutValue, and the gradient value OutGradient.

To create an instance of class vtkImplicitVolume, simply invoke its constructor as follows

```
obj = vtkImplicitVolume
```

31.110.2 Methods

The class vtkImplicitVolume has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitVolume class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkImplicitVolume = obj.NewInstance ()`
- `vtkImplicitVolume = obj.SafeDownCast (vtkObject o)`
- `long = obj.GetMTime ()` - Returns the mtime also considering the volume. This also calls Update on the volume, and it therefore must be called before the function is evaluated.
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double n[3])`
- `obj.SetVolume (vtkImageData )` - Specify the volume for the implicit function.
- `vtkImageData = obj.GetVolume ()` - Specify the volume for the implicit function.
- `obj.SetOutValue (double )` - Set the function value to use for points outside of the dataset.
- `double = obj.GetOutValue ()` - Set the function value to use for points outside of the dataset.
- `obj.SetOutGradient (double , double , double )` - Set the function gradient to use for points outside of the dataset.
- `obj.SetOutGradient (double  a[3])` - Set the function gradient to use for points outside of the dataset.
- `double = obj. GetOutGradient ()` - Set the function gradient to use for points outside of the dataset.

31.111 vtkImplicitWindowFunction

31.111.1 Usage

vtkImplicitWindowFunction is used to modify the output of another implicit function to lie within a specified "window", or function range. This can be used to add "thickness" to cutting or clipping functions.

This class works as follows. First, it evaluates the function value of the user-specified implicit function. Then, based on the window range specified, it maps the function value into the window values specified.

To create an instance of class vtkImplicitWindowFunction, simply invoke its constructor as follows

```
obj = vtkImplicitWindowFunction
```

31.111.2 Methods

The class vtkImplicitWindowFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkImplicitWindowFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkImplicitWindowFunction = obj.NewInstance ()`
- `vtkImplicitWindowFunction = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double n[3])`

- `obj.SetImplicitFunction (vtkImplicitFunction )` - Specify an implicit function to operate on.
- `vtkImplicitFunction = obj.GetImplicitFunction ()` - Specify an implicit function to operate on.
- `obj.SetWindowRange (double , double )` - Specify the range of function values which are considered to lie within the window. WindowRange[0] is assumed to be less than WindowRange[1].
- `obj.SetWindowRange (double a[2])` - Specify the range of function values which are considered to lie within the window. WindowRange[0] is assumed to be less than WindowRange[1].
- `double = obj. GetWindowRange ()` - Specify the range of function values which are considered to lie within the window. WindowRange[0] is assumed to be less than WindowRange[1].
- `obj.SetWindowValues (double , double )` - Specify the range of output values that the window range is mapped into. This is effectively a scaling and shifting of the original function values.
- `obj.SetWindowValues (double a[2])` - Specify the range of output values that the window range is mapped into. This is effectively a scaling and shifting of the original function values.
- `double = obj. GetWindowValues ()` - Specify the range of output values that the window range is mapped into. This is effectively a scaling and shifting of the original function values.
- `long = obj.GetMTime ()` - Override modified time retrieval because of object dependencies.
- `obj.Register (vtkObjectBase o)` - Participate in garbage collection.
- `obj.UnRegister (vtkObjectBase o)` - Participate in garbage collection.

31.112 vtkIncrementalOctreeNode

31.112.1 Usage

Octree nodes serve as spatial sub-division primitives to build the search structure of an incremental octree in a recursive top-down manner. The hierarchy takes the form of a tree-like representation by which a parent node contains eight mutually non-overlapping child nodes. Each child is assigned with an axis-aligned rectangular volume (Spatial Bounding Box) and the eight children together cover exactly the same region as governed by their parent. The eight child nodes / octants are ordered as

(xBBoxMin, xBBoxMid] & (yBBoxMin, yBBoxMid] & (zBBoxMin, zBBoxMid] , (xBBoxMid, xBBoxMax] & (yBBoxMin, yBBoxMid] & (zBBoxMin, zBBoxMid] , (xBBoxMin, xBBoxMid] & (yBBoxMid, yBBoxMax] & (zBBoxMin, zBBoxMid] , (xBBoxMid, xBBoxMax] & (yBBoxMid, yBBoxMax] & (zBBoxMin, zBBoxMid] , (xBBoxMin, xBBoxMid] & (yBBoxMin, yBBoxMid] & (zBBoxMid, zBBoxMax] , (xBBoxMid, xBBoxMax] & (yBBoxMin, yBBoxMid] & (zBBoxMid, zBBoxMax] , (xBBoxMin, xBBoxMid] & (yBBoxMid, yBBoxMax] & (zBBoxMid, zBBoxMax] , (xBBoxMid, xBBoxMax] & (yBBoxMid, yBBoxMax] & (zBBoxMid, zBBoxMax] ,

where xrange & yRange & zRange defines the region of each 3D octant. In addition, the points falling within and registered, by means of point indices, in the parent node are distributed to the child nodes for delegated maintenance. In fact, only leaf nodes, i.e., those without any descendants, actually store point indices while each node, regardless of a leaf or non- leaf node, keeps a dynamically updated Data Bounding Box of the inhabitant points, if any. Given a maximum number of points per leaf node, an octree is initialized with an empty leaf node that is then recursively sub-divided, but only on demand as points are incrementally inserted, to construct a populated tree.

Please note that this octree node class is able to handle a large number of EXACTLY duplicate points that is greater than the specified maximum number of points per leaf node. In other words, as an exception, a leaf node may maintain an arbitrary number of exactly duplicate points to deal with possible extreme cases.

To create an instance of class vtkIncrementalOctreeNode, simply invoke its constructor as follows

```
obj = vtkIncrementalOctreeNode
```

31.112.2 Methods

The class vtkIncrementalOctreeNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIncrementalOctreeNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIncrementalOctreeNode = obj.NewInstance ()`
- `vtkIncrementalOctreeNode = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfPoints ()` - Get the number of points inside or under this node.
- `vtkIdList = obj.GetPointIdSet ()` - Get the list of point indices, NULL for a non-leaf node.
- `obj.DeleteChildNodes ()` - Delete the eight child nodes.
- `obj.SetBounds (double x1, double x2, double y1, double y2, double z1, double z2)` - Set the spatial bounding box of the node. This function sets a default data bounding box.
- `obj.GetBounds (double bounds[6]) const` - Get the spatial bounding box of the node. The values are returned via an array in order of: x_min, x_max, y_min, y_max, z_min, z_max.
- `double = obj. GetMinBounds ()` - Get access to MinBounds. Do not free this pointer.
- `double = obj. GetMaxBounds ()` - Get access to MaxBounds. Do not free this pointer.
- `int = obj.IsLeaf ()` - Determine which specific child / octant contains a given point. Note that the point is assumed to be inside this node and no checking is performed on the inside issue.
- `int = obj.GetChildIndex (double point[3])` - Determine which specific child / octant contains a given point. Note that the point is assumed to be inside this node and no checking is performed on the inside issue.
- `vtkIncrementalOctreeNode = obj.GetChild (int i)` - A point is in a node if and only if MinBounds[i] ¡ p[i] ¡= MaxBounds[i], which allows a node to be divided into eight non-overlapping children.
- `int = obj.ContainsPoint (double pnt[3])` - A point is in a node if and only if MinBounds[i] ¡ p[i] ¡= MaxBounds[i], which allows a node to be divided into eight non-overlapping children.
- `int = obj.ContainsPointByData (double pnt[3])` - A point is in a node, in terms of data, if and only if MinDataBounds[i] ¡= p[i] ¡= MaxDataBounds[i].
- `double = obj.GetDistance2ToInnerBoundary (double point[3], vtkIncrementalOctreeNode rootNode)` - Given a point inside this node, get the minimum squared distance to all inner boundaries. An inner boundary is a node's face that is shared by another non-root node.
- `double = obj.GetDistance2ToBoundary (double point[3], vtkIncrementalOctreeNode rootNode, int checkI` - Compute the minimum squared distance from a point to this node, with all six boundaries considered. The data bounding box is checked if checkData is non-zero.
- `double = obj.GetDistance2ToBoundary (double point[3], double closest[3], vtkIncrementalOctreeNode r` - Compute the minimum squared distance from a point to this node, with all six boundaries considered. The data bounding box is checked if checkData is non-zero. The closest on-boundary point is returned via closest.
- `obj.ExportAllPointIdsByInsertion (vtkIdList idList)` - Export all the indices of the points (contained in or under this node) by inserting them to an allocated vtkIdList via vtkIdList::InsertNextId().

31.113 vtkIncrementalOctreePointLocator

31.113.1 Usage

As opposed to the uniform bin-based search structure (adopted in class vtkPointLocator) with a fixed spatial resolution, an octree mechanism employs a hierarchy of tree-like sub-division of the 3D data domain. Thus it enables data-aware multi-resolution and accordingly accelerated point location as well as insertion, particularly when handling a radically imbalanced layout of points as not uncommon in datasets defined on adaptive meshes. Compared to a static point locator supporting pure location functionalities through some search structure established from a fixed set of points, an incremental point locator allows for, in addition, point insertion capabilities, with the search structure maintaining a dynamically increasing number of points. Class vtkIncrementalOctreePointLocator is an octree-based accelerated implementation of the functionalities of the uniform bin-based incremental point locator vtkPointLocator. For point location, an octree is built by accessing a vtkDataSet, specifically a vtkPointSet. For point insertion, an empty octree is inited and then incrementally populated as points are inserted. Three increasingly complex point insertion modes, i.e., direct check-free insertion, zero tolerance insertion, and non-zero tolerance insertion, are supported. In fact, the octree used in the point location mode is actually constructed via direct check-free point insertion. This class also provides a polygonal representation of the octree boundary.

To create an instance of class vtkIncrementalOctreePointLocator, simply invoke its constructor as follows

```
obj = vtkIncrementalOctreePointLocator
```

31.113.2 Methods

The class vtkIncrementalOctreePointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIncrementalOctreePointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIncrementalOctreePointLocator = obj.NewInstance ()`
- `vtkIncrementalOctreePointLocator = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaxPointsPerLeaf (int )` - Set/Get the maximum number of points that a leaf node may maintain. Note that the actual number of points maintained by a leaf node might exceed this threshold if there is a large number (equal to or greater than the threshold) of exactly duplicate points (with zero distance) to be inserted (e.g., to construct an octree for subsequent point location) in extreme cases. Respecting this threshold in such scenarios would cause endless node sub-division. Thus this threshold is broken, but only in case of such situations.
- `int = obj.GetMaxPointsPerLeafMinValue ()` - Set/Get the maximum number of points that a leaf node may maintain. Note that the actual number of points maintained by a leaf node might exceed this threshold if there is a large number (equal to or greater than the threshold) of exactly duplicate points (with zero distance) to be inserted (e.g., to construct an octree for subsequent point location) in extreme cases. Respecting this threshold in such scenarios would cause endless node sub-division. Thus this threshold is broken, but only in case of such situations.
- `int = obj.GetMaxPointsPerLeafMaxValue ()` - Set/Get the maximum number of points that a leaf node may maintain. Note that the actual number of points maintained by a leaf node might exceed this threshold if there is a large number (equal to or greater than the threshold) of exactly duplicate points (with zero distance) to be inserted (e.g., to construct an octree for subsequent point location) in extreme cases. Respecting this threshold in such scenarios would cause endless node sub-division. Thus this threshold is broken, but only in case of such situations.

- `int = obj.GetMaxPointsPerLeaf ()` - Set/Get the maximum number of points that a leaf node may maintain. Note that the actual number of points maintained by a leaf node might exceed this threshold if there is a large number (equal to or greater than the threshold) of exactly duplicate points (with zero distance) to be inserted (e.g., to construct an octree for subsequent point location) in extreme cases. Respecting this threshold in such scenarios would cause endless node sub-division. Thus this threshold is broken, but only in case of such situations.
- `obj.SetBuildCubicOctree (int )` - Set/Get whether the search octree is built as a cubic shape or not.
- `int = obj.GetBuildCubicOctree ()` - Set/Get whether the search octree is built as a cubic shape or not.
- `obj.BuildCubicOctreeOn ()` - Set/Get whether the search octree is built as a cubic shape or not.
- `obj.BuildCubicOctreeOff ()` - Set/Get whether the search octree is built as a cubic shape or not.
- `vtkPoints = obj.GetLocatorPoints ()` - Get access to the vtkPoints object in which point coordinates are stored for either point location or point insertion.
- `obj.Initialize ()` - Delete the octree search structure.
- `obj.FreeSearchStructure ()` - Delete the octree search structure.
- `obj.GetBounds (double bounds)` - Get the spatial bounding box of the octree.
- `int = obj.GetNumberOfPoints ()` - Get the number of points maintained by the octree.
- `vtkIdType = obj.FindClosestInsertedPoint (double x[3])` - Given a point x assumed to be covered by the octree, return the index of the closest in-octree point regardless of the associated minimum squared distance relative to the squared insertion-tolerance distance. This method is used when performing incremental point insertion. Note -1 indicates that no point is found. InitPointInsertion() should have been called in advance.
- `obj.GenerateRepresentation (int nodeLevel, vtkPolyData polysData)` - Create a polygonal representation of the octree boundary (from the root node to a specified level).
- `obj.BuildLocator ()` - Load points from a dataset to construct an octree for point location. This function resorts to InitPointInsertion() to fulfill some of the work.
- `vtkIdType = obj.FindClosestPoint (double x[3])` - Given a point x, return the id of the closest point. BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `vtkIdType = obj.FindClosestPoint (double x, double y, double z)` - Given a point (x, y, z), return the id of the closest point. Note that BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `vtkIdType = obj.FindClosestPoint (double x[3], double miniDist2)` - Given a point x, return the id of the closest point and the associated minimum squared distance (via miniDist2). Note BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `vtkIdType = obj.FindClosestPoint (double x, double y, double z, double miniDist2)` - Given a point (x, y, z), return the id of the closest point and the associated minimum squared distance (via miniDist2). BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `obj.FindPointsWithinRadius (double R, double x[3], vtkIdList result)` - Find all points within a radius R relative to a given point x. The returned point ids (stored in result) are not sorted in any way. BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindPointsWithinSquaredRadius (double R2, double x[3], vtkIdList result)` - Find all points within a squared radius R2 relative to a given point x. The returned point ids (stored in result) are not sorted in any way. BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindClosestNPoints (int N, double x[3], vtkIdList result)` - Find the closest N points to a given point. The returned point ids (via result) are sorted from closest to farthest. BuildLocator() should have been called prior to this function. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `int = obj.InitPointInsertion (vtkPoints points, double bounds[6])` - Initialize the point insertion process. points is an object, storing 3D point coordinates, to which incremental point insertion put coordinates. It is created and provided by an external VTK class. Argument bounds represents the spatial bounding box, into which the points fall. In fact, an adjusted version of the bounding box is used to build the octree to make sure no any point (to be inserted) falls outside the octree. This function is not thread safe.
- `int = obj.InitPointInsertion (vtkPoints points, double bounds[6], vtkIdType estSize)` - Initialize the point insertion process. points is an object, storing 3D point coordinates, to which incremental point insertion put coordinates. It is created and provided by an external VTK class. Argument bounds represents the spatial bounding box, into which the points fall. In fact, an adjusted version of the bounding box is used to build the octree to make sure no any point (to be inserted) falls outside the octree. Argument estSize specifies the initial estimated size of the vtkPoints object. This function is not thread safe.
- `vtkIdType = obj.IsInsertedPoint (double x[3])` - Determine whether or not a given point has been inserted into the octree. Return the id of the already inserted point if true, otherwise return -1. InitPointInsertion() should have been called in advance.
- `vtkIdType = obj.IsInsertedPoint (double x, double y, double z)` - Determine whether or not a given point has been inserted into the octree. Return the id of the already inserted point if true, otherwise return -1. InitPointInsertion() should have been called in advance.
- `obj.InsertPoint (vtkIdType ptId, double x[3])` - Insert a given point into the octree with a specified point index ptId. InitPointInsertion() should have been called prior to this function. In addition, IsInsertedPoint() should have been called in advance to ensure that the given point has not been inserted unless point duplication is allowed (Note that in this case, this function involves a repeated leaf container location). vtkPoints::InsertPoint() is invoked.
- `vtkIdType = obj.InsertNextPoint (double x[3])` - Insert a given point into the octree and return the point index. Note that InitPointInsertion() should have been called prior to this function. In addition, IsInsertedPoint() should have been called in advance to ensure that the given point has not been inserted unless point duplication is allowed (in this case, this function invovles a repeated leaf container location). vtkPoints::InsertNextPoint() is invoked.

31.114 vtkIncrementalPointLocator

31.114.1 Usage

Compared to a static point locator for pure location functionalities through some search structure established from a fixed set of points, an incremental point locator allows for, in addition, point insertion capabilities, with the search structure maintaining a dynamically increasing number of points. There are two incremental

point locators, i.e., vtkPointLocator and vtkIncrementalOctreePointLocator. As opposed to the uniform bin-based search structure (adopted in vtkPointLocator) with a fixed spatial resolution, an octree mechanism (employed in vtkIncrementalOctreePointlocator) resorts to a hierarchy of tree-like sub-division of the 3D data domain. Thus it enables data-aware multi- resolution and accordingly accelerated point location as well as point insertion, particularly when handling a radically imbalanced layout of points as not uncommon in datasets defined on adaptive meshes. In other words, vtkIncrementalOctreePointLocator is an octree-based accelerated implementation of all functionalities of vtkPointLocator.

To create an instance of class vtkIncrementalPointLocator, simply invoke its constructor as follows

```
obj = vtkIncrementalPointLocator
```

31.114.2 Methods

The class vtkIncrementalPointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkIncrementalPointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkIncrementalPointLocator = obj.NewInstance ()`
- `vtkIncrementalPointLocator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Delete the search structure.
- `vtkIdType = obj.FindClosestInsertedPoint (double x[3])` - Given a point x assumed to be covered by the search structure, return the index of the closest point (already inserted to the search structure) regardless of the associated minimum squared distance relative to the squared insertion-tolerance distance. This method is used when performing incremental point insertion. Note -1 indicates that no point is found. InitPointInsertion() should have been called in advance.
- `int = obj.InitPointInsertion (vtkPoints newPts, double bounds[6])` - Initialize the point insertion process. newPts is an object, storing 3D point coordinates, to which incremental point insertion puts coordinates. It is created and provided by an external VTK class. Argument bounds represents the spatial bounding box, into which the points fall.
- `int = obj.InitPointInsertion (vtkPoints newPts, double bounds[6], vtkIdType estSize)` - Initialize the point insertion process. newPts is an object, storing 3D point coordinates, to which incremental point insertion puts coordinates. It is created and provided by an external VTK class. Argument bounds represents the spatial bounding box, into which the points fall.
- `vtkIdType = obj.IsInsertedPoint (double x, double y, double z)` - Determine whether or not a given point has been inserted. Return the id of the already inserted point if true, else return -1. InitPointInsertion() should have been called in advance.
- `vtkIdType = obj.IsInsertedPoint (double x[3])` - Determine whether or not a given point has been inserted. Return the id of the already inserted point if true, else return -1. InitPointInsertion() should have been called in advance.
- `obj.InsertPoint (vtkIdType ptId, double x[3])` - Insert a given point with a specified point index ptId. InitPointInsertion() should have been called prior to this function. Also, IsInsertedPoint() should have been called in advance to ensure that the given point has not been inserted unless point duplication is allowed.
- `vtkIdType = obj.InsertNextPoint (double x[3])` - Insert a given point and return the point index. InitPointInsertion() should have been called prior to this function. Also, IsInsertedPoint() should have been called in advance to ensure that the given point has not been inserted unless point duplication is allowed.

31.115 vtkInEdgeIterator

31.115.1 Usage

vtkInEdgeIterator iterates through all edges whose target is a particular vertex. Instantiate this class directly and call Initialize() to traverse the vertex of a graph. Alternately, use GetInEdges() on the graph to initialize the iterator. it-¿Next() returns a vtkInEdgeType structure, which contains Id, the edge's id, and Source, the edge's source vertex.

To create an instance of class vtkInEdgeIterator, simply invoke its constructor as follows

```
obj = vtkInEdgeIterator
```

31.115.2 Methods

The class vtkInEdgeIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInEdgeIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInEdgeIterator = obj.NewInstance ()`
- `vtkInEdgeIterator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkGraph g, vtkIdType v)` - Initialize the iterator with a graph and vertex.
- `vtkGraph = obj.GetGraph ()` - Get the graph and vertex associated with this iterator.
- `vtkIdType = obj.GetVertex ()` - Get the graph and vertex associated with this iterator.
- `vtkGraphEdge = obj.NextGraphEdge ()` - Just like Next(), but returns heavy-weight vtkGraphEdge object instead of the vtkEdgeType struct, for use with wrappers. The graph edge is owned by this iterator, and changes after each call to NextGraphEdge().
- `bool = obj.HasNext ()`

31.116 vtkInformationExecutivePortKey

31.116.1 Usage

vtkInformationExecutivePortKey is used to represent keys in vtkInformation for values that are vtkExecutive instances paired with port numbers.

To create an instance of class vtkInformationExecutivePortKey, simply invoke its constructor as follows

```
obj = vtkInformationExecutivePortKey
```

31.116.2 Methods

The class vtkInformationExecutivePortKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationExecutivePortKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkInformationExecutivePortKey = obj.NewInstance ()`
- `vtkInformationExecutivePortKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationExecutivePortKey = obj.(string name, string location)`
- `~vtkInformationExecutivePortKey = obj.()`
- `obj.Set (vtkInformation info, vtkExecutive , int )` - Get/Set the value associated with this key in the given information object.
- `vtkExecutive = obj.GetExecutive (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `int = obj.GetPort (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.Report (vtkInformation info, vtkGarbageCollector collector)` - Report a reference this key has in the given information object.

31.117 vtkInformationExecutivePortVectorKey

31.117.1 Usage

vtkInformationExecutivePortVectorKey is used to represent keys in vtkInformation for values that are vectors of vtkExecutive instances paired with port numbers.

To create an instance of class vtkInformationExecutivePortVectorKey, simply invoke its constructor as follows

```
obj = vtkInformationExecutivePortVectorKey
```

31.117.2 Methods

The class vtkInformationExecutivePortVectorKey has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInformationExecutivePortVectorKey class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInformationExecutivePortVectorKey = obj.NewInstance ()`
- `vtkInformationExecutivePortVectorKey = obj.SafeDownCast (vtkObject o)`
- `vtkInformationExecutivePortVectorKey = obj.(string name, string location)`
- `~vtkInformationExecutivePortVectorKey = obj.()`
- `obj.Append (vtkInformation info, vtkExecutive executive, int port)` - Get/Set the value associated with this key in the given information object.
- `obj.Remove (vtkInformation info, vtkExecutive executive, int port)` - Get/Set the value associated with this key in the given information object.

- `int = obj.Length (vtkInformation info)` - Get/Set the value associated with this key in the given information object.
- `obj.ShallowCopy (vtkInformation from, vtkInformation to)` - Copy the entry associated with this key from one information object to another. If there is no entry in the first information object for this key, the value is removed from the second.
- `obj.Remove (vtkInformation info)` - Remove this key from the given information object.
- `obj.Report (vtkInformation info, vtkGarbageCollector collector)` - Report a reference this key has in the given information object.

31.118 vtkInterpolatedVelocityField

31.118.1 Usage

vtkInterpolatedVelocityField acts as a continuous velocity field via cell interpolation on a vtkDataSet, NumberOfIndependentVariables = 4 (x,y,z,t) and NumberOfFunctions = 3 (u,v,w). As a concrete sub-class of vtkAbstractInterpolatedVelocityField, this class adopts two levels of cell caching for faster though less robust cell location than its sibling class vtkCellLocatorInterpolatedVelocityField. Level #0 begins with intra-cell caching. Specifically, if the previous cell is valid and the nex point is still within it, (vtkCell::EvaluatePosition() returns 1, coupled with the new parametric coordinates and weights), the function values are interpolated and vtkCell::EvaluatePosition() is invoked only. If it fails, level #1 follows by inter-cell location of the target cell (that contains the next point). By inter-cell, the previous cell gives an important clue / guess or serves as an immediate neighbor to aid in the location of the target cell (as is typically the case with integrating a streamline across cells) by means of vtkDataSet:: FindCell(). If this still fails, a global cell search is invoked via vtkDataSet::FindCell().

Regardless of inter-cell or global search, vtkPointLocator is employed as a crucial tool underlying the cell locator. The use of vtkPointLocator casues vtkInterpolatedVelocityField to return false target cells for datasets defined on complex grids.

To create an instance of class vtkInterpolatedVelocityField, simply invoke its constructor as follows

```
obj = vtkInterpolatedVelocityField
```

31.118.2 Methods

The class vtkInterpolatedVelocityField has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkInterpolatedVelocityField class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkInterpolatedVelocityField = obj.NewInstance ()`
- `vtkInterpolatedVelocityField = obj.SafeDownCast (vtkObject o)`
- `obj.AddDataSet (vtkDataSet dataset)` - Add a dataset used for the implicit function evaluation. If more than one dataset is added, the evaluation point is searched in all until a match is found. THIS FUNCTION DOES NOT CHANGE THE REFERENCE COUNT OF DATASET FOR THREAD SAFETY REASONS.
- `int = obj.FunctionValues (double x, double f)` - Evaluate the velocity field f at point (x, y, z).
- `obj.SetLastCellId (vtkIdType c, int dataindex)` - Set the cell id cached by the last evaluation within a specified dataset.
- `obj.SetLastCellId (vtkIdType c)`

31.119 vtkKdNode

31.119.1 Usage

To create an instance of class vtkKdNode, simply invoke its constructor as follows

```
obj = vtkKdNode
```

31.119.2 Methods

The class vtkKdNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKdNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKdNode = obj.NewInstance ()`
- `vtkKdNode = obj.SafeDownCast (vtkObject o)`
- `obj.SetDim (int )` - Set/Get the dimension along which this region is divided. (0 - x, 1 - y, 2 - z, 3 - leaf node (default)).
- `int = obj.GetDim ()` - Set/Get the dimension along which this region is divided. (0 - x, 1 - y, 2 - z, 3 - leaf node (default)).
- `double = obj.GetDivisionPosition ()` - Get the location of the division plane along the axis the region is divided. See also GetDim(). The result is undertermined if this node is not divided (a leaf node).
- `obj.SetNumberOfPoints (int )` - Set/Get the number of points contained in this region.
- `int = obj.GetNumberOfPoints ()` - Set/Get the number of points contained in this region.
- `obj.SetBounds (double x1, double x2, double y1, double y2, double z1, double z2)` - Set/Get the bounds of the spatial region represented by this node. Caller allocates storage for 6-vector in GetBounds.
- `obj.SetBounds (double b[6])` - Set/Get the bounds of the spatial region represented by this node. Caller allocates storage for 6-vector in GetBounds.
- `obj.GetBounds (double b) const` - Set/Get the bounds of the spatial region represented by this node. Caller allocates storage for 6-vector in GetBounds.
- `obj.SetDataBounds (double x1, double x2, double y1, double y2, double z1, double z2)` - Set/Get the bounds of the points contained in this spatial region. This may be smaller than the bounds of the region itself. Caller allocates storage for 6-vector in GetDataBounds.
- `obj.GetDataBounds (double b) const` - Set/Get the bounds of the points contained in this spatial region. This may be smaller than the bounds of the region itself. Caller allocates storage for 6-vector in GetDataBounds.
- `obj.SetDataBounds (float v)` - Given a pointer to NumberOfPoints points, set the DataBounds of this node to the bounds of these points.
- `double = obj.GetMinBounds ()` - Get a pointer to the 3 bound minima (xmin, ymin and zmin) or the 3 bound maxima (xmax, ymax, zmax). Don't free this pointer.
- `double = obj.GetMaxBounds ()` - Set the xmin, ymin and zmin value of the bounds of this region

- `obj.SetMinBounds (double mb)` - Set the xmin, ymin and zmin value of the bounds of this region
- `obj.SetMaxBounds (double mb)` - Set the xmax, ymax and zmax value of the bounds of this region
- `double = obj.GetMinDataBounds ()` - Get a pointer to the 3 data bound minima (xmin, ymin and zmin) or the 3 data bound maxima (xmax, ymax, zmax). Don't free this pointer.
- `double = obj.GetMaxDataBounds ()` - Set the xmin, ymin and zmin value of the bounds of this data within this region
- `obj.SetMinDataBounds (double mb)` - Set the xmin, ymin and zmin value of the bounds of this data within this region
- `obj.SetMaxDataBounds (double mb)` - Set the xmax, ymax and zmax value of the bounds of this data within this region
- `obj.SetID (int )` - Set/Get the ID associated with the region described by this node. If this is not a leaf node, this value should be -1.
- `int = obj.GetID ()` - Set/Get the ID associated with the region described by this node. If this is not a leaf node, this value should be -1.
- `int = obj.GetMinID ()` - If this node is not a leaf node, there are leaf nodes below it whose regions represent a partitioning of this region. The IDs of these leaf nodes form a contigous set. Set/Get the range of the IDs of the leaf nodes below this node. If this is already a leaf node, these values should be the same as the ID.
- `int = obj.GetMaxID ()` - If this node is not a leaf node, there are leaf nodes below it whose regions represent a partitioning of this region. The IDs of these leaf nodes form a contigous set. Set/Get the range of the IDs of the leaf nodes below this node. If this is already a leaf node, these values should be the same as the ID.
- `obj.SetMinID (int )` - If this node is not a leaf node, there are leaf nodes below it whose regions represent a partitioning of this region. The IDs of these leaf nodes form a contigous set. Set/Get the range of the IDs of the leaf nodes below this node. If this is already a leaf node, these values should be the same as the ID.
- `obj.SetMaxID (int )` - If this node is not a leaf node, there are leaf nodes below it whose regions represent a partitioning of this region. The IDs of these leaf nodes form a contigous set. Set/Get the range of the IDs of the leaf nodes below this node. If this is already a leaf node, these values should be the same as the ID.
- `obj.AddChildNodes (vtkKdNode left, vtkKdNode right)` - Add the left and right children.
- `obj.DeleteChildNodes ()` - Delete the left and right children.
- `vtkKdNode = obj.GetLeft ()` - Set/Get a pointer to the left child of this node.
- `obj.SetLeft (vtkKdNode left)` - Set/Get a pointer to the left child of this node.
- `vtkKdNode = obj.GetRight ()` - Set/Get a pointer to the right child of this node.
- `obj.SetRight (vtkKdNode right)` - Set/Get a pointer to the right child of this node.
- `vtkKdNode = obj.GetUp ()` - Set/Get a pointer to the parent of this node.
- `obj.SetUp (vtkKdNode up)` - Set/Get a pointer to the parent of this node.
- `int = obj.IntersectsBox (double x1, double x2, double y1, double y2, double z1, double z2, int useD` - Return 1 if this spatial region intersects the axis-aligned box given by the bounds passed in. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.

- `int = obj.IntersectsSphere2 (double x, double y, double z, double rSquared, int useDataBounds)` - Return 1 if this spatial region intersects a sphere described by it's center and the square of it's radius. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.
- `int = obj.IntersectsRegion (vtkPlanesIntersection pi, int useDataBounds)` - A vtkPlanesIntersection object represents a convex 3D region bounded by planes, and it is capable of computing intersections of boxes with itself. Return 1 if this spatial region intersects the spatial region described by the vtkPlanesIntersection object. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.
- `int = obj.IntersectsCell (vtkCell cell, int useDataBounds, int cellRegion, double cellBoundsNULL)` - Return 1 if the cell specified intersects this region. If you already know the ID of the region containing the cell's centroid, provide that as an argument. If you already know the bounds of the cell, provide that as well, in the form of xmin,xmax,ymin,ymax,zmin, zmax. Either of these may speed the calculation. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.
- `int = obj.ContainsBox (double x1, double x2, double y1, double y2, double z1, double z2, int useDat` - Return 1 if this spatial region entirely contains a box specified by it's bounds. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.
- `int = obj.ContainsPoint (double x, double y, double z, int useDataBounds)` - Return 1 if this spatial region entirely contains the given point. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.
- `double = obj.GetDistance2ToBoundary (double x, double y, double z, int useDataBounds)` - Calculate the distance squared from any point to the boundary of this region. Use the boundary of the points within the region if useDataBounds is non-zero.
- `double = obj.GetDistance2ToBoundary (double x, double y, double z, double boundaryPt, int useDataBo` - Calculate the distance squared from any point to the boundary of this region. Use the boundary of the points within the region if useDataBounds is non-zero. Set boundaryPt to the point on the boundary.
- `double = obj.GetDistance2ToInnerBoundary (double x, double y, double z)` - Calculate the distance from the specified point (which is required to be inside this spatial region) to an interior boundary. An interior boundary is one that is not also an boundary of the entire space partitioned by the tree of vtkKdNode's.
- `obj.PrintNode (int depth)` - For debugging purposes, print out this node.
- `obj.PrintVerboseNode (int depth)` - For debugging purposes, print out this node.

31.120 vtkKdTree

31.120.1 Usage

Given one or more vtkDataSets, create a load balancing k-d tree decomposition of the points at the center of the cells. Or, create a k-d tree point locator from a list of points.

This class can also generate a PolyData representation of the boundaries of the spatial regions in the decomposition.

It can sort the regions with respect to a viewing direction, and it can decompose a list of regions into subsets, each of which represent a convex spatial region (since many algorithms require a convex region).

If the points were derived from cells, vtkKdTree can create a list of cell Ids for each region for each data set. Two lists are available - all cells with centroid in the region, and all cells that intersect the region but whose centroid lies in another region.

For the purpose of removing duplicate points quickly from large data sets, or for finding nearby points, we added another mode for building the locator. BuildLocatorFromPoints will build a k-d tree from one or more vtkPoints objects. This can be followed by BuildMapForDuplicatePoints which returns a mapping from the original ids to a subset of the ids that is unique within a supplied tolerance, or you can use FindPoint and FindClosestPoint to locate points in the original set that the tree was built from.

To create an instance of class vtkKdTree, simply invoke its constructor as follows

```
obj = vtkKdTree
```

31.120.2 Methods

The class vtkKdTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKdTree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKdTree = obj.NewInstance ()`
- `vtkKdTree = obj.SafeDownCast (vtkObject o)`
- `obj.TimingOn ()` - Turn on timing of the k-d tree build
- `obj.TimingOff ()` - Turn on timing of the k-d tree build
- `obj.SetTiming (int )` - Turn on timing of the k-d tree build
- `int = obj.GetTiming ()` - Turn on timing of the k-d tree build
- `obj.SetMinCells (int )` - Minimum number of cells per spatial region. Default is 100.
- `int = obj.GetMinCells ()` - Minimum number of cells per spatial region. Default is 100.
- `int = obj.GetNumberOfRegionsOrLess ()`
- `obj.SetNumberOfRegionsOrLess (int )`
- `int = obj.GetNumberOfRegionsOrMore ()`
- `obj.SetNumberOfRegionsOrMore (int )`
- `double = obj.GetFudgeFactor ()`
- `obj.SetFudgeFactor (double )`
- `vtkBSPCuts = obj.GetCuts ()`
- `obj.SetCuts (vtkBSPCuts cuts)`
- `obj.OmitXPartitioning ()` - Omit partitions along the X axis, yielding shafts in the X direction
- `obj.OmitYPartitioning ()` - Omit partitions along the Y axis, yielding shafts in the Y direction
- `obj.OmitZPartitioning ()` - Omit partitions along the Z axis, yielding shafts in the Z direction
- `obj.OmitXYPartitioning ()` - Omit partitions along the X and Y axes, yielding slabs along Z
- `obj.OmitYZPartitioning ()` - Omit partitions along the Y and Z axes, yielding slabs along X
- `obj.OmitZXPartitioning ()` - Omit partitions along the Z and X axes, yielding slabs along Y

- `obj.OmitNoPartitioning ()` - Partition along all three axes - this is the default
- `obj.SetDataSet (vtkDataSet set)` - Clear out all data sets and replace with single data set. For backward compatibility with superclass.
- `obj.AddDataSet (vtkDataSet set)` - This class can compute a spatial decomposition based on the cells in a list of one or more input data sets. Add them one at a time with this method.
- `obj.RemoveDataSet (int index)` - Remove the given data set.
- `obj.RemoveDataSet (vtkDataSet set)` - Remove the given data set.
- `obj.RemoveAllDataSets ()` - Remove the given data set.
- `int = obj.GetNumberOfDataSets ()` - Get the number of data sets included in spatial paritioning
- `vtkDataSet = obj.GetDataSet (int n)` - Return the n'th data set.
- `vtkDataSet = obj.GetDataSet ()` - Return a collection of all the data sets.
- `vtkDataSetCollection = obj.GetDataSets ()` - Return a collection of all the data sets.
- `int = obj.GetDataSetIndex (vtkDataSet set)` - Return the index of the given data set. Returns -1 if that data set does not exist.
- `obj.GetBounds (double bounds)` - Get the spatial bounds of the entire k-d tree space. Sets bounds array to xmin, xmax, ymin, ymax, zmin, zmax.
- `obj.SetNewBounds (double bounds)`
- `int = obj.GetNumberOfRegions ()` - The number of leaf nodes of the tree, the spatial regions
- `obj.GetRegionBounds (int regionID, double bounds[6])` - Get the spatial bounds of k-d tree region
- `obj.GetRegionDataBounds (int regionID, double bounds[6])` - Get the bounds of the data within the k-d tree region
- `obj.PrintTree ()` - Print out nodes of kd tree
- `obj.PrintVerboseTree ()` - Print out nodes of kd tree
- `obj.PrintRegion (int id)` - Print out leaf node data for given id
- `obj.CreateCellLists (int dataSetIndex, int regionReqList, int reqListSize)`
- `obj.CreateCellLists (vtkDataSet set, int regionReqList, int reqListSize)`
- `obj.CreateCellLists (int regionReqList, int listSize)`
- `obj.CreateCellLists ()`
- `obj.SetIncludeRegionBoundaryCells (int )` - If IncludeRegionBoundaryCells is ON, CreateCellLists() will also create a list of cells which intersect a given region, but are not assigned to the region. These lists are obtained with GetBoundaryCellList(). Default is OFF.
- `int = obj.GetIncludeRegionBoundaryCells ()` - If IncludeRegionBoundaryCells is ON, CreateCellLists() will also create a list of cells which intersect a given region, but are not assigned to the region. These lists are obtained with GetBoundaryCellList(). Default is OFF.
- `obj.IncludeRegionBoundaryCellsOn ()` - If IncludeRegionBoundaryCells is ON, CreateCellLists() will also create a list of cells which intersect a given region, but are not assigned to the region. These lists are obtained with GetBoundaryCellList(). Default is OFF.

- `obj.IncludeRegionBoundaryCellsOff ()` - If IncludeRegionBoundaryCells is ON, CreateCellLists() will also create a list of cells which intersect a given region, but are not assigned to the region. These lists are obtained with GetBoundaryCellList(). Default is OFF.

- `obj.DeleteCellLists ()` - Free the memory used by the cell lists.

- `vtkIdList = obj.GetCellList (int regionID)` - Get the cell list for a region. This returns a pointer to vtkKdTree's memory, so don't free it.

- `vtkIdList = obj.GetBoundaryCellList (int regionID)` - The cell list obtained with GetCellList is the list of all cells such that their centroid is contained in the spatial region. It may also be desirable to get a list of all cells intersecting a spatial region, but with centroid in some other region. This is that list. This list is computed in CreateCellLists() if and only if IncludeRegionBoundaryCells is ON. This returns a pointer to KdTree's memory, so don't free it.

- `vtkIdType = obj.GetCellLists (vtkIntArray regions, int set, vtkIdList inRegionCells, vtkIdList onBo` - For a list of regions, get two cell lists. The first lists the IDs all cells whose centroids lie in one of the regions. The second lists the IDs of all cells that intersect the regions, but whose centroid lies in a region not on the list.

  The total number of cell IDs written to both lists is returned. Either list pointer passed in can be NULL, and it will be ignored. If there are multiple data sets, you must specify which data set you wish cell IDs for.

  The caller should delete these two lists when done. This method uses the cell lists created in CreateCellLists(). If the cell list for any of the requested regions does not exist, then this method will call CreateCellLists() to create cell lists for *every* region of the k-d tree. You must remember to DeleteCellLists() when done with all calls to this method, as cell lists can require a great deal of memory.

- `vtkIdType = obj.GetCellLists (vtkIntArray regions, vtkDataSet set, vtkIdList inRegionCells, vtkIdLi` - For a list of regions, get two cell lists. The first lists the IDs all cells whose centroids lie in one of the regions. The second lists the IDs of all cells that intersect the regions, but whose centroid lies in a region not on the list.

  The total number of cell IDs written to both lists is returned. Either list pointer passed in can be NULL, and it will be ignored. If there are multiple data sets, you must specify which data set you wish cell IDs for.

  The caller should delete these two lists when done. This method uses the cell lists created in CreateCellLists(). If the cell list for any of the requested regions does not exist, then this method will call CreateCellLists() to create cell lists for *every* region of the k-d tree. You must remember to DeleteCellLists() when done with all calls to this method, as cell lists can require a great deal of memory.

- `vtkIdType = obj.GetCellLists (vtkIntArray regions, vtkIdList inRegionCells, vtkIdList onBoundaryCel` - For a list of regions, get two cell lists. The first lists the IDs all cells whose centroids lie in one of the regions. The second lists the IDs of all cells that intersect the regions, but whose centroid lies in a region not on the list.

  The total number of cell IDs written to both lists is returned. Either list pointer passed in can be NULL, and it will be ignored. If there are multiple data sets, you must specify which data set you wish cell IDs for.

  The caller should delete these two lists when done. This method uses the cell lists created in CreateCellLists(). If the cell list for any of the requested regions does not exist, then this method will call CreateCellLists() to create cell lists for *every* region of the k-d tree. You must remember to DeleteCellLists() when done with all calls to this method, as cell lists can require a great deal of memory.

- `int = obj.GetRegionContainingCell (vtkDataSet set, vtkIdType cellID)` - Get the id of the region containing the cell centroid. If no DataSet is specified, assume DataSet 0. If you need the region ID for every cell, use AllGetRegionContainingCell instead. It is more efficient.

- `int = obj.GetRegionContainingCell (int set, vtkIdType cellID)` - Get the id of the region containing the cell centroid. If no DataSet is specified, assume DataSet 0. If you need the region ID for every cell, use AllGetRegionContainingCell instead. It is more efficient.

- `int = obj.GetRegionContainingCell (vtkIdType cellID)` - Get the id of the region containing the cell centroid. If no DataSet is specified, assume DataSet 0. If you need the region ID for every cell, use AllGetRegionContainingCell instead. It is more efficient.

- `int = obj.GetRegionContainingPoint (double x, double y, double z)` - Get the id of the region containing the specified location.

- `obj.BuildLocator ()` - Create the k-d tree decomposition of the cells of the data set or data sets. Cells are assigned to k-d tree spatial regions based on the location of their centroids.

- `int = obj.DepthOrderAllRegions (double dop, vtkIntArray orderedList)` - DO NOT CALL. Depricated in VTK 5.2. Use ViewOrderAllRegionsInDirection or ViewOrderAllRegionsFromPosition.

- `int = obj.DepthOrderRegions (vtkIntArray regionIds, double dop, vtkIntArray orderedList)` - DO NOT CALL. Depricated in VTK 5.2. Use ViewOrderRegionsInDirection or ViewOrderRegionsFromPosition.

- `int = obj.ViewOrderAllRegionsInDirection (double directionOfProjection[3], vtkIntArray orderedList)` - Given a direction of projection (typically obtained with vtkCamera::GetDirectionOfProjection()), this method, creates a list of the k-d tree region IDs in order from front to back with respect to that direction. The number of ordered regions is returned. Use this method to view order regions for cameras that use parallel projection.

- `int = obj.ViewOrderRegionsInDirection (vtkIntArray regionIds, double directionOfProjection[3], vtkI` - Given a direction of projection and a list of k-d tree region IDs, this method, creates a list of the k-d tree region IDs in order from front to back with respect to that direction. The number of ordered regions is returned. Use this method to view order regions for cameras that use parallel projection.

- `int = obj.ViewOrderAllRegionsFromPosition (double directionOfProjection[3], vtkIntArray orderedList` - Given a camera position (typically obtained with vtkCamera::GetPosition()), this method, creates a list of the k-d tree region IDs in order from front to back with respect to that direction. The number of ordered regions is returned. Use this method to view order regions for cameras that use perspective projection.

- `int = obj.ViewOrderRegionsFromPosition (vtkIntArray regionIds, double directionOfProjection[3], vtk` - Given a camera position and a list of k-d tree region IDs, this method, creates a list of the k-d tree region IDs in order from front to back with respect to that direction. The number of ordered regions is returned. Use this method to view order regions for cameras that use perspective projection.

- `obj.BuildLocatorFromPoints (vtkPointSet pointset)` - This is a special purpose locator that builds a k-d tree to find duplicate and near-by points. It builds the tree from one or more vtkPoints objects instead of from the cells of a vtkDataSet. This build would normally be followed by BuildMapForDuplicatePoints, FindPoint, or FindClosestPoint. Since this will build a normal k-d tree, all the region intersection queries will still work, as will most other calls except those that have "Cell" in the name.

  This method works most efficiently when the point arrays are float arrays.

- `obj.BuildLocatorFromPoints (vtkPoints ptArray)` - This is a special purpose locator that builds a k-d tree to find duplicate and near-by points. It builds the tree from one or more vtkPoints objects

instead of from the cells of a vtkDataSet. This build would normally be followed by BuildMapForDuplicatePoints, FindPoint, or FindClosestPoint. Since this will build a normal k-d tree, all the region intersection queries will still work, as will most other calls except those that have "Cell" in the name.

This method works most efficiently when the point arrays are float arrays.

- `vtkIdTypeArray = obj.BuildMapForDuplicatePoints (float tolerance)` - This call returns a mapping from the original point IDs supplied to BuildLocatorFromPoints to a subset of those IDs that is unique within the specified tolerance. If points 2, 5, and 12 are the same, then IdMap[2] = IdMap[5] = IdMap[12] = 2 (or 5 or 12).

  "original point IDs" - For point IDs we start at 0 for the first point in the first vtkPoints object, and increase by 1 for subsequent points and subsequent vtkPoints objects.

  You must have called BuildLocatorFromPoints() before calling this. You are responsible for deleting the returned array.

- `vtkIdType = obj.FindPoint (double x)` - Find the Id of the point that was previously supplied to BuildLocatorFromPoints(). Returns -1 if the point was not in the original array.

- `vtkIdType = obj.FindPoint (double x, double y, double z)` - Find the Id of the point that was previously supplied to BuildLocatorFromPoints(). Returns -1 if the point was not in the original array.

- `obj.FindPointsWithinRadius (double R, double x[3], vtkIdList result)` - Find all points within a specified radius R of position x. The result is not sorted in any specific manner. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `obj.FindClosestNPoints (int N, double x[3], vtkIdList result)` - Find the closest N points to a position. This returns the closest N points to a position. A faster method could be created that returned N close points to a position, but necessarily the exact N closest. The returned points are sorted from closest to farthest. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `vtkIdTypeArray = obj.GetPointsInRegion (int regionId)` - Get a list of the original IDs of all points in a region. You must have called BuildLocatorFromPoints before calling this.

- `obj.FreeSearchStructure ()` - Delete the k-d tree data structure. Also delete any cell lists that were computed with CreateCellLists().

- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - Create a polydata representation of the boundaries of the k-d tree regions. If level equals GetLevel(), the leaf nodes are represented.

- `obj.GenerateRepresentation (int regionList, int len, vtkPolyData pd)` - Generate a polygonal representation of a list of regions. Only leaf nodes have region IDs, so these will be leaf nodes.

- `obj.GenerateRepresentationUsingDataBoundsOn ()` - The polydata representation of the k-d tree shows the boundaries of the k-d tree decomposition spatial regions. The data inside the regions may not occupy the entire space. To draw just the bounds of the data in the regions, set this variable ON.

- `obj.GenerateRepresentationUsingDataBoundsOff ()` - The polydata representation of the k-d tree shows the boundaries of the k-d tree decomposition spatial regions. The data inside the regions may not occupy the entire space. To draw just the bounds of the data in the regions, set this variable ON.

- `obj.SetGenerateRepresentationUsingDataBounds (int )` - The polydata representation of the k-d tree shows the boundaries of the k-d tree decomposition spatial regions. The data inside the regions may not occupy the entire space. To draw just the bounds of the data in the regions, set this variable ON.

- `int = obj.GetGenerateRepresentationUsingDataBounds ()` - The polydata representation of the k-d tree shows the boundaries of the k-d tree decomposition spatial regions. The data inside the regions may not occupy the entire space. To draw just the bounds of the data in the regions, set this variable ON.

- `int = obj.NewGeometry ()` - Return 1 if the geometry of the input data sets has changed since the last time the k-d tree was built.
- `obj.InvalidateGeometry ()` - Forget about the last geometry used. The next call to NewGeometry will return 1. A new k-d tree will be built the next time BuildLocator is called.
- `obj.FindPointsInArea (double area, vtkIdTypeArray ids, bool clearArraytrue)` - Fill ids with points found in area. The area is a 6-tuple containing (xmin, xmax, ymin, ymax, zmin, zmax). This method will clear the array by default. To append ids to an array, set clearArray to false.

31.121 vtkKdTreePointLocator

31.121.1 Usage

vtkKdTreePointLocator is a wrapper class that derives from vtkAbstractPointLocator and calls the search functions in vtkKdTree.

To create an instance of class vtkKdTreePointLocator, simply invoke its constructor as follows

```
obj = vtkKdTreePointLocator
```

31.121.2 Methods

The class vtkKdTreePointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKdTreePointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKdTreePointLocator = obj.NewInstance ()`
- `vtkKdTreePointLocator = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.FindClosestPoint (double x[3])` - Given a position x, return the id of the point closest to it. Alternative method requires separate x-y-z values. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindClosestNPoints (int N, double x[3], vtkIdList result)` - Find the closest N points to a position. This returns the closest N points to a position. A faster method could be created that returned N close points to a position, but necessarily the exact N closest. The returned points are sorted from closest to farthest. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FindPointsWithinRadius (double R, double x[3], vtkIdList result)` - Find all points within a specified radius R of position x. The result is not sorted in any specific manner. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `obj.FreeSearchStructure ()` - See vtkLocator interface documentation. These methods are not thread safe.
- `obj.BuildLocator ()` - See vtkLocator interface documentation. These methods are not thread safe.
- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - See vtkLocator interface documentation. These methods are not thread safe.

31.122 vtkKochanekSpline

31.122.1 Usage

Implements the Kochenek interpolating spline described in: Kochanek, D., Bartels, R., "Interpolating Splines with Local Tension, Continuity, and Bias Control," Computer Graphics, vol. 18, no. 3, pp. 33-41, July 1984. These splines give the user more control over the shape of the curve than the cardinal splines implemented in vtkCardinalSpline. Three parameters can be specified. All have a range from -1 to 1.

Tension controls how sharply the curve bends at an input point. A value of -1 produces more slack in the curve. A value of 1 tightens the curve.

Continuity controls the continuity of the first derivative at input points.

Bias controls the direction of the curve at it passes through an input point. A value of -1 undershoots the point while a value of 1 overshoots the point.

These three parameters give the user broad control over the shape of the interpolating spline. The original Kochanek paper describes the effects nicely and is recommended reading.

To create an instance of class vtkKochanekSpline, simply invoke its constructor as follows

```
obj = vtkKochanekSpline
```

31.122.2 Methods

The class vtkKochanekSpline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkKochanekSpline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkKochanekSpline = obj.NewInstance ()`
- `vtkKochanekSpline = obj.SafeDownCast (vtkObject o)`
- `obj.Compute ()` - Compute Kochanek Spline coefficients.
- `double = obj.Evaluate (double t)` - Evaluate a 1D Kochanek spline.
- `obj.SetDefaultBias (double )` - Set the bias for all points. Default is 0.
- `double = obj.GetDefaultBias ()` - Set the bias for all points. Default is 0.
- `obj.SetDefaultTension (double )` - Set the tension for all points. Default is 0.
- `double = obj.GetDefaultTension ()` - Set the tension for all points. Default is 0.
- `obj.SetDefaultContinuity (double )` - Set the continuity for all points. Default is 0.
- `double = obj.GetDefaultContinuity ()` - Set the continuity for all points. Default is 0.
- `obj.DeepCopy (vtkSpline s)` - Deep copy of cardinal spline data.

31.123 vtkLine

31.123.1 Usage

vtkLine is a concrete implementation of vtkCell to represent a 1D line.

To create an instance of class vtkLine, simply invoke its constructor as follows

```
obj = vtkLine
```

31.123.2 Methods

The class vtkLine has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLine class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLine = obj.NewInstance ()`
- `vtkLine = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this line using scalar value provided. Like contouring, except that it cuts the line to produce other lines.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the triangle in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[2])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[2])`

31.124 vtkLocator

31.124.1 Usage

vtkLocator is an abstract base class for spatial search objects, or locators. The principle behind locators is that they divide 3-space into small pieces (or "buckets") that can be quickly found in response to queries like point location, line intersection, or object-object intersection.

The purpose of this base class is to provide ivars and methods shared by all locators. The GenerateRepresentation() is one such interesting method. This method works in conjunction with vtkLocatorFilter to create polygonal representations for the locator. For example, if the locator is an OBB tree (i.e., vtkOBBTree.h), then the representation is a set of one or more oriented bounding boxes, depending upon the specified level.

Locators typically work as follows. One or more "entities", such as points or cells, are inserted into the tree. These entities are associated with one or more buckets. Then, when performing geometric operations, the operations are performed first on the buckets, and then if the operation tests positive, then on the entities in the bucket. For example, during collision tests, the locators are collided first to identify intersecting buckets. If an intersection is found, more expensive operations are then carried out on the entities in the bucket.

To obtain good performance, locators are often organized in a tree structure. In such a structure, there are frequently multiple "levels" corresponding to different nodes in the tree. So the word level (in the context of the locator) can be used to specify a particular representation in the tree. For example, in an octree (which is a tree with 8 children), level 0 is the bounding box, or root octant, and level 1 consists of its eight children.

To create an instance of class vtkLocator, simply invoke its constructor as follows

```
obj = vtkLocator
```

31.124.2 Methods

The class vtkLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkLocator = obj.NewInstance ()`
- `vtkLocator = obj.SafeDownCast (vtkObject o)`
- `obj.SetDataSet (vtkDataSet )` - Build the locator from the points/cells defining this dataset.
- `vtkDataSet = obj.GetDataSet ()` - Build the locator from the points/cells defining this dataset.
- `obj.SetMaxLevel (int )` - Set the maximum allowable level for the tree. If the Automatic ivar is off, this will be the target depth of the locator. Initial value is 8.
- `int = obj.GetMaxLevelMinValue ()` - Set the maximum allowable level for the tree. If the Automatic ivar is off, this will be the target depth of the locator. Initial value is 8.
- `int = obj.GetMaxLevelMaxValue ()` - Set the maximum allowable level for the tree. If the Automatic ivar is off, this will be the target depth of the locator. Initial value is 8.
- `int = obj.GetMaxLevel ()` - Set the maximum allowable level for the tree. If the Automatic ivar is off, this will be the target depth of the locator. Initial value is 8.
- `int = obj.GetLevel ()` - Get the level of the locator (determined automatically if Automatic is true). The value of this ivar may change each time the locator is built. Initial value is 8.
- `obj.SetAutomatic (int )` - Boolean controls whether locator depth/resolution of locator is computed automatically from average number of entities in bucket. If not set, there will be an explicit method to control the construction of the locator (found in the subclass).
- `int = obj.GetAutomatic ()` - Boolean controls whether locator depth/resolution of locator is computed automatically from average number of entities in bucket. If not set, there will be an explicit method to control the construction of the locator (found in the subclass).
- `obj.AutomaticOn ()` - Boolean controls whether locator depth/resolution of locator is computed automatically from average number of entities in bucket. If not set, there will be an explicit method to control the construction of the locator (found in the subclass).

- `obj.AutomaticOff ()` - Boolean controls whether locator depth/resolution of locator is computed automatically from average number of entities in bucket. If not set, there will be an explicit method to control the construction of the locator (found in the subclass).
- `obj.SetTolerance (double )` - Specify absolute tolerance (in world coordinates) for performing geometric operations.
- `double = obj.GetToleranceMinValue ()` - Specify absolute tolerance (in world coordinates) for performing geometric operations.
- `double = obj.GetToleranceMaxValue ()` - Specify absolute tolerance (in world coordinates) for performing geometric operations.
- `double = obj.GetTolerance ()` - Specify absolute tolerance (in world coordinates) for performing geometric operations.
- `obj.Update ()` - Cause the locator to rebuild itself if it or its input dataset has changed.
- `obj.Initialize ()` - Initialize locator. Frees memory and resets object as appropriate.
- `obj.BuildLocator ()` - Build the locator from the input dataset.
- `obj.FreeSearchStructure ()` - Free the memory required for the spatial data structure.
- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - Method to build a representation at a particular level. Note that the method GetLevel() returns the maximum number of levels available for the tree. You must provide a vtkPolyData object into which to place the data.
- `long = obj.GetBuildTime ()` - Return the time of the last data structure build.
- `obj.Register (vtkObjectBase o)` - Handle the PointSet ¡-¿ Locator loop.
- `obj.UnRegister (vtkObjectBase o)` - Handle the PointSet ¡-¿ Locator loop.

31.125 vtkMapper2D

31.125.1 Usage

vtkMapper2D is an abstract class which defines the interface for objects which render two dimensional actors (vtkActor2D).

To create an instance of class vtkMapper2D, simply invoke its constructor as follows

```
obj = vtkMapper2D
```

31.125.2 Methods

The class vtkMapper2D has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMapper2D class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMapper2D = obj.NewInstance ()`
- `vtkMapper2D = obj.SafeDownCast (vtkObject o)`
- `obj.RenderOverlay (vtkViewport , vtkActor2D )`

- `obj.RenderOpaqueGeometry (vtkViewport , vtkActor2D )`
- `obj.RenderTranslucentPolygonalGeometry (vtkViewport , vtkActor2D )`
- `int = obj.HasTranslucentPolygonalGeometry ()`

31.126 vtkMergePoints

31.126.1 Usage

vtkMergePoints is a locator object to quickly locate points in 3D. The primary difference between vtkMergePoints and its superclass vtkPointLocator is that vtkMergePoints merges precisely coincident points and is therefore much faster.

To create an instance of class vtkMergePoints, simply invoke its constructor as follows

```
obj = vtkMergePoints
```

31.126.2 Methods

The class vtkMergePoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMergePoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMergePoints = obj.NewInstance ()`
- `vtkMergePoints = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.IsInsertedPoint (double x[3])` - Determine whether point given by x[3] has been inserted into points list. Return id of previously inserted point if this is true, otherwise return -1.
- `vtkIdType = obj.IsInsertedPoint (double x, double y, double z)` - Determine whether point given by x[3] has been inserted into points list. Return id of previously inserted point if this is true, otherwise return -1.

31.127 vtkModifiedBSPTree

31.127.1 Usage

vtkModifiedBSPTree creates an evenly balanced BSP tree using a top down implementation. Axis aligned split planes are found which evenly divide cells into two buckets. Generally a split plane will intersect some cells and these are usually stored in both child nodes of the current parent. (Or split into separate cells which we cannot consider in this case). Storing cells in multiple buckets creates problems associated with multiple tests against rays and increases the required storage as complex meshes will have many cells straddling a split plane (and further splits may cause multiple copies of these).

During a discussion with Arno Formella in 1998 he suggested using a third child node to store objects which straddle split planes. I've not seen this published (Yes! - see below), but thought it worth trying. This implementation of the BSP tree creates a third child node for storing cells lying across split planes, the third cell may overlap the other two, but the two 'proper' nodes otherwise conform to usual BSP rules.

The advantage of this implementation is cells only ever lie in one node and mailbox testing is avoided. All BBoxes are axis aligned and a ray cast uses an efficient search strategy based on near/far nodes and rejects all BBoxes using simple tests.

For fast raytracing, 6 copies of cell lists are stored in each leaf node each list is in axis sorted order +/- x,y,z and cells are always tested in the direction of the ray dominant axis. Once an intersection is found any cell or BBox with a closest point further than the I-point can be instantly rejected and raytracing stops as soon as no nodes can be closer than the current best intersection point.

The addition of the 'middle' node upsets the optimal balance of the tree, but is a minor overhead during the raytrace. Each child node is contracted such that it tightly fits all cells inside it, enabling further ray/box rejections.

This class is intented for persons requiring many ray tests and is optimized for this purpose. As no cell ever lies in more than one leaf node, and parent nodes do not maintain cell lists, the memory overhead of the sorted cell lists is 6*num_cells*4 for 6 lists of ints, each num_cells in length. The memory requirement of the nodes themselves is usually of minor significance.

Subdividision is controlled by MaxCellsPerNode - any node with more than this number will be subdivided providing a good split plane can be found and the max depth is not exceeded.

The average cells per leaf will usually be around half the MaxCellsPerNode, though the middle node is usually sparsely populated and lowers the average slightly. The middle node will not be created when not needed. Subdividing down to very small cells per node is not generally suggested as then the 6 stored cell lists are effectively redundant.

Values of MaxcellsPerNode of around 16-¿128 depending on dataset size will usually give good results.

Cells are only sorted into 6 lists once - before tree creation, each node segments the lists and passes them down to the new child nodes whilst maintaining sorted order. This makes for an efficient subdivision strategy.

NB. The following reference has been sent to me @Articleformella-1995-ray, author = "Arno Formella and Christian Gill", title = "Ray Tracing: A Quantitative Analysis and a New Practical Algorithm", journal = "The Visual Computer", year = "1995", month = dec, pages = "465–476", volume = "11", number = "9", publisher = "Springer", keywords = "ray tracing, space subdivision, plane traversal, octree, clustering, benchmark scenes", annote = "We present a new method to accelerate the process of finding nearest ray–object intersections in ray tracing. The algorithm consumes an amount of memory more or less linear in the number of objects. The basic ideas can be characterized with a modified BSP–tree and plane traversal. Plane traversal is a fast linear time algorithm to find the closest intersection point in a list of bounding volumes hit by a ray. We use plane traversal at every node of the high outdegree BSP–tree. Our implementation is competitive to fast ray tracing programs. We present a benchmark suite which allows for an extensive comparison of ray tracing algorithms.",

.SECTION Thanks John Biddiscombe for developing and contributing this class

.SECTION ToDo ———– Implement intersection heap for testing rays against transparent objects

.SECTION Style ———– This class is currently maintained by J. Biddiscombe who has specially requested that the code style not be modified to the kitware standard. Please respect the contribution of this class by keeping the style as close as possible to the author's original.

To create an instance of class vtkModifiedBSPTree, simply invoke its constructor as follows

```
obj = vtkModifiedBSPTree
```

31.127.2 Methods

The class vtkModifiedBSPTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkModifiedBSPTree class.

- `string = obj.GetClassName ()` - Standard Type-Macro
- `int = obj.IsA (string name)` - Standard Type-Macro
- `vtkModifiedBSPTree = obj.NewInstance ()` - Standard Type-Macro
- `vtkModifiedBSPTree = obj.SafeDownCast (vtkObject o)` - Standard Type-Macro
- `obj.FreeSearchStructure ()` - Free tree memory

- `obj.BuildLocator ()` - Build Tree

31.128 vtkMultiBlockDataSet

31.128.1 Usage

vtkMultiBlockDataSet is a vtkCompositeDataSet that stores a hierarchy of datasets. The dataset collection consists of multiple blocks. Each block can itself be a vtkMultiBlockDataSet, thus providing for a full tree structure. Sub-blocks are usually used to distribute blocks across processors. For example, a 1 block dataset can be distributed as following: @verbatim proc 0: Block 0: * ds 0 * (null)
proc 1: Block 0: * (null) * ds 1 @endverbatim
To create an instance of class vtkMultiBlockDataSet, simply invoke its constructor as follows

```
obj = vtkMultiBlockDataSet
```

31.128.2 Methods

The class vtkMultiBlockDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiBlockDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiBlockDataSet = obj.NewInstance ()`
- `vtkMultiBlockDataSet = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Set the number of blocks. This will cause allocation if the new number of blocks is greater than the current size. All new blocks are initialized to null.
- `obj.SetNumberOfBlocks (int numBlocks)` - Set the number of blocks. This will cause allocation if the new number of blocks is greater than the current size. All new blocks are initialized to null.
- `int = obj.GetNumberOfBlocks ()` - Returns the number of blocks.
- `vtkDataObject = obj.GetBlock (int blockno)` - Returns the block at the given index. It is recommended that one uses the iterators to iterate over composite datasets rather than using this API.
- `obj.SetBlock (int blockno, vtkDataObject block)` - Sets the data object as the given block. The total number of blocks will be resized to fit the requested block no.
- `obj.RemoveBlock (int blockno)` - Remove the given block from the dataset.
- `int = obj.HasMetaData (int blockno)` - Returns the meta-data for the block. If none is already present, a new vtkInformation object will be allocated. Use HasMetaData to avoid allocating vtkInformation objects.
- `vtkInformation = obj.GetMetaData (int blockno)` - Unhiding superclass method.
- `vtkInformation = obj.GetMetaData (vtkCompositeDataIterator iter)` - Unhiding superclass method.
- `int = obj.HasMetaData (vtkCompositeDataIterator iter)`

31.129 vtkMultiBlockDataSetAlgorithm

31.129.1 Usage

Algorithms that take any type of data object (including composite dataset) and produce a vtkMultiBlockDataSet in the output can subclass from this class.

To create an instance of class vtkMultiBlockDataSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkMultiBlockDataSetAlgorithm
```

31.129.2 Methods

The class vtkMultiBlockDataSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiBlockDataSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiBlockDataSetAlgorithm = obj.NewInstance ()`
- `vtkMultiBlockDataSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkMultiBlockDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkMultiBlockDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.130 vtkMultiPieceDataSet

31.130.1 Usage

A vtkMultiPieceDataSet dataset groups multiple data pieces together. For example, say that a simulation broke a volume into 16 piece so that each piece can be processed with 1 process in parallel. We want to load this volume in a visualization cluster of 4 nodes. Each node will get 4 pieces, not necessarily forming a whole rectangular piece. In this case, it is not possible to append the 4 pieces together into a vtkImageData. In this case, these 4 pieces can be collected together using a vtkMultiPieceDataSet. Note that vtkMultiPieceDataSet is intended to be included in other composite datasets eg. vtkMultiBlockDataSet, vtkHierarchicalBoxDataSet. Hence the lack of algorithms producting vtkMultiPieceDataSet.

To create an instance of class vtkMultiPieceDataSet, simply invoke its constructor as follows

```
obj = vtkMultiPieceDataSet
```

31.130.2 Methods

The class vtkMultiPieceDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMultiPieceDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMultiPieceDataSet = obj.NewInstance ()`
- `vtkMultiPieceDataSet = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Set the number of pieces. This will cause allocation if the new number of pieces is greater than the current size. All new pieces are initialized to null.
- `obj.SetNumberOfPieces (int numpieces)` - Set the number of pieces. This will cause allocation if the new number of pieces is greater than the current size. All new pieces are initialized to null.
- `int = obj.GetNumberOfPieces ()` - Returns the number of pieces.
- `vtkDataSet = obj.GetPiece (int pieceno)` - Returns the piece at the given index.
- `vtkDataObject = obj.GetPieceAsDataObject (int pieceno)` - Returns the piece at the given index.
- `obj.SetPiece (int pieceno, vtkDataObject piece)` - Sets the data object as the given piece. The total number of pieces will be resized to fit the requested piece no.
- `int = obj.HasMetaData (int piece)` - Returns the meta-data for the piece. If none is already present, a new vtkInformation object will be allocated. Use HasMetaData to avoid allocating vtkInformation objects.
- `vtkInformation = obj.GetMetaData (int pieceno)` - Unhiding superclass method.
- `vtkInformation = obj.GetMetaData (vtkCompositeDataIterator iter)` - Unhiding superclass method.
- `int = obj.HasMetaData (vtkCompositeDataIterator iter)`

31.131 vtkMutableDirectedGraph

31.131.1 Usage

vtkMutableDirectedGraph is a directed graph which has additional methods for adding edges and vertices. AddChild() is a convenience method for constructing trees. ShallowCopy(), DeepCopy(), CheckedShallowCopy() and CheckedDeepCopy() will succeed for instances of vtkDirectedGraph, vtkMutableDirectedGraph and vtkTree.

To create an instance of class vtkMutableDirectedGraph, simply invoke its constructor as follows

```
obj = vtkMutableDirectedGraph
```

31.131.2 Methods

The class vtkMutableDirectedGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMutableDirectedGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMutableDirectedGraph = obj.NewInstance ()`
- `vtkMutableDirectedGraph = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.AddVertex ()` - Adds a vertex to the graph and returns the index of the new vertex.

  Note: In a distributed graph (i.e. a graph whose DistributedHelper is non-null), this routine cannot be used to add a vertex if the vertices in the graph have pedigree IDs, because this routine will always add the vertex locally, which may conflict with the proper location of the vertex based on the distribution of the pedigree IDs.
- `vtkIdType = obj.AddVertex (vtkVariantArray propertyArr)` - Adds a vertex to the graph with associated properties defined in propertyArr and returns the index of the new vertex. The number and order of values in propertyArr must match up with the arrays in the vertex data retrieved by GetVertexData().

  If a vertex with the given pedigree ID already exists, its properties will be overwritten with the properties in propertyArr and the existing vertex index will be returned.

  Note: In a distributed graph (i.e. a graph whose DistributedHelper is non-null) the vertex added or found might not be local. In this case, AddVertex will wait until the vertex can be added or found remotely, so that the proper vertex index can be returned. If you don't actually need to use the vertex index, consider calling LazyAddVertex, which provides better performance by eliminating the delays associated with returning the vertex index.
- `obj.LazyAddVertex ()` - Adds a vertex to the graph.

  This method is lazily evaluated for distributed graphs (i.e. graphs whose DistributedHelper is non-null) the next time Synchronize is called on the helper.
- `obj.LazyAddVertex (vtkVariantArray propertyArr)` - Adds a vertex to the graph with associated properties defined in propertyArr. The number and order of values in propertyArr must match up with the arrays in the vertex data retrieved by GetVertexData().

  If a vertex with the given pedigree ID already exists, its properties will be overwritten with the properties in propertyArr.

  This method is lazily evaluated for distributed graphs (i.e. graphs whose DistributedHelper is non-null) the next time Synchronize is called on the helper.
- `vtkGraphEdge = obj.AddGraphEdge (vtkIdType u, vtkIdType v)` - Variant of AddEdge() that returns a heavyweight vtkGraphEdge object. The graph owns the reference of the edge and will replace its contents on the next call to AddGraphEdge().

  Note: This is a less efficient method for use with wrappers. In C++ you should use the faster AddEdge().
- `vtkIdType = obj.AddChild (vtkIdType parent, vtkVariantArray propertyArr)` - Convenience method for creating trees. Returns the newly created vertex id. Shortcut for

```
vtkIdType v = g->AddVertex();
g->AddEdge(parent, v);
```

If non-null, propertyArr provides edge properties for the newly-created edge. The values in propertyArr must match up with the arrays in the edge data returned by GetEdgeData().

- `vtkIdType = obj.AddChild (vtkIdType parent)` - Removes the vertex from the graph along with any connected edges. Note: This invalidates the last vertex index, which is reassigned to v.
- `obj.RemoveVertex (vtkIdType v)` - Removes the vertex from the graph along with any connected edges. Note: This invalidates the last vertex index, which is reassigned to v.
- `obj.RemoveEdge (vtkIdType e)` - Removes the edge from the graph. Note: This invalidates the last edge index, which is reassigned to e.
- `obj.RemoveVertices (vtkIdTypeArray arr)` - Removes a collection of vertices from the graph along with any connected edges.
- `obj.RemoveEdges (vtkIdTypeArray arr)` - Removes a collection of edges from the graph.

31.132 vtkMutableUndirectedGraph

31.132.1 Usage

vtkMutableUndirectedGraph is an undirected graph with additional functions for adding vertices and edges. ShallowCopy(), DeepCopy(), CheckedShallowCopy(), and CheckedDeepCopy() will succeed when the argument is a vtkUndirectedGraph or vtkMutableUndirectedGraph.

To create an instance of class vtkMutableUndirectedGraph, simply invoke its constructor as follows

```
obj = vtkMutableUndirectedGraph
```

31.132.2 Methods

The class vtkMutableUndirectedGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkMutableUndirectedGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkMutableUndirectedGraph = obj.NewInstance ()`
- `vtkMutableUndirectedGraph = obj.SafeDownCast (vtkObject o)`
- `vtkIdType = obj.AddVertex ()` - Adds a vertex to the graph and returns the index of the new vertex.

  Note: In a distributed graph (i.e. a graph whose DistributedHelper is non-null), this routine cannot be used to add a vertex if the vertices in the graph have pedigree IDs, because this routine will always add the vertex locally, which may conflict with the proper location of the vertex based on the distribution of the pedigree IDs.
- `vtkIdType = obj.AddVertex (vtkVariantArray propertyArr)` - Adds a vertex to the graph with associated properties defined in propertyArr and returns the index of the new vertex. The number and order of values in propertyArr must match up with the arrays in the vertex data retrieved by GetVertexData().

  If a vertex with the given pedigree ID already exists, its properties will be overwritten with the properties in propertyArr and the existing vertex index will be returned.

  Note: In a distributed graph (i.e. a graph whose DistributedHelper is non-null) the vertex added or found might not be local. In this case, AddVertex will wait until the vertex can be added or found

remotely, so that the proper vertex index can be returned. If you don't actually need to use the vertex index, consider calling LazyAddVertex, which provides better performance by eliminating the delays associated with returning the vertex index.

- `obj.LazyAddVertex ()` - Adds a vertex to the graph.

  This method is lazily evaluated for distributed graphs (i.e. graphs whose DistributedHelper is non-null) the next time Synchronize is called on the helper.

- `obj.LazyAddVertex (vtkVariantArray propertyArr)` - Adds a vertex to the graph with associated properties defined in propertyArr. The number and order of values in propertyArr must match up with the arrays in the vertex data retrieved by GetVertexData().

  If a vertex with the given pedigree ID already exists, its properties will be overwritten with the properties in propertyArr.

  This method is lazily evaluated for distributed graphs (i.e. graphs whose DistributedHelper is non-null) the next time Synchronize is called on the helper.

- `obj.LazyAddEdge (vtkIdType u, vtkIdType v)` - Adds an undirected edge from u to v, where u and v are vertex indices.

  This method is lazily evaluated for distributed graphs (i.e. graphs whose DistributedHelper is non-null) the next time Synchronize is called on the helper.

- `obj.LazyAddEdge (vtkIdType u, vtkIdType v, vtkVariantArray propertyArr)` - Adds an undirected edge from u to v, where u and v are vertex indices.

  The number and order of values in propertyArr must match up with the arrays in the edge data retrieved by GetEdgeData().

  This method is lazily evaluated for distributed graphs (i.e. graphs whose DistributedHelper is non-null) the next time Synchronize is called on the helper.

- `vtkGraphEdge = obj.AddGraphEdge (vtkIdType u, vtkIdType v)` - Variant of AddEdge() that returns a heavyweight vtkGraphEdge object. The graph owns the reference of the edge and will replace its contents on the next call to AddGraphEdge().

  Note: This is a less efficient method for use with wrappers. In C++ you should use the faster AddEdge().

- `obj.RemoveVertex (vtkIdType v)` - Removes the vertex from the graph along with any connected edges. Note: This invalidates the last vertex index, which is reassigned to v.

- `obj.RemoveEdge (vtkIdType e)` - Removes the edge from the graph. Note: This invalidates the last edge index, which is reassigned to e.

- `obj.RemoveVertices (vtkIdTypeArray arr)` - Removes a collection of vertices from the graph along with any connected edges.

- `obj.RemoveEdges (vtkIdTypeArray arr)` - Removes a collection of edges from the graph.

31.133 vtkNonLinearCell

31.133.1 Usage

vtkNonLinearCell is an abstract superclass for non-linear cell types. Cells that are a direct subclass of vtkCell or vtkCell3D are linear; cells that are a subclass of vtkNonLinearCell have non-linear interpolation functions. Non-linear cells require special treatment when tessellating or converting to graphics primitives. Note that the linearity of the cell is a function of whether the cell needs tessellation, which does not strictly correlate with interpolation order (e.g., vtkHexahedron has non-linear interpolation functions (a product of three linear functions in r-s-t) even thought vtkHexahedron is considered linear.)

To create an instance of class vtkNonLinearCell, simply invoke its constructor as follows

```
obj = vtkNonLinearCell
```

31.133.2 Methods

The class vtkNonLinearCell has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkNonLinearCell class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkNonLinearCell = obj.NewInstance ()`
- `vtkNonLinearCell = obj.SafeDownCast (vtkObject o)`
- `int = obj.IsLinear ()`

31.134 vtkNonMergingPointLocator

31.134.1 Usage

As a special sub-class of vtkPointLocator, vtkNonMergingPointLocator is intended for direct / check-free insertion of points into a vtkPoints object. In other words, any given point is always directly inserted. The name emphasizes the difference between this class and its sibling class vtkMergePoints in that the latter class performs check-based zero tolerance point insertion (or to 'merge' exactly duplicate / coincident points) by exploiting the uniform bin mechanism employed by the parent class vtkPointLocator. vtkPointLocator allows for generic (zero and non- zero) tolerance point insertion as well as point location.

To create an instance of class vtkNonMergingPointLocator, simply invoke its constructor as follows

```
obj = vtkNonMergingPointLocator
```

31.134.2 Methods

The class vtkNonMergingPointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkNonMergingPointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkNonMergingPointLocator = obj.NewInstance ()`
- `vtkNonMergingPointLocator = obj.SafeDownCast (vtkObject o)`

31.135 vtkOctreePointLocator

31.135.1 Usage

Given a vtkDataSetxs, create an octree that is locally refined such that all leaf octants contain less than a certain amount of points. Note that there is no size constraint that a leaf octant in relation to any of its neighbors.

This class can also generate a PolyData representation of the boundaries of the spatial regions in the decomposition.

To create an instance of class vtkOctreePointLocator, simply invoke its constructor as follows

```
obj = vtkOctreePointLocator
```

31.135.2 Methods

The class vtkOctreePointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOctreePointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOctreePointLocator = obj.NewInstance ()`
- `vtkOctreePointLocator = obj.SafeDownCast (vtkObject o)`
- `obj.SetMaximumPointsPerRegion (int )` - Maximum number of points per spatial region. Default is 100.
- `int = obj.GetMaximumPointsPerRegion ()` - Maximum number of points per spatial region. Default is 100.
- `obj.SetCreateCubicOctants (int )` - Get/Set macro for CreateCubicOctants.
- `int = obj.GetCreateCubicOctants ()` - Get/Set macro for CreateCubicOctants.
- `double = obj.GetFudgeFactor ()` - Some algorithms on octrees require a value that is a very small distance relative to the diameter of the entire space divided by the octree. This factor is the maximum axis-aligned width of the space multipled by 10e-6.
- `obj.SetFudgeFactor (double )` - Some algorithms on octrees require a value that is a very small distance relative to the diameter of the entire space divided by the octree. This factor is the maximum axis-aligned width of the space multipled by 10e-6.
- `obj.GetBounds (double bounds)` - Get the spatial bounds of the entire octree space. Sets bounds array to xmin, xmax, ymin, ymax, zmin, zmax.
- `int = obj.GetNumberOfLeafNodes ()` - The number of leaf nodes of the tree, the spatial regions
- `obj.GetRegionBounds (int regionID, double bounds[6])` - Get the spatial bounds of octree region
- `obj.GetRegionDataBounds (int leafNodeID, double bounds[6])` - Get the bounds of the data within the leaf node
- `int = obj.GetRegionContainingPoint (double x, double y, double z)` - Get the id of the leaf region containing the specified location.
- `obj.BuildLocator ()` - Create the octree decomposition of the cells of the data set or data sets. Cells are assigned to octree spatial regions based on the location of their centroids.
- `vtkIdType = obj.FindClosestPoint (double x[3])` - Return the Id of the point that is closest to the given point. Set the square of the distance between the two points.
- `obj.FindPointsWithinRadius (double radius, double x[3], vtkIdList result)` - Find all points within a specified radius of position x. The result is not sorted in any specific manner.
- `obj.FindClosestNPoints (int N, double x[3], vtkIdList result)` - Find the closest N points to a position. This returns the closest N points to a position. A faster method could be created that returned N close points to a position, but not necessarily the exact N closest. The returned points are sorted from closest to farthest. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `vtkIdTypeArray = obj.GetPointsInRegion (int leafNodeId)` - Get a list of the original IDs of all points in a leaf node.
- `obj.FreeSearchStructure ()` - Delete the octree data structure.
- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - Create a polydata representation of the boundaries of the octree regions.
- `obj.FindPointsInArea (double area, vtkIdTypeArray ids, bool clearArraytrue)` - Fill ids with points found in area. The area is a 6-tuple containing (xmin, xmax, ymin, ymax, zmin, zmax). This method will clear the array by default. To append ids to an array, set clearArray to false.

31.136 vtkOctreePointLocatorNode

31.136.1 Usage

This class represents a single spatial region in a 3D axis octant partitioning. It is intended to work efficiently with the vtkOctreePointLocator and is not meant for general use. It is assumed the region bounds some set of points. The ordering of the children is (-x,-y,-z),(+x,-y,-z),(-x,+y,-z),(+x,+y,-z),(-x,-y,+z),(+x,-y,+z), (-x,+y,+z),(+x,+y,+z). The portion of the domain assigned to an octant is Min ¡ x ¡= Max.

To create an instance of class vtkOctreePointLocatorNode, simply invoke its constructor as follows

```
obj = vtkOctreePointLocatorNode
```

31.136.2 Methods

The class vtkOctreePointLocatorNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOctreePointLocatorNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOctreePointLocatorNode = obj.NewInstance ()`
- `vtkOctreePointLocatorNode = obj.SafeDownCast (vtkObject o)`
- `obj.SetNumberOfPoints (int numberOfPoints)` - Set/Get the number of points contained in this region.
- `int = obj.GetNumberOfPoints ()` - Set/Get the number of points contained in this region.
- `obj.SetBounds (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)` - Set/Get the bounds of the spatial region represented by this node. Caller allocates storage for 6-vector in GetBounds.
- `obj.SetBounds (double b[6])` - Set/Get the bounds of the spatial region represented by this node. Caller allocates storage for 6-vector in GetBounds.
- `obj.GetBounds (double b) const` - Set/Get the bounds of the spatial region represented by this node. Caller allocates storage for 6-vector in GetBounds.
- `obj.SetDataBounds (double xMin, double xMax, double yMin, double yMax, double zMin, double zMax)` - Set/Get the bounds of the points contained in this spatial region. This may be smaller than the bounds of the region itself. Caller allocates storage for 6-vector in GetDataBounds.

- `obj.GetDataBounds (double b) const` - Set/Get the bounds of the points contained in this spatial region. This may be smaller than the bounds of the region itself. Caller allocates storage for 6-vector in GetDataBounds.

- `obj.SetMinBounds (double minBounds[3])` - Set the xmax, ymax and zmax value of the bounds of this region

- `obj.SetMaxBounds (double maxBounds[3])` - Set the xmin, ymin and zmin value of the bounds of this data within this region.

- `obj.SetMinDataBounds (double minDataBounds[3])` - Set the xmax, ymax and zmax value of the bounds of this data within this region.

- `obj.SetMaxDataBounds (double maxDataBounds[3])` - Get the ID associated with the region described by this node. If this is not a leaf node, this value should be -1.

- `int = obj.GetID ()` - Get the ID associated with the region described by this node. If this is not a leaf node, this value should be -1.

- `int = obj.GetMinID ()` - If this node is not a leaf node, there are leaf nodes below it whose regions represent a partitioning of this region. The IDs of these leaf nodes form a contigous set. Get the first of the first point's ID that is contained in this node.

- `obj.CreateChildNodes ()` - Add the 8 children.

- `obj.DeleteChildNodes ()` - Delete the 8 children.

- `vtkOctreePointLocatorNode = obj.GetChild (int i)` - Get a pointer to the ith child of this node.

- `int = obj.IntersectsRegion (vtkPlanesIntersection pi, int useDataBounds)` - A vtkPlanesIntersection object represents a convex 3D region bounded by planes, and it is capable of computing intersections of boxes with itself. Return 1 if this spatial region intersects the spatial region described by the vtkPlanesIntersection object. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.

- `int = obj.ContainsPoint (double x, double y, double z, int useDataBounds)` - Return 1 if this spatial region entirely contains the given point. Use the possibly smaller bounds of the points within the region if useDataBounds is non-zero.

- `double = obj.GetDistance2ToBoundary (double x, double y, double z, vtkOctreePointLocatorNode top, i` - Calculate the distance squared from any point to the boundary of this region. Use the boundary of the points within the region if useDataBounds is non-zero.

- `double = obj.GetDistance2ToBoundary (double x, double y, double z, double boundaryPt, vtkOctreePoir` - Calculate the distance squared from any point to the boundary of this region. Use the boundary of the points within the region if useDataBounds is non-zero. Set boundaryPt to the point on the boundary.

- `double = obj.GetDistance2ToInnerBoundary (double x, double y, double z, vtkOctreePointLocatorNode t` - Calculate the distance from the specified point (which is required to be inside this spatial region) to an interior boundary. An interior boundary is one that is not also an boundary of the entire space partitioned by the tree of vtkOctreePointLocatorNode's.

- `int = obj.GetSubOctantIndex (double point, int CheckContainment)` - Return the id of the suboctant that a given point is in. If CheckContainment is non-zero then it checks whether the point is in the actual bounding box of the suboctant, otherwise it only checks which octant the point is in that is created from the axis-aligned partitioning of the domain at this octant's center.

31.137 vtkOrderedTriangulator

31.137.1 Usage

This class is used to generate unique triangulations of points. The uniqueness of the triangulation is controlled by the id of the inserted points in combination with a Delaunay criterion. The class is designed to be as fast as possible (since the algorithm can be slow) and uses block memory allocations to support rapid triangulation generation. Also, the assumption behind the class is that a maximum of hundreds of points are to be triangulated. If you desire more robust triangulation methods use vtkPolygon::Triangulate(), vtkDelaunay2D, or vtkDelaunay3D.

.SECTION Background This work is documented in the technical paper: W.J. Schroeder, B. Geveci, M. Malaterre. Compatible Triangulations of Spatial Decompositions. In Proceedings of Visualization 2004, IEEE Press October 2004.

Delaunay triangulations are unique assuming a random distribution of input points. The 3D Delaunay criterion is as follows: the circumsphere of each tetrahedron contains no other points of the triangulation except for the four points defining the tetrahedron. In application this property is hard to satisfy because objects like cubes are defined by eight points all sharing the same circumsphere (center and radius); hence the Delaunay triangulation is not unique. These so-called degenerate situations are typically resolved by arbitrary selecting a triangulation. This code does something different: it resolves degenerate triangulations by modifying the "InCircumsphere" method to use a slightly smaller radius. Hence, degenerate points are always considered "out" of the circumsphere. This, in combination with an ordering (based on id) of the input points, guarantees a unique triangulation.

There is another related characteristic of Delaunay triangulations. Given a N-dimensional Delaunay triangulation, points lying on a (N-1) dimensional plane also form a (N-1) Delaunay triangulation. This means for example, that if a 3D cell is defined by a set of (2D) planar faces, then the face triangulations are Delaunay. Combining this with the method to generate unique triangulations described previously, the triangulations on the face are guaranteed unique. This fact can be used to triangulate 3D objects in such a way to guarantee compatible face triangulations. This is a very useful fact for parallel processing, or performing operations like clipping that require compatible triangulations across 3D cell faces. (See vtkClipVolume for an example.)

A special feature of this class is that it can generate triangulation templates on the fly. If template triangulation is enabled, then the ordered triangulator will first triangulate the cell using the slower ordered Delaunay approach, and then store the result as a template. Later, if the same cell type and cell configuration is encountered, then the template is reused which greatly speeds the triangulation.

To create an instance of class vtkOrderedTriangulator, simply invoke its constructor as follows

```
obj = vtkOrderedTriangulator
```

31.137.2 Methods

The class vtkOrderedTriangulator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOrderedTriangulator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOrderedTriangulator = obj.NewInstance ()`
- `vtkOrderedTriangulator = obj.SafeDownCast (vtkObject o)`
- `obj.InitTriangulation (double xmin, double xmax, double ymin, double ymax, double zmin, double zmax`
  - Initialize the triangulation process. Provide a bounding box and the maximum number of points to be inserted. Note that since the triangulation is performed using parametric coordinates (see Insert-Point()) the bounds should be represent the range of the parametric coordinates inserted.

- `obj.InitTriangulation (double bounds[6], int numPts)` - Initialize the triangulation process. Provide a bounding box and the maximum number of points to be inserted. Note that since the triangulation is performed using parametric coordinates (see InsertPoint()) the bounds should be represent the range of the parametric coordinates inserted.

- `vtkIdType = obj.InsertPoint (vtkIdType id, double x[3], double p[3], int type)` - For each point to be inserted, provide an id, a position x, parametric coordinate p, and whether the point is inside (type=0), outside (type=1), or on the boundary (type=2). You must call InitTriangulation() prior to invoking this method. Make sure that the number of points inserted does not exceed the numPts specified in InitTriangulation(). Also note that the "id" can be any integer and can be greater than numPts. It is used to create tetras (in AddTetras()) with the appropriate connectivity ids. The method returns an internal id that can be used prior to the Triangulate() method to update the type of the point with UpdatePointType(). (Note: the algorithm triangulated with the parametric coordinate p[3] and creates tetras with the global coordinate x[3]. The parametric coordinates and global coordinates may be the same.)

- `vtkIdType = obj.InsertPoint (vtkIdType id, vtkIdType sortid, double x[3], double p[3], int type)` - For each point to be inserted, provide an id, a position x, parametric coordinate p, and whether the point is inside (type=0), outside (type=1), or on the boundary (type=2). You must call InitTriangulation() prior to invoking this method. Make sure that the number of points inserted does not exceed the numPts specified in InitTriangulation(). Also note that the "id" can be any integer and can be greater than numPts. It is used to create tetras (in AddTetras()) with the appropriate connectivity ids. The method returns an internal id that can be used prior to the Triangulate() method to update the type of the point with UpdatePointType(). (Note: the algorithm triangulated with the parametric coordinate p[3] and creates tetras with the global coordinate x[3]. The parametric coordinates and global coordinates may be the same.)

- `vtkIdType = obj.InsertPoint (vtkIdType id, vtkIdType sortid, vtkIdType sortid2, double x[3], double` - For each point to be inserted, provide an id, a position x, parametric coordinate p, and whether the point is inside (type=0), outside (type=1), or on the boundary (type=2). You must call InitTriangulation() prior to invoking this method. Make sure that the number of points inserted does not exceed the numPts specified in InitTriangulation(). Also note that the "id" can be any integer and can be greater than numPts. It is used to create tetras (in AddTetras()) with the appropriate connectivity ids. The method returns an internal id that can be used prior to the Triangulate() method to update the type of the point with UpdatePointType(). (Note: the algorithm triangulated with the parametric coordinate p[3] and creates tetras with the global coordinate x[3]. The parametric coordinates and global coordinates may be the same.)

- `obj.Triangulate ()` - Perform the triangulation. (Complete all calls to InsertPoint() prior to invoking this method.) A special version is available when templates should be used.

- `obj.TemplateTriangulate (int cellType, int numPts, int numEdges)` - Perform the triangulation. (Complete all calls to InsertPoint() prior to invoking this method.) A special version is available when templates should be used.

- `obj.UpdatePointType (vtkIdType internalId, int type)` - Update the point type. This is useful when the merging of nearly coincident points is performed. The id is the internal id returned from InsertPoint(). The method should be invoked prior to the Triangulate method. The type is specified as inside (type=0), outside (type=1), or on the boundary (type=2).

- `vtkIdType = obj.GetPointId (vtkIdType internalId)` - Return the Id of point 'internalId'. This id is the one passed in argument of InsertPoint. It assumes that the point has already been inserted. The method should be invoked prior to the Triangulate method.

- `int = obj.GetNumberOfPoints ()` - Return the number of inserted points.

- `obj.SetUseTemplates (int )` - If this flag is set, then the ordered triangulator will create and use templates for the triangulation. To use templates, the TemplateTriangulate() method should be called when appropriate. (Note: the TemplateTriangulate() method works for complete (interior) cells without extra points due to intersection, etc.)

- `int = obj.GetUseTemplates ()` - If this flag is set, then the ordered triangulator will create and use templates for the triangulation. To use templates, the TemplateTriangulate() method should be called when appropriate. (Note: the TemplateTriangulate() method works for complete (interior) cells without extra points due to intersection, etc.)

- `obj.UseTemplatesOn ()` - If this flag is set, then the ordered triangulator will create and use templates for the triangulation. To use templates, the TemplateTriangulate() method should be called when appropriate. (Note: the TemplateTriangulate() method works for complete (interior) cells without extra points due to intersection, etc.)

- `obj.UseTemplatesOff ()` - If this flag is set, then the ordered triangulator will create and use templates for the triangulation. To use templates, the TemplateTriangulate() method should be called when appropriate. (Note: the TemplateTriangulate() method works for complete (interior) cells without extra points due to intersection, etc.)

- `obj.SetPreSorted (int )` - Boolean indicates whether the points have been pre-sorted. If pre-sorted is enabled, the points are not sorted on point id. By default, presorted is off. (The point id is defined in InsertPoint().)

- `int = obj.GetPreSorted ()` - Boolean indicates whether the points have been pre-sorted. If pre-sorted is enabled, the points are not sorted on point id. By default, presorted is off. (The point id is defined in InsertPoint().)

- `obj.PreSortedOn ()` - Boolean indicates whether the points have been pre-sorted. If pre-sorted is enabled, the points are not sorted on point id. By default, presorted is off. (The point id is defined in InsertPoint().)

- `obj.PreSortedOff ()` - Boolean indicates whether the points have been pre-sorted. If pre-sorted is enabled, the points are not sorted on point id. By default, presorted is off. (The point id is defined in InsertPoint().)

- `obj.SetUseTwoSortIds (int )` - Tells the triangulator that a second sort id is provided for each point and should also be considered when sorting.

- `int = obj.GetUseTwoSortIds ()` - Tells the triangulator that a second sort id is provided for each point and should also be considered when sorting.

- `obj.UseTwoSortIdsOn ()` - Tells the triangulator that a second sort id is provided for each point and should also be considered when sorting.

- `obj.UseTwoSortIdsOff ()` - Tells the triangulator that a second sort id is provided for each point and should also be considered when sorting.

- `vtkIdType = obj.GetTetras (int classification, vtkUnstructuredGrid ugrid)` - Initialize and add the tetras and points from the triangulation to the unstructured grid provided. New points are created and the mesh is allocated. (This method differs from AddTetras() in that it inserts points and cells; AddTetras only adds the tetra cells.) The tetrahdera added are of the type specified (0=inside,1=outside,2=all). Inside tetrahedron are those whose points are classified "inside" or on the "boundary." Outside tetrahedron have at least one point classified "outside." The method returns the number of tetrahedrahedron of the type requested.

- `vtkIdType = obj.AddTetras (int classification, vtkUnstructuredGrid ugrid)` - Add the tetras to the unstructured grid provided. The unstructured grid is assumed to have been initialized (with

Allocate()) and points set (with SetPoints()). The tetrahdera added are of the type specified (0=inside,1=outside,2=all). Inside tetrahedron are those whose points are classified "inside" or on the "boundary." Outside tetrahedron have at least one point classified "outside." The method returns the number of tetrahedrahedron of the type requested.

- `vtkIdType = obj.AddTetras (int classification, vtkCellArray connectivity)` - Add the tetrahedra classified (0=inside,1=outside) to the connectivity list provided. Inside tetrahedron are those whose points are all classified "inside." Outside tetrahedron have at least one point classified "outside." The method returns the number of tetrahedron of the type requested.
- `vtkIdType = obj.AddTetras (int classification, vtkIncrementalPointLocator locator, vtkCellArray out` - Assuming that all the inserted points come from a cell 'cellId' to triangulate, get the tetrahedra in outConnectivity, the points in locator and copy point data and cell data. Return the number of added tetras.
- `vtkIdType = obj.AddTetras (int classification, vtkIdList ptIds, vtkPoints pts)` - Add the tetrahedra classified (0=inside,1=outside) to the list of ids and coordinates provided. These assume that the first four points form a tetrahedron, the next four the next, and so on.
- `vtkIdType = obj.AddTriangles (vtkCellArray connectivity)` - Add the triangle faces classified (2=boundary) to the connectivity list provided. The method returns the number of triangles.
- `vtkIdType = obj.AddTriangles (vtkIdType id, vtkCellArray connectivity)` - Add the triangle faces classified (2=boundary) and attached to the specified point id to the connectivity list provided. (The id is the same as that specified in InsertPoint().)
- `obj.InitTetraTraversal ()` - Methods to get one tetra at a time. Start with InitTetraTraversal() and then invoke GetNextTetra() until the method returns 0.
- `int = obj.GetNextTetra (int classification, vtkTetra tet, vtkDataArray cellScalars, vtkDoubleArray` - Methods to get one tetra at a time. Start with InitTetraTraversal() and then invoke GetNextTetra() until the method returns 0. cellScalars are point-centered scalars on the original cell. tetScalars are point-centered scalars on the tetra: the values will be copied from cellScalars.

31.138 vtkOutEdgeIterator

31.138.1 Usage

vtkOutEdgeIterator iterates through all edges whose source is a particular vertex. Instantiate this class directly and call Initialize() to traverse the vertex of a graph. Alternately, use GetInEdges() on the graph to initialize the iterator. it-¿Next() returns a vtkOutEdgeType structure, which contains Id, the edge's id, and Target, the edge's target vertex.

To create an instance of class vtkOutEdgeIterator, simply invoke its constructor as follows

```
obj = vtkOutEdgeIterator
```

31.138.2 Methods

The class vtkOutEdgeIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkOutEdgeIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkOutEdgeIterator = obj.NewInstance ()`

- `vtkOutEdgeIterator = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize (vtkGraph g, vtkIdType v)` - Initialize the iterator with a graph and vertex.
- `vtkGraph = obj.GetGraph ()` - Get the graph and vertex associated with this iterator.
- `vtkIdType = obj.GetVertex ()` - Get the graph and vertex associated with this iterator.
- `vtkGraphEdge = obj.NextGraphEdge ()` - Just like Next(), but returns heavy-weight vtkGraphEdge object instead of the vtkEdgeType struct, for use with wrappers. The graph edge is owned by this iterator, and changes after each call to NextGraphEdge().
- `bool = obj.HasNext ()`

31.139 vtkParametricSpline

31.139.1 Usage

vtkParametricSpline is a parametric function for 1D interpolating splines. vtkParametricSpline maps the single parameter u into a 3D point (x,y,z) using three instances of interpolating splines. This family of 1D splines is quaranteed to be parameterized in the interval [0,1]. Attempting to evaluate outside this interval will cause the parameter u to be clamped in the range [0,1].

When constructed, this class creates instances of vtkCardinalSpline for each of the x-y-z coordinates. The user may choose to replace these with their own instances of subclasses of vtkSpline.

To create an instance of class vtkParametricSpline, simply invoke its constructor as follows

```
obj = vtkParametricSpline
```

31.139.2 Methods

The class vtkParametricSpline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkParametricSpline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkParametricSpline = obj.NewInstance ()`
- `vtkParametricSpline = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDimension ()` - Evaluate the spline at parametric coordinate u[0] returning the point coordinate Pt[3].
- `obj.Evaluate (double u[3], double Pt[3], double Du[9])` - Evaluate the spline at parametric coordinate u[0] returning the point coordinate Pt[3].
- `double = obj.EvaluateScalar (double u[3], double Pt[3], double Du[9])` - Evaluate a scalar value at parametric coordinate u[0] and Pt[3]. The scalar value is just the parameter u[0].
- `obj.SetXSpline (vtkSpline )` - By default, this class is constructed with three instances of vtkCardinalSpline (for each of the x-y-z coordinate axes). The user may choose to create and assign their own instances of vtkSpline.
- `obj.SetYSpline (vtkSpline )` - By default, this class is constructed with three instances of vtkCardinalSpline (for each of the x-y-z coordinate axes). The user may choose to create and assign their own instances of vtkSpline.

- `obj.SetZSpline (vtkSpline )` - By default, this class is constructed with three instances of vtkCardinalSpline (for each of the x-y-z coordinate axes). The user may choose to create and assign their own instances of vtkSpline.
- `vtkSpline = obj.GetXSpline ()` - By default, this class is constructed with three instances of vtkCardinalSpline (for each of the x-y-z coordinate axes). The user may choose to create and assign their own instances of vtkSpline.
- `vtkSpline = obj.GetYSpline ()` - By default, this class is constructed with three instances of vtkCardinalSpline (for each of the x-y-z coordinate axes). The user may choose to create and assign their own instances of vtkSpline.
- `vtkSpline = obj.GetZSpline ()` - By default, this class is constructed with three instances of vtkCardinalSpline (for each of the x-y-z coordinate axes). The user may choose to create and assign their own instances of vtkSpline.
- `obj.SetPoints (vtkPoints )` - Specify the list of points defining the spline. Do this by specifying a vtkPoints array containing the points. Note that the order of the points in vtkPoints is the order that the splines will be fit.
- `vtkPoints = obj.GetPoints ()` - Specify the list of points defining the spline. Do this by specifying a vtkPoints array containing the points. Note that the order of the points in vtkPoints is the order that the splines will be fit.
- `obj.SetNumberOfPoints (vtkIdType numPts)` - Another API to set the points. Set the number of points and then set the individual point coordinates.
- `obj.SetPoint (vtkIdType index, double x, double y, double z)` - Another API to set the points. Set the number of points and then set the individual point coordinates.
- `obj.SetClosed (int )` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `int = obj.GetClosed ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `obj.ClosedOn ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `obj.ClosedOff ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `obj.SetParameterizeByLength (int )` - Control whether the spline is parameterized by length or by point index. Default is by length.
- `int = obj.GetParameterizeByLength ()` - Control whether the spline is parameterized by length or by point index. Default is by length.
- `obj.ParameterizeByLengthOn ()` - Control whether the spline is parameterized by length or by point index. Default is by length.
- `obj.ParameterizeByLengthOff ()` - Control whether the spline is parameterized by length or by point index. Default is by length.
- `obj.SetLeftConstraint (int )` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

2: the second derivative at left(right) most point is set to Left(Right)Value.

3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetLeftConstraintMinValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetLeftConstraintMaxValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetLeftConstraint ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `obj.SetRightConstraint (int )` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetRightConstraintMinValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetRightConstraintMaxValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetRightConstraint ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `obj.SetLeftValue (double )` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.

- `double = obj.GetLeftValue ()` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.

- `obj.SetRightValue (double )` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.

- `double = obj.GetRightValue ()` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.

31.140 vtkPassInputTypeAlgorithm

31.140.1 Usage

vtkPassInputTypeAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. Ther are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this classes contstructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be DataObject. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into seperate functions such as RequestDataObject RequestData and RequestInformation. The default implementation of RequestDataObject will create an output data of the same type as the input.

To create an instance of class vtkPassInputTypeAlgorithm, simply invoke its constructor as follows

```
obj = vtkPassInputTypeAlgorithm
```

31.140.2 Methods

The class vtkPassInputTypeAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPassInputTypeAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPassInputTypeAlgorithm = obj.NewInstance ()`
- `vtkPassInputTypeAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as vtkPolyData.
- `vtkStructuredPoints = obj.GetStructuredPointsOutput ()` - Get the output as vtkStructuredPoints.
- `vtkImageData = obj.GetImageDataOutput ()` - Get the output as vtkStructuredPoints.
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as vtkStructuredGrid.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as vtkUnstructuredGrid.
- `vtkRectilinearGrid = obj.GetRectilinearGridOutput ()` - Get the output as vtkRectilinearGrid.
- `vtkTable = obj.GetTableOutput ()` - Get the output as vtkTable.
- `vtkGraph = obj.GetGraphOutput ()` - Get the output as vtkGraph.
- `vtkDataObject = obj.GetInput ()` - Get the input data object. This method is not recommended for use, but lots of old style filters use it.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.141 vtkPentagonalPrism

31.141.1 Usage

vtkPentagonalPrism is a concrete implementation of vtkCell to represent a linear 3D prism with pentagonal base. Such prism is defined by the ten points (0-9) where (0,1,2,3,4) is the base of the prism which, using the right hand rule, forms a pentagon whose normal points is in the direction of the opposite face (5,6,7,8,9).

To create an instance of class vtkPentagonalPrism, simply invoke its constructor as follows

```
obj = vtkPentagonalPrism
```

31.141.2 Methods

The class vtkPentagonalPrism has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPentagonalPrism class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPentagonalPrism = obj.NewInstance ()`
- `vtkPentagonalPrism = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell3D API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell3D API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell3D API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell3D API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell3D API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell3D API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell3D API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the wedge in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[10])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[30])` - Return the ids of the vertices defining edge/face (‘edgeId‘/‘faceId’). Ids are related to the cell, not to the dataset.

31.142 vtkPerlinNoise

31.142.1 Usage

vtkPerlinNoise computes a Perlin noise field as an implicit function. vtkPerlinNoise is a concrete implementation of vtkImplicitFunction. Perlin noise, originally described by Ken Perlin, is a non-periodic and continuous noise function useful for modeling real-world objects.

The amplitude and frequency of the noise pattern are adjustable. This implementation of Perlin noise is derived closely from Greg Ward’s version in Graphics Gems II.

To create an instance of class vtkPerlinNoise, simply invoke its constructor as follows

```
obj = vtkPerlinNoise
```

31.142.2 Methods

The class vtkPerlinNoise has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPerlinNoise class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPerlinNoise = obj.NewInstance ()`
- `vtkPerlinNoise = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])` - Evaluate PerlinNoise function.
- `double = obj.EvaluateFunction (double x, double y, double z)` - Evaluate PerlinNoise function.
- `obj.EvaluateGradient (double x[3], double n[3])` - Evaluate PerlinNoise gradient. Currently, the method returns a 0 gradient.
- `obj.SetFrequency (double , double , double )` - Set/get the frequency, or physical scale, of the noise function (higher is finer scale). The frequency can be adjusted per axis, or the same for all axes.
- `obj.SetFrequency (double  a[3])` - Set/get the frequency, or physical scale, of the noise function (higher is finer scale). The frequency can be adjusted per axis, or the same for all axes.
- `double = obj. GetFrequency ()` - Set/get the frequency, or physical scale, of the noise function (higher is finer scale). The frequency can be adjusted per axis, or the same for all axes.
- `obj.SetPhase (double , double , double )` - Set/get the phase of the noise function. This parameter can be used to shift the noise function within space (perhaps to avoid a beat with a noise pattern at another scale). Phase tends to repeat about every unit, so a phase of 0.5 is a half-cycle shift.
- `obj.SetPhase (double  a[3])` - Set/get the phase of the noise function. This parameter can be used to shift the noise function within space (perhaps to avoid a beat with a noise pattern at another scale). Phase tends to repeat about every unit, so a phase of 0.5 is a half-cycle shift.
- `double = obj. GetPhase ()` - Set/get the phase of the noise function. This parameter can be used to shift the noise function within space (perhaps to avoid a beat with a noise pattern at another scale). Phase tends to repeat about every unit, so a phase of 0.5 is a half-cycle shift.
- `obj.SetAmplitude (double )` - Set/get the amplitude of the noise function. Amplitude can be negative. The noise function varies randomly between -—Amplitude— and —Amplitude—. Therefore the range of values is 2*—Amplitude— large. The initial amplitude is 1.
- `double = obj.GetAmplitude ()` - Set/get the amplitude of the noise function. Amplitude can be negative. The noise function varies randomly between -—Amplitude— and —Amplitude—. Therefore the range of values is 2*—Amplitude— large. The initial amplitude is 1.

31.143 vtkPiecewiseFunction

31.143.1 Usage

Defines a piecewise function mapping. This mapping allows the addition of control points, and allows the user to control the function between the control points. A piecewise hermite curve is used between control points, based on the sharpness and midpoint parameters. A sharpness of 0 yields a piecewise linear function and a sharpness of 1 yields a piecewise constant function. The midpoint is the normalized distance between

control points at which the curve reaches the median Y value. The midpoint and sharpness values specified when adding a node are used to control the transition to the next node (the last node's values are ignored) Outside the range of nodes, the values are 0 if Clamping is off, or the nearest node point if Clamping is on. Using the legacy methods for adding points (which do not have Sharpness and Midpoint parameters) will default to Midpoint = 0.5 (halfway between the control points) and Sharpness = 0.0 (linear).

To create an instance of class vtkPiecewiseFunction, simply invoke its constructor as follows

```
obj = vtkPiecewiseFunction
```

31.143.2 Methods

The class vtkPiecewiseFunction has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPiecewiseFunction class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPiecewiseFunction = obj.NewInstance ()`
- `vtkPiecewiseFunction = obj.SafeDownCast (vtkObject o)`
- `obj.DeepCopy (vtkDataObject f)`
- `obj.ShallowCopy (vtkDataObject f)`
- `int = obj.GetDataObjectType ()` - Return what type of dataset this is.
- `int = obj.GetSize ()` - Get the number of points used to specify the function
- `int = obj.AddPoint (double x, double y)` - Add/Remove points to/from the function. If a duplicate point is added then the function value is changed at that location. Return the index of the point (0 based), or -1 on error.
- `int = obj.AddPoint (double x, double y, double midpoint, double sharpness)` - Add/Remove points to/from the function. If a duplicate point is added then the function value is changed at that location. Return the index of the point (0 based), or -1 on error.
- `int = obj.RemovePoint (double x)` - Add/Remove points to/from the function. If a duplicate point is added then the function value is changed at that location. Return the index of the point (0 based), or -1 on error.
- `obj.RemoveAllPoints ()` - Removes all points from the function.
- `obj.AddSegment (double x1, double y1, double x2, double y2)` - Add a line segment to the function. All points defined between the two points specified are removed from the function. This is a legacy method that does not allow the specification of the sharpness and midpoint values for the two nodes.
- `double = obj.GetValue (double x)` - Returns the value of the function at the specified location using the specified interpolation.
- `int = obj.GetNodeValue (int index, double val[4])` - For the node specified by index, set/get the location (X), value (Y), midpoint, and sharpness values at the node.
- `int = obj.SetNodeValue (int index, double val[4])` - For the node specified by index, set/get the location (X), value (Y), midpoint, and sharpness values at the node.

- `obj.FillFromDataPointer (int , double )` - Returns a pointer to the data stored in the table. Fills from a pointer to data stored in a similar table. These are legacy methods which will be maintained for compatibility - however, note that the vtkPiecewiseFunction no longer stores the nodes in a double array internally.

- `double = obj. GetRange ()` - Returns the min and max node locations of the function.

- `int = obj.AdjustRange (double range[2])` - Remove all points out of the new range, and make sure there is a point at each end of that range. Return 1 on success, 0 otherwise.

- `obj.GetTable (double x1, double x2, int size, float table, int stride)` - Fills in an array of function values evaluated at regular intervals. Parameter "stride" is used to step through the output "table".

- `obj.GetTable (double x1, double x2, int size, double table, int stride)` - Fills in an array of function values evaluated at regular intervals. Parameter "stride" is used to step through the output "table".

- `obj.BuildFunctionFromTable (double x1, double x2, int size, double table, int stride)` - Constructs a piecewise function from a table. Function range is is set to [x1, x2], function size is set to size, and function points are regularly spaced between x1 and x2. Parameter "stride" is is step through the input table.

- `obj.SetClamping (int )` - When zero range clamping is Off, GetValue() returns 0.0 when a value is requested outside of the points specified. When zero range clamping is On, GetValue() returns the value at the value at the lowest point for a request below all points specified and returns the value at the highest point for a request above all points specified. On is the default.

- `int = obj.GetClamping ()` - When zero range clamping is Off, GetValue() returns 0.0 when a value is requested outside of the points specified. When zero range clamping is On, GetValue() returns the value at the value at the lowest point for a request below all points specified and returns the value at the highest point for a request above all points specified. On is the default.

- `obj.ClampingOn ()` - When zero range clamping is Off, GetValue() returns 0.0 when a value is requested outside of the points specified. When zero range clamping is On, GetValue() returns the value at the value at the lowest point for a request below all points specified and returns the value at the highest point for a request above all points specified. On is the default.

- `obj.ClampingOff ()` - When zero range clamping is Off, GetValue() returns 0.0 when a value is requested outside of the points specified. When zero range clamping is On, GetValue() returns the value at the value at the lowest point for a request below all points specified and returns the value at the highest point for a request above all points specified. On is the default.

- `string = obj.GetType ()` - Return the type of function: Function Types: 0 : Constant (No change in slope between end points) 1 : NonDecreasing (Always increasing or zero slope) 2 : NonIncreasing (Always decreasing or zero slope) 3 : Varied (Contains both decreasing and increasing slopes)

- `double = obj.GetFirstNonZeroValue ()` - Returns the first point location which precedes a non-zero segment of the function. Note that the value at this point may be zero.

- `obj.Initialize ()` - Clears out the current function. A newly created vtkPiecewiseFunction is alreay initialized, so there is no need to call this method which in turn simply calls RemoveAllPoints()

- `obj.SetAllowDuplicateScalars (int )` - Toggle whether to allow duplicate scalar values in the piecewise function (off by default).

- `int = obj.GetAllowDuplicateScalars ()` - Toggle whether to allow duplicate scalar values in the piecewise function (off by default).

- `obj.AllowDuplicateScalarsOn ()` - Toggle whether to allow duplicate scalar values in the piecewise function (off by default).
- `obj.AllowDuplicateScalarsOff ()` - Toggle whether to allow duplicate scalar values in the piecewise function (off by default).

31.144 vtkPiecewiseFunctionAlgorithm

31.144.1 Usage

To create an instance of class vtkPiecewiseFunctionAlgorithm, simply invoke its constructor as follows

```
obj = vtkPiecewiseFunctionAlgorithm
```

31.144.2 Methods

The class vtkPiecewiseFunctionAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPiecewiseFunctionAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPiecewiseFunctionAlgorithm = obj.NewInstance ()`
- `vtkPiecewiseFunctionAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkDataObject = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.145 vtkPiecewiseFunctionShiftScale

31.145.1 Usage

To create an instance of class vtkPiecewiseFunctionShiftScale, simply invoke its constructor as follows

```
obj = vtkPiecewiseFunctionShiftScale
```

31.145.2 Methods

The class vtkPiecewiseFunctionShiftScale has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPiecewiseFunctionShiftScale class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPiecewiseFunctionShiftScale = obj.NewInstance ()`
- `vtkPiecewiseFunctionShiftScale = obj.SafeDownCast (vtkObject o)`
- `obj.SetPositionShift (double )`
- `obj.SetPositionScale (double )`
- `obj.SetValueShift (double )`
- `obj.SetValueScale (double )`
- `double = obj.GetPositionShift ()`
- `double = obj.GetPositionScale ()`
- `double = obj.GetValueShift ()`
- `double = obj.GetValueScale ()`

31.146 vtkPixel

31.146.1 Usage

vtkPixel is a concrete implementation of vtkCell to represent a 2D orthogonal quadrilateral. Unlike vtkQuad, the corners are at right angles, and aligned along x-y-z coordinate axes leading to large increases in computational efficiency.

To create an instance of class vtkPixel, simply invoke its constructor as follows

```
obj = vtkPixel
```

31.146.2 Methods

The class vtkPixel has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPixel class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPixel = obj.NewInstance ()`

- `vtkPixel = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the triangle in parametric coordinates.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.InterpolateFunctions (double pcoords[3], double weights[4])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[8])`

31.147 vtkPlanesIntersection

31.147.1 Usage

A subclass of vtkPlanes, this class determines whether it intersects an axis aligned box. This is motivated by the need to intersect the axis aligned region of a spacial decomposition of volume data with various other regions. It uses the algorithm from Graphics Gems IV, page 81.

.SECTION Caveat An instance of vtkPlanes can be redefined by changing the planes, but this subclass then will not know if the region vertices are up to date. (Region vertices can be specified in SetRegionVertices or computed by the subclass.) So Delete and recreate if you want to change the set of planes.

To create an instance of class vtkPlanesIntersection, simply invoke its constructor as follows

```
obj = vtkPlanesIntersection
```

31.147.2 Methods

The class vtkPlanesIntersection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPlanesIntersection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkPlanesIntersection = obj.NewInstance ()`
- `vtkPlanesIntersection = obj.SafeDownCast (vtkObject o)`
- `obj.SetRegionVertices (vtkPoints pts)`
- `obj.SetRegionVertices (double v, int nvertices)`
- `int = obj.GetNumRegionVertices ()`
- `int = obj.GetRegionVertices (double v, int nvertices)`
- `int = obj.IntersectsRegion (vtkPoints R)`

31.148 vtkPointData

31.148.1 Usage

vtkPointData is a class that is used to represent and manipulate point attribute data (e.g., scalars, vectors, normals, texture coordinates, etc.) Most of the functionality is handled by vtkDataSetAttributes

To create an instance of class vtkPointData, simply invoke its constructor as follows

```
obj = vtkPointData
```

31.148.2 Methods

The class vtkPointData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointData = obj.NewInstance ()`
- `vtkPointData = obj.SafeDownCast (vtkObject o)`
- `obj.NullPoint (vtkIdType ptId)`

31.149 vtkPointLocator

31.149.1 Usage

vtkPointLocator is a spatial search object to quickly locate points in 3D. vtkPointLocator works by dividing a specified region of space into a regular array of "rectangular" buckets, and then keeping a list of points that lie in each bucket. Typical operation involves giving a position in 3D and finding the closest point.

vtkPointLocator has two distinct methods of interaction. In the first method, you supply it with a dataset, and it operates on the points in the dataset. In the second method, you supply it with an array of points, and the object operates on the array.

To create an instance of class vtkPointLocator, simply invoke its constructor as follows

```
obj = vtkPointLocator
```

31.149.2 Methods

The class vtkPointLocator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointLocator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointLocator = obj.NewInstance ()`
- `vtkPointLocator = obj.SafeDownCast (vtkObject o)`
- `obj.SetDivisions (int , int , int )` - Set the number of divisions in x-y-z directions.
- `obj.SetDivisions (int  a[3])` - Set the number of divisions in x-y-z directions.
- `int = obj. GetDivisions ()` - Set the number of divisions in x-y-z directions.
- `obj.SetNumberOfPointsPerBucket (int )` - Specify the average number of points in each bucket.
- `int = obj.GetNumberOfPointsPerBucketMinValue ()` - Specify the average number of points in each bucket.
- `int = obj.GetNumberOfPointsPerBucketMaxValue ()` - Specify the average number of points in each bucket.
- `int = obj.GetNumberOfPointsPerBucket ()` - Specify the average number of points in each bucket.
- `vtkIdType = obj.FindClosestPoint (double x[3])` - Given a position x, return the id of the point closest to it. Alternative method requires separate x-y-z values. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.
- `int = obj.InitPointInsertion (vtkPoints newPts, double bounds[6])` - Initialize the point insertion process. The newPts is an object representing point coordinates into which incremental insertion methods place their data. Bounds are the box that the points lie in. Not thread safe.
- `int = obj.InitPointInsertion (vtkPoints newPts, double bounds[6], vtkIdType estSize)` - Initialize the point insertion process. The newPts is an object representing point coordinates into which incremental insertion methods place their data. Bounds are the box that the points lie in. Not thread safe.
- `obj.InsertPoint (vtkIdType ptId, double x[3])` - Incrementally insert a point into search structure with a particular index value. You should use the method IsInsertedPoint() to see whether this point has already been inserted (that is, if you desire to prevent duplicate points). Before using this method you must make sure that newPts have been supplied, the bounds has been set properly, and that divs are properly set. (See InitPointInsertion().) Not thread safe.
- `vtkIdType = obj.InsertNextPoint (double x[3])` - Incrementally insert a point into search structure. The method returns the insertion location (i.e., point id). You should use the method IsInsertedPoint() to see whether this point has already been inserted (that is, if you desire to prevent duplicate points). Before using this method you must make sure that newPts have been supplied, the bounds has been set properly, and that divs are properly set. (See InitPointInsertion().) Not thread safe.
- `vtkIdType = obj.IsInsertedPoint (double x, double y, double z)` - Determine whether point given by x[3] has been inserted into points list. Return id of previously inserted point if this is true, otherwise return -1. This method is thread safe.

- `vtkIdType = obj.IsInsertedPoint (double x[3])` - Determine whether point given by x[3] has been inserted into points list. Return id of previously inserted point if this is true, otherwise return -1. This method is thread safe.

- `vtkIdType = obj.FindClosestInsertedPoint (double x[3])` - Given a position x, return the id of the point closest to it. This method is used when performing incremental point insertion. Note that -1 indicates that no point was found. This method is thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `obj.FindClosestNPoints (int N, double x[3], vtkIdList result)` - Find the closest N points to a position. This returns the closest N points to a position. A faster method could be created that returned N close points to a position, but necessarily the exact N closest. The returned points are sorted from closest to farthest. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `obj.FindDistributedPoints (int N, double x[3], vtkIdList result, int M)` - Find the closest points to a position such that each octant of space around the position contains at least N points. Loosely limit the search to a maximum number of points evaluated, M. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `obj.FindDistributedPoints (int N, double x, double y, double z, vtkIdList result, int M)` - Find the closest points to a position such that each octant of space around the position contains at least N points. Loosely limit the search to a maximum number of points evaluated, M. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `obj.FindPointsWithinRadius (double R, double x[3], vtkIdList result)` - Find all points within a specified radius R of position x. The result is not sorted in any specific manner. These methods are thread safe if BuildLocator() is directly or indirectly called from a single thread first.

- `vtkIdList = obj.GetPointsInBucket (double x[3], int ijk[3])` - Given a position x, return the list of points in the bucket that contains the point. It is possible that NULL is returned. The user provides an ijk array that is the indices into the locator. This method is thread safe.

- `vtkPoints = obj.GetPoints ()` - Provide an accessor to the points.

- `obj.Initialize ()` - See vtkLocator interface documentation. These methods are not thread safe.

- `obj.FreeSearchStructure ()` - See vtkLocator interface documentation. These methods are not thread safe.

- `obj.BuildLocator ()` - See vtkLocator interface documentation. These methods are not thread safe.

- `obj.GenerateRepresentation (int level, vtkPolyData pd)` - See vtkLocator interface documentation. These methods are not thread safe.

31.150 vtkPointSet

31.150.1 Usage

vtkPointSet is an abstract class that specifies the interface for datasets that explicitly use "point" arrays to represent geometry. For example, vtkPolyData and vtkUnstructuredGrid require point arrays to specify point position, while vtkStructuredPoints generates point positions implicitly.

To create an instance of class vtkPointSet, simply invoke its constructor as follows

```
obj = vtkPointSet
```

31.150.2 Methods

The class vtkPointSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointSet = obj.NewInstance ()`
- `vtkPointSet = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Reset to an empty state and free any memory.
- `obj.CopyStructure (vtkDataSet pd)` - Copy the geometric structure of an input point set object.
- `vtkIdType = obj.GetNumberOfPoints ()` - See vtkDataSet for additional information.
- `double = obj.GetPoint (vtkIdType ptId)` - See vtkDataSet for additional information.
- `obj.GetPoint (vtkIdType ptId, double x[3])` - See vtkDataSet for additional information.
- `vtkIdType = obj.FindPoint (double x[3])` - See vtkDataSet for additional information.
- `vtkIdType = obj.FindPoint (double x, double y, double z)` - See vtkDataSet for additional information.
- `long = obj.GetMTime ()` - Get MTime which also considers its vtkPoints MTime.
- `obj.ComputeBounds ()` - Compute the (X, Y, Z) bounds of the data.
- `obj.Squeeze ()` - Reclaim any unused memory.
- `obj.SetPoints (vtkPoints )` - Specify point array to define point coordinates.
- `vtkPoints = obj.GetPoints ()` - Specify point array to define point coordinates.
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.

31.151 vtkPointSetAlgorithm

31.151.1 Usage

vtkPointSetAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. Ther are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this classes contstructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be PointSet. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into seperate functions such as RequestDataObject RequestData and ExecuteInformation. The default implementation of RequestDataObject will create an output data of the same type as the input.

To create an instance of class vtkPointSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkPointSetAlgorithm
```

31.151.2 Methods

The class vtkPointSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointSetAlgorithm = obj.NewInstance ()`
- `vtkPointSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkPointSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkPointSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as vtkPolyData.
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as vtkStructuredGrid.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as vtkUnstructuredGrid.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (vtkPointSet )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkPointSet )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (vtkPointSet )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkPointSet )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

- `vtkDataObject = obj.GetInput ()`

31.152 vtkPointSetSource

31.152.1 Usage

vtkPointSetSource is an abstract class whose subclasses generate pointdata.

To create an instance of class vtkPointSetSource, simply invoke its constructor as follows

```
obj = vtkPointSetSource
```

31.152.2 Methods

The class vtkPointSetSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointSetSource class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkPointSetSource = obj.NewInstance ()`

- `vtkPointSetSource = obj.SafeDownCast (vtkObject o)`

- `vtkPointSet = obj.GetOutput ()` - Get the output of this source.

- `vtkPointSet = obj.GetOutput (int idx)` - Get the output of this source.

- `obj.SetOutput (vtkPointSet output)` - Get the output of this source.

31.153 vtkPointSetToPointSetFilter

31.153.1 Usage

vtkPointSetToPointSetFilter is an abstract filter class whose subclasses take as input a point set and generates a point set on output. At a minimum, the concrete subclasses of vtkPointSetToPointSetFilter modify their point coordinates. They never modify their topological form, however.

This is an abstract filter type. What that means is that the output of the filter is an abstract type (i.e., vtkPointSet), no matter what the input of the filter is. This can cause problems connecting together filters due to the change in dataset type. (For example, in a series of filters processing vtkPolyData, when a vtkPointSetToPointSetFilter or subclass is introduced into the pipeline, if the filter downstream of it takes vtkPolyData as input, the pipeline connection cannot be made.) To get around this problem, use one of the convenience methods to return a concrete type (e.g., vtkGetPolyDataOutput(), GetStructuredGridOutput(), etc.).

To create an instance of class vtkPointSetToPointSetFilter, simply invoke its constructor as follows

```
obj = vtkPointSetToPointSetFilter
```

31.153.2 Methods

The class vtkPointSetToPointSetFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointSetToPointSetFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointSetToPointSetFilter = obj.NewInstance ()`
- `vtkPointSetToPointSetFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkPointSet input)` - Specify the input data or filter.
- `vtkPointSet = obj.GetInput ()` - Get the input data or filter.
- `vtkPointSet = obj.GetOutput ()` - Get the output of this filter. If output is NULL, then input hasn't been set, which is necessary for abstract filter objects.
- `vtkPointSet = obj.GetOutput (int idx)` - Get the output as vtkPolyData. Performs run-time checking.
- `vtkPolyData = obj.GetPolyDataOutput ()` - Get the output as vtkPolyData. Performs run-time checking.
- `vtkStructuredGrid = obj.GetStructuredGridOutput ()` - Get the output as vtkStructuredGrid. Performs run-time checking.
- `vtkUnstructuredGrid = obj.GetUnstructuredGridOutput ()` - Get the output as vtkUnstructured-Grid. Performs run-time checking.
- `obj.ComputeInputUpdateExtents (vtkDataObject output)` - By default copy the output update extent to the input

31.154 vtkPointsProjectedHull

31.154.1 Usage

a subclass of vtkPoints, it maintains the counter clockwise convex hull of the points (projected orthogonally in the three coordinate directions) and has a method to test for intersection of that hull with an axis aligned rectangle. This is used for intersection tests of 3D volumes.

To create an instance of class vtkPointsProjectedHull, simply invoke its constructor as follows

```
obj = vtkPointsProjectedHull
```

31.154.2 Methods

The class vtkPointsProjectedHull has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPointsProjectedHull class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPointsProjectedHull = obj.NewInstance ()`

- vtkPointsProjectedHull = obj.SafeDownCast (vtkObject o)
- int = obj.RectangleIntersectionX (vtkPoints R)
- int = obj.RectangleIntersectionX (float ymin, float ymax, float zmin, float zmax)
- int = obj.RectangleIntersectionX (double ymin, double ymax, double zmin, double zmax)
- int = obj.RectangleIntersectionY (vtkPoints R)
- int = obj.RectangleIntersectionY (float zmin, float zmax, float xmin, float xmax)
- int = obj.RectangleIntersectionY (double zmin, double zmax, double xmin, double xmax)
- int = obj.RectangleIntersectionZ (vtkPoints R)
- int = obj.RectangleIntersectionZ (float xmin, float xmax, float ymin, float ymax)
- int = obj.RectangleIntersectionZ (double xmin, double xmax, double ymin, double ymax)
- int = obj.GetCCWHullX (float pts, int len)
- int = obj.GetCCWHullX (double pts, int len)
- int = obj.GetCCWHullY (float pts, int len)
- int = obj.GetCCWHullY (double pts, int len)
- int = obj.GetCCWHullZ (float pts, int len)
- int = obj.GetCCWHullZ (double pts, int len)
- int = obj.GetSizeCCWHullX ()
- int = obj.GetSizeCCWHullY ()
- int = obj.GetSizeCCWHullZ ()
- obj.Initialize ()
- obj.Reset ()
- obj.Update ()

31.155 vtkPolyData

31.155.1 Usage

vtkPolyData is a data object that is a concrete implementation of vtkDataSet. vtkPolyData represents a geometric structure consisting of vertices, lines, polygons, and/or triangle strips. Point and cell attribute values (e.g., scalars, vectors, etc.) also are represented.

The actual cell types (vtkCellType.h) supported by vtkPolyData are: vtkVertex, vtkPolyVertex, vtkLine, vtkPolyLine, vtkTriangle, vtkQuad, vtkPolygon, and vtkTriangleStrip.

One important feature of vtkPolyData objects is that special traversal and data manipulation methods are available to process data. These methods are generally more efficient than vtkDataSet methods and should be used whenever possible. For example, traversing the cells in a dataset we would use GetCell(). To traverse cells with vtkPolyData we would retrieve the cell array object representing polygons (for example using GetPolys()) and then use vtkCellArray's InitTraversal() and GetNextCell() methods.

To create an instance of class vtkPolyData, simply invoke its constructor as follows

```
obj = vtkPolyData
```

31.155.2 Methods

The class vtkPolyData has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyData class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyData = obj.NewInstance ()`
- `vtkPolyData = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Copy the geometric and topological structure of an input poly data object.
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an input poly data object.
- `vtkIdType = obj.GetNumberOfCells ()` - Standard vtkDataSet interface.
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Standard vtkDataSet interface.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Standard vtkDataSet interface.
- `int = obj.GetCellType (vtkIdType cellId)` - Standard vtkDataSet interface.
- `obj.GetCellBounds (vtkIdType cellId, double bounds[6])` - Standard vtkDataSet interface.
- `obj.GetCellNeighbors (vtkIdType cellId, vtkIdList ptIds, vtkIdList cellIds)` - Standard vtkDataSet interface.
- `obj.CopyCells (vtkPolyData pd, vtkIdList idList, vtkPointLocator locatorNULL)` - Copy cells listed in idList from pd, including points, point data, and cell data. This method assumes that point and cell data have been allocated. If you pass in a point locator, then the points won't be duplicated in the output.
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Copy a cells point ids into list provided. (Less efficient.)
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Efficient method to obtain cells using a particular point. Make sure that routine BuildLinks() has been called.
- `obj.ComputeBounds ()` - Compute the (X, Y, Z) bounds of the data.
- `obj.Squeeze ()` - Recover extra allocated memory when creating data whose initial size is unknown. Examples include using the InsertNextCell() method, or when using the CellArray::EstimateSize() method to create vertices, lines, polygons, or triangle strips.
- `int = obj.GetMaxCellSize ()` - Return the maximum cell size in this poly data.
- `obj.SetVerts (vtkCellArray v)` - Set the cell array defining vertices.
- `vtkCellArray = obj.GetVerts ()` - Get the cell array defining vertices. If there are no vertices, an empty array will be returned (convenience to simplify traversal).
- `obj.SetLines (vtkCellArray l)` - Set the cell array defining lines.
- `vtkCellArray = obj.GetLines ()` - Get the cell array defining lines. If there are no lines, an empty array will be returned (convenience to simplify traversal).

- `obj.SetPolys (vtkCellArray p)` - Set the cell array defining polygons.
- `vtkCellArray = obj.GetPolys ()` - Get the cell array defining polygons. If there are no polygons, an empty array will be returned (convenience to simplify traversal).
- `obj.SetStrips (vtkCellArray s)` - Set the cell array defining triangle strips.
- `vtkCellArray = obj.GetStrips ()` - Get the cell array defining triangle strips. If there are no triangle strips, an empty array will be returned (convenience to simplify traversal).
- `vtkIdType = obj.GetNumberOfVerts ()` - Return the number of primitives of a particular type held..
- `vtkIdType = obj.GetNumberOfLines ()` - Return the number of primitives of a particular type held..
- `vtkIdType = obj.GetNumberOfPolys ()` - Return the number of primitives of a particular type held..
- `vtkIdType = obj.GetNumberOfStrips ()` - Return the number of primitives of a particular type held..
- `obj.Allocate (vtkIdType numCells, int extSize)` - Method allocates initial storage for vertex, line, polygon, and triangle strip arrays. Use this method before the method PolyData::InsertNextCell(). (Or, provide vertex, line, polygon, and triangle strip cell arrays.)
- `obj.Allocate (vtkPolyData inPolyData, vtkIdType numCells, int extSize)` - Similar to the method above, this method allocates initial storage for vertex, line, polygon, and triangle strip arrays. It does this more intelligently, examining the supplied inPolyData to determine whether to allocate the verts, lines, polys, and strips arrays. (These arrays are allocated only if there is data in the corresponding arrays in the inPolyData.) Caution: if the inPolyData has no verts, and after allocating with this method an PolyData::InsertNextCell() is invoked where a vertex is inserted, bad things will happen.
- `int = obj.InsertNextCell (int type, vtkIdList pts)` - Insert a cell of type VTK_VERTEX, VTK_POLY_VERTEX, VTK_LINE, VTK_POLY_LINE, VTK_TRIANGLE, VTK_QUAD, VTK_POLYGON, or VTK_TRIANGLE_STRIP. Make sure that the PolyData::Allocate() function has been called first or that vertex, line, polygon, and triangle strip arrays have been supplied. Note: will also insert VTK_PIXEL, but converts it to VTK_QUAD.
- `obj.Reset ()` - Begin inserting data all over again. Memory is not freed but otherwise objects are returned to their initial state.
- `obj.BuildCells ()` - Create data structure that allows random access of cells.
- `obj.BuildLinks (int initialSize)` - Create upward links from points to cells that use each point. Enables topologically complex queries. Normally the links array is allocated based on the number of points in the vtkPolyData. The optional initialSize parameter can be used to allocate a larger size initially.
- `obj.DeleteCells ()` - Release data structure that allows random access of the cells. This must be done before a 2nd call to BuildLinks(). DeleteCells implicitly deletes the links as well since they are no longer valid.
- `obj.DeleteLinks ()` - Release the upward links from point to cells that use each point.
- `obj.GetCellEdgeNeighbors (vtkIdType cellId, vtkIdType p1, vtkIdType p2, vtkIdList cellIds)` - Get the neighbors at an edge. More efficient than the general GetCellNeighbors(). Assumes links have been built (with BuildLinks()), and looks specifically for edge neighbors.
- `int = obj.IsTriangle (int v1, int v2, int v3)` - Given three vertices, determine whether it's a triangle. Make sure BuildLinks() has been called first.

- `int = obj.IsEdge (vtkIdType p1, vtkIdType p2)` - Determine whether two points form an edge. If they do, return non-zero. By definition PolyVertex and PolyLine have no edges since 1-dimensional edges are only found on cells 2D and higher. Edges are defined as 1-D boundary entities to cells. Make sure BuildLinks() has been called first.
- `int = obj.IsPointUsedByCell (vtkIdType ptId, vtkIdType cellId)` - Determine whether a point is used by a particular cell. If it is, return non-zero. Make sure BuildCells() has been called first.
- `obj.ReplaceCellPoint (vtkIdType cellId, vtkIdType oldPtId, vtkIdType newPtId)` - Replace a point in the cell connectivity list with a different point.
- `obj.ReverseCell (vtkIdType cellId)` - Reverse the order of point ids defining the cell.
- `obj.DeletePoint (vtkIdType ptId)` - Mark a point/cell as deleted from this vtkPolyData.
- `obj.DeleteCell (vtkIdType cellId)` - Mark a point/cell as deleted from this vtkPolyData.
- `obj.RemoveDeletedCells ()` - The cells marked by calls to DeleteCell are stored in the Cell Array VTK_EMPTY_CELL, but they still exist in the polys array. Calling RemoveDeletedCells will travers the poly array and remove/compact the cell array as well as any cell data thus truly removing the cells from the polydata object. WARNING. This only handles the polys at the moment
- `int = obj.InsertNextLinkedPoint (int numLinks)` - Add a point to the cell data structure (after cell pointers have been built). This method adds the point and then allocates memory for the links to the cells. (To use this method, make sure points are available and BuildLinks() has been invoked.) Of the two methods below, one inserts a point coordinate and the other just makes room for cell links.
- `int = obj.InsertNextLinkedPoint (double x[3], int numLinks)` - Add a point to the cell data structure (after cell pointers have been built). This method adds the point and then allocates memory for the links to the cells. (To use this method, make sure points are available and BuildLinks() has been invoked.) Of the two methods below, one inserts a point coordinate and the other just makes room for cell links.
- `obj.RemoveCellReference (vtkIdType cellId)` - Remove all references to cell in cell structure. This means the links from the cell's points to the cell are deleted. Memory is not reclaimed. Use the method ResizeCellList() to resize the link list from a point to its using cells. (This operator assumes BuildLinks() has been called.)
- `obj.AddCellReference (vtkIdType cellId)` - Add references to cell in cell structure. This means the links from the cell's points to the cell are modified. Memory is not extended. Use the method ResizeCellList() to resize the link list from a point to its using cells. (This operator assumes BuildLinks() has been called.)
- `obj.RemoveReferenceToCell (vtkIdType ptId, vtkIdType cellId)` - Remove a reference to a cell in a particular point's link list. You may also consider using RemoveCellReference() to remove the references from all the cell's points to the cell. This operator does not reallocate memory; use the operator ResizeCellList() to do this if necessary.
- `obj.AddReferenceToCell (vtkIdType ptId, vtkIdType cellId)` - Add a reference to a cell in a particular point's link list. (You may also consider using AddCellReference() to add the references from all the cell's points to the cell.) This operator does not realloc memory; use the operator ResizeCellList() to do this if necessary.
- `obj.ResizeCellList (vtkIdType ptId, int size)` - Resize the list of cells using a particular point. (This operator assumes that BuildLinks() has been called.)
- `obj.Initialize ()` - Restore object to initial state. Release memory back to system.
- `int = obj.GetUpdateExtent ()` - We need this here to avoid hiding superclass method

- `obj.GetUpdateExtent (int extent[6])` - We need this here to avoid hiding superclass method
- `int = obj.GetPiece ()` - Get the piece and the number of pieces. Similar to extent in 3D.
- `int = obj.GetNumberOfPieces ()` - Get the piece and the number of pieces. Similar to extent in 3D.
- `int = obj.GetGhostLevel ()` - Get the ghost level.
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.RemoveGhostCells (int level)` - This method will remove any cell that has a ghost level array value greater or equal to level. It does not remove unused points (yet).
- `int = obj.GetScalarFieldCriticalIndex (vtkIdType pointId, vtkDataArray scalarField)` - Scalar field critical point classification (for manifold 2D meshes). Reference: J. Milnor "Morse Theory", Princeton University Press, 1963.

  Given a pointId and an attribute representing a scalar field, this member returns the index of the critical point: vtkPolyData::MINIMUM (index 0): local minimum; vtkPolyData::SADDLE (index 1): local saddle; vtkPolyData::MAXIMUM (index 2): local maximum.

  Other returned values are: vtkPolyData::REGULAR_POINT: regular point (the gradient does not vanish); vtkPolyData::ERR_NON_MANIFOLD_STAR: the star of the considered vertex is not manifold (could not evaluate the index) vtkPolyData::ERR_INCORRECT_FIELD: the number of entries in the scalar field array is different form the number of vertices in the mesh. vtkPolyData::ERR_NO_SUCH_FIELD: the specified scalar field does not exist.
- `int = obj.GetScalarFieldCriticalIndex (vtkIdType pointId, int fieldId)` - Scalar field critical point classification (for manifold 2D meshes). Reference: J. Milnor "Morse Theory", Princeton University Press, 1963.

  Given a pointId and an attribute representing a scalar field, this member returns the index of the critical point: vtkPolyData::MINIMUM (index 0): local minimum; vtkPolyData::SADDLE (index 1): local saddle; vtkPolyData::MAXIMUM (index 2): local maximum.

  Other returned values are: vtkPolyData::REGULAR_POINT: regular point (the gradient does not vanish); vtkPolyData::ERR_NON_MANIFOLD_STAR: the star of the considered vertex is not manifold (could not evaluate the index) vtkPolyData::ERR_INCORRECT_FIELD: the number of entries in the scalar field array is different form the number of vertices in the mesh. vtkPolyData::ERR_NO_SUCH_FIELD: the specified scalar field does not exist.
- `int = obj.GetScalarFieldCriticalIndex (vtkIdType pointId, string fieldName)` - Scalar field critical point classification (for manifold 2D meshes). Reference: J. Milnor "Morse Theory", Princeton University Press, 1963.

  Given a pointId and an attribute representing a scalar field, this member returns the index of the critical point: vtkPolyData::MINIMUM (index 0): local minimum; vtkPolyData::SADDLE (index 1): local saddle; vtkPolyData::MAXIMUM (index 2): local maximum.

  Other returned values are: vtkPolyData::REGULAR_POINT: regular point (the gradient does not vanish); vtkPolyData::ERR_NON_MANIFOLD_STAR: the star of the considered vertex is not manifold (could not evaluate the index) vtkPolyData::ERR_INCORRECT_FIELD: the number of entries in the scalar field array is different form the number of vertices in the mesh. vtkPolyData::ERR_NO_SUCH_FIELD: the specified scalar field does not exist.

31.156 vtkPolyDataAlgorithm

31.156.1 Usage

To create an instance of class vtkPolyDataAlgorithm, simply invoke its constructor as follows

```
obj = vtkPolyDataAlgorithm
```

31.156.2 Methods

The class vtkPolyDataAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataAlgorithm = obj.NewInstance ()`
- `vtkPolyDataAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkPolyData = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `vtkPolyData = obj.GetPolyDataInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.157 vtkPolyDataCollection

31.157.1 Usage

vtkPolyDataCollection is an object that creates and manipulates lists of datasets of type vtkPolyData.

To create an instance of class vtkPolyDataCollection, simply invoke its constructor as follows

```
obj = vtkPolyDataCollection
```

31.157.2 Methods

The class vtkPolyDataCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataCollection = obj.NewInstance ()`
- `vtkPolyDataCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkPolyData pd)` - Get the next poly data in the list.
- `vtkPolyData = obj.GetNextItem ()` - Get the next poly data in the list.

31.158 vtkPolyDataSource

31.158.1 Usage

vtkPolyDataSource is an abstract class whose subclasses generate polygonal data.

To create an instance of class vtkPolyDataSource, simply invoke its constructor as follows

```
obj = vtkPolyDataSource
```

31.158.2 Methods

The class vtkPolyDataSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataSource = obj.NewInstance ()`
- `vtkPolyDataSource = obj.SafeDownCast (vtkObject o)`
- `vtkPolyData = obj.GetOutput ()` - Get the output of this source.
- `vtkPolyData = obj.GetOutput (int idx)` - Get the output of this source.
- `obj.SetOutput (vtkPolyData output)` - Get the output of this source.

31.159 vtkPolyDataToPolyDataFilter

31.159.1 Usage

vtkPolyDataToPolyDataFilter is an abstract filter class whose subclasses take as input polygonal data and generate polygonal data on output. .SECTION Warning This used to be the parent class for most polydata filter in VTK4.x, now this role has been replaced by vtkPolyDataAlgorithm. You should consider using vtkPolyDataAlgorithm instead of this class, when writing filter for VTK5 and above. This class was kept to ensure full backward compatibility.

To create an instance of class vtkPolyDataToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkPolyDataToPolyDataFilter
```

31.159.2 Methods

The class vtkPolyDataToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyDataToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyDataToPolyDataFilter = obj.NewInstance ()`
- `vtkPolyDataToPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkPolyData input)` - Set / get the input data or filter.
- `vtkPolyData = obj.GetInput ()` - Set / get the input data or filter.

31.160 vtkPolygon

31.160.1 Usage

vtkPolygon is a concrete implementation of vtkCell to represent a 2D n-sided polygon. The polygons cannot have any internal holes, and cannot self-intersect. Define the polygon with n-points ordered in the counter-clockwise direction; do not repeat the last point.

To create an instance of class vtkPolygon, simply invoke its constructor as follows

```
obj = vtkPolygon
```

31.160.2 Methods

The class vtkPolygon has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolygon class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolygon = obj.NewInstance ()`
- `vtkPolygon = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.

- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.IsPrimaryCell ()` - Compute the area of a polygon. This is a convenience function which simply calls static double ComputeArea(vtkPoints *p, vtkIdType numPts, vtkIdType *pts, double normal[3]); with the appropriate parameters from the instantiated vtkPolygon.
- `double = obj.ComputeArea ()` - Compute the area of a polygon. This is a convenience function which simply calls static double ComputeArea(vtkPoints *p, vtkIdType numPts, vtkIdType *pts, double normal[3]); with the appropriate parameters from the instantiated vtkPolygon.
- `obj.InterpolateFunctions (double pcoords[3], double sf)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.ComputeWeights (double x[3], double weights)` - Compute interpolation weights using 1/r**2 normalized sum. @deprecated Replaced by vtkPolygon::InterpolateFunctions as of VTK 5.2
- `int = obj.Triangulate (vtkIdList outTris)` - Triangulate this polygon. The user must provide the vtkIdList outTris. On output, the outTris list contains the ids of the points defining the triangulation. The ids are ordered into groups of three: each three-group defines one triangle.
- `int = obj.NonDegenerateTriangulate (vtkIdList outTris)` - Same as Triangulate(vtkIdList *outTris) but with a first pass to split the polygon into non-degenerate polygons.

31.161 vtkPolyLine

31.161.1 Usage

vtkPolyLine is a concrete implementation of vtkCell to represent a set of 1D lines.

To create an instance of class vtkPolyLine, simply invoke its constructor as follows

```
obj = vtkPolyLine
```

31.161.2 Methods

The class vtkPolyLine has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyLine class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyLine = obj.NewInstance ()`
- `vtkPolyLine = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.

- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.IsPrimaryCell ()` - Return the center of the point cloud in parametric coordinates.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the point cloud in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

31.162 vtkPolyVertex

31.162.1 Usage

vtkPolyVertex is a concrete implementation of vtkCell to represent a set of 3D vertices.

To create an instance of class vtkPolyVertex, simply invoke its constructor as follows

```
obj = vtkPolyVertex
```

31.162.2 Methods

The class vtkPolyVertex has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPolyVertex class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPolyVertex = obj.NewInstance ()`
- `vtkPolyVertex = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.

- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.IsPrimaryCell ()` - Return the center of the point cloud in parametric coordinates.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the point cloud in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

31.163 vtkProcessObject

31.163.1 Usage

vtkProcessObject is an abstract object that specifies behavior and interface of visualization network process objects (sources, filters, mappers). Source objects are creators of visualization data; filters input, process, and output visualization data; and mappers transform data into another form (like rendering primitives or write data to a file).

vtkProcessObject fires events for Start and End events before and after object execution (via Execute()). These events can be used for any purpose (e.g., debugging info, highlighting/notifying user interface, etc.)

Another event, Progress, can be observed. Some filters fire this event periodically during their execution. The use is similar to that of Start and End events. Filters may also check their AbortExecute flag to determine whether to prematurely end their execution.

An important feature of subclasses of vtkProcessObject is that it is possible to control the memory-management model (i.e., retain output versus delete output data). If enabled the ReleaseDataFlag enables the deletion of the output data once the downstream process object finishes processing the data (please see text).

To create an instance of class vtkProcessObject, simply invoke its constructor as follows

```
obj = vtkProcessObject
```

31.163.2 Methods

The class vtkProcessObject has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkProcessObject class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkProcessObject = obj.NewInstance ()`
- `vtkProcessObject = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetNumberOfInputs ()` - Return an array with all the inputs of this process object. This is useful for tracing back in the pipeline to construct graphs etc.
- `obj.SqueezeInputArray ()` - This method will rearrange the input array so that all NULL entries are removed.
- `obj.RemoveAllInputs ()` - Remove all the input data.
- `obj.SetInputConnection (vtkAlgorithmOutput input)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.
- `obj.SetInputConnection (int port, vtkAlgorithmOutput input)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.
- `obj.AddInputConnection (int port, vtkAlgorithmOutput input)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.
- `obj.AddInputConnection (vtkAlgorithmOutput input)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.
- `obj.RemoveInputConnection (int port, vtkAlgorithmOutput input)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.
- `obj.SetNthInputConnection (int port, int index, vtkAlgorithmOutput input)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.
- `obj.SetNumberOfInputConnections (int port, int n)` - Reimplemented from vtkAlgorithm to maintain backward compatibility for vtkProcessObject.

31.164 vtkPropAssembly

31.164.1 Usage

vtkPropAssembly is an object that groups props and other prop assemblies into a tree-like hierarchy. The props can then be treated as a group (e.g., turning visibility on and off).

A vtkPropAssembly object can be used in place of an vtkProp since it is a subclass of vtkProp. The difference is that vtkPropAssembly maintains a list of other prop and prop assembly instances (its "parts") that form the assembly. Note that this process is recursive: you can create groups consisting of prop assemblies to arbitrary depth.

vtkPropAssembly's and vtkProp's that compose a prop assembly need not be added to a renderer's list of props, as long as the parent assembly is in the prop list. This is because they are automatically renderered during the hierarchical traversal process.

To create an instance of class vtkPropAssembly, simply invoke its constructor as follows

```
obj = vtkPropAssembly
```

31.164.2 Methods

The class vtkPropAssembly has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPropAssembly class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPropAssembly = obj.NewInstance ()`
- `vtkPropAssembly = obj.SafeDownCast (vtkObject o)`
- `obj.AddPart (vtkProp )` - Add a part to the list of parts.
- `obj.RemovePart (vtkProp )` - Remove a part from the list of parts,
- `vtkPropCollection = obj.GetParts ()` - Return the list of parts.
- `int = obj.RenderOpaqueGeometry (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. The parts of each assembly are rendered only if the visibility for the prop is turned on.
- `int = obj.RenderTranslucentPolygonalGeometry (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. The parts of each assembly are rendered only if the visibility for the prop is turned on.
- `int = obj.RenderVolumetricGeometry (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. The parts of each assembly are rendered only if the visibility for the prop is turned on.
- `int = obj.RenderOverlay (vtkViewport ren)` - Render this assembly and all its parts. The rendering process is recursive. The parts of each assembly are rendered only if the visibility for the prop is turned on.
- `int = obj.HasTranslucentPolygonalGeometry ()` - Does this prop have some translucent polygonal geometry?
- `obj.ReleaseGraphicsResources (vtkWindow )` - Release any graphics resources that are being consumed by this actor. The parameter window could be used to determine which graphic resources to release.
- `double = obj.GetBounds ()` - Get the bounds for this prop assembly as (Xmin,Xmax,Ymin,Ymax,Zmin,Zmax). May return NULL in some cases (meaning the bounds is undefined).
- `obj.ShallowCopy (vtkProp Prop)` - Shallow copy of this vtkPropAssembly.
- `long = obj.GetMTime ()` - Override default GetMTime method to also consider all of the prop assembly's parts.
- `obj.InitPathTraversal ()` - Methods to traverse the paths (i.e., leaf nodes) of a prop assembly. These methods should be contrasted to those that traverse the list of parts using GetParts(). GetParts() returns a list of children of this assembly, not necessarily the leaf nodes of the assembly. To use the methods below - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted. (See the superclass vtkProp for more information about paths.)

- `vtkAssemblyPath = obj.GetNextPath ()` - Methods to traverse the paths (i.e., leaf nodes) of a prop assembly. These methods should be contrasted to those that traverse the list of parts using GetParts(). GetParts() returns a list of children of this assembly, not necessarily the leaf nodes of the assembly. To use the methods below - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted. (See the superclass vtkProp for more information about paths.)

- `int = obj.GetNumberOfPaths ()` - Methods to traverse the paths (i.e., leaf nodes) of a prop assembly. These methods should be contrasted to those that traverse the list of parts using GetParts(). GetParts() returns a list of children of this assembly, not necessarily the leaf nodes of the assembly. To use the methods below - first invoke InitPathTraversal() followed by repeated calls to GetNextPath(). GetNextPath() returns a NULL pointer when the list is exhausted. (See the superclass vtkProp for more information about paths.)

31.165 vtkPyramid

31.165.1 Usage

vtkPyramid is a concrete implementation of vtkCell to represent a 3D pyramid. A pyramid consists of a rectangular base with four triangular faces. vtkPyramid uses the standard isoparametric shape functions for a linear pyramid. The pyramid is defined by the five points (0-4) where (0,1,2,3) is the base of the pyramid which, using the right hand rule, forms a quadrilaterial whose normal points in the direction of the pyramid apex at vertex #4.

To create an instance of class vtkPyramid, simply invoke its constructor as follows

```
obj = vtkPyramid
```

31.165.2 Methods

The class vtkPyramid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkPyramid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkPyramid = obj.NewInstance ()`
- `vtkPyramid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.

- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the pyramid in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[5])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[15])`

31.166 vtkQuad

31.166.1 Usage

vtkQuad is a concrete implementation of vtkCell to represent a 2D quadrilateral. vtkQuad is defined by the four points (0,1,2,3) in counterclockwise order. vtkQuad uses the standard isoparametric interpolation functions for a linear quadrilateral.

To create an instance of class vtkQuad, simply invoke its constructor as follows

```
obj = vtkQuad
```

31.166.2 Methods

The class vtkQuad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuad = obj.NewInstance ()`
- `vtkQuad = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.

- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the triangle in parametric coordinates.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quad using scalar value provided. Like contouring, except that it cuts the quad to produce other quads and/or triangles.
- `obj.InterpolateFunctions (double pcoords[3], double sf[4])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[8])` - Return the ids of the vertices defining edge (‘edgeId‘). Ids are related to the cell, not to the dataset.

31.167 vtkQuadraticEdge

31.167.1 Usage

vtkQuadraticEdge is a concrete implementation of vtkNonLinearCell to represent a one-dimensional, 3-nodes, isoparametric parabolic line. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node. The ordering of the three points defining the cell is point ids (0,1,2) where id #2 is the midedge node.

To create an instance of class vtkQuadraticEdge, simply invoke its constructor as follows

```
obj = vtkQuadraticEdge
```

31.167.2 Methods

The class vtkQuadraticEdge has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticEdge class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticEdge = obj.NewInstance ()`
- `vtkQuadraticEdge = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )`

- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this edge using scalar value provided. Like contouring, except that it cuts the edge to produce linear line segments.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic tetra in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[3])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[3])`

31.168 vtkQuadraticHexahedron

31.168.1 Usage

vtkQuadraticHexahedron is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 20-node isoparametric parabolic hexahedron. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node. The ordering of the twenty points defining the cell is point ids (0-7,8-19) where point ids 0-7 are the eight corner vertices of the cube; followed by twelve midedge nodes (8-19). Note that these midedge nodes correspond lie on the edges defined by (0,1), (1,2), (2,3), (3,0), (4,5), (5,6), (6,7), (7,4), (0,4), (1,5), (2,6), (3,7).

To create an instance of class vtkQuadraticHexahedron, simply invoke its constructor as follows

```
obj = vtkQuadraticHexahedron
```

31.168.2 Methods

The class vtkQuadraticHexahedron has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticHexahedron class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticHexahedron = obj.NewInstance ()`
- `vtkQuadraticHexahedron = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.

- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic hexahedron using scalar value provided. Like contouring, except that it cuts the hex to produce linear tetrahedron.
- `obj.InterpolateFunctions (double pcoords[3], double weights[20])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[60])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.169 vtkQuadraticLinearQuad

31.169.1 Usage

vtkQuadraticQuad is a concrete implementation of vtkNonLinearCell to represent a two-dimensional, 6-node isoparametric quadratic-linear quadrilateral element. The interpolation is the standard finite element, quadratic-linear isoparametric shape function. The cell includes a mid-edge node for two of the four edges. The ordering of the six points defining the cell are point ids (0-3,4-5) where ids 0-3 define the four corner vertices of the quad; ids 4-7 define the midedge nodes (0,1) and (2,3) .

To create an instance of class vtkQuadraticLinearQuad, simply invoke its constructor as follows

```
obj = vtkQuadraticLinearQuad
```

31.169.2 Methods

The class vtkQuadraticLinearQuad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticLinearQuad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticLinearQuad = obj.NewInstance ()`
- `vtkQuadraticLinearQuad = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.

- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )`
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic linear quad using scalar value provided. Like contouring, except that it cuts the quad to produce linear triangles.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the pyramid in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[6])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[12])` - Return the ids of the vertices defining edge (‘edgeId‘). Ids are related to the cell, not to the dataset.

31.170 vtkQuadraticLinearWedge

31.170.1 Usage

vtkQuadraticLinearWedge is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 12-node isoparametric linear quadratic wedge. The interpolation is the standard finite element, quadratic isoparametric shape function in xy - layer and the linear functions in z - direction. The cell includes midedge node in the triangle edges. The ordering of the 12 points defining the cell is point ids (0-5,6-12) where point ids 0-5 are the six corner vertices of the wedge; followed by six midedge nodes (6-12). Note that these midedge nodes correspond lie on the edges defined by (0,1), (1,2), (2,0), (3,4), (4,5), (5,3). The Edges (0,3), (1,4), (2,5) dont have midedge nodes.

To create an instance of class vtkQuadraticLinearWedge, simply invoke its constructor as follows

```
obj = vtkQuadraticLinearWedge
```

31.170.2 Methods

The class vtkQuadraticLinearWedge has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticLinearWedge class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticLinearWedge = obj.NewInstance ()`
- `vtkQuadraticLinearWedge = obj.SafeDownCast (vtkObject o)`

- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - The quadratic linear wege is splitted into 4 linear wedges, each of them is contoured by a provided scalar value
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - The quadratic linear wege is splitted into 4 linear wedges, each of them is contoured by a provided scalar value
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - The quadratic linear wege is splitted into 4 linear wedges, each of them is contoured by a provided scalar value
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic linear wedge using scalar value provided. Like contouring, except that it cuts the hex to produce linear tetrahedron.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic linear wedge in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[15])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[45])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.171 vtkQuadraticPyramid

31.171.1 Usage

vtkQuadraticPyramid is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 13-node isoparametric parabolic pyramid. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node. The ordering of the thirteen points defining the cell is point ids (0-4,5-12) where point ids 0-4 are the five corner vertices of the pyramid; followed by eight midedge nodes (5-12). Note that these midedge nodes correspond lie on the edges defined by (0,1), (1,2), (2,3), (3,0), (0,4), (1,4), (2,4), (3,4).

To create an instance of class vtkQuadraticPyramid, simply invoke its constructor as follows

```
obj = vtkQuadraticPyramid
```

31.171.2 Methods

The class vtkQuadraticPyramid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticPyramid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticPyramid = obj.NewInstance ()`
- `vtkQuadraticPyramid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic triangle using scalar value provided. Like contouring, except that it cuts the triangle to produce linear triangles.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic pyramid in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[13])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[39])` - Return the ids of the vertices defining edge/face (‘edgeId‘/‘faceId’). Ids are related to the cell, not to the dataset.

31.172 vtkQuadraticQuad

31.172.1 Usage

vtkQuadraticQuad is a concrete implementation of vtkNonLinearCell to represent a two-dimensional, 8-node isoparametric parabolic quadrilateral element. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node for each of the four edges of the cell. The ordering of the eight points defining the cell are point ids (0-3,4-7) where ids 0-3 define the four corner vertices of the quad; ids 4-7 define the midedge nodes (0,1), (1,2), (2,3), (3,0).

To create an instance of class vtkQuadraticQuad, simply invoke its constructor as follows

```
obj = vtkQuadraticQuad
```

31.172.2 Methods

The class vtkQuadraticQuad has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticQuad class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticQuad = obj.NewInstance ()`
- `vtkQuadraticQuad = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )`
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic quad using scalar value provided. Like contouring, except that it cuts the quad to produce linear triangles.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the pyramid in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[8])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[16])`

31.173 vtkQuadraticTetra

31.173.1 Usage

vtkQuadraticTetra is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 10-node, isoparametric parabolic tetrahedron. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node on each of the size edges of the tetrahedron. The ordering of the ten points defining the cell is point ids (0-3,4-9) where ids 0-3 are the four tetra vertices; and point ids 4-9 are the midedge nodes between (0,1), (1,2), (2,0), (0,3), (1,3), and (2,3).

To create an instance of class vtkQuadraticTetra, simply invoke its constructor as follows

```
obj = vtkQuadraticTetra
```

31.173.2 Methods

The class vtkQuadraticTetra has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticTetra class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticTetra = obj.NewInstance ()`
- `vtkQuadraticTetra = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this edge using scalar value provided. Like contouring, except that it cuts the tetra to produce new tetras.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic tetra in parametric coordinates.

- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned.
- `obj.InterpolateFunctions (double pcoords[3], double weights[10])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[30])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.174 vtkQuadraticTriangle

31.174.1 Usage

vtkQuadraticTriangle is a concrete implementation of vtkNonLinearCell to represent a two-dimensional, 6-node, isoparametric parabolic triangle. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes three mid-edge nodes besides the three triangle vertices. The ordering of the three points defining the cell is point ids (0-2,3-5) where id #3 is the midedge node between points (0,1); id #4 is the midedge node between points (1,2); and id #5 is the midedge node between points (2,0).

To create an instance of class vtkQuadraticTriangle, simply invoke its constructor as follows

```
obj = vtkQuadraticTriangle
```

31.174.2 Methods

The class vtkQuadraticTriangle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticTriangle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticTriangle = obj.NewInstance ()`
- `vtkQuadraticTriangle = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )`
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`

- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic triangle using scalar value provided. Like contouring, except that it cuts the triangle to produce linear triangles.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic triangle in parametric coordinates.
- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned.
- `obj.InterpolateFunctions (double pcoords[3], double weights[6])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[12])`

31.175 vtkQuadraticWedge

31.175.1 Usage

vtkQuadraticWedge is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 15-node isoparametric parabolic wedge. The interpolation is the standard finite element, quadratic isoparametric shape function. The cell includes a mid-edge node. The ordering of the fifteen points defining the cell is point ids (0-5,6-14) where point ids 0-5 are the six corner vertices of the wedge; followed by nine midedge nodes (6-14). Note that these midedge nodes correspond lie on the edges defined by (0,1), (1,2), (2,0), (3,4), (4,5), (5,3), (0,3), (1,4), (2,5).

To create an instance of class vtkQuadraticWedge, simply invoke its constructor as follows

```
obj = vtkQuadraticWedge
```

31.175.2 Methods

The class vtkQuadraticWedge has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkQuadraticWedge class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkQuadraticWedge = obj.NewInstance ()`
- `vtkQuadraticWedge = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.

- `vtkCell = obj.GetFace (int faceId)` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this quadratic hexahedron using scalar value provided. Like contouring, except that it cuts the hex to produce linear tetrahedron.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the quadratic wedge in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[15])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[45])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.176 vtkRectilinearGrid

31.176.1 Usage

vtkRectilinearGrid is a data object that is a concrete implementation of vtkDataSet. vtkRectilinearGrid represents a geometric structure that is topologically regular with variable spacing in the three coordinate directions x-y-z.

To define a vtkRectilinearGrid, you must specify the dimensions of the data and provide three arrays of values specifying the coordinates along the x-y-z axes. The coordinate arrays are specified using three vtkDataArray objects (one for x, one for y, one for z).

To create an instance of class vtkRectilinearGrid, simply invoke its constructor as follows

```
obj = vtkRectilinearGrid
```

31.176.2 Methods

The class vtkRectilinearGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGrid = obj.NewInstance ()`
- `vtkRectilinearGrid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Return what type of dataset this is.
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an input rectilinear grid object.
- `obj.Initialize ()` - Restore object to initial state. Release memory back to system.

- `vtkIdType = obj.GetNumberOfCells ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.GetNumberOfPoints ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `double = obj.GetPoint (vtkIdType ptId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPoint (vtkIdType id, double x[3])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellBounds (vtkIdType cellId, double bounds[6])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.FindPoint (double x, double y, double z)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.FindPoint (double x[3])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetCellType (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.ComputeBounds ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetMaxCellSize ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellNeighbors (vtkIdType cellId, vtkIdList ptIds, vtkIdList cellIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.SetDimensions (int i, int j, int k)` - Set dimensions of rectilinear grid dataset. This also sets the extent.
- `obj.SetDimensions (int dim[3])` - Set dimensions of rectilinear grid dataset. This also sets the extent.
- `int = obj. GetDimensions ()` - Get dimensions of this rectilinear grid dataset.
- `int = obj.GetDataDimension ()` - Return the dimensionality of the data.
- `int = obj.ComputeStructuredCoordinates (double x[3], int ijk[3], double pcoords[3])` - Convenience function computes the structured coordinates for a point x[3]. The cell is specified by the array ijk[3], and the parametric coordinates in the cell are specified with pcoords[3]. The function returns a 0 if the point x is outside of the grid, and a 1 if inside the grid.
- `vtkIdType = obj.ComputePointId (int ijk[3])` - Given a location in structured coordinates (i-j-k), return the point id.

- `vtkIdType = obj.ComputeCellId (int ijk[3])` - Given a location in structured coordinates (i-j-k), return the cell id.
- `obj.SetXCoordinates (vtkDataArray )` - Specify the grid coordinates in the x-direction.
- `vtkDataArray = obj.GetXCoordinates ()` - Specify the grid coordinates in the x-direction.
- `obj.SetYCoordinates (vtkDataArray )` - Specify the grid coordinates in the y-direction.
- `vtkDataArray = obj.GetYCoordinates ()` - Specify the grid coordinates in the y-direction.
- `obj.SetZCoordinates (vtkDataArray )` - Specify the grid coordinates in the z-direction.
- `vtkDataArray = obj.GetZCoordinates ()` - Specify the grid coordinates in the z-direction.
- `obj.SetExtent (int extent[6])` - Different ways to set the extent of the data array. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z).
- `obj.SetExtent (int x1, int x2, int y1, int y2, int z1, int z2)` - Different ways to set the extent of the data array. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z).
- `int = obj. GetExtent ()` - Different ways to set the extent of the data array. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z).
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `int = obj.GetExtentType ()` - Structured extent. The extent type is a 3D extent
- `obj.Crop ()` - Reallocates and copies to set the Extent to the UpdateExtent. This is used internally when the exact extent is requested, and the source generated more than the update extent.

31.177 vtkRectilinearGridAlgorithm

31.177.1 Usage

To create an instance of class vtkRectilinearGridAlgorithm, simply invoke its constructor as follows

```
obj = vtkRectilinearGridAlgorithm
```

31.177.2 Methods

The class vtkRectilinearGridAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridAlgorithm = obj.NewInstance ()`
- `vtkRectilinearGridAlgorithm = obj.SafeDownCast (vtkObject o)`

- `vtkRectilinearGrid = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkRectilinearGrid = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `vtkRectilinearGrid = obj.GetRectilinearGridInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.178 vtkRectilinearGridSource

31.178.1 Usage

vtkRectilinearGridSource is an abstract class whose subclasses generate rectilinear grid data.

To create an instance of class vtkRectilinearGridSource, simply invoke its constructor as follows

```
obj = vtkRectilinearGridSource
```

31.178.2 Methods

The class vtkRectilinearGridSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridSource = obj.NewInstance ()`
- `vtkRectilinearGridSource = obj.SafeDownCast (vtkObject o)`
- `vtkRectilinearGrid = obj.GetOutput ()` - Get the output of this source.
- `vtkRectilinearGrid = obj.GetOutput (int idx)` - Get the output of this source.
- `obj.SetOutput (vtkRectilinearGrid output)` - Get the output of this source.

31.179 vtkRectilinearGridToPolyDataFilter

31.179.1 Usage

vtkRectilinearGridToPolyDataFilter is a filter whose subclasses take as input rectilinear grid datasets and generate polygonal data on output.

To create an instance of class vtkRectilinearGridToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkRectilinearGridToPolyDataFilter
```

31.179.2 Methods

The class vtkRectilinearGridToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkRectilinearGridToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkRectilinearGridToPolyDataFilter = obj.NewInstance ()`
- `vtkRectilinearGridToPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkRectilinearGrid input)` - Set / get the input Grid or filter.
- `vtkRectilinearGrid = obj.GetInput ()` - Set / get the input Grid or filter.

31.180 vtkScalarTree

31.180.1 Usage

vtkScalarTree is an abstract class that defines the API to concrete scalar tree subclasses. A scalar tree is a data structure that organizes data according to its scalar value. This allows rapid access to data for those algorithms that access the data based on scalar value. For example, isocontouring operates on cells based on the scalar (isocontour) value.

To use subclasses of this class, you must specify a dataset to operate on, and then specify a scalar value in the InitTraversal() method. Then calls to GetNextCell() return cells whose scalar data contains the scalar value specified.

To create an instance of class vtkScalarTree, simply invoke its constructor as follows

```
obj = vtkScalarTree
```

31.180.2 Methods

The class vtkScalarTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkScalarTree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkScalarTree = obj.NewInstance ()`
- `vtkScalarTree = obj.SafeDownCast (vtkObject o)`

- `obj.SetDataSet (vtkDataSet )` - Build the tree from the points/cells defining this dataset.
- `vtkDataSet = obj.GetDataSet ()` - Build the tree from the points/cells defining this dataset.
- `obj.BuildTree ()` - Construct the scalar tree from the dataset provided. Checks build times and modified time from input and reconstructs the tree if necessary.
- `obj.Initialize ()` - Initialize locator. Frees memory and resets object as appropriate.
- `obj.InitTraversal (double scalarValue)` - Begin to traverse the cells based on a scalar value. Returned cells will have scalar values that span the scalar value specified.

31.181 vtkSelection

31.181.1 Usage

To create an instance of class vtkSelection, simply invoke its constructor as follows

```
obj = vtkSelection
```

31.181.2 Methods

The class vtkSelection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSelection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSelection = obj.NewInstance ()`
- `vtkSelection = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Restore data object to initial state,
- `int = obj.GetDataObjectType ()` - Returns the number of nodes in this selection. Each node contains information about part of the selection.
- `int = obj.GetNumberOfNodes ()` - Returns the number of nodes in this selection. Each node contains information about part of the selection.
- `vtkSelectionNode = obj.GetNode (int idx)` - Returns a node given it's index. Performs bound checking and will return 0 if out-of-bounds.
- `obj.AddNode (vtkSelectionNode )` - Adds a selection node.
- `obj.RemoveNode (int idx)` - Removes a selection node.
- `obj.RemoveNode (vtkSelectionNode )` - Removes a selection node.
- `obj.RemoveAllNodes ()` - Removes a selection node.
- `obj.DeepCopy (vtkDataObject src)` - Copy selection nodes of the input.
- `obj.ShallowCopy (vtkDataObject src)` - Copy selection nodes of the input. This is a shallow copy: selection lists and pointers in the properties are passed by reference.
- `obj.Union (vtkSelection selection)` - Union this selection with the specified selection. Attempts to reuse selection nodes in this selection if properties match exactly. Otherwise, creates new selection nodes.

- `obj.Union (vtkSelectionNode node)` - Union this selection with the specified selection node. Attempts to reuse a selection node in this selection if properties match exactly. Otherwise, creates a new selection node.
- `long = obj.GetMTime ()` - Return the MTime taking into account changes to the properties
- `obj.Dump ()` - Dumps the contents of the selection, giving basic information only.

31.182 vtkSelectionAlgorithm

31.182.1 Usage

vtkSelectionAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline edgehitecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be Selection. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation. For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

.SECTION Thanks Thanks to Patricia Crossno, Ken Moreland, Andrew Wilson and Brian Wylie from Sandia National Laboratories for their help in developing this class.

To create an instance of class vtkSelectionAlgorithm, simply invoke its constructor as follows

```
obj = vtkSelectionAlgorithm
```

31.182.2 Methods

The class vtkSelectionAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSelectionAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSelectionAlgorithm = obj.NewInstance ()`
- `vtkSelectionAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkSelection = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkSelection = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.183 vtkSelectionNode

31.183.1 Usage

To create an instance of class vtkSelectionNode, simply invoke its constructor as follows

```
obj = vtkSelectionNode
```

31.183.2 Methods

The class vtkSelectionNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSelectionNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSelectionNode = obj.NewInstance ()`
- `vtkSelectionNode = obj.SafeDownCast (vtkObject o)`
- `obj.Initialize ()` - Restore data object to initial state,
- `obj.SetSelectionList (vtkAbstractArray )` - Sets the selection list.
- `vtkAbstractArray = obj.GetSelectionList ()` - Sets the selection list.
- `obj.SetSelectionData (vtkDataSetAttributes data)` - Sets the selection table.
- `vtkDataSetAttributes = obj.GetSelectionData ()` - Sets the selection table.
- `vtkInformation = obj.GetProperties ()` - Returns the property map.
- `obj.DeepCopy (vtkSelectionNode src)` - Copy properties, selection list and children of the input.
- `obj.ShallowCopy (vtkSelectionNode src)` - Copy properties, selection list and children of the input. This is a shallow copy: selection lists and pointers in the properties are passed by reference.
- `long = obj.GetMTime ()` - Return the MTime taking into account changes to the properties
- `obj.SetContentType (int type)` - Get or set the content type of the selection. This is the same as setting the CONTENT_TYPE() key on the property.
- `int = obj.GetContentType ()` - Get or set the content type of the selection. This is the same as setting the CONTENT_TYPE() key on the property.
- `obj.SetFieldType (int type)` - Get or set the field type of the selection. This is the same as setting the FIELD_TYPE() key on the property.
- `int = obj.GetFieldType ()` - Get or set the field type of the selection. This is the same as setting the FIELD_TYPE() key on the property.
- `obj.SetSelectedProp (vtkProp prop)` - Get or set the prop of the selection. This is the same as setting the PROP() key on the property.
- `vtkProp = obj.GetSelectedProp ()` - Get or set the prop of the selection. This is the same as setting the PROP() key on the property.
- `obj.UnionSelectionList (vtkSelectionNode other)` - Merges the selection list between self and the other. Assumes that both has identical properties.
- `bool = obj.EqualProperties (vtkSelectionNode other, bool fullcomparetrue)` - Compares Properties of self and other to ensure that they are exactly same.

31.184 vtkSimpleCellTessellator

31.184.1 Usage

vtkSimpleCellTessellator is a helper class to perform adaptive tessellation of particular cell topologies. The major purpose for this class is to transform higher-order cell types (e.g., higher-order finite elements) into linear cells that can then be easily visualized by VTK. This class works in conjunction with the vtkGenericDataSet and vtkGenericAdaptorCell classes.

This algorithm is based on edge subdivision. An error metric along each edge is evaluated, and if the error is greater than some tolerance, the edge is subdivided (as well as all connected 2D and 3D cells). The process repeats until the error metric is satisfied. Since the algorithm is based on edge subdivision it inherently avoid T-junctions.

A significant issue addressed by this algorithm is to insure face compatibility across neigboring cells. That is, diagonals due to face triangulation must match to insure that the mesh is compatible. The algorithm employs a precomputed table to accelerate the tessellation process. The table was generated with the help of vtkOrderedTriangulator the basic idea is that the choice of diagonal is made only by considering the relative value of the point ids.

To create an instance of class vtkSimpleCellTessellator, simply invoke its constructor as follows

```
obj = vtkSimpleCellTessellator
```

31.184.2 Methods

The class vtkSimpleCellTessellator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimpleCellTessellator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSimpleCellTessellator = obj.NewInstance ()`
- `vtkSimpleCellTessellator = obj.SafeDownCast (vtkObject o)`
- `vtkGenericAdaptorCell = obj.GetGenericCell ()` - Get the higher order cell in order to access the evaluation function.
- `obj.TessellateFace (vtkGenericAdaptorCell cell, vtkGenericAttributeCollection att, vtkIdType index,` - Tessellate a face of a 3D 'cell'. The face is specified by the index value. The result is a set of smaller linear triangles in 'cellArray' with 'points' and point data 'internalPd'.
- `obj.Tessellate (vtkGenericAdaptorCell cell, vtkGenericAttributeCollection att, vtkDoubleArray point` - Tessellate a 3D 'cell'. The result is a set of smaller linear tetrahedra in 'cellArray' with 'points' and point data 'internalPd'.
- `obj.Triangulate (vtkGenericAdaptorCell cell, vtkGenericAttributeCollection att, vtkDoubleArray poir` - Triangulate a 2D 'cell'. The result is a set of smaller linear triangles in 'cellArray' with 'points' and point data 'internalPd'.
- `obj.Reset ()` - Reset the output for repeated use of this class.
- `obj.Initialize (vtkGenericDataSet ds)` - Initialize the tessellator with a data set 'ds'.
- `int = obj.GetFixedSubdivisions ()` - Return the number of fixed subdivisions. It is used to prevent from infinite loop in degenerated cases. For order 3 or higher, if the inflection point is exactly on the mid-point, error metric will not detect that a subdivision is required. 0 means no fixed subdivision: there will be only adaptive subdivisions.

The algorithm first performs 'GetFixedSubdivisions' non adaptive subdivisions followed by at most 'GetMaxAdaptiveSubdivisions' adaptive subdivisions. Hence, there are at most 'GetMaxSubdivisionLevel' subdivisions.

- `int = obj.GetMaxSubdivisionLevel ()` - Return the maximum level of subdivision. It is used to prevent from infinite loop in degenerated cases. For order 3 or higher, if the inflection point is exactly on the mid-point, error metric will not detect that a subdivision is required. 0 means no subdivision, neither fixed nor adaptive.

- `int = obj.GetMaxAdaptiveSubdivisions ()` - Return the maximum number of adaptive subdivisions.

- `obj.SetFixedSubdivisions (int level)` - Set the number of fixed subdivisions. See GetFixedSubdivisions() for more explanations.

- `obj.SetMaxSubdivisionLevel (int level)` - Set the maximum level of subdivision. See GetMaxSubdivisionLevel() for more explanations.

- `obj.SetSubdivisionLevels (int fixed, int maxLevel)` - Set both the number of fixed subdivisions and the maximum level of subdivisions. See GetFixedSubdivisions(), GetMaxSubdivisionLevel() and GetMaxAdaptiveSubdivisions() for more explanations.

31.185 vtkSimpleImageToImageFilter

31.185.1 Usage

vtkSimpleImageToImageFilter is a filter which aims to avoid much of the complexity associated with vtkImageAlgorithm (i.e. support for pieces, multi-threaded operation). If you need to write a simple image-image filter which operates on the whole input, use this as the superclass. The subclass has to provide only an execute method which takes input and output as arguments. Memory allocation is handled in vtkSimpleImageToImageFilter. Also, you are guaranteed to have a valid input in the Execute(input, output) method. By default, this filter requests it's input's whole extent and copies the input's information (spacing, whole extent etc...) to the output. If the output's setup is different (for example, if it performs some sort of sub-sampling), ExecuteInformation has to be overwritten. As an example of how this can be done, you can look at vtkImageShrink3D::ExecuteInformation. For a complete example which uses templates to support generic data types, see vtkSimpleImageToImageFilter.

To create an instance of class vtkSimpleImageToImageFilter, simply invoke its constructor as follows

```
obj = vtkSimpleImageToImageFilter
```

31.185.2 Methods

The class vtkSimpleImageToImageFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimpleImageToImageFilter class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkSimpleImageToImageFilter = obj.NewInstance ()`

- `vtkSimpleImageToImageFilter = obj.SafeDownCast (vtkObject o)`

31.186 vtkSimpleScalarTree

31.186.1 Usage

vtkSimpleScalarTree creates a pointerless binary tree that helps search for cells that lie within a particular scalar range. This object is used to accelerate some contouring (and other scalar-based techniques).

The tree consists of an array of (min,max) scalar range pairs per node in the tree. The (min,max) range is determined from looking at the range of the children of the tree node. If the node is a leaf, then the range is determined by scanning the range of scalar data in n cells in the dataset. The n cells are determined by arbitrary selecting cell ids from id(i) to id(i+n), and where n is specified using the BranchingFactor ivar. Note that leaf node i=0 contains the scalar range computed from cell ids (0,n-1); leaf node i=1 contains the range from cell ids (n,2n-1); and so on. The implication is that there are no direct lists of cell ids per leaf node, instead the cell ids are implicitly known.

To create an instance of class vtkSimpleScalarTree, simply invoke its constructor as follows

```
obj = vtkSimpleScalarTree
```

31.186.2 Methods

The class vtkSimpleScalarTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSimpleScalarTree class.

- `string = obj.GetClassName ()` - Standard type related macros and PrintSelf() method.
- `int = obj.IsA (string name)` - Standard type related macros and PrintSelf() method.
- `vtkSimpleScalarTree = obj.NewInstance ()` - Standard type related macros and PrintSelf() method.
- `vtkSimpleScalarTree = obj.SafeDownCast (vtkObject o)` - Standard type related macros and PrintSelf() method.
- `obj.SetBranchingFactor (int )` - Set the branching factor for the tree. This is the number of children per tree node. Smaller values (minimum is 2) mean deeper trees and more memory overhead. Larger values mean shallower trees, less memory usage, but worse performance.
- `int = obj.GetBranchingFactorMinValue ()` - Set the branching factor for the tree. This is the number of children per tree node. Smaller values (minimum is 2) mean deeper trees and more memory overhead. Larger values mean shallower trees, less memory usage, but worse performance.
- `int = obj.GetBranchingFactorMaxValue ()` - Set the branching factor for the tree. This is the number of children per tree node. Smaller values (minimum is 2) mean deeper trees and more memory overhead. Larger values mean shallower trees, less memory usage, but worse performance.
- `int = obj.GetBranchingFactor ()` - Set the branching factor for the tree. This is the number of children per tree node. Smaller values (minimum is 2) mean deeper trees and more memory overhead. Larger values mean shallower trees, less memory usage, but worse performance.
- `int = obj.GetLevel ()` - Get the level of the scalar tree. This value may change each time the scalar tree is built and the branching factor changes.
- `obj.SetMaxLevel (int )` - Set the maximum allowable level for the tree.
- `int = obj.GetMaxLevelMinValue ()` - Set the maximum allowable level for the tree.
- `int = obj.GetMaxLevelMaxValue ()` - Set the maximum allowable level for the tree.
- `int = obj.GetMaxLevel ()` - Set the maximum allowable level for the tree.

- `obj.BuildTree ()` - Construct the scalar tree from the dataset provided. Checks build times and modified time from input and reconstructs the tree if necessary.
- `obj.Initialize ()` - Initialize locator. Frees memory and resets object as appropriate.
- `obj.InitTraversal (double scalarValue)` - Begin to traverse the cells based on a scalar value. Returned cells will have scalar values that span the scalar value specified.

31.187 vtkSmoothErrorMetric

31.187.1 Usage

It is a concrete error metric, based on a geometric criterium: a max angle between the chord passing through the midpoint and one of the endpoints and the other chord passing through the midpoint and the other endpoint of the edge. It is related to the flatness of an edge.

To create an instance of class vtkSmoothErrorMetric, simply invoke its constructor as follows

```
obj = vtkSmoothErrorMetric
```

31.187.2 Methods

The class vtkSmoothErrorMetric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSmoothErrorMetric class.

- `string = obj.GetClassName ()` - Standard VTK type and error macros.
- `int = obj.IsA (string name)` - Standard VTK type and error macros.
- `vtkSmoothErrorMetric = obj.NewInstance ()` - Standard VTK type and error macros.
- `vtkSmoothErrorMetric = obj.SafeDownCast (vtkObject o)` - Standard VTK type and error macros.
- `double = obj.GetAngleTolerance ()` - Return the flatness threshold.
- `obj.SetAngleTolerance (double value)` - Set the flatness threshold with an angle in degrees. Internally compute the cosine. value is supposed to be in]90,180[, if not it is clamped in [90.1,179.9]. For instance 178 will give better result than 150.
- `int = obj.RequiresEdgeSubdivision (double leftPoint, double midPoint, double rightPoint, double alp` - Does the edge need to be subdivided according to the cosine between the two chords passing through the mid-point and the endpoints? The edge is defined by its 'leftPoint' and its 'rightPoint'. 'leftPoint', 'midPoint' and 'rightPoint' have to be initialized before calling RequiresEdgeSubdivision(). Their format is global coordinates, parametric coordinates and point centered attributes: xyx rst abc de... 'alpha' is the normalized abscissa of the midpoint along the edge. (close to 0 means close to the left point, close to 1 means close to the right point)

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `double = obj.GetError (double leftPoint, double midPoint, double rightPoint, double alpha)` - Return the error at the mid-point. It will return an error relative to the bounding box size if GetRelative() is true, a square absolute error otherwise. See RequiresEdgeSubdivision() for a description of the arguments.

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6

31.188 vtkSource

31.188.1 Usage

vtkSource is an abstract object that specifies behavior and interface of source objects. Source objects are objects that begin visualization pipeline. Sources include readers (read data from file or communications port) and procedural sources (generate data programmatically). vtkSource objects are also objects that generate output data. In this sense vtkSource is used as a superclass to vtkFilter.

Concrete subclasses of vtkSource must define Update() and Execute() methods. The public method Update() invokes network execution and will bring the network up-to-date. The protected Execute() method actually does the work of data creation/generation. The difference between the two methods is that Update() implements input consistency checks and modified time comparisons and then invokes the Execute() which is an implementation of a particular algorithm.

An important feature of subclasses of vtkSource is that it is possible to control the memory-management model (i.e., retain output versus delete output data). If enabled the ReleaseDataFlag enables the deletion of the output data once the downstream process object finishes processing the data (please see text).

To create an instance of class vtkSource, simply invoke its constructor as follows

```
obj = vtkSource
```

31.188.2 Methods

The class vtkSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSource = obj.NewInstance ()`
- `vtkSource = obj.SafeDownCast (vtkObject o)`
- `obj.Update ()` - Bring object up-to-date before execution. Update() checks modified time against last execution time, and re-executes object if necessary.
- `obj.UpdateWholeExtent ()` - Like update, but make sure the update extent is the whole extent in the output.
- `obj.UpdateInformation ()` - Updates any global information about the data (like spacing for images)
- `obj.PropagateUpdateExtent (vtkDataObject output)` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. The update extent for this object is propagated up the pipeline. This propagation may early terminate based on the PipelineMTime.
- `obj.TriggerAsynchronousUpdate ()` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. Propagate back up the pipeline for ports and trigger the update on the other side of the port to allow for asynchronous parallel processing in the pipeline. This propagation may early terminate based on the PipelineMTime.
- `obj.UpdateData (vtkDataObject output)` - WARNING: INTERNAL METHOD - NOT FOR GENERAL USE. THIS METHOD IS PART OF THE PIPELINE UPDATE FUNCTIONALITY. Propagate the update back up the pipeline, and perform the actual work of updating on the way down. When the propagate arrives at a port, block and wait for the asynchronous update to finish on the other side. This propagation may early terminate based on the PipelineMTime.

- `obj.ComputeInputUpdateExtents (vtkDataObject output)` - What is the input update extent that is required to produce the desired output? By default, the whole input is always required but this is overridden in many subclasses.
- `obj.SetReleaseDataFlag (int )` - Turn on/off flag to control whether this object's data is released after being used by a source.
- `int = obj.GetReleaseDataFlag ()` - Turn on/off flag to control whether this object's data is released after being used by a source.
- `obj.ReleaseDataFlagOn ()` - Turn on/off flag to control whether this object's data is released after being used by a source.
- `obj.ReleaseDataFlagOff ()` - Turn on/off flag to control whether this object's data is released after being used by a source.
- `int = obj.GetNumberOfOutputs ()` - Return an array with all the inputs of this process object. This is useful for tracing back in the pipeline to construct graphs etc.
- `obj.UnRegisterAllOutputs (void )` - Release/disconnect all outputs of this source. This is intended to be called prior to Delete() if the user is concerned about outputs holding on to the filter/source.
- `int = obj.GetOutputIndex (vtkDataObject out)` - Return what index output the passed in output is, return -1 if it does not match any of the outputs
- `obj.SetExecutive (vtkExecutive executive)` - Set this algorithm's executive. This algorithm is removed from any executive to which it has previously been assigned and then assigned to the given executive.

31.189 vtkSphere

31.189.1 Usage

vtkSphere computes the implicit function and/or gradient for a sphere. vtkSphere is a concrete implementation of vtkImplicitFunction. Additional methods are available for sphere-related computations, such as computing bounding spheres for a set of points, or set of spheres.

To create an instance of class vtkSphere, simply invoke its constructor as follows

```
obj = vtkSphere
```

31.189.2 Methods

The class vtkSphere has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSphere class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSphere = obj.NewInstance ()`
- `vtkSphere = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double n[3])`

- `obj.SetRadius (double )` - Set / get the radius of the sphere.
- `double = obj.GetRadius ()` - Set / get the radius of the sphere.
- `obj.SetCenter (double , double , double )` - Set / get the center of the sphere.
- `obj.SetCenter (double  a[3])` - Set / get the center of the sphere.
- `double = obj. GetCenter ()` - Set / get the center of the sphere.

31.190 vtkSpline

31.190.1 Usage

vtkSpline interpolates a set of data points (i.e., interpolation means that the spline passes through the points). vtkSpline is an abstract class: its subclasses vtkCardinalSpline and vtkKochenekSpline do the interpolation. Note that this spline maps the 1D parametric coordinate t into a single value x. Thus if you want to use the spline to interpolate points (i.e. x[3]), you have to create three splines for each of the x-y-z coordinates. Fortunately, the vtkParametricSpline class does this for you.

Typically a spline is used by adding a sequence of parametric coordinate / data (t,x) values followed by use of an evaluation function (e.g., vtkCardinalSpline::Evaluate()). Since these splines are 1D, a point in this context is an independent / dependent variable pair.

Splines can also be set up to be closed or open. Closed splines continue from the last point to the first point with continuous function and derivative values. (You don't need to duplicate the first point to close the spline, just set ClosedOn.)

This implementation of splines does not use a normalized parametric coordinate. If the spline is open, then the parameter space is (tMin ¡= t ¡= tMax) where tMin and tMax are the minimum and maximum parametric values seen when performing AddPoint(). If the spline is closed, then the parameter space is (tMin ¡= t ¡= (tMax+1)) where tMin and tMax are the minimum and maximum parametric values seen when performing AddPoint(). Note, however, that this behavior can be changed by explicitly setting the ParametricRange(tMin,tMax). If set, the parameter space remains (tMin ¡= t ¡= tMax), except that additions of data with parametric values outside this range are clamped within this range.

To create an instance of class vtkSpline, simply invoke its constructor as follows

```
obj = vtkSpline
```

31.190.2 Methods

The class vtkSpline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSpline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSpline = obj.NewInstance ()`
- `vtkSpline = obj.SafeDownCast (vtkObject o)`
- `obj.SetParametricRange (double tMin, double tMax)` - Set/Get the parametric range. If not set, the range is determined implicitly by keeping track of the (min,max) parameter values for t. If set, the AddPoint() method will clamp the t value to lie within the specified range.
- `obj.SetParametricRange (double tRange[2])` - Set/Get the parametric range. If not set, the range is determined implicitly by keeping track of the (min,max) parameter values for t. If set, the AddPoint() method will clamp the t value to lie within the specified range.

- `obj.GetParametricRange (double tRange[2]) const` - Set/Get the parametric range. If not set, the range is determined implicitly by keeping track of the (min,max) parameter values for t. If set, the AddPoint() method will clamp the t value to lie within the specified range.
- `obj.SetClampValue (int )` - Set/Get ClampValue. If On, results of the interpolation will be clamped to the min/max of the input data.
- `int = obj.GetClampValue ()` - Set/Get ClampValue. If On, results of the interpolation will be clamped to the min/max of the input data.
- `obj.ClampValueOn ()` - Set/Get ClampValue. If On, results of the interpolation will be clamped to the min/max of the input data.
- `obj.ClampValueOff ()` - Set/Get ClampValue. If On, results of the interpolation will be clamped to the min/max of the input data.
- `obj.Compute ()` - Compute the coefficients for the spline.
- `double = obj.Evaluate (double t)` - Interpolate the value of the spline at parametric location of t.
- `int = obj.GetNumberOfPoints ()` - Return the number of points inserted thus far.
- `obj.AddPoint (double t, double x)` - Add a pair of points to be fit with the spline.
- `obj.RemovePoint (double t)` - Remove a point from the data to be fit with the spline.
- `obj.RemoveAllPoints ()` - Remove all points from the data.
- `obj.SetClosed (int )` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `int = obj.GetClosed ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `obj.ClosedOn ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `obj.ClosedOff ()` - Control whether the spline is open or closed. A closed spline forms a continuous loop: the first and last points are the same, and derivatives are continuous.
- `obj.SetLeftConstraint (int )` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.
- `int = obj.GetLeftConstraintMinValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetLeftConstraintMaxValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetLeftConstraint ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `obj.SetRightConstraint (int )` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetRightConstraintMinValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetRightConstraintMaxValue ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

  1: the first derivative at left(right) most point is set to Left(Right)Value.

  2: the second derivative at left(right) most point is set to Left(Right)Value.

  3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `int = obj.GetRightConstraint ()` - Set the type of constraint of the left(right) end points. Four constraints are available:

  0: the first derivative at left(right) most point is determined from the line defined from the first(last) two points.

1: the first derivative at left(right) most point is set to Left(Right)Value.

2: the second derivative at left(right) most point is set to Left(Right)Value.

3: the second derivative at left(right)most points is Left(Right)Value times second derivative at first interior point.

- `obj.SetLeftValue (double )` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.
- `double = obj.GetLeftValue ()` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.
- `obj.SetRightValue (double )` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.
- `double = obj.GetRightValue ()` - The values of the derivative on the left and right sides. The value is used only if the left(right) constraint is type 1-3.
- `long = obj.GetMTime ()` - Return the MTime also considering the Piecewise function.
- `obj.DeepCopy (vtkSpline s)` - Deep copy of spline data.

31.191 vtkStreamingDemandDrivenPipeline

31.191.1 Usage

vtkStreamingDemandDrivenPipeline is an executive that supports updating only a portion of the data set in the pipeline. This is the style of pipeline update that is provided by the old-style VTK 4.x pipeline. Instead of always updating an entire data set, this executive supports asking for pieces or sub-extents.

To create an instance of class vtkStreamingDemandDrivenPipeline, simply invoke its constructor as follows

```
obj = vtkStreamingDemandDrivenPipeline
```

31.191.2 Methods

The class vtkStreamingDemandDrivenPipeline has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStreamingDemandDrivenPipeline class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStreamingDemandDrivenPipeline = obj.NewInstance ()`
- `vtkStreamingDemandDrivenPipeline = obj.SafeDownCast (vtkObject o)`
- `int = obj.Update ()` - Bring the outputs up-to-date.
- `int = obj.Update (int port)` - Bring the outputs up-to-date.
- `int = obj.UpdateWholeExtent ()` - Bring the outputs up-to-date.
- `int = obj.PropagateUpdateExtent (int outputPort)` - Propagate the update request from the given output port back through the pipeline. Should be called only when information is up to date.

- `int = obj.SetMaximumNumberOfPieces (int port, int n)` - Set/Get the maximum number of pieces that can be requested from the given port. The maximum number of pieces is meta data for unstructured data sets. It gets set by the source during the update information call. A value of -1 indicates that there is no maximum.

- `int = obj.SetMaximumNumberOfPieces (vtkInformation , int n)` - Set/Get the maximum number of pieces that can be requested from the given port. The maximum number of pieces is meta data for unstructured data sets. It gets set by the source during the update information call. A value of -1 indicates that there is no maximum.

- `int = obj.GetMaximumNumberOfPieces (int port)` - Set/Get the maximum number of pieces that can be requested from the given port. The maximum number of pieces is meta data for unstructured data sets. It gets set by the source during the update information call. A value of -1 indicates that there is no maximum.

- `int = obj.GetMaximumNumberOfPieces (vtkInformation )` - Set/Get the maximum number of pieces that can be requested from the given port. The maximum number of pieces is meta data for unstructured data sets. It gets set by the source during the update information call. A value of -1 indicates that there is no maximum.

- `int = obj.SetWholeExtent (vtkInformation , int extent[6])` - Set/Get the whole extent of an output port. The whole extent is meta data for structured data sets. It gets set by the algorithm during the update information pass.

- `obj.GetWholeExtent (vtkInformation , int extent[6])` - Set/Get the whole extent of an output port. The whole extent is meta data for structured data sets. It gets set by the algorithm during the update information pass.

- `int = obj.SetUpdateExtentToWholeExtent (int port)` - If the whole input extent is required to generate the requested output extent, this method can be called to set the input update extent to the whole input extent. This method assumes that the whole extent is known (that UpdateInformation has been called)

- `int = obj.SetUpdateExtentToWholeExtent (vtkInformation )` - If the whole input extent is required to generate the requested output extent, this method can be called to set the input update extent to the whole input extent. This method assumes that the whole extent is known (that UpdateInformation has been called)

- `int = obj.SetUpdateExtent (int port, int extent[6])` - Get/Set the update extent for output ports that use 3D extents.

- `int = obj.SetUpdateExtent (vtkInformation , int extent[6])` - Get/Set the update extent for output ports that use 3D extents.

- `obj.GetUpdateExtent (vtkInformation , int extent[6])` - Get/Set the update extent for output ports that use 3D extents.

- `int = obj.SetUpdateExtent (int port, int piece, int numPieces, int ghostLevel)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.

- `int = obj.SetUpdateExtent (vtkInformation , int piece, int numPieces, int ghostLevel)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.

- `int = obj.SetUpdatePiece (vtkInformation , int piece)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.

- `int = obj.GetUpdatePiece (vtkInformation )` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.SetUpdateNumberOfPieces (vtkInformation , int n)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.GetUpdateNumberOfPieces (vtkInformation )` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.SetUpdateGhostLevel (vtkInformation , int n)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.GetUpdateGhostLevel (vtkInformation )` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.SetUpdateResolution (int port, double r)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.SetUpdateResolution (vtkInformation , double r)` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `double = obj.GetUpdateResolution (vtkInformation )` - Set/Get the update piece, update number of pieces, and update number of ghost levels for an output port. Similar to update extent in 3D.
- `int = obj.SetSplitUpdateExtent (int port, int major, int minor, int numPieces, int ghostLevel)` - Get/Set the update extent for output ports that use Temporal Extents
- `int = obj.SetUpdateTimeSteps (int port, double times, int length)` - Get/Set the update extent for output ports that use Temporal Extents
- `int = obj.SetUpdateTimeSteps (vtkInformation , double times, int length)` - Get/Set the update extent for output ports that use Temporal Extents
- `int = obj.SetUpdateTimeStep (int port, double time)` - Get/Set the update extent for output ports that use Temporal Extents
- `int = obj.SetRequestExactExtent (int port, int flag)` - This request flag indicates whether the requester can handle more data than requested for the given port. Right now it is used in vtkImageData. Image filters can return more data than requested. The the consumer cannot handle this (i.e. DataSetToDataSetFitler) the image will crop itself. This functionality used to be in ImageToStructuredPoints.
- `int = obj.GetRequestExactExtent (int port)` - This request flag indicates whether the requester can handle more data than requested for the given port. Right now it is used in vtkImageData. Image filters can return more data than requested. The the consumer cannot handle this (i.e. DataSetToDataSetFitler) the image will crop itself. This functionality used to be in ImageToStructuredPoints.
- `int = obj.SetExtentTranslator (int port, vtkExtentTranslator translator)` - Get/Set the object that will translate pieces into structured extents for an output port.
- `int = obj.SetExtentTranslator (vtkInformation , vtkExtentTranslator translator)` - Get/Set the object that will translate pieces into structured extents for an output port.
- `vtkExtentTranslator = obj.GetExtentTranslator (int port)` - Get/Set the object that will translate pieces into structured extents for an output port.

- `vtkExtentTranslator = obj.GetExtentTranslator (vtkInformation info)` - Get/Set the object that will translate pieces into structured extents for an output port.
- `int = obj.SetWholeBoundingBox (int port, double bb[6])` - Set/Get the whole bounding box of an output port data object. The whole whole bounding box is meta data for data sets. It gets set by the algorithm during the update information pass.
- `obj.GetWholeBoundingBox (int port, double bb[6])` - Set/Get the whole bounding box of an output port data object. The whole whole bounding box is meta data for data sets. It gets set by the algorithm during the update information pass.
- `int = obj.SetPieceBoundingBox (int port, double bb[6])` - Set/Get the piece bounding box of an output port data object. The piece bounding box is meta data for data sets. It gets set by the algorithm during the update extent information pass.
- `obj.GetPieceBoundingBox (int port, double bb[6])` - Set/Get the piece bounding box of an output port data object. The piece bounding box is meta data for data sets. It gets set by the algorithm during the update extent information pass.
- `double = obj.ComputePriority ()` - Issues pipeline request to determine and return the priority of the piece described by the current update extent. The priority is a number between 0.0 and 1.0 with 0 meaning skippable (REQUEST_DATA not needed) and 1.0 meaning important.
- `double = obj.ComputePriority (int port)` - Issues pipeline request to determine and return the priority of the piece described by the current update extent. The priority is a number between 0.0 and 1.0 with 0 meaning skippable (REQUEST_DATA not needed) and 1.0 meaning important.

31.192 vtkStructuredGrid

31.192.1 Usage

vtkStructuredGrid is a data object that is a concrete implementation of vtkDataSet. vtkStructuredGrid represents a geometric structure that is a topologically regular array of points. The topology is that of a cube that has been subdivided into a regular array of smaller cubes. Each point/cell can be addressed with i-j-k indices. Examples include finite difference grids.

The order and number of points must match that specified by the dimensions of the grid. The point order increases in i fastest (from 0¡=i¡dims[0]), then j (0¡=j¡dims[1]), then k (0¡=k¡dims[2]) where dims[] are the dimensions of the grid in the i-j-k topological directions. The number of points is dims[0]*dims[1]*dims[2]. The same is true for the cells of the grid. The order and number of cells must match that specified by the dimensions of the grid. The cell order increases in i fastest (from 0¡=i¡(dims[0]-1)), then j (0¡=j¡(dims[1]-1)), then k (0¡=k¡(dims[2]-1)) The number of cells is (dims[0]-1)*(dims[1]-1)*(dims[2]-1).

A unusual feature of vtkStructuredGrid is the ability to blank, or "turn-off" points and cells in the dataset. This is controlled by defining a "blanking array" whose values (0,1) specify whether a point should be blanked or not.

To create an instance of class vtkStructuredGrid, simply invoke its constructor as follows

```
obj = vtkStructuredGrid
```

31.192.2 Methods

The class vtkStructuredGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGrid class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkStructuredGrid = obj.NewInstance ()`
- `vtkStructuredGrid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Copy the geometric and topological structure of an input poly data object.
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an input poly data object.
- `vtkIdType = obj.GetNumberOfPoints ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `double = obj.GetPoint (vtkIdType ptId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPoint (vtkIdType ptId, double p[3])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellBounds (vtkIdType cellId, double bounds[6])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetCellType (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.GetNumberOfCells ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.Initialize ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetMaxCellSize ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellNeighbors (vtkIdType cellId, vtkIdList ptIds, vtkIdList cellIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetScalarRange (double range[2])` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `double = obj.GetScalarRange ()` - following methods are specific to structured grid
- `obj.SetDimensions (int i, int j, int k)` - following methods are specific to structured grid
- `obj.SetDimensions (int dim[3])` - following methods are specific to structured grid
- `int = obj.GetDimensions ()` - Get dimensions of this structured points dataset.
- `obj.GetDimensions (int dim[3])` - Get dimensions of this structured points dataset.

- `int = obj.GetDataDimension ()` - Return the dimensionality of the data.
- `obj.SetExtent (int extent[6])` - Different ways to set the extent of the data array. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z).
- `obj.SetExtent (int x1, int x2, int y1, int y2, int z1, int z2)` - Different ways to set the extent of the data array. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z).
- `int = obj. GetExtent ()` - Different ways to set the extent of the data array. The extent should be set before the "Scalars" are set or allocated. The Extent is stored in the order (X, Y, Z).
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `int = obj.GetExtentType ()` - Methods for supporting blanking of cells. Blanking turns on or off points in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `obj.BlankPoint (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off points in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `obj.UnBlankPoint (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off points in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `obj.BlankCell (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off cells in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `obj.UnBlankCell (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off cells in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `vtkUnsignedCharArray = obj.GetPointVisibilityArray ()` - Get the array that defines the blanking (visibility) of each point.
- `obj.SetPointVisibilityArray (vtkUnsignedCharArray pointVisibility)` - Set an array that defines the (blanking) visibility of the points in the grid. Make sure that length of the visibility array matches the number of points in the grid.
- `vtkUnsignedCharArray = obj.GetCellVisibilityArray ()` - Get the array that defines the blanking (visibility) of each cell.
- `obj.SetCellVisibilityArray (vtkUnsignedCharArray pointVisibility)` - Set an array that defines the (blanking) visibility of the cells in the grid. Make sure that length of the visibility array matches the number of points in the grid.
- `char = obj.IsPointVisible (vtkIdType ptId)` - Return non-zero value if specified point is visible. These methods should be called only after the dimensions of the grid are set.
- `char = obj.IsCellVisible (vtkIdType cellId)` - Return non-zero value if specified point is visible. These methods should be called only after the dimensions of the grid are set.

- `char = obj.GetPointBlanking ()` - Returns 1 if there is any visibility constraint on the points, 0 otherwise.
- `char = obj.GetCellBlanking ()` - Returns 1 if there is any visibility constraint on the cells, 0 otherwise.
- `obj.Crop ()` - Reallocates and copies to set the Extent to the UpdateExtent. This is used internally when the exact extent is requested, and the source generated more than the update extent.
- `obj.GetPoint (int i, int j, int k, double p[3], bool adjustForExtenttrue)` - Get a point in the grid. If adjustForExtent is true, (i,j,k) is interpreted as a position relative to the beginning of the extent. If adjustForExtent is false, (i,j,k) is interpreted literally and the (i,j,k) point of the grid is returned regardless of the extent beginning. The point coordinate is returned in 'p'. The default adjustForExtent is true.

31.193 vtkStructuredGridAlgorithm

31.193.1 Usage

To create an instance of class vtkStructuredGridAlgorithm, simply invoke its constructor as follows

```
obj = vtkStructuredGridAlgorithm
```

31.193.2 Methods

The class vtkStructuredGridAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridAlgorithm = obj.NewInstance ()`
- `vtkStructuredGridAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkStructuredGrid = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkStructuredGrid = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput ()`
- `vtkDataObject = obj.GetInput (int port)`
- `vtkStructuredGrid = obj.GetStructuredGridInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.194 vtkStructuredGridSource

31.194.1 Usage

vtkStructuredGridSource is an abstract class whose subclasses generate structured grid data.

To create an instance of class vtkStructuredGridSource, simply invoke its constructor as follows

```
obj = vtkStructuredGridSource
```

31.194.2 Methods

The class vtkStructuredGridSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridSource class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`

- `vtkStructuredGridSource = obj.NewInstance ()`

- `vtkStructuredGridSource = obj.SafeDownCast (vtkObject o)`

- `vtkStructuredGrid = obj.GetOutput ()` - Get the output of this source.

- `vtkStructuredGrid = obj.GetOutput (int idx)` - Get the output of this source.

- `obj.SetOutput (vtkStructuredGrid output)` - Get the output of this source.

31.195 vtkStructuredGridToPolyDataFilter

31.195.1 Usage

vtkStructuredGridToPolyDataFilter is a filter whose subclasses take as input structured grid datasets and generate polygonal data on output.

To create an instance of class vtkStructuredGridToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkStructuredGridToPolyDataFilter
```

31.195.2 Methods

The class vtkStructuredGridToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridToPolyDataFilter = obj.NewInstance ()`
- `vtkStructuredGridToPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkStructuredGrid input)` - Set / get the input Grid or filter.
- `vtkStructuredGrid = obj.GetInput ()` - Set / get the input Grid or filter.

31.196 vtkStructuredGridToStructuredGridFilter

31.196.1 Usage

vtkStructuredPointsToStructuredPointsFilter is an abstract filter class whose subclasses take on input a structured grid and generate a structured grid on output.

To create an instance of class vtkStructuredGridToStructuredGridFilter, simply invoke its constructor as follows

```
obj = vtkStructuredGridToStructuredGridFilter
```

31.196.2 Methods

The class vtkStructuredGridToStructuredGridFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredGridToStructuredGridFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredGridToStructuredGridFilter = obj.NewInstance ()`
- `vtkStructuredGridToStructuredGridFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkStructuredGrid input)` - Set / get the input Grid or filter.
- `vtkStructuredGrid = obj.GetInput ()` - Set / get the input Grid or filter.

31.197 vtkStructuredPoints

31.197.1 Usage

StructuredPoints is a subclass of ImageData that requires the data extent to exactly match the update extent. Normall image data allows that the data extent may be larger than the update extent. StructuredPoints also defines the origin differently that vtkImageData. For structured points the origin is the location of first point. Whereas images define the origin as the location of point 0, 0, 0. Image Origin is stored in ivar, and structured points have special methods for setting/getting the origin/extents.

To create an instance of class vtkStructuredPoints, simply invoke its constructor as follows

```
obj = vtkStructuredPoints
```

31.197.2 Methods

The class vtkStructuredPoints has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPoints class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPoints = obj.NewInstance ()`
- `vtkStructuredPoints = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()`

31.198 vtkStructuredPointsCollection

31.198.1 Usage

vtkStructuredPointsCollection is an object that creates and manipulates lists of structured points datasets. See also vtkCollection and subclasses.

To create an instance of class vtkStructuredPointsCollection, simply invoke its constructor as follows

```
obj = vtkStructuredPointsCollection
```

31.198.2 Methods

The class vtkStructuredPointsCollection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsCollection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsCollection = obj.NewInstance ()`
- `vtkStructuredPointsCollection = obj.SafeDownCast (vtkObject o)`
- `obj.AddItem (vtkStructuredPoints ds)` - Get the next item in the collection. NULL is returned if the collection is exhausted.
- `vtkStructuredPoints = obj.GetNextItem ()` - Get the next item in the collection. NULL is returned if the collection is exhausted.

31.199 vtkStructuredPointsSource

31.199.1 Usage

vtkStructuredPointsSource is an abstract class whose subclasses generate structured Points data.

To create an instance of class vtkStructuredPointsSource, simply invoke its constructor as follows

```
obj = vtkStructuredPointsSource
```

31.199.2 Methods

The class vtkStructuredPointsSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsSource = obj.NewInstance ()`
- `vtkStructuredPointsSource = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutput (vtkStructuredPoints output)` - Set/Get the output of this source.
- `vtkStructuredPoints = obj.GetOutput ()` - Set/Get the output of this source.
- `vtkStructuredPoints = obj.GetOutput (int idx)` - Set/Get the output of this source.

31.200 vtkStructuredPointsToPolyDataFilter

31.200.1 Usage

vtkStructuredPointsToPolyDataFilter is an abstract filter class whose subclasses take on input structured points and generate polygonal data on output.

To create an instance of class vtkStructuredPointsToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkStructuredPointsToPolyDataFilter
```

31.200.2 Methods

The class vtkStructuredPointsToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsToPolyDataFilter = obj.NewInstance ()`
- `vtkStructuredPointsToPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData input)` - Set / get the input data or filter.
- `vtkImageData = obj.GetInput ()` - Set / get the input data or filter.

31.201 vtkStructuredPointsToStructuredPointsFilter

31.201.1 Usage

vtkStructuredPointsToStructuredPointsFilter is an abstract filter class whose subclasses take on input structured points and generate structured points on output.

To create an instance of class vtkStructuredPointsToStructuredPointsFilter, simply invoke its constructor as follows

```
obj = vtkStructuredPointsToStructuredPointsFilter
```

31.201.2 Methods

The class vtkStructuredPointsToStructuredPointsFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsToStructuredPointsFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsToStructuredPointsFilter = obj.NewInstance ()`
- `vtkStructuredPointsToStructuredPointsFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData input)` - Set / get the input data or filter.
- `vtkImageData = obj.GetInput ()` - Set / get the input data or filter.

31.202 vtkStructuredPointsToUnstructuredGridFilter

31.202.1 Usage

vtkStructuredPointsToUnstructuredGridFilter is an abstract filter class whose subclasses take on input structured points and generate unstructured grid data on output.

To create an instance of class vtkStructuredPointsToUnstructuredGridFilter, simply invoke its constructor as follows

```
obj = vtkStructuredPointsToUnstructuredGridFilter
```

31.202.2 Methods

The class vtkStructuredPointsToUnstructuredGridFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkStructuredPointsToUnstructuredGridFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkStructuredPointsToUnstructuredGridFilter = obj.NewInstance ()`
- `vtkStructuredPointsToUnstructuredGridFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkImageData input)` - Set / get the input data or filter.
- `vtkImageData = obj.GetInput ()` - Set / get the input data or filter.

31.203 vtkSuperquadric

31.203.1 Usage

vtkSuperquadric computes the implicit function and function gradient for a superquadric. vtkSuperquadric is a concrete implementation of vtkImplicitFunction. The superquadric is centered at Center and axes of rotation is along the y-axis. (Use the superclass' vtkImplicitFunction transformation matrix if necessary to reposition.) Roundness parameters (PhiRoundness and ThetaRoundness) control the shape of the superquadric. The Toroidal boolean controls whether a toroidal superquadric is produced. If so, the Thickness parameter controls the thickness of the toroid: 0 is the thinnest allowable toroid, and 1 has a minimum sized

hole. The Scale parameters allow the superquadric to be scaled in x, y, and z (normal vectors are correctly generated in any case). The Size parameter controls size of the superquadric.

This code is based on "Rigid physically based superquadrics", A. H. Barr, in "Graphics Gems III", David Kirk, ed., Academic Press, 1992.

To create an instance of class vtkSuperquadric, simply invoke its constructor as follows

```
obj = vtkSuperquadric
```

31.203.2 Methods

The class vtkSuperquadric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkSuperquadric class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkSuperquadric = obj.NewInstance ()`
- `vtkSuperquadric = obj.SafeDownCast (vtkObject o)`
- `double = obj.EvaluateFunction (double x[3])`
- `double = obj.EvaluateFunction (double x, double y, double z)`
- `obj.EvaluateGradient (double x[3], double g[3])`
- `obj.SetCenter (double , double , double )` - Set the center of the superquadric. Default is 0,0,0.
- `obj.SetCenter (double  a[3])` - Set the center of the superquadric. Default is 0,0,0.
- `double = obj. GetCenter ()` - Set the center of the superquadric. Default is 0,0,0.
- `obj.SetScale (double , double , double )` - Set the scale factors of the superquadric. Default is 1,1,1.
- `obj.SetScale (double  a[3])` - Set the scale factors of the superquadric. Default is 1,1,1.
- `double = obj. GetScale ()` - Set the scale factors of the superquadric. Default is 1,1,1.
- `double = obj.GetThickness ()` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid.
- `obj.SetThickness (double )` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid.
- `double = obj.GetThicknessMinValue ()` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid.
- `double = obj.GetThicknessMaxValue ()` - Set/Get Superquadric ring thickness (toroids only). Changing thickness maintains the outside diameter of the toroid.
- `double = obj.GetPhiRoundness ()` - Set/Get Superquadric north/south roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders.
- `obj.SetPhiRoundness (double e)` - Set/Get Superquadric north/south roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders.
- `double = obj.GetThetaRoundness ()` - Set/Get Superquadric east/west roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders.

- `obj.SetThetaRoundness (double e)` - Set/Get Superquadric east/west roundness. Values range from 0 (rectangular) to 1 (circular) to higher orders.
- `obj.SetSize (double )` - Set/Get Superquadric isotropic size.
- `double = obj.GetSize ()` - Set/Get Superquadric isotropic size.
- `obj.ToroidalOn ()` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0).
- `obj.ToroidalOff ()` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0).
- `int = obj.GetToroidal ()` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0).
- `obj.SetToroidal (int )` - Set/Get whether or not the superquadric is toroidal (1) or ellipsoidal (0).

31.204 vtkTable

31.204.1 Usage

vtkTable is a basic data structure for storing columns of data. Internally, columns are stored in a vtkDataSetAttributes structure called RowData. However, using the vtkTable API additionally ensures that every column has the same number of entries, and provides row access (using vtkVariantArray) and single entry access (using vtkVariant).

The field data inherited from vtkDataObject may be used to store metadata related to the table.

To create an instance of class vtkTable, simply invoke its constructor as follows

```
obj = vtkTable
```

31.204.2 Methods

The class vtkTable has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTable class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTable = obj.NewInstance ()`
- `vtkTable = obj.SafeDownCast (vtkObject o)`
- `obj.Dump (int colWidth)` - Dump table contents.
- `int = obj.GetDataObjectType ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value).
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value).
- `vtkDataSetAttributes = obj.GetRowData ()` - Get/Set the main data (columns) of the table.
- `obj.SetRowData (vtkDataSetAttributes data)` - Get/Set the main data (columns) of the table.
- `vtkIdType = obj.GetNumberOfRows ()` - Get the number of rows in the table.

- `obj.SetNumberOfRows (vtkIdType )` - Set the number of rows in the table. Note that memory allocation might be performed as a result of this, but no memory will be released.
- `vtkVariantArray = obj.GetRow (vtkIdType row)` - Get a row of the table as a vtkVariantArray which has one entry for each column. NOTE: This version of the method is NOT thread safe.
- `obj.GetRow (vtkIdType row, vtkVariantArray values)` - Get a row of the table as a vtkVariantArray which has one entry for each column.
- `obj.SetRow (vtkIdType row, vtkVariantArray values)` - Set a row of the table with a vtkVariantArray which has one entry for each column.
- `vtkIdType = obj.InsertNextBlankRow (double default\_num\_val)` - Insert a blank row at the end of the table.
- `vtkIdType = obj.InsertNextRow (vtkVariantArray arr)` - Insert a row specified by a vtkVariantArray. The number of entries in the array should match the number of columns in the table.
- `obj.RemoveRow (vtkIdType row)` - Delete a row from the table. Rows below the deleted row are shifted up.
- `vtkIdType = obj.GetNumberOfColumns ()` - Get the number of columns in the table.
- `string = obj.GetColumnName (vtkIdType col)`
- `vtkAbstractArray = obj.GetColumnByName (string name)` - Get a column of the table by its name.
- `vtkAbstractArray = obj.GetColumn (vtkIdType col)` - Get a column of the table by its column index.
- `obj.AddColumn (vtkAbstractArray arr)` - Add a column to the table.
- `obj.RemoveColumnByName (string name)` - Remove a column from the table by its name.
- `obj.RemoveColumn (vtkIdType col)` - Remove a column from the table by its column index.
- `obj.Initialize ()` - Initialize to an empty table.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow/deep copy the data from src into this object.
- `obj.DeepCopy (vtkDataObject src)` - Shallow/deep copy the data from src into this object.
- `vtkFieldData = obj.GetAttributesAsFieldData (int type)` - Returns the attributes of the data object as a vtkFieldData. This returns non-null values in all the same cases as GetAttributes, in addition to the case of FIELD, which will return the field data for any vtkDataObject subclass.
- `vtkIdType = obj.GetNumberOfElements (int type)` - Get the number of elements for a specific attribute type (ROW, etc.).

31.205 vtkTableAlgorithm

31.205.1 Usage

vtkTableAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline architecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be Tree. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation.

For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

.SECTION Thanks Thanks to Brian Wylie for creating this class.

To create an instance of class vtkTableAlgorithm, simply invoke its constructor as follows

```
obj = vtkTableAlgorithm
```

31.205.2 Methods

The class vtkTableAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTableAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTableAlgorithm = obj.NewInstance ()`
- `vtkTableAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkTable = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkTable = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.206 vtkTemporalDataSet

31.206.1 Usage

vtkTemporalDataSet is a vtkCompositeDataSet that stores multiple time steps of data.

To create an instance of class vtkTemporalDataSet, simply invoke its constructor as follows

```
obj = vtkTemporalDataSet
```

31.206.2 Methods

The class vtkTemporalDataSet has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalDataSet class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`

- `vtkTemporalDataSet = obj.NewInstance ()`
- `vtkTemporalDataSet = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Set the number of time steps in theis dataset
- `obj.SetNumberOfTimeSteps (int numLevels)` - Returns the number of time steps.
- `int = obj.GetNumberOfTimeSteps ()` - Set a data object as a timestep. Cannot be vtkTemporalDataSet.
- `obj.SetTimeStep (int timestep, vtkDataObject dobj)` - Set a data object as a timestep. Cannot be vtkTemporalDataSet.
- `vtkDataObject = obj.GetTimeStep (int timestep)` - Get timestep meta-data.
- `vtkInformation = obj.GetMetaData (int timestep)` - Returns if timestep meta-data is present.
- `int = obj.HasMetaData (int timestep)` - The extent type is a 3D extent
- `int = obj.GetExtentType ()` - The extent type is a 3D extent
- `vtkInformation = obj.GetMetaData (vtkCompositeDataIterator iter)` - Unhiding superclass method.
- `int = obj.HasMetaData (vtkCompositeDataIterator iter)`

31.207 vtkTemporalDataSetAlgorithm

31.207.1 Usage

Algorithms that take any type of data object (including composite dataset) and produce a vtkTemporalDataSet in the output can subclass from this class.

To create an instance of class vtkTemporalDataSetAlgorithm, simply invoke its constructor as follows

```
obj = vtkTemporalDataSetAlgorithm
```

31.207.2 Methods

The class vtkTemporalDataSetAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTemporalDataSetAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTemporalDataSetAlgorithm = obj.NewInstance ()`
- `vtkTemporalDataSetAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkTemporalDataSet = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkTemporalDataSet = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.208 vtkTetra

31.208.1 Usage

vtkTetra is a concrete implementation of vtkCell to represent a 3D tetrahedron. vtkTetra uses the standard isoparametric shape functions for a linear tetrahedron. The tetrahedron is defined by the four points (0-3); where (0,1,2) is the base of the tetrahedron which, using the right hand rule, forms a triangle whose normal points in the direction of the fourth point.

To create an instance of class vtkTetra, simply invoke its constructor as follows

```
obj = vtkTetra
```

31.208.2 Methods

The class vtkTetra has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTetra class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTetra = obj.NewInstance ()`
- `vtkTetra = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - Returns the set of points that are on the boundary of the tetrahedron that are closest parametrically to the point specified. This may include faces, edges, or vertices.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the tetrahedron in parametric coordinates.

- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned.
- `obj.InterpolateFunctions (double pcoords[3], double weights[4])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[12])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.209 vtkThreadedImageAlgorithm

31.209.1 Usage

vtkThreadedImageAlgorithm is a filter superclass that hides much of the pipeline complexity. It handles breaking the pipeline execution into smaller extents so that the vtkImageData limits are observed. It also provides support for multithreading. If you don't need any of this functionality, consider using vtkSimpleImageToImageAlgorithm instead. .SECTION See also vtkSimpleImageToImageAlgorithm

To create an instance of class vtkThreadedImageAlgorithm, simply invoke its constructor as follows

```
obj = vtkThreadedImageAlgorithm
```

31.209.2 Methods

The class vtkThreadedImageAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkThreadedImageAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkThreadedImageAlgorithm = obj.NewInstance ()`
- `vtkThreadedImageAlgorithm = obj.SafeDownCast (vtkObject o)`
- `obj.ThreadedExecute (vtkImageData inData, vtkImageData outData, int extent[6], int threadId)`
- `obj.SetNumberOfThreads (int )` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreadsMinValue ()` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreadsMaxValue ()` - Get/Set the number of threads to create when rendering
- `int = obj.GetNumberOfThreads ()` - Get/Set the number of threads to create when rendering
- `int = obj.SplitExtent (int splitExt[6], int startExt[6], int num, int total)` - Putting this here until I merge graphics and imaging streaming.

31.210 vtkTree

31.210.1 Usage

vtkTree is a connected directed graph with no cycles. A tree is a type of directed graph, so works with all graph algorithms.

vtkTree is a read-only data structure. To construct a tree, create an instance of vtkMutableDirectedGraph. Add vertices and edges with AddVertex() and AddEdge(). You may alternately start by adding a single vertex as the root then call graph-¿AddChild(parent) which adds a new vertex and connects the parent to the child. The tree MUST have all edges in the proper direction, from parent to child. After building the tree, call tree-¿CheckedShallowCopy(graph) to copy the structure into a vtkTree. This method will return false if the graph is an invalid tree.

vtkTree provides some convenience methods for obtaining the parent and children of a vertex, for finding the root, and determining if a vertex is a leaf (a vertex with no children).

To create an instance of class vtkTree, simply invoke its constructor as follows

```
obj = vtkTree
```

31.210.2 Methods

The class vtkTree has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTree class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTree = obj.NewInstance ()`
- `vtkTree = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Get the root vertex of the tree.
- `vtkIdType = obj.GetRoot ()` - Get the root vertex of the tree.
- `vtkIdType = obj.GetNumberOfChildren (vtkIdType v)` - Get the i-th child of a parent vertex.
- `vtkIdType = obj.GetChild (vtkIdType v, vtkIdType i)` - Get the i-th child of a parent vertex.
- `obj.GetChildren (vtkIdType v, vtkAdjacentVertexIterator it)` - Get the parent of a vertex.
- `vtkIdType = obj.GetParent (vtkIdType v)` - Get the parent of a vertex.
- `vtkIdType = obj.GetLevel (vtkIdType v)` - Get the level of the vertex in the tree. The root vertex has level 0. Returns -1 if the vertex id is ¡ 0 or greater than the number of vertices in the tree.
- `bool = obj.IsLeaf (vtkIdType vertex)` - Return whether the vertex is a leaf (i.e. it has no children).
- `obj.ReorderChildren (vtkIdType parent, vtkIdTypeArray children)` - Reorder the children of a parent vertex. The children array must contain all the children of parent, just in a different order. This does not change the topology of the tree.

31.211 vtkTreeAlgorithm

31.211.1 Usage

vtkTreeAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline edgehitecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be Tree. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation.

For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

To create an instance of class vtkTreeAlgorithm, simply invoke its constructor as follows

```
obj = vtkTreeAlgorithm
```

31.211.2 Methods

The class vtkTreeAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeAlgorithm = obj.NewInstance ()`
- `vtkTreeAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkTree = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkTree = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.212 vtkTreeDFSIterator

31.212.1 Usage

vtkTreeDFSIterator performs a depth first seedgeh of a tree. First, you must set the tree on which you are going to iterate, and set the starting vertex and mode. The mode is either DISCOVER, in which case vertices are visited as they are first reached, or FINISH, in which case vertices are visited when they are done, i.e. all adjacent vertices have been discovered already.

After setting up the iterator, the normal mode of operation is to set up a ¡code¿while(iter-¿HasNext())¡/code¿ loop, with the statement ¡code¿vtkIdType vertex = iter-¿Next()¡/code¿ inside the loop.

To create an instance of class vtkTreeDFSIterator, simply invoke its constructor as follows

```
obj = vtkTreeDFSIterator
```

31.212.2 Methods

The class vtkTreeDFSIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTreeDFSIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTreeDFSIterator = obj.NewInstance ()`
- `vtkTreeDFSIterator = obj.SafeDownCast (vtkObject o)`
- `obj.SetTree (vtkTree graph)` - Set the graph to iterate over.
- `obj.SetMode (int mode)` - Set the visit mode of the iterator. Mode can be DISCOVER (0): Order by discovery time FINISH (1): Order by finish time Default is DISCOVER. Use DISCOVER for top-down algorithms where parents need to be processed before children. Use FINISH for bottom-up algorithms where children need to be processed before parents.
- `int = obj.GetMode ()` - Set the visit mode of the iterator. Mode can be DISCOVER (0): Order by discovery time FINISH (1): Order by finish time Default is DISCOVER. Use DISCOVER for top-down algorithms where parents need to be processed before children. Use FINISH for bottom-up algorithms where children need to be processed before parents.
- `obj.SetStartVertex (vtkIdType vertex)` - The start vertex of the seedgeh. The tree iterator will only iterate over the subtree rooted at vertex. If not set (or set to a negative value), starts at the root of the tree.
- `vtkIdType = obj.GetStartVertex ()` - The start vertex of the seedgeh. The tree iterator will only iterate over the subtree rooted at vertex. If not set (or set to a negative value), starts at the root of the tree.
- `vtkIdType = obj.Next ()` - The next vertex visited in the graph.
- `bool = obj.HasNext ()` - Return true when all vertices have been visited.

31.213 vtkTriangle

31.213.1 Usage

vtkTriangle is a concrete implementation of vtkCell to represent a triangle located in 3-space.

To create an instance of class vtkTriangle, simply invoke its constructor as follows

```
obj = vtkTriangle
```

31.213.2 Methods

The class vtkTriangle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTriangle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTriangle = obj.NewInstance ()`

- `vtkTriangle = obj.SafeDownCast (vtkObject o)`
- `vtkCell = obj.GetEdge (int edgeId)` - Get the edge specified by edgeId (range 0 to 2) and return that edge's coordinates.
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `double = obj.ComputeArea ()` - A convenience function to compute the area of a vtkTriangle.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this triangle using scalar value provided. Like contouring, except that it cuts the triangle to produce other triangles.
- `obj.InterpolateFunctions (double pcoords[3], double sf[3])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[6])` - Return the ids of the vertices defining edge ('edgeId'). Ids are related to the cell, not to the dataset.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the triangle in parametric coordinates.
- `double = obj.GetParametricDistance (double pcoords[3])` - Return the distance of the parametric coordinate provided to the cell. If inside the cell, a distance of zero is returned.

31.214 vtkTriangleStrip

31.214.1 Usage

vtkTriangleStrip is a concrete implementation of vtkCell to represent a 2D triangle strip. A triangle strip is a compact representation of triangles connected edge to edge in strip fashion. The connectivity of a triangle strip is three points defining an initial triangle, then for each additional triangle, a single point that, combined with the previous two points, defines the next triangle.

To create an instance of class vtkTriangleStrip, simply invoke its constructor as follows

```
obj = vtkTriangleStrip
```

31.214.2 Methods

The class vtkTriangleStrip has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTriangleStrip class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTriangleStrip = obj.NewInstance ()`
- `vtkTriangleStrip = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `int = obj.IsPrimaryCell ()` - Return the center of the point cloud in parametric coordinates.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the point cloud in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs)` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

31.215 vtkTriQuadraticHexahedron

31.215.1 Usage

vtkTriQuadraticHexahedron is a concrete implementation of vtkNonLinearCell to represent a three-dimensional, 27-node isoparametric triquadratic hexahedron. The interpolation is the standard finite element, triquadratic isoparametric shape function. The cell includes 8 edge nodes, 12 mid-edge nodes, 6 mid-face nodes and one mid-volume node. The ordering of the 27 points defining the cell is point ids (0-7,8-19, 20-25, 26) where point ids 0-7 are the eight corner vertices of the cube; followed by twelve midedge nodes (8-19); followed by 6 mid-face nodes (20-25) and the last node (26) is the mid-volume node. Note that these midedge

nodes correspond lie on the edges defined by (0,1), (1,2), (2,3), (3,0), (4,5), (5,6), (6,7), (7,4), (0,4), (1,5), (2,6), (3,7). The mid-surface nodes lies on the faces defined by (first edge nodes id's, than mid-edge nodes id's): (0,1,5,4;8,17,12,16), (1,2,6,5;9,18,13,17), (2,3,7,6,10,19,14,18), (3,0,4,7;11,16,15,19), (0,1,2,3;8,9,10,11), (4,5,6,7;12,13,14,15). The last point lies in the center of the cell (0,1,2,3,4,5,6,7).

```

To create an instance of class vtkTriQuadraticHexahedron, simply invoke its constructor as follows

```
obj = vtkTriQuadraticHexahedron
```

31.215.2 Methods

The class vtkTriQuadraticHexahedron has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTriQuadraticHexahedron class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTriQuadraticHexahedron = obj.NewInstance ()`
- `vtkTriQuadraticHexahedron = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.

- `int = obj.GetNumberOfFaces ()` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - Implement the vtkCell API. See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)`
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr`
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)`
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)`
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - Clip this triquadratic hexahedron using scalar value provided. Like contouring, except that it cuts the hex to produce linear tetrahedron.
- `obj.InterpolateFunctions (double pcoords[3], double weights[27])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[81])` - Return the ids of the vertices defining edge/face ('edgeId'/'faceId'). Ids are related to the cell, not to the dataset.

31.216 vtkTrivialProducer

31.216.1 Usage

vtkTrivialProducer allows stand-alone data objects to be connected as inputs in a pipeline. All data objects that are connected to a pipeline involving vtkAlgorithm must have a producer. This trivial producer allows data objects that are hand-constructed in a program without another vtk producer to be connected.

To create an instance of class vtkTrivialProducer, simply invoke its constructor as follows

```
obj = vtkTrivialProducer
```

31.216.2 Methods

The class vtkTrivialProducer has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkTrivialProducer class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkTrivialProducer = obj.NewInstance ()`
- `vtkTrivialProducer = obj.SafeDownCast (vtkObject o)`
- `obj.SetOutput (vtkDataObject output)` - Set the data object that is "produced" by this producer. It is never really modified.
- `long = obj.GetMTime ()` - The modified time of this producer is the newer of this object or the assigned output.

31.217 vtkUndirectedGraph

31.217.1 Usage

vtkUndirectedGraph is a collection of vertices along with a collection of undirected edges (they connect two vertices in no particular order). ShallowCopy(), DeepCopy(), CheckedShallowCopy(), CheckedDeepCopy() accept instances of vtkUndirectedGraph and vtkMutableUndirectedGraph. GetOutEdges(v, it) and GetInEdges(v, it) return the same list of edges, which is the list of all edges which have a v as an endpoint. GetInDegree(v), GetOutDegree(v) and GetDegree(v) all return the full degree of vertex v.

vtkUndirectedGraph is read-only. To create an undirected graph, use an instance of vtkMutableUndirectedGraph, then you may set the structure to a vtkUndirectedGraph using ShallowCopy().

To create an instance of class vtkUndirectedGraph, simply invoke its constructor as follows

```
obj = vtkUndirectedGraph
```

31.217.2 Methods

The class vtkUndirectedGraph has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUndirectedGraph class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUndirectedGraph = obj.NewInstance ()`
- `vtkUndirectedGraph = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Returns the full degree of the vertex.
- `vtkIdType = obj.GetInDegree (vtkIdType v)` - Returns the full degree of the vertex.
- `obj.GetInEdge (vtkIdType v, vtkIdType i, vtkGraphEdge e)` - Initialize the iterator to get the incoming edges to a vertex. For an undirected graph, this is all incident edges.
- `obj.GetInEdges (vtkIdType v, vtkInEdgeIterator it)`

31.218 vtkUndirectedGraphAlgorithm

31.218.1 Usage

vtkUndirectedGraphAlgorithm is a convenience class to make writing algorithms easier. It is also designed to help transition old algorithms to the new pipeline edgehitecture. There are some assumptions and defaults made by this class you should be aware of. This class defaults such that your filter will have one input port and one output port. If that is not the case simply change it with SetNumberOfInputPorts etc. See this class constructor for the default. This class also provides a FillInputPortInfo method that by default says that all inputs will be Graph. If that isn't the case then please override this method in your subclass. This class breaks out the downstream requests into separate functions such as ExecuteData and ExecuteInformation. For new algorithms you should implement RequestData(request, inputVec, outputVec) but for older filters there is a default implementation that calls the old ExecuteData(output) signature. For even older filters that don't implement ExecuteData the default implementation calls the even older Execute() signature.

.SECTION Thanks Thanks to Patricia Crossno, Ken Moreland, Andrew Wilson and Brian Wylie from Sandia National Laboratories for their help in developing this class.

To create an instance of class vtkUndirectedGraphAlgorithm, simply invoke its constructor as follows

```
obj = vtkUndirectedGraphAlgorithm
```

31.218.2 Methods

The class vtkUndirectedGraphAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUndirectedGraphAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUndirectedGraphAlgorithm = obj.NewInstance ()`
- `vtkUndirectedGraphAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkUndirectedGraph = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkUndirectedGraph = obj.GetOutput (int index)` - Get the output data object for a port on this algorithm.
- `obj.SetInput (vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int index, vtkDataObject obj)` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.

31.219 vtkUniformGrid

31.219.1 Usage

vtkUniformGrid is a subclass of vtkImageData. In addition to all the image data functionality, it supports blanking.

To create an instance of class vtkUniformGrid, simply invoke its constructor as follows

```
obj = vtkUniformGrid
```

31.219.2 Methods

The class vtkUniformGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUniformGrid class.

- `string = obj.GetClassName ()` - Construct an empty uniform grid.
- `int = obj.IsA (string name)` - Construct an empty uniform grid.
- `vtkUniformGrid = obj.NewInstance ()` - Construct an empty uniform grid.
- `vtkUniformGrid = obj.SafeDownCast (vtkObject o)` - Construct an empty uniform grid.
- `obj.CopyStructure (vtkDataSet ds)` - Copy the geometric and topological structure of an input image data object.

- `int = obj.GetDataObjectType ()` - Return what type of dataset this is.
- `vtkCell = obj.GetCell (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetCellType (vtkIdType cellId)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.Initialize ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `int = obj.GetMaxCellSize ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.BlankPoint (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off points in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `obj.UnBlankPoint (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off points in the structured grid, and hence the cells connected to them. These methods should be called only after the dimensions of the grid are set.
- `obj.BlankCell (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off cells in the structured grid. These methods should be called only after the dimensions of the grid are set.
- `obj.UnBlankCell (vtkIdType ptId)` - Methods for supporting blanking of cells. Blanking turns on or off cells in the structured grid. These methods should be called only after the dimensions of the grid are set.
- `vtkUnsignedCharArray = obj.GetPointVisibilityArray ()` - Get the array that defines the blanking (visibility) of each point.
- `obj.SetPointVisibilityArray (vtkUnsignedCharArray pointVisibility)` - Set an array that defines the (blanking) visibility of the points in the grid. Make sure that length of the visibility array matches the number of points in the grid.
- `vtkUnsignedCharArray = obj.GetCellVisibilityArray ()` - Get the array that defines the blanking (visibility) of each cell.
- `obj.SetCellVisibilityArray (vtkUnsignedCharArray pointVisibility)` - Set an array that defines the (blanking) visibility of the cells in the grid. Make sure that length of the visibility array matches the number of points in the grid.
- `char = obj.IsPointVisible (vtkIdType ptId)` - Return non-zero value if specified point is visible. These methods should be called only after the dimensions of the grid are set.
- `char = obj.IsCellVisible (vtkIdType cellId)` - Return non-zero value if specified cell is visible. These methods should be called only after the dimensions of the grid are set.

- `char = obj.GetPointBlanking ()` - Returns 1 if there is any visibility constraint on the points, 0 otherwise.
- `char = obj.GetCellBlanking ()` - Returns 1 if there is any visibility constraint on the cells, 0 otherwise.
- `vtkImageData = obj.NewImageDataCopy ()`

31.220 vtkUnstructuredGrid

31.220.1 Usage

vtkUnstructuredGrid is a data object that is a concrete implementation of vtkDataSet. vtkUnstructuredGrid represents any combinations of any cell types. This includes 0D (e.g., points), 1D (e.g., lines, polylines), 2D (e.g., triangles, polygons), and 3D (e.g., hexahedron, tetrahedron).

To create an instance of class vtkUnstructuredGrid, simply invoke its constructor as follows

```
obj = vtkUnstructuredGrid
```

31.220.2 Methods

The class vtkUnstructuredGrid has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGrid class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGrid = obj.NewInstance ()`
- `vtkUnstructuredGrid = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetDataObjectType ()` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `obj.Allocate (vtkIdType numCells, int extSize)` - Standard vtkDataSet API methods. See vtkDataSet for more information.
- `vtkIdType = obj.InsertNextCell (int type, vtkIdList ptIds)` - Insert/create cell in object by type and list of point ids defining cell topology.
- `obj.Reset ()`
- `obj.CopyStructure (vtkDataSet ds)`
- `vtkIdType = obj.GetNumberOfCells ()`
- `vtkCell = obj.GetCell (vtkIdType cellId)`
- `obj.GetCell (vtkIdType cellId, vtkGenericCell cell)`
- `obj.GetCellBounds (vtkIdType cellId, double bounds[6])`
- `obj.GetCellPoints (vtkIdType cellId, vtkIdList ptIds)`
- `obj.GetPointCells (vtkIdType ptId, vtkIdList cellIds)`
- `int = obj.GetCellType (vtkIdType cellId)`

- `vtkUnsignedCharArray = obj.GetCellTypesArray ()`
- `vtkIdTypeArray = obj.GetCellLocationsArray ()`
- `obj.Squeeze ()`
- `obj.Initialize ()`
- `int = obj.GetMaxCellSize ()`
- `obj.BuildLinks ()`
- `vtkCellLinks = obj.GetCellLinks ()`
- `obj.SetCells (int type, vtkCellArray cells)` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `obj.SetCells (int types, vtkCellArray cells)` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `obj.SetCells (vtkUnsignedCharArray cellTypes, vtkIdTypeArray cellLocations, vtkCellArray cells)` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `vtkCellArray = obj.GetCells ()` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `obj.RemoveReferenceToCell (vtkIdType ptId, vtkIdType cellId)` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `obj.AddReferenceToCell (vtkIdType ptId, vtkIdType cellId)` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `obj.ResizeCellList (vtkIdType ptId, int size)` - Special methods specific to vtkUnstructuredGrid for defining the cells composing the dataset.
- `obj.GetCellNeighbors (vtkIdType cellId, vtkIdList ptIds, vtkIdList cellIds)` - Topological inquiry to get all cells using list of points exclusive of cell specified (e.g., cellId). THIS METHOD IS THREAD SAFE IF FIRST CALLED FROM A SINGLE THREAD AND THE DATASET IS NOT MODIFIED
- `int = obj.GetUpdateExtent ()` - We need this here to avoid hiding superclass method
- `obj.GetUpdateExtent (int extent[6])` - We need this here to avoid hiding superclass method
- `int = obj.GetPiece ()` - Set / Get the piece and the number of pieces. Similar to extent in 3D.
- `int = obj.GetNumberOfPieces ()` - Set / Get the piece and the number of pieces. Similar to extent in 3D.
- `int = obj.GetGhostLevel ()` - Get the ghost level.
- `long = obj.GetActualMemorySize ()` - Return the actual size of the data in kilobytes. This number is valid only after the pipeline has updated. The memory size returned is guaranteed to be greater than or equal to the memory required to represent the data (e.g., extra space in arrays, etc. are not included in the return value). THIS METHOD IS THREAD SAFE.
- `obj.ShallowCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkDataObject src)` - Shallow and Deep copy.
- `obj.GetIdsOfCellsOfType (int type, vtkIdTypeArray array)` - Fill vtkIdTypeArray container with list of cell Ids. This method traverses all cells and, for a particular cell type, inserts the cell Id into the container.

- `int = obj.IsHomogeneous ()` - Traverse cells and determine if cells are all of the same type.
- `obj.RemoveGhostCells (int level)` - This method will remove any cell that has a ghost level array value greater or equal to level.

31.221 vtkUnstructuredGridAlgorithm

31.221.1 Usage

To create an instance of class vtkUnstructuredGridAlgorithm, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridAlgorithm
```

31.221.2 Methods

The class vtkUnstructuredGridAlgorithm has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridAlgorithm class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridAlgorithm = obj.NewInstance ()`
- `vtkUnstructuredGridAlgorithm = obj.SafeDownCast (vtkObject o)`
- `vtkUnstructuredGrid = obj.GetOutput ()` - Get the output data object for a port on this algorithm.
- `vtkUnstructuredGrid = obj.GetOutput (int )` - Get the output data object for a port on this algorithm.
- `obj.SetOutput (vtkDataObject d)` - Get the output data object for a port on this algorithm.
- `vtkDataObject = obj.GetInput (int port)`
- `vtkDataObject = obj.GetInput ()`
- `vtkUnstructuredGrid = obj.GetUnstructuredGridInput (int port)`
- `obj.SetInput (vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.SetInput (int , vtkDataObject )` - Set an input of this algorithm. You should not override these methods because they are not the only way to connect a pipeline. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::SetInputConnection(). These methods transform the input index to the input port index, not an index of a connection within a single port.
- `obj.AddInput (vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.
- `obj.AddInput (int , vtkDataObject )` - Add an input of this algorithm. Note that these methods support old-style pipeline connections. When writing new code you should use the more general vtkAlgorithm::AddInputConnection(). See SetInput() for details.

31.222 vtkUnstructuredGridSource

31.222.1 Usage

vtkUnstructuredGridSource is an abstract class whose subclasses generate unstructured grid data.

To create an instance of class vtkUnstructuredGridSource, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridSource
```

31.222.2 Methods

The class vtkUnstructuredGridSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridSource = obj.NewInstance ()`
- `vtkUnstructuredGridSource = obj.SafeDownCast (vtkObject o)`
- `vtkUnstructuredGrid = obj.GetOutput ()` - Get the output of this source.
- `vtkUnstructuredGrid = obj.GetOutput (int idx)` - Get the output of this source.
- `obj.SetOutput (vtkUnstructuredGrid output)` - Get the output of this source.

31.223 vtkUnstructuredGridToPolyDataFilter

31.223.1 Usage

vtkUnstructuredGridToPolyDataFilter is an abstract filter class whose subclasses take as input datasets of type vtkUnstructuredGrid and generate polygonal data on output.

To create an instance of class vtkUnstructuredGridToPolyDataFilter, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridToPolyDataFilter
```

31.223.2 Methods

The class vtkUnstructuredGridToPolyDataFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridToPolyDataFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridToPolyDataFilter = obj.NewInstance ()`
- `vtkUnstructuredGridToPolyDataFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkUnstructuredGrid input)` - Set / get the input data or filter.
- `vtkUnstructuredGrid = obj.GetInput ()` - Set / get the input data or filter.
- `obj.ComputeInputUpdateExtents (vtkDataObject output)` - Do not let datasets return more than requested.

31.224 vtkUnstructuredGridToUnstructuredGridFilter

31.224.1 Usage

To create an instance of class vtkUnstructuredGridToUnstructuredGridFilter, simply invoke its constructor as follows

```
obj = vtkUnstructuredGridToUnstructuredGridFilter
```

31.224.2 Methods

The class vtkUnstructuredGridToUnstructuredGridFilter has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkUnstructuredGridToUnstructuredGridFilter class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkUnstructuredGridToUnstructuredGridFilter = obj.NewInstance ()`
- `vtkUnstructuredGridToUnstructuredGridFilter = obj.SafeDownCast (vtkObject o)`
- `obj.SetInput (vtkUnstructuredGrid input)` - Set / get the input Grid or filter.
- `vtkUnstructuredGrid = obj.GetInput ()` - Set / get the input Grid or filter.
- `int = obj.FillInputPortInformation (int , vtkInformation )`

31.225 vtkVertex

31.225.1 Usage

vtkVertex is a concrete implementation of vtkCell to represent a 3D point.

To create an instance of class vtkVertex, simply invoke its constructor as follows

```
obj = vtkVertex
```

31.225.2 Methods

The class vtkVertex has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVertex class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVertex = obj.NewInstance ()`
- `vtkVertex = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.

- `vtkCell = obj.GetEdge (int )` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int )` - See the vtkCell API for descriptions of these methods.
- `obj.Clip (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArray` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - Given parametric coordinates of a point, return the closest cell boundary, and whether the point is inside or outside of the cell. The cell boundary is defined by a list of points (pts) that specify a vertex (1D cell). If the return value of the method is != 0, then the point is inside the cell.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellArr` - Generate contouring primitives. The scalar list cellScalars are scalar values at each cell point. The point locator is essentially a points list that merges points as they are inserted (i.e., prevents duplicates).
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the triangle in parametric coordinates.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - Triangulate the vertex. This method fills pts and ptIds with information from the only point in the vertex.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - Get the derivative of the vertex. Returns (0.0, 0.0, 0.0) for all dimensions.
- `obj.InterpolateFunctions (double pcoords[3], double weights[1])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[3])`

31.226 vtkVertexListIterator

31.226.1 Usage

vtkVertexListIterator iterates through all vertices in a graph. Create an instance of this and call graph-¿GetVertices(it) to initialize this iterator. You may alternately call SetGraph() to initialize the iterator.

To create an instance of class vtkVertexListIterator, simply invoke its constructor as follows

```
obj = vtkVertexListIterator
```

31.226.2 Methods

The class vtkVertexListIterator has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVertexListIterator class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVertexListIterator = obj.NewInstance ()`
- `vtkVertexListIterator = obj.SafeDownCast (vtkObject o)`
- `obj.SetGraph (vtkGraph graph)` - Setup the iterator with a graph.
- `vtkGraph = obj.GetGraph ()` - Get the graph associated with this iterator.
- `vtkIdType = obj.Next ()` - Whether this iterator has more edges.
- `bool = obj.HasNext ()`

31.227 vtkViewDependentErrorMetric

31.227.1 Usage

It is a concrete error metric, based on a geometric criterium in the screen space: the variation of the projected edge from a projected straight line

To create an instance of class vtkViewDependentErrorMetric, simply invoke its constructor as follows

```
obj = vtkViewDependentErrorMetric
```

31.227.2 Methods

The class vtkViewDependentErrorMetric has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkViewDependentErrorMetric class.

- `string = obj.GetClassName ()` - Standard VTK type and error macros.
- `int = obj.IsA (string name)` - Standard VTK type and error macros.
- `vtkViewDependentErrorMetric = obj.NewInstance ()` - Standard VTK type and error macros.
- `vtkViewDependentErrorMetric = obj.SafeDownCast (vtkObject o)` - Standard VTK type and error macros.
- `double = obj.GetPixelTolerance ()` - Return the squared screen-based geometric accurary measured in pixels. An accuracy less or equal to 0.25 ($0.5\hat{2}$) ensures that the screen-space interpolation of a mid-point matchs exactly with the projection of the mid-point (a value less than 1 but greater than 0.25 is not enough, because of 8-neighbors). Maybe it is useful for lower accuracy in case of anti-aliasing?
- `obj.SetPixelTolerance (double value)` - Set the squared screen-based geometric accuracy measured in pixels. Subdivision will be required if the square distance between the projection of the real point and the straight line passing through the projection of the vertices of the edge is greater than 'value'. For instance, 0.25 will give better result than 1.
- `vtkViewport = obj.GetViewport ()` - Set/Get the renderer with 'renderer' on which the error metric is based. The error metric use the active camera of the renderer.
- `obj.SetViewport (vtkViewport viewport)` - Set/Get the renderer with 'renderer' on which the error metric is based. The error metric use the active camera of the renderer.
- `int = obj.RequiresEdgeSubdivision (double leftPoint, double midPoint, double rightPoint, double alp` - Does the edge need to be subdivided according to the distance between the line passing through its endpoints in screen space and the projection of its mid point? The edge is defined by its 'leftPoint' and its 'rightPoint'. 'leftPoint', 'midPoint' and 'rightPoint' have to be initialized before calling RequiresEdgeSubdivision(). Their format is global coordinates, parametric coordinates and point centered attributes: xyx rst abc de... 'alpha' is the normalized abscissa of the midpoint along the edge. (close to 0 means close to the left point, close to 1 means close to the right point)

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6
- `double = obj.GetError (double leftPoint, double midPoint, double rightPoint, double alpha)` - Return the error at the mid-point. The type of error depends on the state of the concrete error metric. For instance, it can return an absolute or relative error metric. See RequiresEdgeSubdivision() for a description of the arguments.

  =GetAttributeCollection()-¿GetNumberOfPointCenteredComponents()+6

31.228 vtkViewport

31.228.1 Usage

vtkViewport provides an abstract specification for Viewports. A Viewport is an object that controls the rendering process for objects. Rendering is the process of converting geometry, a specification for lights, and a camera view into an image. vtkViewport also performs coordinate transformation between world coordinates, view coordinates (the computer graphics rendering coordinate system), and display coordinates (the actual screen coordinates on the display device). Certain advanced rendering features such as two-sided lighting can also be controlled.

To create an instance of class vtkViewport, simply invoke its constructor as follows

```
obj = vtkViewport
```

31.228.2 Methods

The class vtkViewport has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkViewport class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkViewport = obj.NewInstance ()`
- `vtkViewport = obj.SafeDownCast (vtkObject o)`
- `obj.AddViewProp (vtkProp )` - Add a prop to the list of props. Prop is the superclass of all actors, volumes, 2D actors, composite props etc.
- `vtkPropCollection = obj.GetViewProps ()` - Return any props in this viewport.
- `int = obj.HasViewProp (vtkProp )` - Query if a prop is in the list of props.
- `obj.RemoveViewProp (vtkProp )` - Remove an actor from the list of actors.
- `obj.RemoveAllViewProps (void )` - Remove all actors from the list of actors.
- `obj.AddActor2D (vtkProp p)` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `obj.RemoveActor2D (vtkProp p)` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `vtkActor2DCollection = obj.GetActors2D ()` - Add/Remove different types of props to the renderer. These methods are all synonyms to AddViewProp and RemoveViewProp. They are here for convenience and backwards compatibility.
- `obj.SetBackground (double , double , double )` - Set/Get the background color of the rendering screen using an rgb color specification.
- `obj.SetBackground (double  a[3])` - Set/Get the background color of the rendering screen using an rgb color specification.
- `double = obj. GetBackground ()` - Set/Get the background color of the rendering screen using an rgb color specification.

- `obj.SetBackground2 (double , double , double )` - Set/Get the second background color of the rendering screen for gradient backgrounds using an rgb color specification.
- `obj.SetBackground2 (double a[3])` - Set/Get the second background color of the rendering screen for gradient backgrounds using an rgb color specification.
- `double = obj. GetBackground2 ()` - Set/Get the second background color of the rendering screen for gradient backgrounds using an rgb color specification.
- `obj.SetGradientBackground (bool )` - Set/Get whether this viewport should have a gradient background using the Background (top) and Background2 (bottom) colors. Default is off.
- `bool = obj.GetGradientBackground ()` - Set/Get whether this viewport should have a gradient background using the Background (top) and Background2 (bottom) colors. Default is off.
- `obj.GradientBackgroundOn ()` - Set/Get whether this viewport should have a gradient background using the Background (top) and Background2 (bottom) colors. Default is off.
- `obj.GradientBackgroundOff ()` - Set/Get whether this viewport should have a gradient background using the Background (top) and Background2 (bottom) colors. Default is off.
- `obj.SetAspect (double , double )` - Set the aspect ratio of the rendered image. This is computed automatically and should not be set by the user.
- `obj.SetAspect (double a[2])` - Set the aspect ratio of the rendered image. This is computed automatically and should not be set by the user.
- `double = obj. GetAspect ()` - Set the aspect ratio of the rendered image. This is computed automatically and should not be set by the user.
- `obj.ComputeAspect ()` - Set the aspect ratio of the rendered image. This is computed automatically and should not be set by the user.
- `obj.SetPixelAspect (double , double )` - Set the aspect ratio of a pixel in the rendered image. This factor permits the image to rendered anisotropically (i.e., stretched in one direction or the other).
- `obj.SetPixelAspect (double a[2])` - Set the aspect ratio of a pixel in the rendered image. This factor permits the image to rendered anisotropically (i.e., stretched in one direction or the other).
- `double = obj. GetPixelAspect ()` - Set the aspect ratio of a pixel in the rendered image. This factor permits the image to rendered anisotropically (i.e., stretched in one direction or the other).
- `obj.SetViewport (double , double , double , double )` - Specify the viewport for the Viewport to draw in the rendering window. Coordinates are expressed as (xmin,ymin,xmax,ymax), where each coordinate is 0 ¡= coordinate ¡= 1.0.
- `obj.SetViewport (double a[4])` - Specify the viewport for the Viewport to draw in the rendering window. Coordinates are expressed as (xmin,ymin,xmax,ymax), where each coordinate is 0 ¡= coordinate ¡= 1.0.
- `double = obj. GetViewport ()` - Specify the viewport for the Viewport to draw in the rendering window. Coordinates are expressed as (xmin,ymin,xmax,ymax), where each coordinate is 0 ¡= coordinate ¡= 1.0.
- `obj.SetDisplayPoint (double , double , double )` - Set/get a point location in display (or screen) coordinates. The lower left corner of the window is the origin and y increases as you go up the screen.
- `obj.SetDisplayPoint (double a[3])` - Set/get a point location in display (or screen) coordinates. The lower left corner of the window is the origin and y increases as you go up the screen.

- `double = obj. GetDisplayPoint ()` - Set/get a point location in display (or screen) coordinates. The lower left corner of the window is the origin and y increases as you go up the screen.
- `obj.SetViewPoint (double , double , double )` - Specify a point location in view coordinates. The origin is in the middle of the viewport and it extends from -1 to 1 in all three dimensions.
- `obj.SetViewPoint (double a[3])` - Specify a point location in view coordinates. The origin is in the middle of the viewport and it extends from -1 to 1 in all three dimensions.
- `double = obj. GetViewPoint ()` - Specify a point location in view coordinates. The origin is in the middle of the viewport and it extends from -1 to 1 in all three dimensions.
- `obj.SetWorldPoint (double , double , double , double )` - Specify a point location in world coordinates. This method takes homogeneous coordinates.
- `obj.SetWorldPoint (double a[4])` - Specify a point location in world coordinates. This method takes homogeneous coordinates.
- `double = obj. GetWorldPoint ()` - Specify a point location in world coordinates. This method takes homogeneous coordinates.
- `double = obj.GetCenter ()` - Return the center of this viewport in display coordinates.
- `int = obj.IsInViewport (int x, int y)` - Is a given display point in this Viewport's viewport.
- `vtkWindow = obj.GetVTKWindow ()` - Return the vtkWindow that owns this vtkViewport.
- `obj.DisplayToView ()` - Convert display coordinates to view coordinates.
- `obj.ViewToDisplay ()` - Convert view coordinates to display coordinates.
- `obj.WorldToView ()` - Convert world point coordinates to view coordinates.
- `obj.ViewToWorld ()` - Convert view point coordinates to world coordinates.
- `obj.DisplayToWorld ()` - Convert display (or screen) coordinates to world coordinates.
- `obj.WorldToDisplay ()` - Convert world point coordinates to display (or screen) coordinates.
- `int = obj.GetSize ()` - Get the size and origin of the viewport in display coordinates. Note: if the window has not yet been realized, GetSize() and GetOrigin() return (0,0).
- `int = obj.GetOrigin ()` - Get the size and origin of the viewport in display coordinates. Note: if the window has not yet been realized, GetSize() and GetOrigin() return (0,0).
- `obj.GetTiledSize (int width, int height)` - Get the size and origin of the viewport in display coordinates. Note: if the window has not yet been realized, GetSize() and GetOrigin() return (0,0).
- `obj.GetTiledSizeAndOrigin (int width, int height, int lowerLeftX, int lowerLeftY)` - Get the size and origin of the viewport in display coordinates. Note: if the window has not yet been realized, GetSize() and GetOrigin() return (0,0).
- `vtkAssemblyPath = obj.PickProp (double selectionX, double selectionY)` - Return the Prop that has the highest z value at the given x, y position in the viewport. Basically, the top most prop that renders the pixel at selectionX, selectionY will be returned. If no Props are there NULL is returned. This method selects from the Viewports Prop list.
- `vtkAssemblyPath = obj.PickPropFrom (double selectionX, double selectionY, vtkPropCollection )` - Same as PickProp with two arguments, but selects from the given collection of Props instead of the Renderers props. Make sure the Props in the collection are in this renderer.

- `double = obj.GetPickX () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickY () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickWidth () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickHeight () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickX1 () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickY1 () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickX2 () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickY2 () const` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `int = obj.GetIsPicking ()` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `vtkPropCollection = obj.GetPickResultProps ()` - Methods used to return the pick (x,y) in local display coordinates (i.e., it's that same as selectionX and selectionY).
- `double = obj.GetPickedZ ()` - Return the Z value for the last picked Prop.
- `obj.RemoveProp (vtkProp )` - @deprecated Replaced by vtkViewport::RemoveViewProp() as of VTK 5.0.
- `obj.AddProp (vtkProp )` - @deprecated Replaced by vtkViewport::AddViewProp() as of VTK 5.0.
- `vtkPropCollection = obj.GetProps ()` - @deprecated Replaced by vtkViewport::GetViewProps() as of VTK 5.0.
- `int = obj.HasProp (vtkProp )` - @deprecated Replaced by vtkViewport::HasViewProp() as of VTK 5.0.
- `obj.RemoveAllProps ()` - @deprecated Replaced by vtkViewport::RemoveAllViewProps() as of VTK 5.0.

31.229 vtkVoxel

31.229.1 Usage

vtkVoxel is a concrete implementation of vtkCell to represent a 3D orthogonal parallelepiped. Unlike vtkHexahedron, vtkVoxel has interior angles of 90 degrees, and sides are parallel to coordinate axes. This results in large increases in computational performance.

To create an instance of class vtkVoxel, simply invoke its constructor as follows

```
obj = vtkVoxel
```

31.229.2 Methods

The class vtkVoxel has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkVoxel class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkVoxel = obj.NewInstance ()`
- `vtkVoxel = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `obj.InterpolateFunctions (double pcoords[3], double weights[8])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[24])` - Return the ids of the vertices defining edge/face (‘edgeId‘/‘faceId’). Ids are related to the cell, not to the dataset.

31.230 vtkWedge

31.230.1 Usage

vtkWedge is a concrete implementation of vtkCell to represent a linear 3D wedge. A wedge consists of two triangular and three quadrilateral faces and is defined by the six points (0-5). vtkWedge uses the standard isoparametric shape functions for a linear wedge. The wedge is defined by the six points (0-5) where (0,1,2) is the base of the wedge which, using the right hand rule, forms a triangle whose normal points outward (away from the triangular face (3,4,5)).

To create an instance of class vtkWedge, simply invoke its constructor as follows

```
obj = vtkWedge
```

31.230.2 Methods

The class vtkWedge has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkWedge class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkWedge = obj.NewInstance ()`
- `vtkWedge = obj.SafeDownCast (vtkObject o)`
- `int = obj.GetCellType ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetCellDimension ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfEdges ()` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetNumberOfFaces ()` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetEdge (int edgeId)` - See the vtkCell API for descriptions of these methods.
- `vtkCell = obj.GetFace (int faceId)` - See the vtkCell API for descriptions of these methods.
- `int = obj.CellBoundary (int subId, double pcoords[3], vtkIdList pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Contour (double value, vtkDataArray cellScalars, vtkIncrementalPointLocator locator, vtkCellAr` - See the vtkCell API for descriptions of these methods.
- `int = obj.Triangulate (int index, vtkIdList ptIds, vtkPoints pts)` - See the vtkCell API for descriptions of these methods.
- `obj.Derivatives (int subId, double pcoords[3], double values, int dim, double derivs)` - See the vtkCell API for descriptions of these methods.
- `int = obj.GetParametricCenter (double pcoords[3])` - Return the center of the wedge in parametric coordinates.
- `obj.InterpolateFunctions (double pcoords[3], double weights[6])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)
- `obj.InterpolateDerivs (double pcoords[3], double derivs[18])` - Compute the interpolation functions/derivatives (aka shape functions/derivatives)

Chapter 32

Visualization Toolkit Geo Vis Classes

32.1 vtkCompassRepresentation

32.1.1 Usage

This class is used to represent and render a compass.

To create an instance of class vtkCompassRepresentation, simply invoke its constructor as follows

```
obj = vtkCompassRepresentation
```

32.1.2 Methods

The class vtkCompassRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompassRepresentation class.

- `string = obj.GetClassName ()` - Standard methods for the class.
- `int = obj.IsA (string name)` - Standard methods for the class.
- `vtkCompassRepresentation = obj.NewInstance ()` - Standard methods for the class.
- `vtkCompassRepresentation = obj.SafeDownCast (vtkObject o)` - Standard methods for the class.
- `vtkCoordinate = obj.GetPoint1Coordinate ()` - Position the first end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point1Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `vtkCoordinate = obj.GetPoint2Coordinate ()` - Position the second end point of the slider. Note that this point is an instance of vtkCoordinate, meaning that Point 1 can be specified in a variety of coordinate systems, and can even be relative to another point. To set the point, you'll want to get the Point2Coordinate and then invoke the necessary methods to put it into the correct coordinate system and set the correct initial value.
- `vtkProperty2D = obj.GetRingProperty ()` - Get the slider properties. The properties of the slider when selected and unselected can be manipulated.
- `vtkProperty2D = obj.GetSelectedProperty ()` - Get the selection property. This property is used to modify the appearance of selected objects (e.g., the slider).
- `vtkTextProperty = obj.GetLabelProperty ()` - Set/Get the properties for the label and title text.

- `obj.PlaceWidget (double bounds[6])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.BuildRepresentation ()` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.StartWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.WidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.TiltWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.DistanceWidgetInteraction (double eventPos[2])` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `int = obj.ComputeInteractionState (int X, int Y, int modify)` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.Highlight (int )` - Methods to interface with the vtkSliderWidget. The PlaceWidget() method assumes that the parameter bounds[6] specifies the location in display space where the widget should be placed.
- `obj.GetActors (vtkPropCollection )`
- `obj.ReleaseGraphicsResources (vtkWindow )`
- `int = obj.RenderOverlay (vtkViewport )`
- `int = obj.RenderOpaqueGeometry (vtkViewport )`
- `obj.SetHeading (double value)`
- `double = obj.GetHeading ()`
- `obj.SetTilt (double value)`
- `double = obj.GetTilt ()`
- `obj.UpdateTilt (double time)`
- `obj.EndTilt ()`
- `obj.SetDistance (double value)`
- `double = obj.GetDistance ()`
- `obj.UpdateDistance (double time)`
- `obj.EndDistance ()`
- `obj.SetRenderer (vtkRenderer ren)`

32.2 vtkCompassWidget

32.2.1 Usage

The vtkCompassWidget is used to adjust a scalar value in an application. Note that the actual appearance of the widget depends on the specific representation for the widget.

To use this widget, set the widget representation. (the details may vary depending on the particulars of the representation).

.SECTION Event Bindings By default, the widget responds to the following VTK events (i.e., it watches the vtkRenderWindowInteractor for these events):

```
If the slider bead is selected:
  LeftButtonPressEvent - select slider
  LeftButtonReleaseEvent - release slider
  MouseMoveEvent - move slider
```

Note that the event bindings described above can be changed using this class's vtkWidgetEventTranslator. This class translates VTK events into the vtkCompassWidget's widget events:

```
vtkWidgetEvent::Select -- some part of the widget has been selected
vtkWidgetEvent::EndSelect -- the selection process has completed
vtkWidgetEvent::Move -- a request for slider motion has been invoked
```

In turn, when these widget events are processed, the vtkCompassWidget invokes the following VTK events on itself (which observers can listen for):

```
vtkCommand::StartInteractionEvent (on vtkWidgetEvent::Select)
vtkCommand::EndInteractionEvent (on vtkWidgetEvent::EndSelect)
vtkCommand::InteractionEvent (on vtkWidgetEvent::Move)
```

To create an instance of class vtkCompassWidget, simply invoke its constructor as follows

```
obj = vtkCompassWidget
```

32.2.2 Methods

The class vtkCompassWidget has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkCompassWidget class.

- `string = obj.GetClassName ()` - Standard macros.
- `int = obj.IsA (string name)` - Standard macros.
- `vtkCompassWidget = obj.NewInstance ()` - Standard macros.
- `vtkCompassWidget = obj.SafeDownCast (vtkObject o)` - Standard macros.
- `obj.SetRepresentation (vtkCompassRepresentation r)` - Create the default widget representation if one is not set.
- `obj.CreateDefaultRepresentation ()` - Create the default widget representation if one is not set.
- `double = obj.GetHeading ()` - Get the value for this widget.
- `obj.SetHeading (double v)` - Get the value for this widget.

- `double = obj.GetTilt ()` - Get the value for this widget.
- `obj.SetTilt (double t)` - Get the value for this widget.
- `double = obj.GetDistance ()` - Get the value for this widget.
- `obj.SetDistance (double t)` - Get the value for this widget.

32.3 vtkGeoAdaptiveArcs

32.3.1 Usage

To create an instance of class vtkGeoAdaptiveArcs, simply invoke its constructor as follows

```
obj = vtkGeoAdaptiveArcs
```

32.3.2 Methods

The class vtkGeoAdaptiveArcs has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoAdaptiveArcs class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoAdaptiveArcs = obj.NewInstance ()`
- `vtkGeoAdaptiveArcs = obj.SafeDownCast (vtkObject o)`
- `obj.SetGlobeRadius (double )` - The base radius used to determine the earth's surface. Default is the earth's radius in meters. TODO: Change this to take in a vtkGeoTerrain to get altitude.
- `double = obj.GetGlobeRadius ()` - The base radius used to determine the earth's surface. Default is the earth's radius in meters. TODO: Change this to take in a vtkGeoTerrain to get altitude.
- `obj.SetMaximumPixelSeparation (double )` - The maximum number of pixels between points on the arcs. If two adjacent points are farther than the threshold, the line segment will be subdivided such that each point is separated by at most the threshold.
- `double = obj.GetMaximumPixelSeparation ()` - The maximum number of pixels between points on the arcs. If two adjacent points are farther than the threshold, the line segment will be subdivided such that each point is separated by at most the threshold.
- `obj.SetMinimumPixelSeparation (double )` - The minimum number of pixels between points on the arcs. Points closer than the threshold will be skipped until a point farther than the minimum threshold is reached.
- `double = obj.GetMinimumPixelSeparation ()` - The minimum number of pixels between points on the arcs. Points closer than the threshold will be skipped until a point farther than the minimum threshold is reached.
- `obj.SetRenderer (vtkRenderer ren)` - The renderer used to estimate the number of pixels between points.
- `vtkRenderer = obj.GetRenderer ()` - The renderer used to estimate the number of pixels between points.
- `long = obj.GetMTime ()` - Return the modified time of this object.

32.4 vtkGeoAlignedImageRepresentation

32.4.1 Usage

vtkGeoAlignedImageRepresentation represents a high resolution image over the globle. It has an associated vtkGeoSource which is responsible for fetching new data. This class keeps the fetched data in a quad-tree structure organized by latitude and longitude.

To create an instance of class vtkGeoAlignedImageRepresentation, simply invoke its constructor as follows

```
obj = vtkGeoAlignedImageRepresentation
```

32.4.2 Methods

The class vtkGeoAlignedImageRepresentation has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoAlignedImageRepresentation class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoAlignedImageRepresentation = obj.NewInstance ()`
- `vtkGeoAlignedImageRepresentation = obj.SafeDownCast (vtkObject o)`
- `vtkGeoImageNode = obj.GetBestImageForBounds (double bounds[4])` - Retrieve the most refined image patch that covers the specified latitude and longitude bounds (lat-min, lat-max, long-min, long-max).
- `vtkGeoSource = obj.GetSource ()` - The source for this representation. This must be set first before calling GetBestImageForBounds.
- `obj.SetSource (vtkGeoSource source)` - The source for this representation. This must be set first before calling GetBestImageForBounds.
- `obj.SaveDatabase (string path)` - Serialize the database to the specified directory. Each image is stored as a .vti file. The Origin and Spacing of the saved image contain (lat-min, long-min) and (lat-max, long-max), respectively. Files are named based on their level and id within that level.

32.5 vtkGeoAlignedImageSource

32.5.1 Usage

vtkGeoAlignedImageSource uses a high resolution image to generate tiles at multiple resolutions in a hierarchy. It should be used as a source in vtkGeoAlignedImageRepresentation.

To create an instance of class vtkGeoAlignedImageSource, simply invoke its constructor as follows

```
obj = vtkGeoAlignedImageSource
```

32.5.2 Methods

The class vtkGeoAlignedImageSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoAlignedImageSource class.

- `string = obj.GetClassName ()`

- `int = obj.IsA (string name)`
- `vtkGeoAlignedImageSource = obj.NewInstance ()`
- `vtkGeoAlignedImageSource = obj.SafeDownCast (vtkObject o)`
- `bool = obj.FetchRoot (vtkGeoTreeNode node)` - Fetch the root image.
- `bool = obj.FetchChild (vtkGeoTreeNode parent, int index, vtkGeoTreeNode child)` - Fetch a child image.
- `vtkImageData = obj.GetImage ()` - The high-resolution image to be used to cover the globe.
- `obj.SetImage (vtkImageData image)` - The high-resolution image to be used to cover the globe.
- `obj.SetLatitudeRange (double , double )` - The range of the input hi-res image.
- `obj.SetLatitudeRange (double  a[2])` - The range of the input hi-res image.
- `double = obj. GetLatitudeRange ()` - The range of the input hi-res image.
- `obj.SetLongitudeRange (double , double )` - The range of the input hi-res image.
- `obj.SetLongitudeRange (double  a[2])` - The range of the input hi-res image.
- `double = obj. GetLongitudeRange ()` - The range of the input hi-res image.
- `obj.SetOverlap (double )` - The overlap of adjacent tiles.
- `double = obj.GetOverlapMinValue ()` - The overlap of adjacent tiles.
- `double = obj.GetOverlapMaxValue ()` - The overlap of adjacent tiles.
- `double = obj.GetOverlap ()` - The overlap of adjacent tiles.
- `obj.SetPowerOfTwoSize (bool )` - Whether to force image sizes to a power of two.
- `bool = obj.GetPowerOfTwoSize ()` - Whether to force image sizes to a power of two.
- `obj.PowerOfTwoSizeOn ()` - Whether to force image sizes to a power of two.
- `obj.PowerOfTwoSizeOff ()` - Whether to force image sizes to a power of two.

32.6 vtkGeoArcs

32.6.1 Usage

vtkGeoArcs produces arcs for each line in the input polydata. This is useful for viewing lines on a sphere (e.g. the earth). The arcs may "jump" above the sphere's surface using ExplodeFactor.

To create an instance of class vtkGeoArcs, simply invoke its constructor as follows

```
obj = vtkGeoArcs
```

32.6.2 Methods

The class vtkGeoArcs has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoArcs class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoArcs = obj.NewInstance ()`
- `vtkGeoArcs = obj.SafeDownCast (vtkObject o)`
- `obj.SetGlobeRadius (double )` - The base radius used to determine the earth's surface. Default is the earth's radius in meters.
- `double = obj.GetGlobeRadius ()` - The base radius used to determine the earth's surface. Default is the earth's radius in meters.
- `obj.SetExplodeFactor (double )` - Factor on which to "explode" the arcs away from the surface. A value of 0.0 keeps the values on the surface. Values larger than 0.0 push the arcs away from the surface by a distance proportional to the distance between the points. The default is 0.2.
- `double = obj.GetExplodeFactor ()` - Factor on which to "explode" the arcs away from the surface. A value of 0.0 keeps the values on the surface. Values larger than 0.0 push the arcs away from the surface by a distance proportional to the distance between the points. The default is 0.2.
- `obj.SetNumberOfSubdivisions (int )` - The number of subdivisions in the arc. The default is 20.
- `int = obj.GetNumberOfSubdivisions ()` - The number of subdivisions in the arc. The default is 20.

32.7 vtkGeoAssignCoordinates

32.7.1 Usage

Givem latitude and longitude arrays, take the values in those arrays and convert them to x,y,z world coordinates. Uses a spherical model of the earth to do the conversion. The position is in meters relative to the center of the earth.

If a transform is given, use the transform to convert latitude and longitude to the world coordinate.

To create an instance of class vtkGeoAssignCoordinates, simply invoke its constructor as follows

```
obj = vtkGeoAssignCoordinates
```

32.7.2 Methods

The class vtkGeoAssignCoordinates has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoAssignCoordinates class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoAssignCoordinates = obj.NewInstance ()`
- `vtkGeoAssignCoordinates = obj.SafeDownCast (vtkObject o)`
- `obj.SetLongitudeArrayName (string )` - Set the longitude coordinate array name.

- `string = obj.GetLongitudeArrayName ()` - Set the longitude coordinate array name.
- `obj.SetLatitudeArrayName (string )` - Set the latitude coordinate array name.
- `string = obj.GetLatitudeArrayName ()` - Set the latitude coordinate array name.
- `obj.SetGlobeRadius (double )` - The base radius to use in GLOBAL mode. Default is the earth's radius.
- `double = obj.GetGlobeRadius ()` - The base radius to use in GLOBAL mode. Default is the earth's radius.
- `obj.SetTransform (vtkAbstractTransform trans)` - The transform to use to convert coordinates of the form (lat, long, 0) to (x, y z). If this is NULL (the default), use GlobeRadius to perform a spherical embedding.
- `vtkAbstractTransform = obj.GetTransform ()` - The transform to use to convert coordinates of the form (lat, long, 0) to (x, y z). If this is NULL (the default), use GlobeRadius to perform a spherical embedding.
- `obj.SetCoordinatesInArrays (bool )` - If on, uses LatitudeArrayName and LongitudeArrayName to move values in data arrays into the points of the data set. Turn off if the lattitude and longitude are already in the points.
- `bool = obj.GetCoordinatesInArrays ()` - If on, uses LatitudeArrayName and LongitudeArrayName to move values in data arrays into the points of the data set. Turn off if the lattitude and longitude are already in the points.
- `obj.CoordinatesInArraysOn ()` - If on, uses LatitudeArrayName and LongitudeArrayName to move values in data arrays into the points of the data set. Turn off if the lattitude and longitude are already in the points.
- `obj.CoordinatesInArraysOff ()` - If on, uses LatitudeArrayName and LongitudeArrayName to move values in data arrays into the points of the data set. Turn off if the lattitude and longitude are already in the points.

32.8 vtkGeoCamera

32.8.1 Usage

I wanted to hide the normal vtkCamera API so I did not make this a subclass. The camera is a helper object. You can get a pointer to the camera, but it should be treated like a const.

To create an instance of class vtkGeoCamera, simply invoke its constructor as follows

```
obj = vtkGeoCamera
```

32.8.2 Methods

The class vtkGeoCamera has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoCamera class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoCamera = obj.NewInstance ()`

- `vtkGeoCamera = obj.SafeDownCast (vtkObject o)`
- `double = obj. GetPosition ()` - Get the world position without the origin shift.
- `obj.SetLongitude (double longitude)` - Longitude is in degrees: (-180-¿180) Relative to absolute coordinates. Rotate Longitude around z axis (earth axis),
- `double = obj.GetLongitude ()` - Longitude is in degrees: (-180-¿180) Relative to absolute coordinates. Rotate Longitude around z axis (earth axis),
- `obj.SetLatitude (double latitude)` - Latitude is in degrees: (-90-¿90) Relative to Longitude. Rotate Latitude around x axis by Latitude,
- `double = obj.GetLatitude ()` - Latitude is in degrees: (-90-¿90) Relative to Longitude. Rotate Latitude around x axis by Latitude,
- `obj.SetDistance (double Distance)` - Distance is in Meters Relative to Longitude and Latitude. above sea level ???? should we make this from center of earth ???? ???? what about equatorial bulge ????
- `double = obj.GetDistance ()` - Distance is in Meters Relative to Longitude and Latitude. above sea level ???? should we make this from center of earth ???? ???? what about equatorial bulge ????
- `obj.SetHeading (double heading)` - Heading is in degrees: (-180-¿180) Relative to Logitude and Latitude. 0 is north. 90 is east. ???? what is the standard ???? 180 is south. -90 is west. Rotate Heading around -y axis Center,
- `double = obj.GetHeading ()` - Heading is in degrees: (-180-¿180) Relative to Logitude and Latitude. 0 is north. 90 is east. ???? what is the standard ???? 180 is south. -90 is west. Rotate Heading around -y axis Center,
- `obj.SetTilt (double tilt)` - Tilt is also know as pitch. Tilt is in degrees: (0-¿90) Relative to Longitude, Latitude, and Heading. Rotate Tilt around x axis,
- `double = obj.GetTilt ()` - Tilt is also know as pitch. Tilt is in degrees: (0-¿90) Relative to Longitude, Latitude, and Heading. Rotate Tilt around x axis,
- `vtkCamera = obj.GetVTKCamera ()` - This vtk camera is updated to match this geo cameras state. It should be treated as a const and should not be modified.
- `obj.InitializeNodeAnalysis (int rendererSize[2])` - We precompute some values to speed up update of the terrain. Unfortunately, they have to be manually/explicitely updated when the camera or renderer size changes.
- `double = obj.GetNodeCoverage (vtkGeoTerrainNode node)` - This method estimates how much of the view is covered by the sphere. Returns a value from 0 to 1.
- `bool = obj.GetLockHeading ()`
- `obj.SetLockHeading (bool )`
- `obj.LockHeadingOn ()`
- `obj.LockHeadingOff ()`
- `obj.SetOriginLatitude (double oLat)` - This point is shifted to 0,0,0 to avoid openGL issues.
- `double = obj.GetOriginLatitude ()` - This point is shifted to 0,0,0 to avoid openGL issues.
- `obj.SetOriginLongitude (double oLat)` - This point is shifted to 0,0,0 to avoid openGL issues.
- `double = obj.GetOriginLongitude ()` - This point is shifted to 0,0,0 to avoid openGL issues.

- `double = obj. GetOrigin ()` - Get the rectilinear cooridinate location of the origin. This is used to shift the terrain points.
- `obj.SetOrigin (double ox, double oy, double oz)`

32.9 vtkGeoFileImageSource

32.9.1 Usage

vtkGeoFileImageSource is a vtkGeoSource that fetches .vti images from disk in a directory with a certain naming scheme. You may use vtkGeoAlignedImageRepresentation's SaveDatabase method to generate an database of image tiles in this format.

To create an instance of class vtkGeoFileImageSource, simply invoke its constructor as follows

```
obj = vtkGeoFileImageSource
```

32.9.2 Methods

The class vtkGeoFileImageSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoFileImageSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoFileImageSource = obj.NewInstance ()`
- `vtkGeoFileImageSource = obj.SafeDownCast (vtkObject o)`
- `vtkGeoFileImageSource = obj.()`
- `~vtkGeoFileImageSource = obj.()`
- `bool = obj.FetchRoot (vtkGeoTreeNode root)` - Fetches the root image representing the whole globe.
- `bool = obj.FetchChild (vtkGeoTreeNode node, int index, vtkGeoTreeNode child)` - Fetches the child image of a parent from disk.
- `obj.SetPath (string )` - The path the tiled image database.
- `string = obj.GetPath ()` - The path the tiled image database.

32.10 vtkGeoFileTerrainSource

32.10.1 Usage

vtkGeoFileTerrainSource reads geometry tiles as .vtp files from a directory that follow a certain naming convention containing the level of the patch and the position within that level. Use vtkGeoTerrain's SaveDatabase method to create a database of files in this format.

To create an instance of class vtkGeoFileTerrainSource, simply invoke its constructor as follows

```
obj = vtkGeoFileTerrainSource
```

32.10.2 Methods

The class vtkGeoFileTerrainSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoFileTerrainSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoFileTerrainSource = obj.NewInstance ()`
- `vtkGeoFileTerrainSource = obj.SafeDownCast (vtkObject o)`
- `vtkGeoFileTerrainSource = obj.()`
- `~vtkGeoFileTerrainSource = obj.()`
- `bool = obj.FetchRoot (vtkGeoTreeNode root)` - Retrieve the root geometry representing the entire globe.
- `bool = obj.FetchChild (vtkGeoTreeNode node, int index, vtkGeoTreeNode child)`
- `obj.SetPath (string )` - The path the tiled geometry database.
- `string = obj.GetPath ()` - The path the tiled geometry database.

32.11 vtkGeoGlobeSource

32.11.1 Usage

vtkGeoGlobeSource is a 3D vtkGeoSource suitable for use in vtkGeoTerrain. It uses the vtkGlobeSource filter to produce terrain patches.

To create an instance of class vtkGeoGlobeSource, simply invoke its constructor as follows

```
obj = vtkGeoGlobeSource
```

32.11.2 Methods

The class vtkGeoGlobeSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoGlobeSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoGlobeSource = obj.NewInstance ()`
- `vtkGeoGlobeSource = obj.SafeDownCast (vtkObject o)`
- `bool = obj.FetchRoot (vtkGeoTreeNode root)` - Fetches a low-resolution sphere for the entire globe.
- `bool = obj.FetchChild (vtkGeoTreeNode node, int index, vtkGeoTreeNode child)` - Fetches a refined geometry patch, a section of a sphere.

32.12 vtkGeoGraticule

32.12.1 Usage

This filter generates polydata to illustrate the distortions introduced by a map projection. The level parameter specifies the number of lines to be drawn. Poles are treated differently than other regions; hence the use of a Level parameter instead of a NumberOfLines parameter. The latitude and longitude are specified as half-open intervals with units of degrees. By default the latitude bounds are [-90,90[and the longitude bounds are [0,180[.

To create an instance of class vtkGeoGraticule, simply invoke its constructor as follows

```
obj = vtkGeoGraticule
```

32.12.2 Methods

The class vtkGeoGraticule has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoGraticule class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoGraticule = obj.NewInstance ()`
- `vtkGeoGraticule = obj.SafeDownCast (vtkObject o)`
- `obj.SetLatitudeBounds (double , double )` - The latitude bounds of the graticule.
- `obj.SetLatitudeBounds (double  a[2])` - The latitude bounds of the graticule.
- `double = obj. GetLatitudeBounds ()` - The latitude bounds of the graticule.
- `obj.SetLongitudeBounds (double , double )` - The longitude bounds of the graticule.
- `obj.SetLongitudeBounds (double  a[2])` - The longitude bounds of the graticule.
- `double = obj. GetLongitudeBounds ()` - The longitude bounds of the graticule.
- `obj.SetLatitudeLevel (int )` - The frequency level of latitude lines.
- `int = obj.GetLatitudeLevelMinValue ()` - The frequency level of latitude lines.
- `int = obj.GetLatitudeLevelMaxValue ()` - The frequency level of latitude lines.
- `int = obj.GetLatitudeLevel ()` - The frequency level of latitude lines.
- `obj.SetLongitudeLevel (int )` - The frequency level of longitude lines.
- `int = obj.GetLongitudeLevelMinValue ()` - The frequency level of longitude lines.
- `int = obj.GetLongitudeLevelMaxValue ()` - The frequency level of longitude lines.
- `int = obj.GetLongitudeLevel ()` - The frequency level of longitude lines.
- `obj.SetGeometryType (int )` - Set//get the type(s) of cells that will be output by the filter. By default, polylines are output. You may also request quadrilaterals. This is a bit vector of GeometryType enums.
- `int = obj.GetGeometryType ()` - Set//get the type(s) of cells that will be output by the filter. By default, polylines are output. You may also request quadrilaterals. This is a bit vector of GeometryType enums.

32.13 vtkGeoImageNode

32.13.1 Usage

vtkGeoImageNode contains an image tile in a multi-resolution image tree, along with metadata about that image's extents.

To create an instance of class vtkGeoImageNode, simply invoke its constructor as follows

```
obj = vtkGeoImageNode
```

32.13.2 Methods

The class vtkGeoImageNode has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoImageNode class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoImageNode = obj.NewInstance ()`
- `vtkGeoImageNode = obj.SafeDownCast (vtkObject o)`
- `vtkGeoImageNode = obj.GetChild (int idx)`
- `vtkGeoImageNode = obj.GetParent ()`
- `vtkImageData = obj.GetImage ()` - Get the image tile.
- `obj.SetImage (vtkImageData image)` - Get the image tile.
- `vtkTexture = obj.GetTexture ()` - Get the image tile.
- `obj.SetTexture (vtkTexture texture)` - Get the image tile.
- `obj.CropImageForTile (vtkImageData image, double imageLonLatExt, string prefix)` - This crops the image as small as possible while still covering the patch. The Longitude Latitude range may get bigger to reflect the actual size of the image. If prefix is specified, writes the tile to that location.
- `obj.LoadAnImage (string prefix)` - This loads the image from a tile database at the specified location.
- `obj.ShallowCopy (vtkGeoTreeNode src)` - Shallow and Deep copy.
- `obj.DeepCopy (vtkGeoTreeNode src)` - Shallow and Deep copy.
- `bool = obj.HasData ()`
- `obj.DeleteData ()` - Deletes the data associated with the node to make this an "empty" node. This is performed when the node has been unused for a certain amount of time.

32.14 vtkGeoInteractorStyle

32.14.1 Usage

vtkGeoInteractorStyle contains interaction capabilities for a geographic view including orbit, zoom, and tilt. It also includes a compass widget for changing view parameters.

To create an instance of class vtkGeoInteractorStyle, simply invoke its constructor as follows

```
obj = vtkGeoInteractorStyle
```

32.14.2 Methods

The class vtkGeoInteractorStyle has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoInteractorStyle class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoInteractorStyle = obj.NewInstance ()`
- `vtkGeoInteractorStyle = obj.SafeDownCast (vtkObject o)`
- `obj.OnEnter ()` - Event bindings
- `obj.OnLeave ()` - Event bindings
- `obj.OnMouseMove ()` - Event bindings
- `obj.OnLeftButtonUp ()` - Event bindings
- `obj.OnMiddleButtonUp ()` - Event bindings
- `obj.OnRightButtonUp ()` - Event bindings
- `obj.OnLeftButtonDown ()` - Event bindings
- `obj.OnMiddleButtonDown ()` - Event bindings
- `obj.OnRightButtonDown ()` - Event bindings
- `obj.OnChar ()` - Event bindings
- `obj.RubberBandZoom ()`
- `obj.Pan ()`
- `obj.Dolly ()`
- `obj.RedrawRectangle ()`
- `obj.StartState (int newstate)`
- `vtkGeoCamera = obj.GetGeoCamera ()`
- `obj.ResetCamera ()` - This can be used to set the camera to the standard view of the earth.
- `obj.WidgetInteraction (vtkObject caller)`
- `obj.SetInteractor (vtkRenderWindowInteractor interactor)` - Set/Get the Interactor wrapper being controlled by this object. (Satisfy superclass API.)
- `int = obj.GetRayIntersection (double origin[3], double direction[3], double intersection[3])`
- `obj.SetCurrentRenderer (vtkRenderer )` - Override to make the renderer use this camera subclass
- `bool = obj.GetLockHeading ()`
- `obj.SetLockHeading (bool )`
- `obj.LockHeadingOn ()`
- `obj.LockHeadingOff ()`
- `obj.ResetCameraClippingRange ()`

32.15 vtkGeoProjection

32.15.1 Usage

This class uses the PROJ.4 library to represent geographic coordinate projections.

To create an instance of class vtkGeoProjection, simply invoke its constructor as follows

```
obj = vtkGeoProjection
```

32.15.2 Methods

The class vtkGeoProjection has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoProjection class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoProjection = obj.NewInstance ()`
- `vtkGeoProjection = obj.SafeDownCast (vtkObject o)`
- `obj.SetName (string )` - Set/get the short name describing the projection you wish to use. This defaults to "rpoly" for no reason other than I like it. To get a list of valid values, use the GetNumberOfProjections() and GetProjectionName(int) static methods.
- `string = obj.GetName ()` - Set/get the short name describing the projection you wish to use. This defaults to "rpoly" for no reason other than I like it. To get a list of valid values, use the GetNumberOfProjections() and GetProjectionName(int) static methods.
- `int = obj.GetIndex ()` - Return the index of the current projection's type in the list of all projection types. On error, this will return -1. On success, it returns a number in [0,GetNumberOfProjections()[.
- `string = obj.GetDescription ()` - Get the description of a projection. This will return NULL if the projection name is invalid.
- `obj.SetCentralMeridian (double )` - Set/get the longitude which corresponds to the central meridian of the projection. This defaults to 0, the Greenwich Meridian.
- `double = obj.GetCentralMeridian ()` - Set/get the longitude which corresponds to the central meridian of the projection. This defaults to 0, the Greenwich Meridian.

32.16 vtkGeoProjectionSource

32.16.1 Usage

vtkGeoProjectionSource is a vtkGeoSource suitable for use in vtkTerrain2D. This source uses the libproj4 library to produce geometry patches at multiple resolutions. Each patch covers a specific region in projected space.

To create an instance of class vtkGeoProjectionSource, simply invoke its constructor as follows

```
obj = vtkGeoProjectionSource
```

32.16.2 Methods

The class vtkGeoProjectionSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoProjectionSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoProjectionSource = obj.NewInstance ()`
- `vtkGeoProjectionSource = obj.SafeDownCast (vtkObject o)`
- `vtkGeoProjectionSource = obj.()`
- `~vtkGeoProjectionSource = obj.()`
- `bool = obj.FetchRoot (vtkGeoTreeNode root)` - Blocking methods for sources with low latency.
- `bool = obj.FetchChild (vtkGeoTreeNode node, int index, vtkGeoTreeNode child)` - Blocking methods for sources with low latency.
- `int = obj.GetProjection ()` - The projection ID defining the projection. Initial value is 0.
- `obj.SetProjection (int projection)` - The projection ID defining the projection. Initial value is 0.
- `int = obj.GetMinCellsPerNode ()` - The minimum number of cells per node.
- `obj.SetMinCellsPerNode (int )` - The minimum number of cells per node.
- `vtkAbstractTransform = obj.GetTransform ()` - Return the projection transformation used by this 2D terrain.

32.17 vtkGeoRandomGraphSource

32.17.1 Usage

Generates a graph with a specified number of vertices, with the density of edges specified by either an exact number of edges or the probability of an edge. You may additionally specify whether to begin with a random tree (which enforces graph connectivity).

The filter also adds random vertex attributes called latitude and longitude. The latitude is distributed uniformly from -90 to 90, while longitude is distributed uniformly from -180 to 180.

To create an instance of class vtkGeoRandomGraphSource, simply invoke its constructor as follows

```
obj = vtkGeoRandomGraphSource
```

32.17.2 Methods

The class vtkGeoRandomGraphSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoRandomGraphSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoRandomGraphSource = obj.NewInstance ()`
- `vtkGeoRandomGraphSource = obj.SafeDownCast (vtkObject o)`

32.18 vtkGeoSampleArcs

32.18.1 Usage

vtkGeoSampleArcs refines lines in the input polygonal data so that the distance between adjacent points is no more than a threshold distance. Points are interpolated along the surface of the globe. This is useful in order to keep lines such as political boundaries from intersecting the globe and becoming invisible.

To create an instance of class vtkGeoSampleArcs, simply invoke its constructor as follows

```
obj = vtkGeoSampleArcs
```

32.18.2 Methods

The class vtkGeoSampleArcs has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoSampleArcs class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoSampleArcs = obj.NewInstance ()`
- `vtkGeoSampleArcs = obj.SafeDownCast (vtkObject o)`
- `obj.SetGlobeRadius (double )` - The base radius used to determine the earth's surface. Default is the earth's radius in meters. TODO: Change this to take in a vtkGeoTerrain to get altitude.
- `double = obj.GetGlobeRadius ()` - The base radius used to determine the earth's surface. Default is the earth's radius in meters. TODO: Change this to take in a vtkGeoTerrain to get altitude.
- `obj.SetMaximumDistanceMeters (double )` - The maximum distance, in meters, between adjacent points.
- `double = obj.GetMaximumDistanceMeters ()` - The maximum distance, in meters, between adjacent points.
- `obj.SetInputCoordinateSystem (int )` - The input coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `int = obj.GetInputCoordinateSystem ()` - The input coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `obj.SetInputCoordinateSystemToRectangular ()` - The input coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `obj.SetInputCoordinateSystemToSpherical ()` - The desired output coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `obj.SetOutputCoordinateSystem (int )` - The desired output coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `int = obj.GetOutputCoordinateSystem ()` - The desired output coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `obj.SetOutputCoordinateSystemToRectangular ()` - The desired output coordinate system. RECTANGULAR is x,y,z meters relative the the earth center. SPHERICAL is longitude,latitude,altitude.
- `obj.SetOutputCoordinateSystemToSpherical ()`

32.19 vtkGeoSource

32.19.1 Usage

vtkGeoSource is an abstract superclass for all multi-resolution data sources shown in a geographic view like vtkGeoView or vtkGeoView2D. vtkGeoSource subclasses need to implement the FetchRoot() method, which fills a vtkGeoTreeNode with the low-res data at the root, and FetchChild(), which produces a refinement of a parent node. Other geovis classes such as vtkGeoTerrain, vtkGeoTerrain2D, and vtkGeoAlignedImageSource use a vtkGeoSource subclass to build their geometry or image caches which are stored in trees. The source itself does not maintain the tree, but simply provides a mechanism for generating refined tree nodes.

Sources are multi-threaded. Each source may have one or more worker threads associated with it, which this superclass manages. It is essential that the FetchChild() method is thread-safe, since it may be called from multiple workers simultaneously.

To create an instance of class vtkGeoSource, simply invoke its constructor as follows

```
obj = vtkGeoSource
```

32.19.2 Methods

The class vtkGeoSource has several methods that can be used. They are listed below. Note that the documentation is translated automatically from the VTK sources, and may not be completely intelligible. When in doubt, consult the VTK website. In the methods listed below, `obj` is an instance of the vtkGeoSource class.

- `string = obj.GetClassName ()`
- `int = obj.IsA (string name)`
- `vtkGeoSource = obj.NewInstance ()`
- `vtkGeoSource = obj.SafeDownCast (vtkObject o)`
- `vtkGeoSource = obj.()`
- `~vtkGeoSource = obj.()`
- `bool = obj.FetchRoot (vtkGeoTreeNode root)` - Blocking access methods to be implemented in subclasses.
- `bool = obj.FetchChild (vtkGeoTreeNode node, int index, vtkGeoTreeNode child)` - Blocking access methods to be implemented in subclasses.
- `obj.RequestChildren (vtkGeoTreeNode node)` - Non-blocking methods for to use from the main application. After calling RequestChildren() for a certain node, GetRequestedNodes() will after a certain period of time return a non-null pointer to a collection of four vtkGeoTreeNode objects, which are the four children of the requested node. The collection is reference counted, so you need to eventually call Delete() on the returned collection pointer (if it is non-null).
- `vtkCollection = obj.GetRequestedNodes (vtkGeoTreeNode node)` - Non-blocking methods for to use from the main application. After calling RequestChildren() for a certain node, GetRequestedNodes() will after a certain period of time return a non-null pointer to a collection of four vtkGeoTreeNode objects, which are the four children of the requested node. The collection is reference counted, so you need to eventually call Delete() on the returned collection pointer (if it is non-null).
- `obj.Initialize (int numThreads)` - Spawn worker threads.
- `obj.ShutDown ()` - Shut down the source. This terminates the thread and releases memory.
- `obj.WorkerThread ()`
- `vtkAbstractTransform = obj.GetTransform ()`

32.20 vtkGeoSphereTransform

32.20.1 Usage

the cartesian coordinate system is the following (if BaseAltitude is 0), - the origin is at the center of the earth - the x axis goes from the origin to (longtitude=-90,latitude=0), intersection of equator and the meridian passing just east of Galapagos Islands - the y axis goes from the origin to the intersection of Greenwitch meridian and equator (longitude=0,latitude=0) - the z axis goes from the origin to the Geographic North Pole (latitude=90) - therefore the frame is right-handed.

To create an instance of class vtkGeoSphereTransform, simply invoke its constructor as follows

```
obj = vtkGeoSphereTransform
```

32.20.2 Methods
